**Background:** Steroid-sensitive nephrotic syndrome (SSNS) is the most common form of NS observed in children. Previous genome-wide association studies (GWAS) have identified associations at four loci, including HLA. Additional heritability of SSNS has remained unknown.

**Methods:** We conducted a multi-population meta-analysis of 2,486 pediatric SSNS patients of Admixed-American, African, East Asian, European and South Asian ancestries vs. 35,739 ancestry-matched controls. Significant and suggestive loci were followed-up with gene-based annotation, and colocalization with immune- and kidney-cell eQTL data. The HLA locus was fine-mapped via HLA-specific imputation using a multi-ethnic HLA reference for association at classical HLA alleles, haplotypes, and amino acid positions.

**Results:** Multi-population meta-analysis discovered 5 new significant associations near *CAPDS*, *CD28*, *AH11*, *BTC*, and *CLEC16A*. There were 12 additional suggestive risk loci. The known GWAS loci were replicated. We found three non-HLA GWAS loci with high colocalization probability across various immune cell eQTLs, including *CALHM6*, *AH11*, *TNFSF15*. Colocalization with monocytes was observed for all three loci. HLA-focused analyses discovered two independent associations within the HLA-DR/DQ region and fine-mapping identified an association at amino acid position 47 and position 52 in *HLA-DQA1*. Conditional analysis identified a secondary association at amino acid position 26 in *HLA-DQB1*. Of note, no new GWAS loci colocalized with kidney eQTLs.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** Increased cohort diversity and size empowered the discovery of novel pediatric SSNS risk loci, further implicating the key role of immune dysregulation in this disease.

### Polygenic Risk Score for CKD: Association Between Dyslipidemia and the Risk of Incident CKD Affected by Genetic Susceptibility

Boram Weon, Jeonghwan Lee, Jung Pyo Lee, Chun Soo Lim. *Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.*

**Background:** Polygenic risk score (PRS) provides information of the overall contribution of numerous genetic variants on disease outcomes. The effect of dyslipidemia on kidney disease outcome are inconsistent according to the individual's clinical characteristics including eGFR and genetic background. We aimed to investigate the genetic effect on the association between dyslipidemia and risk of CKD using PRS.

**Methods:** We constructed PRS for incident CKD using GWAS summary statistics of CKDGen Overall European Ancestry (n=480,898). UK biobank participants (aged 40 to 69) registered between 2006 and 2010 were enrolled in this study (n=389,281). Incident CKD was defined as eGFR below 60 ml/min/1.73 m<sup>2</sup> and ICD-10 code of CKD during follow-up period. The effect of lipid profile [total cholesterol (Total-C), LDL cholesterol (LDL-C), HDL cholesterol (HDL-C) and triglyceride(TG)] and PRS on incident CKD was investigated using the Cox proportional hazard model. Multivariable analysis included age, sex, comorbidities (diabetes mellitus and hypertension), body mass index, baseline kidney function, proteinuria, uric acid levels, alcohol consumption, and smoking as covariates. Interactions between lipid profile and PRS were tested in the whole participants and subgroups stratified by PRS for incident CKD.

**Results:** A total of 4,890 (1.24%) of participants developed CKD. High PRS (HR 1.117, 95% CI 1.086-1.149 as continuous variable) was associated with increased risk of CKD in univariable analysis. In multivariable analysis, high TG (HR 1.097, 95% CI 1.069-1.125), low HDL-C (HR 0.606, 95% CI 0.545-0.674), low LDL-C (HR 0.838, 95% CI 0.806-0.871), and low total-C (HR 0.866, 95% CI 0.841-0.892) were associated with incident CKD. High PRS (HR 1.173, 95% CI 1.107-1.243) was associated with CKD only in conjunction with TG. There were positive interaction between PRS and lipid profile of total-C (HR 1.030, 95% CI 1.006-1.055) and HDL-C (HR 1.138, 95% CI 1.044-1.242). When stratified by PRS tertiles, significant interaction was discovered only in high PRS group.

**Conclusions:** PRS can significantly predict the risk of incident CKD. High TG and low HDL-C are associated with increased risk of CKD. Low LDL-C and TG are also associated with high incidence of CKD, and their effect on CKD tends to increase as the genetic risk of CKD increases.

## FR-PO305

### Identification of Kidney Cell-Type-Specific Regulatory Elements Reveals Genetic Variants, Genes, and Cell Types Influencing Kidney Function Heritability

Gabriel Loeb,<sup>1</sup> Pooja Kathail,<sup>2</sup> Richard W. Shuai,<sup>2</sup> Kennix-Kalen Cheung,<sup>1</sup> Ryan K. Chung,<sup>2</sup> Nilah Ioannidis,<sup>2</sup> Jeremy Reiter.<sup>1</sup> <sup>1</sup>University of California San Francisco, San Francisco, CA; <sup>2</sup>University of California Berkeley, Berkeley, CA.

**Background:** Kidney disease is highly heritable. Understanding how genetic variants influence kidney function can reveal molecular pathways underlying kidney disease. Genome-wide association studies have identified hundreds of genomic loci associated with kidney function. However, due to linkage disequilibrium and localization of most risk variants within noncoding regions, the cell types and genes affected by the vast majority of these risk loci remain unclear.

**Methods:** We used single-cell ATAC-seq of human kidneys, partitioned LD-score regression of kidney biomarker genome-wide association studies, functionally informed fine-mapping, and deep learning models that predict chromatin accessibility from sequence to functionalize the variants, genes, and cell types associated with decreased kidney function.

**Results:** We mapped chromatin accessibility in over 40,000 human kidney cells, allowing us to identify kidney regulatory elements genome-wide. Tubule epithelial cell type-specific regulatory elements demonstrated strong enrichment for kidney function

heritability. Functionally informed fine-mapping revealed putative causal variants in both monogenic kidney disease genes and novel genes. A deep learning model trained to predict cell type-specific chromatin accessibility from sequence predicted the effect of variants on chromatin accessibility (AUROC = 0.77). We used this model and allele-specific ATAC-seq to identify kidney function variants that disrupt tubule epithelial chromatin accessibility, providing mechanistic insight into how these variants alter tubule gene expression to affect kidney function.

**Conclusions:** Enrichment of kidney function heritability within tubule epithelial cells suggests that perturbation of tubule gene expression is a major driver of kidney disease. Using functionally informed fine-mapping of kidney function variants, we identified regulatory elements and genes, which, when perturbed in tubule epithelial cells, affect human kidney function.

## FR-PO306

### Novel Renal Phenotype of a Rare Genetic Syndrome: Pericentri (PCNT) Gene Related Microcephalic Osteodysplastic Primordial Dwarfism Type II

Maria Llanos, Xiangling Wang, Leal C. Herlitz, Fariha Shad, Fadi A. Hijazi, Mary-Beth Roberts. *Cleveland Clinic foundation Cleveland Clinic, Cleveland, OH.*

**Introduction:** Microcephalic osteodysplastic primordial dwarfism type II (MOPDII) is a rare genetic syndrome caused by biallelic mutations or deletions in the pericentri gene (PCNT), characterized by short stature and microcephaly. Aside from its classic features, its association with vasculopathy including moyamoya disease has been increasingly recognized. CKD, renal artery stenosis and aneurysm have also been reported. However, the kidney histopathological data is limited. Here we report a patient who presented with proteinuric CKD, Moya Moya disease, microcephalic short stature and was found to have distinct and novel renal phenotype with endotheliopathy, and homozygous PCNT gene deletion.

**Case Description:** 30 yr old male presented to renal genetics clinic due to CKD III, Moya Moya disease with multiple intracranial hemorrhages requiring multiple bypasses, hypertension, and family history of consanguinity and CKD in his mother and sisters. Exam was notable for short stature and microcephaly. He had estimated GFR of 36mL/min with a 1.2 UPCR. Serological work-up included negative ANA, DSDNA, ANCA, Hepatitis B, C antibody, HIV, lupus anticoagulant, monoclonals, anti-GBM, anti-MPO/PR3 antibodies and normal complements. Kidney biopsy demonstrated FSGS with endothelial abnormalities including mesangiolysis, segmental duplication of the GBMs, subendothelial widening and loss of endothelial fenestrations. Exome sequencing disclosed a pathogenic homozygous microdeletion on chromosome 21 involving multiple coding exons of the PCNT gene. This established the diagnosis of MOPDII. Familial genetic testing was also offered. He was treated with Lisinopril with stable proteinuria and kidney function.

**Discussion:** The renal biopsy performed in this case highlighted the prominent endothelial injury in MOPDII related vasculopathy due to PCNT gene deletion. This expanded renal phenotype of MOPDII suggests that the vasculopathy observed with PCNT mutations may be related to endothelialopathy which deserves further investigation. This case also highlights the importance of genetic study in patients with systemic presentations and family history of kidney disease.

## FR-PO307

### Genetically Determined Adiponectin Levels Are Associated With CKD

Jefferson L. Triozzi,<sup>1</sup> Guanchao Wang,<sup>1,2</sup> Edward D. Siew,<sup>1,2</sup> Talat Alp Ikizler,<sup>1,2</sup> Otis D. Wilson,<sup>1,2</sup> Alexander Bick,<sup>1</sup> Ran Tao,<sup>1,2</sup> Cassianne Robinson-Cohen,<sup>1</sup> Adriana Hung,<sup>1,2</sup> <sup>1</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN.

**Background:** Adiponectin is a potent insulin-sensitizing hormone with multiple anti-inflammatory, anti-oxidant and anti-atherogenic properties. Insulin resistance is associated with chronic kidney disease (CKD) incidence and progression. We investigated the causal relationship between genetically determined adiponectin levels and chronic kidney disease using a mendelian randomization experiment.

**Methods:** We performed a mendelian randomization experiment using 12 single nucleotide polymorphisms (SNPs) from a genome wide association study of adiponectin as the exposure (ADIPOGen Consortium, n = 25,513), and CKD defined as eGFR creatinine <60 mL/min/1.73 m<sup>2</sup> from a genome wide association study of European ancestry individuals with and without diabetes as the outcome (CKDGen, n = 12,385 cases, n = 104,780 controls). Mendelian randomization was performed using inverse variance weighted (IVW), weighted median, weighted mode, and MR-Egger regression analyses.

**Results:** Genetically predicted adiponectin levels demonstrated a causal relation with risk of chronic kidney disease in the IVW analysis (OR: 0.72, 95% CI: 0.58–0.89) and weighted median analysis (OR: 0.73, 95% CI: 0.55–0.96). Results were consistent in sensitivity analyses and there was no evidence of pleiotropy.

**Conclusions:** Our study finds that higher levels of adiponectin may have protective effects for CKD consistent with previous observational and pre-clinical data regarding the protective role for adiponectin in kidney disease. The mendelian randomization methodology supports a causal relationship and is less susceptible to confounding and reverse causation biases.

### Mapping Genomic Regulation of Kidney Disease and Traits Through High-Resolution and Interpretable Expression Quantitative Trait Loci (eQTLs)

Michelle McNulty,<sup>1</sup> Seong Kyu Han,<sup>1,2</sup> Christopher Benway,<sup>1</sup> Pei Wen,<sup>6</sup> Anya Greenberg,<sup>1</sup> Ana C. Onuchic-Whitford,<sup>1,5</sup> Parker C. Wilson,<sup>3</sup> Benjamin D. Humphreys,<sup>3</sup> Xiaquan Wen,<sup>4</sup> Zhe Han,<sup>6</sup> Dongwon Lee,<sup>1,2</sup> Matt G. Sampson.<sup>1,2</sup> NEPTUNE <sup>1</sup>Boston Children's Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>Washington University in St Louis, St Louis, MO; <sup>4</sup>University of Michigan, Ann Arbor, MI; <sup>5</sup>Brigham and Women's Hospital, Boston, MA; <sup>6</sup>University of Maryland School of Medicine, Baltimore, MD.

**Background:** The genomic contributors to kidney diseases and traits extend well beyond rare, pathogenic, exonic variants that typified the initial discoveries in this area. Genome-wide association studies (GWAS) have demonstrated that heritability of diverse kidney traits and diseases are polygenic and primarily non-coding. eQTL studies illuminate genomic variants that regulate specific genes providing biological insight and fine mapping of loci discovered via GWAS. Efforts to maximize eQTL accuracy and precision are ongoing.

**Methods:** We conducted an eQTL analysis using RNA-seq from micro-dissected glomeruli (N=240) and tubulointerstitial (N=311) kidney tissue and paired whole genome sequencing (WGS) from the nephrotic syndrome cohort NEPTUNE. Single-nuclear open chromatin annotations and the distance to each gene's transcription start site were combined into an "integrative" Bayesian prior for multi-SNP fine mapping. To validate precision and accuracy of our eQTL maps, we assessed fine-mapping resolution, predicted impact on gene regulation, and heritability of estimated glomerular filtration rate (eGFR) and urine albumin-to-creatinine ratio (UACR). We highlighted the value of our eQTL maps through colocalization and transcription-wide association studies with eGFR and UACR GWAS. A subset of variants and genes were experimentally validated *in vitro* and using a *Drosophila* nephrocyte model.

**Results:** We discovered 5,371 glomerular and 9,787 tubulointerstitial eGenes. The integrative prior resulted in higher resolution eQTLs illustrated by (1) smaller credible sets with greater confidence, (2) increased enrichment of partitioned heritability for GWAS traits, (3) an increased number of variants colocalized with GWAS loci, and (4) enrichment of computationally predicted functional regulatory variants. We also functionally validated *NCOA7* and *LARP4B* eQTLs on a gene and variant level.

**Conclusions:** This study demonstrates that tissue-specific eQTL maps informed by single-nucleus open chromatin data have enhanced utility for diverse downstream analyses. Results can be explored and downloaded at [www.nephqt2.org](http://www.nephqt2.org).

## FR-PO309

### Allele-Specific Expression in the Human Kidney: An Analysis of the NEPTUNE Cohort

Ana C. Onuchic-Whitford,<sup>1,2</sup> Anya Greenberg,<sup>1</sup> Michelle McNulty,<sup>1</sup> Seong Kyu Han,<sup>1</sup> Jihoon Yoon,<sup>1</sup> Dongwon Lee,<sup>1</sup> Matt G. Sampson.<sup>1,2</sup> NEPTUNE <sup>1</sup>Boston Children's Hospital, Boston, MA; <sup>2</sup>Brigham and Women's Hospital, Boston, MA.

**Background:** Allele-specific expression (ASE) is a genomic phenomenon in which one copy of a gene (from one parental chromosome) is expressed more than the other, often due to cis-regulatory genetic variation. ASE has been shown to contribute to autism, heart disease and cancer. However, the extent of ASE in human kidney and its role in the pathogenesis of chronic kidney diseases is not well defined. To address this, we performed ASE analysis using whole genome sequencing data paired with kidney biopsy-derived glomerular RNA-seq data from 240 individuals in the Nephrotic Syndrome Study Network (NEPTUNE).

**Methods:** By integrating genomic and transcriptomic data from the same individual, we quantified mRNA expression originating from either of their parental chromosomes, distinguished by heterozygous loci. To do this, cohort-level genotype data was imputed

and population-phased using the Michigan Imputation Server. For each participant, gene-level ASE data for chromosome 19 (chr19) was generated by phASER (phasing and Allele Specific Expression from RNA-seq), and subsequently combined to generate cohort-level ASE data.

**Results:** 1653 genes on chr19 had sufficient glomerular expression for ASE analysis. Of these, 880 genes (53%) had ASE in  $\geq 1$  individual. We then focused on the cohort prevalence of ASE for 947 "highly expressed" genes, defined as read count  $> 100$  in  $\geq 1$  individual. The median number of highly expressed glomerular genes with ASE per person was 79. *NPHS1* – encoding nephrin, a crucial component of the glomerular slit diaphragm – was the 4th most common. Moreover, many of the individuals were outliers for *NPHS1* ASE: 13 participants had  $> 5x$  higher expression of one *NPHS1* allele compared to the other. Kallikrein related peptidase 6 (*KLK6*), the 3rd most common chr19 ASE gene, is expressed in kidney cancers and degrades the glomerular basement membrane proteins collagen and laminin.

**Conclusions:** This preliminary study of chr19 demonstrates that ASE is a pervasive phenomenon in glomerular cells, occurs in genes implicated in kidney disorders, and is found extensively across patients. This provides strong rationale to extend this ASE study genome-wide, to determine the spectrum of kidney ASE genes, the genetic variants that drive it, and their potential contribution to kidney diseases and traits.

## FR-PO310

### Single-Cell Transcriptomics Reveals Disrupted Cell Communication in the Glomerular Niche in the Initiation of Childhood WT1 Glomerulopathy

Jennifer C. Chandler,<sup>1</sup> Daniyal J. Jafree,<sup>1</sup> Saif N. Malik,<sup>1</sup> Gideon Pomeranz,<sup>1</sup> Maria K. Joannou,<sup>1</sup> Andrew S. Mason,<sup>2</sup> Aoife M. Waters,<sup>1</sup> David A. Long.<sup>1</sup> Long Research Group <sup>1</sup>University College London Institute of Child Health, London, United Kingdom; <sup>2</sup>University of York, York, United Kingdom.

**Background:** The glomerulus is comprised of podocytes and glomerular endothelial cells that enclose a core of mesangial cells; parietal epithelial cells enclose this specialised niche from the tubulointerstitium. Cellular communication within the glomerulus is critical for healthy filtration and its disruption is associated with adult diseases such as diabetic nephropathy. However, little is known about glomerular communication in childhood glomerulopathies.

**Methods:** Disease progression was characterised in a murine model (*Wt1*<sup>R394W/+</sup>) of childhood WT1 glomerulopathy, using biochemical and histological analyses. Single-cell RNA sequencing (scRNA-seq) and bioinformatic analyses were conducted on glomeruli isolated from wildtype (*Wt1*<sup>+/+</sup>) and mutant (*Wt1*<sup>R394W/+</sup>) mice. Validation was performed using tissue immunofluorescence and RT-qPCR.

**Results:** *Wt1*<sup>R394W/+</sup> mice have elevated urinary albumin ( $p < 0.0001$ ) from 4 weeks of age, prior to any histological features of glomerulosclerosis which occur by 8 weeks. To identify changes in cell communication that initiate glomerular damage, we performed scRNA-seq at 4 weeks, generating a dataset enriched for podocytes. Podocytes exhibited the most differentially expressed genes between *Wt1*<sup>R394W/+</sup> and *Wt1*<sup>+/+</sup> and changes in pathways associated with cell death were paralleled by a reduced WT1+ cell count ( $p < 0.0001$ ). Using ligand-receptor analysis, we identified vascular signalling to be the cellular interaction most disrupted in *Wt1*<sup>R394W/+</sup> glomeruli and CD31+ staining showed a loss of the glomerular endothelium by 8 weeks of age ( $p < 0.0001$ ). Finally, we performed a cross-disease comparison of *Wt1*<sup>R394W/+</sup> with other models of early glomerular disease (nephrotoxic nephritis, diabetes and *Cd2ap*<sup>-/-</sup>). This highlighted a common signature of podocyte transcripts that are upregulated or downregulated across early disease and others which are unique to each pathology.

**Conclusions:** This work has generated a glomerular dataset for childhood WT1 glomerulopathy. *Wt1*<sup>R394W/+</sup> podocytes have a unique transcriptional profile in early disease, driving endothelial loss. Signatures of podocyte injury exist across glomerulopathies, revealing therapeutic candidates of a disease-specific and generic nature that offer future promise in disease management.

## FR-PO311

### Multi-Ethnic Polygenic Risk Modifies the Association Between APOL1 High Risk Genotypes and CKD

Thi ha my Vy, Faris F. Gulamali, Girish N. Nadkarni. Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** The burden of advanced chronic kidney disease (CKD) falls disproportionately on minorities including African Americans (AAs) and Hispanic Americans (HAs) with admixed ancestry. Even though *APOL1* high-risk genotypes increase risk of kidney disease, their penetrance is incomplete i.e., only some individuals with high-risk genotypes develop kidney disease. This indicates that alongside interactions with social determinants, common single nucleotide polymorphisms (SNPs) may attenuate the effect of *APOL1*'s high risk genotypes on kidney disease via epistasis. Prior studies have only shown a small number of epistatic SNPs with small effect sizes, indicating that the modification of *APOL1* high risk may be polygenic

**Methods:** For each individual, we calculated two polygenic risk scores using summary statistics for Stage 3 CKD from two training sources: a publicly available European summary statistics generated for 118,147 individuals of European ancestry and an African summary statistics generated for 8,398 individuals of African ancestry from UK biobank. A multiethnic PRS was then derived as the linear combination of the two PRS with mixing weights  $\alpha_1$  and  $\alpha_2$  estimated from a single regression of Stage 3 CKD against each PRS. Association between PRS and risk of Stage 3 CKD was modeled using

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

logistic regression adjusting for age, sex, type 2 diabetes (T2D), and the first ten genetic principal components to account for population stratification.

**Results:** Using mixing weights estimated from the joint model, we computed a multi-ethnic PRS and tested for the association with CKD stage 3. As expected, we observed strong association ( $p=0.002$ ) with odds ratio=1.46 (1.16-1.96) per standard deviation increment in PRS. When stratifying individuals into distinct groups by PRS quintiles: low, intermediate and high-risk groups, the intermediate-risk group had 1.49-fold (95% CI 0.89-2.56;  $p=0.14$ ) and the high-risk group had 1.82-fold increased risk of CKD (95% CI 1.04-3.29;  $p=0.04$ ) compared to the low-risk group.

**Conclusions:** Standardizing population screening for CKD by including *APOL1* high-risk genotypes and polygenic risk score may improve risk stratification and outcomes. PRS may serve as another feature in comprehensive models for risk prediction to power precision medicine approaches to address health disparities in kidney disease.

FR-PO312

**Sickle Cell Trait, APOL1 Renal Risk Variants, and Kidney Outcomes in the Million Veteran Program**  
Trevor Thompson,<sup>1,2</sup> Zhihong Yu,<sup>1,3</sup> Hua-Chang Chen,<sup>1,3</sup> Ran Tao,<sup>1,3</sup> Jennifer E. Huffman,<sup>4,5</sup> Otis D. Wilson,<sup>1,3</sup> J. M. Gaziano,<sup>4,5</sup> Peter W. Wilson,<sup>6,7</sup> Edward D. Siew,<sup>3,1</sup> Katalin Susztak,<sup>8,9</sup> Alexander Bick,<sup>1</sup> Cassianne Robinson-Cohen,<sup>1</sup> Adriana Hung,<sup>3,1</sup> Million Veteran Program <sup>1</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>2</sup>Meharry Medical College, Nashville, TN; <sup>3</sup>VA Tennessee Valley Healthcare System, Nashville, TN; <sup>4</sup>VA Boston Healthcare System, Boston, MA; <sup>5</sup>Harvard Medical School, Boston, MA; <sup>6</sup>Atlanta VA Medical Center, Atlanta, GA; <sup>7</sup>Emory University School of Medicine, Atlanta, GA; <sup>8</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>9</sup>Philadelphia VA Medical Center, Philadelphia, PA.

**Background:** Individuals of African ancestry, have a 4-fold increased risk of progression to End Stage Renal Disease (ESRD). Apolipoprotein 1 high risk variants (*APOL1* HR) & Sickle Cell Trait (SCT), also denoted as the rs334 mutation, have been associated with greater ESRD risk. Both mutations arise in the same regions of West Africa due to positive evolutionary selection. Our previous GWAS in African American and Latinx populations showed that both the rs334 mutation in the *HBB* gene and *APOL1* high risk variants were associated with lower GFR. It is not known if the association described for SCT and ESRD varies by *APOL1* risk status.

**Methods:** We conducted a retrospective cohort study including 109,047 participants with African ancestry enrolled in the Million Veteran Program. We excluded patients with preexisting ESRD or Sickle Cell Disease. The primary exposure was *APOL1* high risk variants (RV) (G1 and/or G2) and/or SCT, defined by heterozygosity at the *HBB* gene for the rs334 mutation. Our primary outcome was a 40% decline in eGFR or reaching ESRD. Patients were followed to an outcome, death, or last day of follow up. Multivariable Cox regression was used for the comparison.

**Results:** Overall, the median age was 59 years [IQR 51,66], 86.2% were male, 33% had diabetes (DM) and 66% had hypertension (HTN). 5,285 (4.85%) experienced an eGFR decline of 40% and 1,796 experienced incident ESRD. Cox regression results are presented in **Table 1**.

**Conclusions:** In patients without diabetes the *APOL1* HR genotypes and SCT had the largest risk of progression. SCT did not confer increased risk of progression to ESRD for G0/G0 individuals. In diabetic patients with SCT and one high risk *APOL1* variant, there was an increased risk of renal disease progression to the clinical outcomes described above. Understanding the interaction of DM and SCT in the risk of CKD progression deserves further investigation.

**Funding:** Veterans Affairs Support

**Risk-Variant APOL1 Expression in iPSC-Derived Macrophages Increases Cellular Stress and Inflammation**  
Esther Liu,<sup>1</sup> Jennie Lin,<sup>1,2</sup> <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>Jesse Brown VA Chicago Healthcare System, Chicago, IL.

**Background:** DNA variants for the *APOL1* gene have been linked to a higher risk of developing kidney and cardiovascular disease in individuals with recent African ancestry. *APOL1* is expressed endogenously in not only kidney cells but also immune cells such as macrophages. Recent studies show that severe acute inflammatory illness such as COVID-19 increases the likelihood of individuals with the high-risk *APOL1*

genotype developing glomerulopathy, raising the question of the role of immune cells in *APOL1*-mediated disease. Therefore, we aim to understand the cellular stress and pro-inflammatory pathways increased by risk variant *APOL1* expression in iPSC-derived macrophages (iPSDM).

**Methods:** Induced pluripotent stem cell (iPSC) expressing G0 and G1 variants of *APOL1* were generated through CRISPR/Cas9. Macrophages (iPSDM) were differentiated from these iPSC lines. Expression of *APOL1* in the cultured iPSDMs, was induced with IFN $\gamma$  (20 ng/mL). Cytokine expression in the cell culture supernatant was measured by ELISA. Metabolic respiration was measured by Seahorse Mito Stress Test (Agilent).

**Results:** Upon stimulation with IFN $\gamma$ , we observed a 4.6-fold decrease in TGF- $\beta$  secretion ( $n=3$ ,  $p<0.001$ ) in G1 iPSDM compared to G0. When polarized to an M1-like phenotype with IFN $\gamma$  and LPS, IL-1 $\beta$  secretion was 1.4-fold increased ( $n=3$ ,  $p<0.005$ ) in G1 iPSDM compared to G0. G1 macrophages also had decreased levels of basal respiration compared to G0 ( $n=3$ ,  $p=0.04$ ). However, there was no observed difference in mitochondrial reactive oxygen species as measured by MitoSOX Red staining. Additionally, we observe a decrease in protein levels of LC3-II, an indicator of active autophagy, and a 4.4-fold increase of autophagy substrate P62 levels in G1 macrophages compared to G0.

**Conclusions:** The findings in our experiments show a significant increase in inflammatory cytokine expression in G1 macrophages and decreased levels of basal respiration and autophagy markers. These results suggest that *APOL1* risk variant expression modulates macrophage functions which are relevant to kidney homeostasis and disease.

FR-PO314

**Naturally Occurring Variants in APOL1: Channel Activity and Toxicity to Trypanosomes vs. Cultured Cells**  
John C. Edwards, Rebecca L. Winkler, Jonathan M. Bruno, Jonathan Oliva. Saint Louis University, Saint Louis, MO.

**Background:** Wild type ApoL1 (G0) confers resistance to certain African trypanosomes. Two ApoL1 variants (G1, G2) provide resistance to a broader range of trypanosomes and contribute to risk of kidney disease. ApoL1 enters membranes at low pH where it functions as an anion permease. After titration to neutral, ApoL1 transitions to a cation channel. Compared to G0, G1 and G2 have increased cation channel activity and increased toxicity to cultured cells, supporting the hypothesis that this activity contributes to disease. Other ApoL1 variants exist that are inherited as haplotypes. Whether haplotype would impact ApoL1-associated kidney injury is unknown, but haplotype does alter toxicity of ApoL1 expressed in cultured cells.

**Methods:** Purified recombinant G0, G1, and G2 in each of the three major haplotypes were assayed for channel activity and membrane association. A subset of these were assayed for toxicity to Trypanosoma brucei brucei and for toxicity to cultured human podocytes using standard assays.

**Results:** K channel activity for all variants is greatest in the EIK (African) haplotype and least in the EMR (Neanderthal) haplotype. K channel activity of G1 and G2 is about double that of G0 in all haplotypes. The activity variation among haplotypes is not paralleled by differences in membrane association, but activity variation among G0, G1, and G2 is tightly correlated with membrane association. Trypanosome toxicity of G0 variant is greatest in the EIK haplotype and least in the EMR haplotype. G1 variant has no effect on trypanosome toxicity in the EIK haplotype.

**Conclusions:** Among haplotype encoded isoforms, cation channel activity correlates with toxicity to both trypanosomes and cultured cells but not with membrane association. In contrast, among the disease associated variants, cation channel activity correlates with membrane association and with cultured cell toxicity but not with trypanosome toxicity. The data suggest 1) that differences in cation channel activity among the variants is due to effects on membrane association/insertion, while differences among the haplotypes is due to differences in intrinsic activity of membrane-inserted protein; and 2) either the mechanism of ApoL1 toxicity to trypanosomes and cultured cells may be significantly different, or if identical, is not directly related to the cation channel activity of ApoL1.

FR-PO315

**A Novel Role of APOL1 Risk-Alleles in T-Cell Activation and Focal Segmental Glomerulosclerosis**  
John F. Pell, Anand Reghuvaran, Soichiro Nagata, Khadija Banu, Hongmei Shi, Irene Chernova, Shuta Ishibe, Madhav C. Menon. Yale University Department of Internal Medicine, New Haven, CT.

**Background:** G1-, G2-variants in apolipoprotein-L1 (*APOL1*) increase the risk of FSGS vs. the major allele (G0). While podocyte *APOL1* expression is needed for FSGS, we recently reported a provocative role for *APOL1* within the immune system, as activated CD4<sup>+</sup> and CD8<sup>+</sup> T cells which expressed *APOL1* showed more activation in G1- or G2-genotypes by single cell transcriptomics.

**Methods:** We studied *APOL1*'s immunological role using a novel BAC-transgenic mouse (BAC-Tg) for G0-, G1- or G2-*APOL1* expression under the human *APOL1* promoter (G0-, G1-, G2-pure), and crossed each BAC-Tg line with dox-inducible interferon  $\gamma$  (*Ifng*)-expressing mice (either *Rosa-Ifng*- or *Nphs2-Ifng*-G0-, G1-, or -G2), as IFN $\gamma$  regulates *APOL1* expression.

**Results:** In splenocytes, *APOL1*- and dox-induced *IFN* $\gamma$ -expression were confirmed by qPCR. FACS analysis showed that adult BAC-Tg spleens had similar proportions of major immune cell types in all variants with/without dox. The proportion of CD8<sup>+</sup> T cells that were activated (CD44<sup>+</sup>CD8<sup>+</sup>) was significantly higher in *G1* and *G2* mice following dox vs. *G0* [Fig.A-B]. T cell receptor stimulated *G1*-, *G2*-CD8<sup>+</sup> T cells showed greater proliferation and marked *IFN* $\gamma$  production vs. *G0* [C-D]. In response to viral nucleic acid, *G1*-CD8<sup>+</sup> T cells showed further increases in *IFN* $\gamma$  and IL-2 intracellular staining (*P*<0.01 vs *G0*). To test the role of *APOL1*-variant immune cells in FSGS, we used bone marrow transfer [E]. *Rosa-lfng-G1*-, *-G2* mice that received *Rosa-lfng-G1*-marrow developed FSGS after dox feeding (positive control). Strikingly, *lfng-G1* marrow (IFN $\gamma$  induced only in donor cells) induced albuminuria in *G1*-, *G2*-pure recipients (without podocyte IFN $\gamma$  excess) while *Nphs2*-driven IFN $\gamma$  expression did not induce FSGS, suggesting FSGS was induced in variant-glomeruli by *G1*-marrow-derived IFN $\gamma$  [F-G; n=4]. *Ex vivo*, primary *G1*-podocytes treated with supernatant from TCR-stimulated *G1*-CD8<sup>+</sup> T cells showed greater apoptosis (Annexin V) vs. *G0* supernatant [n=3 each; H].

**Conclusions:** Our data suggest a novel role for activated CD8<sup>+</sup> T cells as a key source of IFN $\gamma$  in *G1*- and *G2* risk-genotype-Bac-Tg mice, inducing FSGS.

Figure 1. Association of APOL1 high-risk and p.N264K allele with end-stage kidney disease among MVP participants

FR-PO316

Genetic Inhibition of APOL1 Pore Forming Function Prevents APOL1 Kidney Disease

**Adriana Hung**,<sup>1,2</sup> Victoria Assimon,<sup>3</sup> Hua-Chang Chen,<sup>2,1</sup> Zhihong Yu,<sup>2,1</sup> Ran Tao,<sup>2,1</sup> Edward D. Siew,<sup>1,2</sup> Katalin Susztak,<sup>5,4</sup> Robert R. Graham,<sup>3</sup> Maarten Hoek,<sup>3</sup> Cassianne Robinson-Cohen,<sup>2</sup> Eric Green,<sup>3</sup> Alexander Bick,<sup>2</sup> Million Veteran Program <sup>1</sup>VA Tennessee Valley Healthcare System, Nashville, TN; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>3</sup>MAZE Therapeutics, San Francisco, CA; <sup>4</sup>Philadelphia VA Medical Center, Philadelphia, PA; <sup>5</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.

**Background:** African Americans are at increased risk for non-diabetic chronic kidney disease (CKD) in part due to high-risk variants in the apolipoprotein L1 (*APOL1*) gene.

**Methods:** We tested whether a different *APOL1* variant, p.N264K, modified the association between *APOL1* high-risk variants and CKD in cross-sectional analysis of 121,492 participants of African ancestry from the Million Veteran Program (MVP). We replicated our analyses in the Vanderbilt BioVU Biobank (n=14,386). The co-primary outcomes were CKD and end stage kidney disease (ESKD) among non-diabetic patients. We expressed *APOL1* high-risk mutations with and without *APOL1* p.N264K in podocytes to study mechanisms of action.

**Results:** In the MVP cohort, 15,604 (12.8%) had two *APOL1* high-risk mutations, of these 582 (0.5%) also had *APOL1* p.N264K. In the MVP cohort, 18,831 (15%) had CKD, 4,177 (3%) had ESKD and 34% had diabetes. *APOL1* high-risk variants were associated with an increased odds of CKD (odds ratio [OR] 1.72; 95% confidence interval [CI], 1.60 to 1.85) and ESKD (OR 3.94; 95% CI, 3.52 to 4.41). *APOL1* p.N264K mitigated the risk of *APOL1* high-risk variations in CKD (OR 0.70; 95% CI, 0.45 to 1.08, interaction p=0.001) and ESKD (OR 0.73; 95% CI, 0.27 to 1.96, interaction p=0.003) (Figure 1). *APOL1* p.N264K risk mitigation was replicated in BioVU. In mechanistic studies, *APOL1* p.N264K blocked *APOL1* pore-forming function and reduced toxicity of *APOL1* high-risk mutations in podocytes.

**Conclusions:** *APOL1* p.N264K is associated with reduced risk of CKD and ESKD among carriers of *APOL1* high-risk variants.

**Funding:** Veterans Affairs Support

FR-PO317

Systems Genetics Approaches Uncover Pathway-Level Interactions in Mice Carrying APOL1 G0/G2 Transgene and Gstm1 Null Alleles

**Josyf Mychaleckyj**,<sup>1</sup> Yves T. Wang,<sup>2</sup> Thu H. Le,<sup>2</sup> <sup>1</sup>University of Virginia Center for Public Health Genomics, Charlottesville, VA; <sup>2</sup>University of Rochester Medical Center, Rochester, NY.

**Background:** *APOL1* G1/G2 and *GSTM1* null alleles are associated with decline of kidney function but the cellular and molecular processes that effect the genetic risk remain poorly understood. We tested the interaction of an *APOL1* podocyte-specific transgene and *Gstm1* in cross-engineered mouse lines to examine the systems by which these two genes modulate kidney disease susceptibility.

**Methods:** We crossed FVB mouse lines carrying *Gstm1*(-/-) and podocyte specific *APOL1* G0 or G2 transgenes (tg) in a 2x3 factorial design with 6-8 mice per group (Figure 1). RNA was extracted from kidney cortices and subjected to RNA-seq analysis. Sequence reads were aligned using a STAR/SEM pipeline against an *APOL1*-spiked mouse genome. Analyses included cell-type deconvolution, differential expression, and independent components analysis to identify transcriptional gene modules. Differential gene sets and gene modules were tested for pathway enrichment and modular networks inferred (Figure 2).

**Results:** There was a significant increase in %neutrophils in *Gstm1*(-/-) mice compared to wild type (WT) (p=0.004), while tgG0 and tgG2 mice showed lower %nephron/duct cells (p=0.047/0.0078). There were 39 genes with altered expression at FDR< 0.05 in tgG2 vs tgG0 and 53 in *Gstm1*(-/-) vs WT. There was strong evidence for an interaction between the *APOL1*(tg) and *Gstm1* genotypes through coordinated changes in pathways and gene sets, including cytochrome P450, glutathione, amino acid, and sphingolipid metabolism. In tgG2 vs tgG0, there were changes in oxidative phosphorylation, Th1/Th2/Th17 cell differentiation, neurodegeneration, diabetic cardiomyopathy-related, and AGE-RAGE signaling pathways. Functional cluster enrichment analysis of the modules recapitulated this through pervasive associations with immune response, innate immunity, cell adhesion, and synaptic response.

**Conclusions:** We have identified a complex of set of overlapping molecular and cellular processes that are dysregulated by these genotypic changes in *APOL1* and *Gstm1*. The risk allele (G2 and *Gstm1*(-/-) interaction suggests that additional genetic variability could be one source of the additional 'hit' needed to express a susceptibility phenotype within *APOL1* G1/G2 risk carriers.

FR-PO318

MZ-301 Is a Small Molecule Inhibitor of APOL1 Pore Function That Attenuates Albuminuria in a Mouse Model of APOL1-Mediated Kidney Disease

**Victoria Assimon**, Sarah Bronner, Cecile Yu, Weibin Zha, Maarten Hoek, Christopher Sinz, Eric Green, David J. Morgans. *Maze Therapeutics, South San Francisco, CA.*

**Background:** APOL1 genetic variants (G1 and G2) increase risk for a spectrum of progressive kidney diseases in people of African ancestry. To date, no APOL1-targeted therapies are available that address the underlying genetic driver of disease. Here we

describe the *in vitro* and *in vivo* activity of MZ-301, a small molecule APOL1 pore blocker that reduces APOL1-driven toxicity in multiple cell systems and attenuates albuminuria in a mouse model of APOL1-mediated kidney disease.

**Methods:** A parasite viability assay was used to quantify the ability of recombinant APOL1 protein to lyse trypanosomes in the presence and absence of MZ-301. MZ-301 inhibition of APOL1 pore function was determined in HEK293 cells overexpressing APOL1. Additionally, MZ-301 inhibition of APOL1 cytotoxicity was assessed in HEK293 cells and immortalized podocytes overexpressing APOL1. Finally, transgenic mice homozygous for the APOL1 G2 (G2<sub>HOM</sub>) variant were administered an IFN- $\gamma$  challenge to elevate APOL1 levels and induce albuminuria. This mouse model was used to assess the effect of MZ-301 on urine albumin-to-creatinine ratios.

**Results:** MZ-301 potentially blocked the lytic activity of APOL1, preventing APOL1-mediated killing of trypanosomes. This compound also inhibited APOL1-dependent cytotoxicity in HEK293 cells and immortalized podocytes and reduced APOL1 ion conductance in APOL1-overexpressing HEK293 cells. Cellular effects were consistent across G1 and G2 variants. Finally, oral administration of MZ-301 robustly and dose-dependently attenuated IFN- $\gamma$ -induced albuminuria in APOL1 G2<sub>HOM</sub> mice to baseline levels in a preventative treatment paradigm.

**Conclusions:** MZ-301 is a potent orally bioavailable small molecule inhibitor of APOL1 pore function that blocks APOL1 lytic activity and reduces APOL1-mediated cytotoxicity in kidney cells. MZ-301 ameliorates proteinuria in a mouse model of APOL1 kidney disease. Together, these findings support inhibition of APOL1 pore function as a precision medicine approach for patients with APOL1 nephropathies and the further development of MZ-301.

### N6-Methyladenosine Methylation Regulatory Genes Modified the Effect of APOL1 Risk Genotype on Progression of CKD

Changwei Li,<sup>1</sup> Adrianna Westbrook,<sup>1</sup> Ruiyuan Zhang,<sup>1</sup> L. Lee Hamm,<sup>2</sup> Jing Chen,<sup>1,2</sup> Jiang He,<sup>1,2</sup> Tanika Kelly,<sup>1</sup> <sup>1</sup>Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; <sup>2</sup>Tulane University School of Medicine, New Orleans, LA.

**Background:** The *APOL1* risk alleles is a major cause of chronic kidney disease (CKD) and its progression among Blacks. N(6)-methyladenosine (m6A) is the most abundant modification in mammalian mRNA and regulates all stages of RNA life cycle. m6A is regulated by 10 writer genes encoding m6A methyltransferase enzymes, 9 reader genes encoding m6A binding proteins to stabilize, splice and translate mRNA, and 2 eraser genes encoding m6A demethylase enzymes. We aim to evaluate whether expression quantitative trait loci (eQTLs) of the m6A regulatory genes modify the effect of *APOL1* risk alleles on CKD progression.

**Methods:** A total of 666 independent ( $r^2 \leq 0.3$ ) eQTLs of m6A regulatory genes (Writer genes: *METTL3*, *METTL14*, *WTAP*, *VIRMA*, *HAKAI*, *ZC3H13*, *RBM15*, *RBM15B*, *METTL16*, *PCIF1/CAPAM*; Reader genes: *YTHDC1*, *YTHDF1*, *YTHDF2*, *YTHDF3*, *YTHDC2*, *HNRNPA2B1*, *FMR1/FMRP*, *HNRNPC*, and *HNRNPG*; and Eraser genes: *FTO* and *ALKBH5*) were retrieved from the GTEx. The variants were tested for interactions with *APOL1* risk status on CKD progression among 1,224 Black participants of the Chronic Renal Insufficiency Cohort (CRIC) in Cox regression models. We adjusted for age, sex, study site, and the first 10 ancestry principal components (PCs) in the base model and additionally adjusted for baseline kidney function in the full model. We also performed stratified analyses to evaluate *APOL1* risk allele effects on CKD progression according to genotypes of the significant variants.

**Results:** After Bonferroni correction, a cluster of four *LAMTOR5* variants (lead SNP: rs6671673,  $P=6.58 \times 10^{-3}$ ) modified the effect of *APOL1* risk alleles on CKD progression. The *LAMTOR5* rs6671673 is an eQTL for the writer gene *RMB15*, with major T allele increasing expression of *RMB15* in the whole blood ( $P=5.4 \times 10^{-3}$ ). In stratified analyses, effects of *APOL1* risk alleles on CKD progression decreased with the number of T alleles of *LAMTOR5* rs6671673. Hazard ratios and their corresponding 95% confidence intervals associated with the *APOL1* risk alleles were 1.87 (1.18-2.97), 1.39 (1.13-1.71) and 0.85 (0.67-1.07), respectively, for participants carrying 0, 1, and 2 T alleles at the *LAMTOR5* rs6671673.

**Conclusions:** An eQTL for the m6A writer gene *RMB15* reduced the risk of *APOL1* associated CKD progression, and stabilizing *APOL1* mRNA may reduce the risk of CKD progression.

## FR-PO320

### Design and Rationale of GUARDD-US: A Pragmatic, Randomized Trial of Genetic Testing for APOL1 and Pharmacogenomic Predictors of Antihypertensive Efficacy in Patients With Hypertension

Michael T. Eadon,<sup>1</sup> Kerri L. Cavanaugh,<sup>2</sup> Girish N. Nadkarni,<sup>3</sup> Rhonda M. Cooper-DeHoff,<sup>4</sup> Carol Horowitz,<sup>3</sup> IGNITE <sup>1</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>2</sup>Vanderbilt University, Nashville, TN; <sup>3</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>4</sup>University of Florida, Gainesville, FL.

**Background:** *APOL1* risk alleles are associated with increased cardiovascular and chronic kidney disease (CKD) risk. It is unknown whether knowledge of *APOL1* risk status motivates patients and providers to attain recommended blood pressure (BP) targets to reduce cardiovascular disease.

**Methods:** This is a multicenter, pragmatic, randomized controlled clinical trial of 6650 individuals with African ancestry and hypertension from 13 health systems. *APOL1* genotyping with clinical decision support (CDS) results are returned to participants and providers immediately (intervention) or at 6 months (control). A subset of participants are re-randomized to pharmacogenomic testing for relevant antihypertensive medications (pharmacogenomic sub-study). CDS alerts encourage appropriate CKD screening and antihypertensive agent use. Blood pressure and surveys are assessed at baseline, 3 and 6 months. The primary outcome is change in systolic BP from enrollment to 3 months in individuals with two *APOL1* risk alleles. Secondary outcomes include new diagnoses of CKD, systolic blood pressure at 6 months, diastolic BP, and survey results. The pharmacogenomic sub-study will evaluate the relationship of pharmacogenomic genotype and change in systolic BP between baseline and 3 months.

**Results:** As of January 2022, the trial had enrolled 3423 participants.

**Conclusions:** The effect of patient and provider knowledge of *APOL1* genotype on systolic blood pressure has not been well-studied. GUARDD-US addresses whether blood pressure improves when patients and providers have this information. GUARDD-US provides a CDS framework for primary care and specialty clinics to incorporate *APOL1* genetic risk and pharmacogenomic prescribing in the electronic health record.

## FR-PO321

### Extracellular Vesicles Rescue Alport Glomerular Endothelial Lipid Dysfunction

Sargis Sedrakyan,<sup>1,2</sup> Hasmik Soloyan,<sup>1</sup> Matthew E. Thornton,<sup>2</sup> Paolo Cravedi,<sup>3</sup> Andrea Angeletti,<sup>4</sup> Laura Perin.<sup>1,2</sup> <sup>1</sup>Children's Hospital Los Angeles Department of Pediatrics, Los Angeles, CA; <sup>2</sup>University of Southern California, Los Angeles, CA; <sup>3</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>4</sup>IRCCS Istituto Giannina Gaslini, Genoa, Italy.

**Background:** Glomerular endothelial dysfunction plays a key role in the development of chronic kidney disease (CKD), however, its role in Alport syndrome (AS), a kidney disorder characterized by mutations in collagen IV $\alpha$ 3 $\alpha$ 4 $\alpha$ 5 progression has been elusive and understudied. We have previously shown that glomerular endothelial cell (GEC) injury is an early event that precedes podocyte damage in AS, manifested by enlarged fenestrations, altered glycocalyx and re-expression of GEC injury marker, plasmalemma vesicle associated protein (PLVAP). Here, we report on the link between altered lipid metabolism and GEC injury in AS, and the use of extracellular vesicles derived from amniotic fluid stem cells (AFSC-EVs) as a rescue strategy to re-establish lipid homeostasis.

**Methods:** GEC were isolated from tdTomato-reporter AS (Col4a5 mutation on C57BL/6 background) and WT mice at 4 months of age by FACS and transcriptome was analyzed and compared by bulk RNA-seq. Kidney tissue from patients affected by AS were used to confirm our findings by spatial transcriptomics and histology. In vitro, silencing experiments using human primary GEC were used to study the role of fatty acid synthase (FASN) loss in GEC dysfunction. AFSC-EVs (which contain FASN in their cargo) were applied as a rescue strategy to normalize FASN expression and restore lipid homeostasis. Data were confirmed using AFSC-EV <sup>FASN-/-</sup>.

**Results:** AS GEC were highly enriched for differentially expressed genes associated with cellular lipid metabolism. Genes associated with fatty acid transport (CD36, FATP-1, Fabp3) and synthesis (FASN) among others were downregulated, which was further associated with glomerular accumulation of lipid droplets in mice and onset of heavy proteinuria. Spatial transcriptional profiling of glomeruli from AS patients revealed strong correlation between GEC specific markers and lipid metabolism associated genes, confirming our findings in human. In vitro, AFSC-EVs were able to rescue FASN deficiency and improve GEC function, unlike AFSC-EV <sup>FASN-/-</sup>.

**Conclusions:** We report for the first time a lipid metabolic dysfunction in Alport GEC, and the ability of AFSC-EVs to rescue this phenotype. Therefore, better understanding of the functional role of GEC in AS could lead to the development of targeted new therapies for the treatment of this and other forms of CKD.

## FR-PO322

### Investigational Therapy of Alport Syndrome With ELX-02

Vasudeo Badarinarayana,<sup>1</sup> Kohei Omachi,<sup>2</sup> Megan K. Cox,<sup>1</sup> Ali Hariri,<sup>1</sup> Jeffrey H. Miner,<sup>2</sup> Vijay Modur.<sup>1</sup> <sup>1</sup>Eloxx Pharmaceuticals Inc., Watertown, MA; <sup>2</sup>Washington University in St Louis, St Louis, MO.

**Background:** Alport syndrome is a genetic disease caused by mutations in COL4A3, COL4A4 and COL4A5 genes leading to glomerular fragility, hematuria and proteinuria resulting in ESRD early in life. The most frequent form is X-linked Alport syndrome, which is caused by mutations in COL4A5. ELX-02 is an aminoglycoside analog specifically designed to readthrough premature termination (nonsense) codon mutations and produce full-length proteins instead of truncated proteins. We show here the potential for ELX-02 as an investigational therapy in Alport Syndrome.

**Methods:** A list of nonsense mutations in COL4A5 associated with Alport syndrome was compiled from ClinVar, LOVD, Ensemble and deafness variation database. The number of unique nonsense mutations and frequency of each were determined. Type of nonsense codon (UGA, UAG or UAA) was derived from sequence variant. 13 of the mutants were selected for analysis by dual reporter assay for responsiveness to ELX-02 induced readthrough. To assess expected clinical exposure in kidney for ELX-02, a Physiologically Based Pharmacokinetic (PBPK) model was built based on preclinical pharmacokinetic data from mouse, rat and dog studies using Gastroplus simulation software.

**Results:** Analysis of reported nonsense mutations compiled across different variant databases showed approximately 6% of reported pathogenic mutations in COL4A5 are of the nonsense subtype. Dual reporter assays were designed for 13 of these mutations to test for responsiveness to ELX-02. All the tested mutations had >3-fold increase in readthrough with an average of XX-Fold. PBPK modeling showed that ELX-02 levels in the kidney are >50-fold greater than plasma levels across a range of doses suggesting high exposures in the kidneys even at 0.71 mg/kg dose.

**Conclusions:** The promise of this investigational therapy in Alport syndrome is supported by several lines of evidence. 1) Nonsense mutations in COL4A5 are a significant cause of Alport Syndrome. 2) ELX-02 shows nonsense mutation readthrough across a range of nonsense mutations in Alport Syndrome. 3) PBPK modeling shows high levels of ELX-02 exposures can be achieved in the kidneys even at doses below those currently being used in clinical trials.

## FR-PO323

### Empagliflozin Reduces Renal Lipotoxicity in Alport Syndrome

Mengyuan Ge, Judith T. Molina David, Jin Ju Kim, Javier T. Varona Santos, Flavia Fontanesi, Sandra M. Merscher, Alessia Fornoni. *University of Miami School of Medicine, Miami, FL.*

**Background:** Sodium-glucose cotransporter-2 inhibitors (SGLT2i) are antidiabetic drugs that prevent glucose reabsorption in proximal tubular cells. SGLT2i improves renal outcomes in both diabetic and non-diabetic patients, indicating it may have beneficial effects beyond glycemic control. Alport Syndrome (AS) is a genetic disorder that leads to progressive kidney disease. We and others have shown that lipid accumulation in podocytes and tubular cells contributes to the pathogenesis of AS. Tubular cells preferentially use fatty acids as the main energy source, while podocytes rely on glucose. With this study, we test the hypothesis that SGLT2i affects energy metabolism in podocytes and tubular cells in experimental AS.

**Methods:** SGLT2 expression was analyzed by Western blot. Lipid droplet (LD) accumulation was determined by Nile red staining. Respiration was measured using Oroboros O2k respirometer. Blood samples were studied for BUN and creatinine levels. Albumin-to-creatinine ratios (ACR) were determined by albumin ELISA and creatinine assay. Kidney cortices were collected for lipid content analysis using Amplex Red assay and triglyceride (TG) assay.

**Results:** *In vitro*, we demonstrated a similar level of SGLT2 protein expression in cultured human and mouse podocytes when compared to tubular cells. Newly established immortalized podocytes from Col4a3KO mice (AS) accumulate LDs in association with increased apoptosis when compared to wildtype (WT) podocytes. Treatment with empagliflozin (empa, SGLT2i) reduces LD accumulation and apoptosis in AS podocytes. Empa inhibits the utilization of glucose as a metabolic substrate in AS podocytes. Interestingly, empa did not affect LD content and glucose utilization in tubular cells isolated from AS mice when compared to WT. *In vivo*, we demonstrated that empa reduces ACR and prolongs the survival of AS mice. Empa-treated AS mice showed decreased serum BUN and creatinine levels in association with reduced TGs and cholesterol esters (CE) levels in the kidney cortices when compared to AS mice. Lipid accumulation (TG, CE) in kidney cortices correlated with the decline in renal function (ACR, serum BUN and creatinine).

**Conclusions:** Empa reduces renal lipotoxicity and improves kidney function in experimental AS in association with a shift in the use of energy substrates from glucose to fatty acids in podocytes.

**Funding:** NIDDK Support

## FR-PO324

### High-Resolution Imaging of Inter-Organelle Interaction and Vesicle Trafficking in Live-Cells Expressing the INF2 Variants

Huong Quynh Tran Thuy,<sup>1</sup> Hiroko Ueda,<sup>1</sup> Linh N. Tran,<sup>1</sup> Naoyuki Kondo,<sup>2</sup> Hiroyasu Tsukaguchi.<sup>1</sup> <sup>1</sup>Kansai Medical University Second Department of Internal Medicine, Hirakata, Japan; <sup>2</sup>Kansai Medical University Department of Molecular Genetics, Hirakata, Japan.

**Background:** Focal segmental glomerulosclerosis (FSGS) is primarily caused by podocyte deletion. Regulation of cytoskeleton plays a key role in maintaining the slit diaphragm integrity. *INF2*, an actin regulator, is one of the most prevalent genes in monogenic FSGS. The DID domain *INF2* mutations cause two subtypes of disorders; one is FSGS alone and FSGS/CMT dual phenotypes. However, the detail mechanisms by which the DID mutations exert differential tissue effect remain unclear.

**Methods:** We characterized the cytoskeletal organization and inter-organelle interaction in HeLa/COS7 cells expressing pathogenic *INF2* variants identified in our cohort. Cellular effects are compared between FSGS only and CMT/FSGS variants. To clarify the actin dynamics and vesicle trafficking, we took advantage of the Spinning Disk Microscope DragonFly, which allows real-time imaging with 100nm resolution.

**Results:** When expressed in HeLa and COS7 cells, *INF2* variants causing FSGS alone (T161N, N202S) distributed a diffuse cytoplasmic ER pattern with Golgi enrichment similar to wild-type. In contrast, CMT/FSGS variants (G73D, V108D) exhibited a coarse granular distribution with aberrant accumulation at cell periphery. In fixed cells, actin stress fibers were more remarkably reduced in cells expressing CMT/FSGS variants than in FSGS variants. The extent of stress fiber reduction correlated with the severity of intracellular *INF2* misdistribution. Spinning Disk Microscopy with time-lapse imaging of living COS7 cells revealed that T161N variant increases the frequency of mitochondrial fragmentation as well as the number of mitochondria-ER interfaces than the wild-type. Moreover, trajectory analysis of lysotracker-labeled vesicles in living COS7 disclosed

that in T161N variant reduces the motility of cytoplasmic vesicles than the wild-type (n=100 for each group,  $P<0.0001$ ), suggesting that disorganized actin network may perturb the intracellular vesicular trafficking.

**Conclusions:** Our expression study indicates that the *INF2* variants cause severer actin network disarrangement and thus more deteriorating effects on the ER-mitochondria interaction and endosomal trafficking than wild-type. Such mechanisms may represent a common, global feature that underlies the pathogenesis of *INF2*-related disorders, affecting podocyte and/or Schwann cells.

## FR-PO325

### Trafficking and Localization of Disease-Causing Podocin Mutants in Human Podocytes

Pei-Chen Lu,<sup>1,2</sup> Gavin I. Welsh,<sup>1</sup> Moin Saleem.<sup>1</sup> Renal group, University of Bristol <sup>1</sup>University of Bristol, Bristol, United Kingdom; <sup>2</sup>Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung, Taiwan.

**Background:** Mutations in the slit diaphragm protein podocin result in the commonest form of monogenic steroid-resistant nephrotic syndrome (SRNS). Podocin localizes to the podocyte slit diaphragm, which is crucial for the filtration process. Most disease-causing mutations of podocin cause it to be trafficked incorrectly intracellularly and this results in aberrant formation/function of the slit diaphragm complex. We have developed human podocyte cell lines expressing several disease-causing mutants of podocin to further understand the trafficking, intracellular localization and protein binding partners of this protein in both health and disease.

**Methods:** Wild type and R138Q, R238S, G92C, V180M, and R291W disease-causing mutants of podocin were tagged with Myc and stably expressed in conditionally immortalized human. Intracellular trafficking and localization of the tagged podocin constructs was determined by high resolution confocal and total internal reflection fluorescence (TIRF) microscopy. Sucrose density gradient centrifugation was used to study lipid raft localization. Proteomic analysis of podocin interacting proteins was carried out using mass spectrometry of co-immunoprecipitated proteins.

**Results:** Confocal and TIRF microscopy (Fig 1) showed that all the mutant proteins, except for the R138Q mutant, localized to the plasma membrane of podocytes. However, only the wild type and R238S protein were found to be associated with lipid raft structures. Mass spectrometry analysis of podocin binding proteins has identified several novel interactors including trafficking proteins and regulators of cell adhesion. Interestingly these protein/protein interactions are altered differentially by the podocin mutants.

**Conclusions:** Defining how disease-causing mutations alter the localization and protein binding partners of podocin will lead to a greater understanding of the pathogenesis of Nephrotic Syndrome.

**Funding:** Private Foundation Support

**Figure 1.** podocin in the total internal reflection fluorescence (TIRF) imaging. The wild type podocin-myc is in green and caveolin-1 is in red, and merged parts is in yellow.

### Phenotypic Quantification of Nphs1 Deficient Mice

Ronen Schneider,<sup>1,2</sup> Bshara Mansour,<sup>1,2</sup> Caroline M. Kolvenbach,<sup>1,2</sup> Aaron Bao,<sup>1,2</sup> Florian Buerger,<sup>1,2</sup> Shirlee Shril,<sup>1,2</sup> Friedhelm Hildebrandt.<sup>1,2</sup> <sup>1</sup>Boston Children's Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA.

**Background:** The majority of children with steroid resistant nephrotic syndrome (SRNS) progress to end-stage renal disease (ESRD). Monogenic causes of SRNS have been detected in ~30% of pediatric cases, in one of 68 genes discovered so far, the most common being *NPHS1* and *NPHS2* (Kopp *Nat Rev Dis Primers* 6:68, 2020) affecting signaling pathways of podocytes biology (Connaughton *NDT* 35:390, 2020). Since each of these genes represents a rare cause of SRNS, tailoring therapeutic interventions to multiple molecular targets is challenging, and current treatments are limited. Therefore, gene replacement therapy (GRT) approaches have recently been considered (Zhao *JCI Insight* 22:e145936, 2021). To set the ground for GRT studies *in-vivo*, we established exact phenotypic quantification of a published *Nphs1* knockout (ko) mouse model.

**Methods:** We have acquired a floxed nephrin mouse model (*Nphs1<sup>tm1AfrnJ</sup>*) that was previously studied for pathways linked to pancreatic  $\beta$ -cell survival (Villarreal *J Am Soc Nephrol* 27:1029, 2016). We bred *Nphs1<sup>fl/fl</sup>* mice with a CRE recombinase expressing mouse under the control of podocin promoter [*Tg(NPHS2-cre)<sup>205Lhh/L</sup>*] (Moeller *Genesis* 35:39, 2003), to generate podocyte specific nephrin deficient mice. We then performed survival analysis, renal light microscopic (LM) and TEM analyses, and proteinuria assesment to quantiatively phenotype these mice.

**Results:** Mice were born in Mendelian ratios. We observed median survival of 5 days in *Nphs1<sup>-/-</sup>* mice (n=27) as compared to 100% survival in *Nphs1<sup>+/-</sup>* (n=20) and *Nphs1<sup>+/+</sup>* mice (n=13) until age 50 days. Quantification by LM of the ratio of proteinaceous casts in proximal tubules to number of glomeruli in the same sequential coronal kidney sections revealed a ratio of 0.92 casts/glomeruli (545/592) in *Nphs1<sup>-/-</sup>* mice (n=3), and 0/443 in *Nphs1<sup>+/+</sup>* controls (n=2). We counted the number of foot process cross sections (FPCS) per  $\mu$ m glomerular basement membrane (GBM) length in electron microscopy images. While *Nphs1<sup>+/+</sup>* mice (n=3) showed an average of 2.9 FPCS per  $\mu$ m of GBM, ko mice (n=3) showed 0.9 /1  $\mu$ m GBM (p<0.05). Finally, *Nphs1<sup>-/-</sup>* pups had +4 albumin on urine stick (n=2), and *Nphs1<sup>+/-</sup>* mice had trace to +1 readings (n=4).

**Conclusions:** We have quantitatively phenotyped *Nphs1<sup>-/-</sup>* mice, in a model that can provide reliable phenotypic read-outs for gene-replacement therapy in *Nphs1* deficient mice.

## FR-PO327

**Quantifiable Phenotyping of an Existing Nphs1 Knockout Mouse Model**  
 Katharina Lemberg,<sup>1,2</sup> Kirolos Yousef,<sup>1</sup> Nils D. Mertens,<sup>1</sup> Florian Buerger,<sup>1</sup> Ronen Schneider,<sup>1</sup> Bshara Mansour,<sup>1</sup> Lea M. Merz,<sup>1</sup> Caroline M. Kolvenbach,<sup>1</sup> Ken Saida,<sup>1</sup> Camille H. Nicolas Frank,<sup>1</sup> Shirlee Shril,<sup>1</sup> Friedhelm Hildebrandt.<sup>1</sup>  
<sup>1</sup>Boston Children's Hospital, Boston, MA; <sup>2</sup>Uniklinik Köln, Köln, Germany.

**Background:** Steroid resistant nephrotic syndrome (SRNS) is the second leading cause of chronic kidney disease in the first three decades of life. The majority of children with SRNS progress to ESRD requiring dialysis or transplantation. The identification of monogenic causes of SRNS has revealed ~60 single-gene etiologies. Monogenic causes of SRNS predominantly cause glomerular podocyte dysfunction (Lovric *NDT* 31:1802-1813, 2015). Congenital nephrotic syndrome (CNS) is the most severe monogenic form of nephrotic syndrome. The second most frequent gene causing CNS when harboring biallelic mutations is *NPHS1*, which encodes the protein nephrin. Nephrin is located at the slit diaphragm and essential for the renal filtration barrier. There is no causal therapy so far. In order to enable eventual gene replacement therapy for CNS, we are developing quantifiable phenotyping in *Nphs1<sup>-/-</sup>* mouse models of CNS to provide a reproducible reference of evaluation for *in vivo* studies.

**Methods:** We developed a breeding colony for a previously published unconditional *Nphs1<sup>-/-</sup>* knockout mouse model (*Nphs1<sup>tm1RK</sup>*) and performed phenotypic evaluation, comparing homozygous mice to heterozygous controls. We quantitatively evaluated them for three independent conditions: Kaplan-Meier survival curves, frequency of proteinaceous casts in proximal tubules upon light microscopy and foot process effacement upon electron microscopy.

**Results:** Mice were born in Mendelian ratios. Homozygous segregation of the *Nphs1*-KO allele led to a) a perinatally lethal phenotype with a median survival of 1.0 day (n=18), b) light microscopic changes by counting the ratio between proteinaceous casts in proximal tubules per mature glomerulus in coronal equatorial sections, with a ratio of 0.38 in homozygous mice (n=5) vs 0.0 in heterozygous mice (n=5) and c) TEM studies revealed reduced number of podocytes, which we quantified by counting foot process cross sections (fp) over a defined length of the glomerular basement membrane, with 0.49 fp/ $\mu$ m *Nphs1<sup>-/-</sup>* (n=2) and 2.5 fp/ $\mu$ m in *Nphs1<sup>+/+</sup>* (n=3).

**Conclusions:** We hereby provide a quantifiable phenotyping of *Nphs1<sup>tm1RK/tm1RK</sup>* KO mice which can be useful for further *in vivo* studies of CNS.

**Funding:** Other NIH Support - NIH 5RC2DK122397-02

## FR-PO328

**Phenotypic Quantification of a NPHS1 Knockout Mouse Model**  
 Lea M. Merz,<sup>1</sup> Florian Buerger,<sup>2</sup> Ken Saida,<sup>2</sup> Nils D. Mertens,<sup>2</sup> Katharina Lemberg,<sup>2</sup> Kirolos Yousef,<sup>2</sup> Bshara Mansour,<sup>2</sup> Caroline M. Kolvenbach,<sup>2</sup> Shirlee Shril,<sup>2</sup> Ronen Schneider,<sup>2</sup> Friedhelm Hildebrandt.<sup>2</sup>  
<sup>1</sup>Department of Pediatrics, University Hospital Leipzig, Leipzig, Germany; <sup>2</sup>Department of Pediatric Nephrology, Boston Children's Hospital & Harvard Medical School, Boston, MA.

**Background:** Steroid-resistant nephrotic (SRNS) syndrome is the second most frequent cause of chronic kidney disease before the age of 25 years. Nephrin (*NPHS1*) is localized at the slit diaphragm of glomerular podocytes and plays a pivotal role in the filtration barrier. Biallelic mutations in *NPHS1* cause congenital nephrotic syndrome type 1 (CNS-1). To date, no causative therapy for CNS-1 is available. Recently, AAV vectors targeting the glomerular podocyte, have been assessed as a means for gene replacement therapy (Rocca, *Methods Mol Biol* 1937:227, 2019).

**Methods:** We acquired a conditional transgenic mouse model (*Nphs1tm1.1Parg/J*) using a podocyte-specific Cre-recombinase (Verma, *Plos One* 13(6):e0198013, 2018). We phenotypically characterized the nephrin-deficient mice by analyzing the presence of proteinaceous casts by renal histology, and density of podocyte foot processes by TEM. We also performed proteinuria measurements at different time points. To quantify foot process effacement, we detected the number of foot process cross-sections per length of the glomerular basement membrane (GBM). Furthermore, we characterized median survival of the *Nphs1<sup>-/-</sup>* mice in comparison to wildtype or heterozygous controls, to determine potential time-points of postnatal treatment.

**Results:** We found the average survival rate after birth to be 17 days (range from 9-23 days, n=8). The *Nphs1<sup>-/-</sup>* mice develop proteinuria within the first week, increasing to massive proteinuria 3-4.1 mg albumin/g creatinine from day 9 until time of death. The average density of foot processes per GBM length was 1.5 fp/ $\mu$ m in the *Nphs1<sup>-/-</sup>* mice compared to 1.7 fp/ $\mu$ m in the controls at day 9. At day 14 we detected a more distinct difference with an average of 1.2 fp/ $\mu$ m in knockout mice and 2.3 fp/ $\mu$ m in the matching controls.

**Conclusions:** We quantitatively characterized the phenotype of the mouse model published by Verma *et al.* (*Plos One* 13(6):e0198013, 2018).

**Funding:** NIDDK Support

## FR-PO329

### Characterization of the Human Podocin Short Isoform In Vivo Using a New Mouse Model

Linus Butt,<sup>1</sup> David Unnersjö-Jess,<sup>1,2</sup> Markus M. Rinschen,<sup>3,4</sup> Bernhard Schermer,<sup>1</sup> Thomas Benzing,<sup>1,5</sup> Martin Höhne.<sup>1,5</sup>  
<sup>1</sup>Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; <sup>2</sup>SciLifeLab, Stockholm, Sweden; <sup>3</sup>Aarhus Universitet Institut for Biomedicin, Aarhus, Denmark; <sup>4</sup>III Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; <sup>5</sup>Exzellenzcluster CECADE in der Universität zu Köln, Köln, Germany.

**Background:** To date, many mutations affecting podocyte-specific genes are known to cause steroid-resistant nephrotic syndrome, which usually progresses to end-stage renal disease due to a lack of effective therapeutic strategies. *NPHS2*, encoding the podocyte-specific protein podocin, is among the most frequently mutated genes in patients with hereditary steroid-resistant nephrotic syndromes. Previously, a short isoform of podocin lacking exon 5 was identified in human kidney tissue and characterized *in vitro*. However, its role *in vivo* remained elusive.

**Methods:** The short isoform of podocin is not found in any other organism except humans. To examine its functional relevance *in vivo* we generated a mouse line expressing the equivalent podocin isoform (podocin<sup>Axon5</sup>) using CRISPR/Cas9 mediated genome editing. We characterized the phenotype of mice expressing podocin<sup>Axon5</sup> resembling the human short isoform. Targeted mass spectrometry and qPCR were used to compare protein and RNA levels of podocin<sup>wildtype</sup> and podocin<sup>Axon5</sup>. STED microscopy following immunolabeling of slit diaphragm components was applied to visualize alterations of the podocytes' foot process morphology.

**Results:** Homozygous podocin<sup>Axon5</sup> mice born heavily albuminuric, hardly produced any urine and did not survive past the first day after birth. Targeted mass spectrometry revealed decreased protein levels of podocin<sup>Axon5</sup> whereas RNA abundance was not different to the canonical form (podocin<sup>wildtype</sup>). STED microscopy revealed the complete absence of podocin at the podocytes' slit diaphragm and severe morphological alterations of podocyte foot processes. Mice heterozygous for podocin<sup>Axon5</sup> were phenotypically unaffected but decreased podocin levels and altered foot process morphology could be detected.

**Conclusions:** The murine equivalent to the human short isoform of podocin is unable to stabilize the lipid-protein complex at the slit diaphragm. Reduction of podocin levels at the site of the slit diaphragm complex has a detrimental effect on podocyte morphology and decreases protein abundance of nephrin, the core protein of the extracellular slit diaphragm complex. In conclusion, our data support the hypothesis that podocin acts an orchestrator of the slit diaphragm complex, which allows for kidney ultrafiltration. The functional role of the short human isoform remains elusive.

## FR-PO330

### FVB/N-Nos1apEx3/Ex3- Mice Develop Severe Glomerular Kidney Disease, Which Is Ameliorated by Antiproteinuric Treatment

Florian Buerger, Lorrin Liang, Daanya Salmanullah, Vineeta Sharma, David A. Ball, Friedhelm Hildebrandt, Amar J. Majmundar. *Boston Children's Hospital, Harvard Medical School, Boston, MA.*

**Background:** Nephrotic syndrome (NS) is a leading cause of pediatric chronic kidney disease and frequently caused by Mendelian genetic variants. We previously discovered recessive *NOS1AP* variants as a novel cause of early onset NS in children and observed moderate glomerular disease without kidney failure in *Nos1ap<sup>Ex3-Ex3</sup>* mice on a C57BL/6 background (Majmundar & Buerger *Sci. Adv.* 7:1386, 2021). We, next, hypothesized that the *Nos1ap<sup>Ex3-Ex3</sup>* phenotype depends on the genetic background and that FVB/N and 129/sv mice may fully recapitulate the human disease.

**Methods:** C57BL/6-*Nos1ap<sup>Ex3-Ex3</sup>* mice were crossed onto FVB/N and 129/sv backgrounds. Urine albumin-to-creatinine ratios (ACR) in urine, blood parameters of kidney failure, and histology by light microscopy were measured.

**Results:** FVB/N-*Nos1ap<sup>Ex3-Ex3</sup>* mice developed significantly increased albuminuria, beginning at weaning age, relative to wildtype or heterozygote controls. ACRs in FVB/N-*Nos1ap<sup>Ex3-Ex3</sup>* mice were one order of magnitude higher than in C57BL/6-*Nos1ap<sup>Ex3-Ex3</sup>* and 129/sv mice-*Nos1ap<sup>Ex3-Ex3</sup>* at 3-6 months (mean ACRs 13.47-16.04 g/g, 0.86-1.53 g/g, and 0.99-1.69 g/g, respectively). Furthermore, FVB/N-*Nos1ap<sup>Ex3-Ex3</sup>* mice exhibited markedly reduced serum albumin, elevated serum levels of renal dysfunction marker BUN, and increased mortality compared to controls, which were all previously not observed on the C57BL/6 background. Histologic studies demonstrated increased mesangial matrix deposition, proteinaceous tubular casts, and tubular dilation in homozygous FVB/N mouse kidneys. FVB/N-*Nos1ap<sup>Ex3-Ex3</sup>* mice with comparable baseline ACRs received

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

drinking water with vehicle (water), 100 mg/L lisinopril, or 200 mg/L lisinopril at 6 weeks of age. Lisinopril treatment resulted in reduced albuminuria (mean ACRs between 2-12 weeks of treatment: vehicle, 14.06-29.84 g/g; 100 mg/L lisinopril, 5.54-9.97 g/g; 200 mg/L lisinopril, 7.15-11.20 g/g). Finally, lisinopril-treated mice exhibited increased survival at 14 weeks of treatment (11/11 viable) relative to vehicle-treated FVB/N-*Nos1ap*<sup>Ex3-Ex3+</sup> mice (1/5 viable).

**Conclusions:** FVB/N-*Nos1ap*<sup>Ex3-Ex3+</sup> mice develop severe proteinuric kidney disease, consistent with human SRNS, which is ameliorated by ACE inhibition.

## FR-PO331

### Recovering Impaired Cell Adhesion in Cystinosis Podocytes: A New Therapeutic Strategy?

Sante Princiero Berlingerio,<sup>1</sup> Sarah Tassinari,<sup>2</sup> Tjessa Bondue,<sup>1</sup> Marc Fransen,<sup>1</sup> Lambertus P. Van den heuvel,<sup>1</sup> Elena N. Levchenko.<sup>1</sup> Prof. Levchenko <sup>1</sup>Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium; <sup>2</sup>Universita degli Studi di Torino, Torino, Italy.

**Background:** Cystinosis is a rare, incurable autosomal recessive storage kidney disease caused by mutations in *CTNS* gene, which encodes the cystine transporter cystinosin and leads to lysosomal cystine accumulation in all the body. In addition to proximal tubular cells, cystinosis also affects the glomerulus since podocytes are lost into urine leading to proteinuria and kidney failure. Cysteamine, the current treatment, decrease cystine accumulation but does not reverse proximal tubular injury (renal Fanconi syndrome) neither glomerular injury. These evidences suggest that different mechanisms are involved and further studies are necessary to understand the disease in order to develop new therapeutic options.

**Methods:** Immortalized patient-derived cystinosis and healthy podocytes were used and the results were validated in our newly in-house developed fluorescent CTNS zebrafish larvae model (*l-fabp:DBP-eGFP;CTNS*). To understand the impaired podocyte functionality, static and dynamic permeability assay, metabolomic analysis (LC-MS), flow cytometry, RT-qPCR, western blot, chemical and dynamic roGFP2 redox-sensing fluorescent probes were used.

**Results:** Cystinosis podocytes present decreased adhesion and increased permeability caused by an accumulation of mitochondrial ROS. Moreover, they show fragmented mitochondrial network with impaired TCA cycle, energy metabolism and decreased superoxide scavenging SOD2 enzyme. Interestingly, treatment with the mitochondrial superoxide scavenger mitoTEMPO can rescue the impaired adhesion and permeability *in vitro* and *in vivo*.

**Conclusions:** An impaired mitochondrial oxidative stress is a critical feature in cystinosis podocytes and the combinatory treatment of cysteamine with targeted antioxidant improves podocytes adhesion and permeability. Moreover, our developed fluorescent CTNS zebrafish larvae model is a useful high-throughput tool for screening new therapeutic strategies aiming at restoring the kidney functionality in cystinosis.

## FR-PO332

### Using Nanocomplexes to Deliver Therapies for Glomerular Disease

Saif N. Malik,<sup>1</sup> Jennifer C. Chandler,<sup>1</sup> Ruhina Maeshima,<sup>1</sup> Aoife M. Waters,<sup>2</sup> Stephen L. Hart,<sup>1</sup> Tammy L. Kalber,<sup>1</sup> David A. Long.<sup>1</sup> <sup>1</sup>University College London, London, United Kingdom; <sup>2</sup>Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom.

**Background:** The onset of chronic kidney disease is often caused by damage to the kidneys' filtration unit, the glomerulus and in particular the podocyte epithelial cells lining the outer surface of glomerular capillaries. Therefore, treatment strategies that specifically target podocytes have the potential to improve glomerular disease. For glomerular disease caused by mutations, lipid nanocomplexes provide a promising strategy as they allow nucleic acid encapsulation for gene therapy and can be conjugated with peptides for targeted delivery to receptors on podocytes such as integrin  $\alpha\text{v}\beta3$ . Therefore, we aimed to deliver lipid nanocomplexes directly to podocytes as a potential therapeutic strategy for glomerular disease.

**Methods:** We utilised a murine model of childhood glomerular disease with a mutation in *Wilms Tumour 1* (WT1;*c.1180C>T;p.R394W*) to compare the ability of cyclic RGD and RWrNM peptide nanocomplexes to target integrin  $\alpha\text{v}\beta3$  and transfect primary healthy and diseased podocytes. We first sought transcript levels of  $\alpha\text{v}\beta3$  in podocytes compared with the rest of the kidney by qPCR before transfecting podocytes with luciferase nanocomplexes (n=3/group). Transfection was quantified by luciferase assay and normalised to total protein. We then directly compared RWrNM transfection in healthy and diseased podocytes (n=5&4). *In vivo* kidney targeting was assessed following a novel ultrasound guided intra-renal artery injection in healthy mice (n=3/group).

**Results:** We found enrichment of  $\alpha\text{v}\beta3$  in healthy and diseased podocytes ( $P=0.003$  &  $0.008$ ) compared with the rest of the kidney. RWrNM nanocomplexes were more effective for  $\alpha\text{v}\beta3$  targeting in health and disease than cyclic RGD ( $P=0.004$  &  $0.013$ ). Furthermore, RWrNM uptake did not diminish in disease when directly compared to healthy podocytes ( $P=0.81$ ). *In vivo* experiments show high kidney localisation following ultrasound guided delivery of luciferase cyclic RGD and RWrNM nanocomplexes with 75% and 88% of the total signal accounted for by the injected kidney respectively.

**Conclusions:** This study has demonstrated that integrin  $\alpha\text{v}\beta3$  can be used to target nanocomplexes directly to healthy and diseased podocytes. High kidney localisation is achieved *in vivo* by ultrasound guided renal artery injection. This forms the basis for delivery of genes that may protect podocytes using nanocomplexes in *Wt1*<sup>Wt1-R394W</sup> mice.

**Funding:** Government Support - Non-U.S.

## FR-PO333

### Methionine Restriction Prevents Cystine Urolithiasis in a Mouse Model of Cystinuria

Mylene Perreault,<sup>1</sup> Amrik Sahota,<sup>2</sup> Min Yang,<sup>2</sup> Jay A. Tischfield,<sup>2</sup> Julia Xu,<sup>1</sup> David Hava.<sup>1</sup> <sup>1</sup>Synlogic, Cambridge, MA; <sup>2</sup>Rutgers The State University of New Jersey, New Brunswick, NJ.

**Background:** Cystinuria is an inherited metabolic disorder caused by mutations in the *SLC3A1* and/or *SLC7A9* genes responsible for cystine reabsorption in the kidney. Defects in either of these genes is characterized by excessive excretion of cystine in the urine, which can result in the formation of crystals and/or stones in the kidney or bladder. Cystine is formed by the binding of two cysteine molecules, and strategies that aim at reducing cystine concentration in urine are recommended and include increased fluid intake, urine alkalization, and a reduction in protein intake enriched in cysteine and methionine. In mammals, the transsulfuration pathway is the only cysteine biosynthesis route and it requires the essential amino acid methionine. SYN1353 is an engineered strain of *E. coli* Nissle that metabolizes methionine in the gastrointestinal (GI) tract and prevents its absorption. To determine whether the metabolism of methionine in the GI tract could lower cystine levels and hence prevent stone formation, we assessed the impact of dietary methionine restriction in the *Slc3a1* knockout (KO) mouse model of cystinuria.

**Methods:** Six weeks old male *Slc3a1* KO mice were provided with regular (0.62%) or low (0.12%) methionine diets for 8 weeks. Body weight and food intake were measured weekly, urine collected every 2 weeks, and bladder stone volume was determined every 2 weeks by computed tomography (CT) scan. At the end of the experiment, bladders were dissected, and stones removed and weighed.

**Results:** In *Slc3a1* KO mice, methionine restriction caused 39% body weight loss, whereas mice maintained on regular diet gained 7% of their initial body weight. Bladder stones were detected by CT scan in 7 of the 12 KO mice on regular diet, with the onset of stone detection ranging from 2 to 8 weeks of dietary treatment. However, bladder stones were not detected in mice fed the low methionine diet. Following bladder dissection, stones were identified in 2 additional mice on regular diet, with bladder and stone weights in the 9 mice ranging from 13.9-82.1 mg and 0.2-83.3 mg, respectively. Bladder weight in 12 mice maintained on low methionine diet averaged 5.7-11.0 mg.

**Conclusions:** Overall, these data indicate that methionine restriction prevents stone formation in *Slc3a1* KO mice and SYN1353 may offer a viable approach for the treatment of cystinuria.

**Funding:** Commercial Support - Synlogic

## FR-PO334

### Preclinical Efficacy of CHK-336: A First in Class, Liver-Targeted, Small Molecule Inhibitor of Lactate Dehydrogenase for the Treatment of Primary Hyperoxalurias

Jennifer H. Cox,<sup>1</sup> Marc-Olivier Boily,<sup>1</sup> Alex Caron,<sup>1</sup> Oliver Chong,<sup>1</sup> Jim Ding,<sup>1</sup> Samuel Gaudreault,<sup>1</sup> Robert Gomez,<sup>1</sup> John Knight,<sup>2</sup> Jeff Lester,<sup>1</sup> Xingsheng Li,<sup>2</sup> W. T. Lowther,<sup>3</sup> Renata Oballa,<sup>1</sup> David A. Powell,<sup>1</sup> Tao Sheng,<sup>1</sup> Jayakumar Surendrass,<sup>1</sup> Vincent Tong,<sup>1</sup> Joyce Wu,<sup>1</sup> Andrew J. King.<sup>1</sup> <sup>1</sup>Chinook Therapeutics Inc, Seattle, WA; <sup>2</sup>The University of Alabama at Birmingham, Birmingham, AL; <sup>3</sup>Wake Forest University School of Medicine, Winston-Salem, NC.

**Background:** Primary hyperoxalurias (PH) 1-3 are disorders involving excess hepatic oxalate production, resulting in calcium oxalate kidney stones, progressive CKD, and potentially ESKD. There are limited therapeutic options, with only one approved agent for PH1, and no approved therapies for PH2-3. Lactate dehydrogenase (LDH) catalyzes the final step in hepatic oxalate synthesis and represents a potential therapeutic target for all forms of PH and other forms of hyperoxaluria driven by increased oxalate production. Herein we describe the preclinical efficacy profile of CHK-336, a potent and selective LDH inhibitor currently in development.

**Methods:** CHK-336 was evaluated in biochemical and cellular LDH activity assays, a <sup>13</sup>C<sub>2</sub>-glycolate stable isotope tracer pharmacodynamic model, an *Agxt* knockout PH1 mouse model, and a *Ghrpr* knockout PH2 mouse model.

**Results:** CHK-336 demonstrates potent and selective inhibition of LDH in human enzyme assays and hepatocyte assays across multiple species, including hepatocytes isolated from PH1 mice. A liver-targeted tissue distribution profile was engineered into the molecule; CHK-336 demonstrates effective liver-targeting across species. In a rat pharmacodynamic model, CHK-336 inhibited the conversion of <sup>13</sup>C<sub>2</sub>-glycolate to <sup>13</sup>C<sub>2</sub>-oxalate in a dose-dependent manner. In a novel PH1 mouse model, low once-daily oral doses of CHK-336 produced robust and dose-dependent reductions in urinary oxalate to the normal range. The magnitude of effect was comparable, but with a more rapid onset than a GO-targeting siRNA. Seven days of CHK-336 treatment resulted in a statistically significant reduction in urinary oxalate in a PH2 mouse model.

**Conclusions:** By potentially blocking LDH, the final step in hepatic oxalate synthesis, along with a liver-targeted tissue distribution profile, CHK-336 is a novel oral small molecule with the potential to treat all types of primary hyperoxaluria and other disorders resulting in increased oxalate production. The human safety, pharmacokinetic and pharmacodynamic profile of CHK-336 are currently under investigation in a healthy volunteer SAD/MAD study (NCT05367661).

**Funding:** Commercial Support - Chinook Therapeutics, Inc

## FR-PO335

### Lumasiran for Patients With Primary Hyperoxaluria Type 1 and Impaired Kidney Function: 12-Month Analysis of the Phase 3 ILLUMINATE-C Trial

Yaacov Frishberg,<sup>1</sup> Mini Michael,<sup>2,3</sup> Jaap Groothoff,<sup>4,5</sup> Hadas Shasha-Lavsky,<sup>6</sup> John C. Lieske,<sup>7</sup> Eva Simkova,<sup>8</sup> Anne-Laure A. Singer,<sup>14</sup> Richard G. Willey,<sup>15</sup> John M. Gansner,<sup>15</sup> Daniella Magen.<sup>16</sup> <sup>1</sup>Shaare Zedek Medical Center, Jerusalem, Israel; <sup>2</sup>Texas Children's Hospital, Houston, TX; <sup>3</sup>Baylor College of Medicine, Houston, TX; <sup>4</sup>Emma's Children's Hospital, Amsterdam, Netherlands; <sup>5</sup>University of Amsterdam Department of Pediatric Nephrology, Amsterdam, Netherlands; <sup>6</sup>Galilee Medical Center, Nahariya, Israel; <sup>7</sup>Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; <sup>8</sup>Al Jalila Children's Specialty Hospital, Dubai, United Arab Emirates; <sup>9</sup>Hopital Femme Mere Enfant, Bron, France; <sup>10</sup>Cliniques universitaires Saint-Luc, Bruxelles, Belgium; <sup>11</sup>Edouard Herriot Hospital, Lyon, France; <sup>12</sup>Gazi Universitesi, Ankara, Turkey; <sup>13</sup>Jordan University of Science and Technology, Irbid, Jordan; <sup>14</sup>Canberra Health Services, Garran, ACT, Australia; <sup>15</sup>Alnylam Pharmaceuticals Inc, Cambridge, MA; <sup>16</sup>Rambam Health Care Campus, Haifa, Israel; <sup>17</sup>Hotel-Dieu De France, Beirut, Lebanon.

**Background:** Primary hyperoxaluria type 1 (PH1) is a rare genetic disease characterized by hepatic oxalate overproduction leading to progressive kidney disease. In PH1, plasma oxalate (POx) increases as kidney function declines; in CKD 3b–5, POx is typically elevated and is associated with an increased risk of systemic oxalosis, making it a relevant trial endpoint. In the ILLUMINATE-C 6-month (M) primary analysis, administration of lumasiran, an RNA interference therapeutic designed to reduce hepatic oxalate production, produced substantial POx reductions and acceptable safety in PH1 patients with impaired kidney function. Here we present 12M results.

**Methods:** ILLUMINATE-C (NCT04152200) is an ongoing Phase 3, single-arm study (Cohort A: N=6, no hemodialysis [HD] at study start; Cohort B: N=15, on HD). The primary analysis period is followed by an extension period (EP) of up to 54M. Key inclusion criteria included genetically confirmed PH1, eGFR  $\leq 45$  mL/min/1.73m<sup>2</sup>, and POx  $\geq 20$   $\mu$ mol/L.

**Results:** All 21 patients entered the EP (median [range] exposure, 14.2 [8.3–19.7] M). As of the M12 assessments, 2 Cohort A patients (baseline eGFR, 8.6–16.0 mL/min/1.73m<sup>2</sup>) initiated HD. In Cohort B, 1 patient received a kidney transplant, discontinued HD, and continued lumasiran; 1 received a liver/kidney transplant and discontinued lumasiran. POx mean % reduction from baseline at M12 was 69.3% and 34.3% in Cohorts A and B, respectively; mean absolute reduction was 60.7 and 42.4  $\mu$ mol/L. POx AUC<sub>0–24h</sub> mean % reduction from baseline between HD sessions was 40.9% at M12 (Cohort B). Most burdensome symptoms improved or remained stable with lumasiran. The most common lumasiran-related adverse events (AEs) were mild, transient injection-site reactions. There were no deaths or lumasiran-related serious or severe AEs, discontinuations, or withdrawals.

**Conclusions:** Lumasiran showed sustained POx reductions in PH1 patients with CKD 3b–5, with an acceptable safety profile through M12. The impact on systemic oxalosis and transplant outcomes will be further monitored in the EP.

### Karyomegalic Interstitial Nephritis Is Triggered by Oxidative Stress Caused by Mitochondrial Deficiency in FAN1-Deficient Proximal Tubule Cells

Merlin Airik,<sup>1</sup> Amy B. Huynh,<sup>1</sup> Eric S. Goetzman,<sup>2</sup> Rannar Airik.<sup>1</sup> <sup>1</sup>University of Pittsburgh, Pittsburgh, PA; <sup>2</sup>Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA.

**Background:** Karyomegalic interstitial nephritis (KIN) is a genetic form of chronic kidney disease (CKD) caused by mutations in FAN1, a DNA repair enzyme. Accordingly, accumulation of DNA damage in the kidney tubular epithelium is a hallmark of KIN. However, the source and nature of the agent(s) responsible for inducing DNA lesions that trigger KIN have remained elusive. Here, we show using *in vivo* and *in vitro* models, that mitochondrial-derived ROS is critical for inducing KIN pathogenesis.

**Methods:** KIN was induced in 12-week-old *Fan1* KO mice by employing 2 cisplatin injury models: one mimicking AKI (weekly 2 x 4 mg/kg cisplatin), and another CKD (weekly 5 x 2 mg/kg cisplatin). Coincident with cisplatin, mice were administered a novel mitochondrial ROS scavenger at a dose of 10 mg/kg. Histological analysis was performed using PAS and HE. Markers of tubular injury, DNA damage and fibrosis were assessed by IF and IHC. Human kidney proximal tubular cells (PTECs) were used to model FAN1 loss of function *in vitro*. RNA-seq analysis was performed to identify transcriptional changes in KIN. Mitochondrial OXPHOS was measured using the Oroboros Oxygraph-2k System. Metabolite measurements were performed using YSI 7100 Bioanalyzer.

**Results:** Transcriptional profiling of kidneys with KIN revealed a significant downregulation of genes involved in mitochondrial energy metabolism - OXPHOS, fatty acid oxidation (FAO) and peroxisomal function. Metabolic analysis of *FAN1* KO PTECs showed a defect in respiratory chain, increased oxidative stress and a shift to increased lactate secretion. Similarly, *Fan1* KO kidneys revealed marked increase in oxidative DNA damage (8-OHdG), lipid peroxidation (4-HNE) and tubular lipotoxicity

(OilRedO) after AKI or CKD. Treatment with mitochondrial ROS scavenger reduced the level of oxidative lesions in *Fan1* KO kidneys, mitigated tubular damage and blocked the formation of KIN.

**Conclusions:** Loss of *FAN1* causes defective mitochondrial metabolism and increased ROS generation in the kidney which give rise to oxidative DNA lesions and results in KIN. Blocking mitochondrial ROS protects *Fan1* KO kidneys from DNA damage accumulation, mitigates tubular injury and improves kidney function in mice.

### Using an Innovative N-of-1 Trial Approach Testing Efficacy of Salt Supplementation in Gitelman Syndrome

Maartje F. Verploegen,<sup>1</sup> Michiel L. Wieërs,<sup>2</sup> Federica Giardina,<sup>3</sup> Francesco Trepiccione,<sup>4</sup> Stephen B. Walsh,<sup>5</sup> Ewout J. Hoorn,<sup>2</sup> Tom Nijenhuis.<sup>1</sup> <sup>1</sup>Radboudumc Afdeling Nierziekten, Nijmegen, Netherlands; <sup>2</sup>Erasmus MC Afdeling Inwendige Geneeskunde, Rotterdam, Netherlands; <sup>3</sup>Radboudumc Department for Health Evidence, Nijmegen, Netherlands; <sup>4</sup>Università degli Studi della Campania Luigi Vanvitelli Dipartimento di Scienze Mediche Traslazionali, Napoli, Italy; <sup>5</sup>University College London Department of Renal Medicine, London, United Kingdom.

**Background:** Gitelman syndrome is a rare hereditary salt-losing tubulopathy resulting in hypokalemic alkalosis and hypomagnesemia. Treatment practices to correct hypokalemia include high-dose potassium supplementation and potassium-sparing diuretics. Furthermore, ad libitum dietary salt intake is advised. The efficacy of supraphysiological salt supplementation has yet to be investigated. We aim to investigate this salt supplementation in an individualized manner using N-of-1 trials, which are crossover trials conducted in a single patient. This unique study design facilitates research into individual treatment effects.

**Methods:** We are currently performing multiple randomized, double-blind, placebo-controlled N-of-1 trials in patients with symptomatic, genetically-proven Gitelman syndrome. Sodium chloride (NaCl; 12 gr/day) and placebo are compared during 6 consecutive four-week treatment periods (3 periods of each treatment). Treatment periods are randomly allocated. After each treatment period, outcome parameters, among which serum potassium and symptoms, are measured. Because of the N-of-1 design, the data of each patient will be analyzed individually to draw conclusions about the effect of salt supplementation in that individual patient. Finally, all N-of-1 trials will be aggregated to draw conclusions at group level.

**Results:** Currently, five patients have completed their N-of-1 trial. Preliminary analyses demonstrate that NaCl supplementation increased serum potassium in three patients with a mean of 0.13 mmol/L, 0.17 mmol/L, and 0.35 mmol/L, respectively. In the other two patients, no increase in potassium was apparent. During Kidney Week in November 2022, we will be able to present the results of 12 patients that have completed an N-of-1 trial.

**Conclusions:** The N-of-1 trial is an inventive method producing an individualized verdict on the efficacy of an intervention and is suited for use in rare diseases. NaCl supplementation resulted in a clinically relevant increase in serum potassium in three out of five patients with Gitelman syndrome. The results of the ongoing N-of-1 trials will provide further insight into the effect of NaCl supplementation and might enable the (prior) identification of patients who benefit from NaCl supplementation.

## FR-PO338

### Modelling APRT Deficiency in Kidney Cells In Vitro

Hildur R. Helgudottir,<sup>1</sup> Runolfur Palsson,<sup>2,1</sup> Vidar O. Edvardsson,<sup>2,1</sup> Thorarinn Gudjonsson.<sup>1,2</sup> APRT Deficiency Research Program of the Rare Kidney Stone Consortium <sup>1</sup>Heilbrigdisvisindasvid - Haskoli Island, Reykjavik, Iceland; <sup>2</sup>Landspítali–The National University Hospital of Iceland, Reykjavik, Iceland.

**Background:** Adenine phosphoribosyltransferase deficiency (APRTd) is a rare autosomal recessive disorder of adenine metabolism that results in the generation and renal excretion of large amounts of the poorly soluble 2,8-dihydroxyadenine (DHA). Affected individuals form urinary stones and crystal nephropathy characterized by inflammation and fibrosis leading to progressive chronic kidney disease. Improved understanding of the mechanisms of DHA crystal-induced kidney injury and identification of alternative therapeutic approaches remain essential unmet needs. The aim of this study was to establish a cell culture model for the characterization of inflammatory and phenotypic changes associated with DHA crystal-induced kidney injury that may be used as targets for clinical interventions.

**Methods:** Two kidney cell lines, Madin-Darby canine cell line (MDCK) and human embryonic cell line (HEK293) were used in the study. Both cell lines were treated with DHA in concentrations similar to those observed in the urine of untreated humans with APRTd, both in monolayers and 3D/transwell assays. Further, siRNA against APRT was utilized to knock down the gene in HEK293. Read-out assay included cell viability, RT-PCR, western blot and immunostaining.

**Results:** APRT knockdown was successful and confirmed with RT-qPCR. Expression of the APRT gene was significantly reduced, and the morphology of the cells changed with knockdown, cells showing more elongated protrusions than control cells. The addition of DHA did not significantly affect cell viability. Initial analysis demonstrated an increase in the expression of proinflammatory markers (interleukin (IL)-1 $\beta$  and IL-8) in HEK293 cells upon DHA treatment, indicating an inflammatory response.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** We have established a cell culture model that captures APRT deficiency in MDCK and HEK293 kidney cell lines. Preliminary data suggest that DHA treatment of these cell lines in vitro induces an inflammatory response. Ongoing experiments focus on further characterizing the inflammatory response pathways and phenotypic changes in the search for disease-specific targets for clinical interventions.

**Funding:** Government Support - Non-U.S.

**Baseline Characteristics of Patients With Fabry Disease Enrolled in the Pegunigalsidase Alfa Expanded-Access Program**  
Ankit Mehta,<sup>1</sup> William Wilcox,<sup>2</sup> Khan J. Nedd,<sup>3</sup> John A. Bernat,<sup>4</sup> Jasmine Knoll,<sup>5</sup> John L. Jefferies,<sup>6</sup> Nicola Longo,<sup>7</sup> Eric L. Wallace,<sup>8</sup> Einat Almon,<sup>9</sup> Sari Alon,<sup>9</sup> Raul Chertkoff,<sup>9</sup> Dawn Sullivan,<sup>10</sup> Rossana Rocco,<sup>10</sup> Irene Koulinksa,<sup>10</sup> Ozlem Goker-Alpan.<sup>11</sup> <sup>1</sup>*Baylor University Medical Center at Dallas, Dallas, TX;* <sup>2</sup>*Emory University School of Medicine, Atlanta, GA;* <sup>3</sup>*Infusion Associates, Grand Rapids, MI;* <sup>4</sup>*University of Iowa Hospital and Clinics Iowa City, Iowa City, IA;* <sup>5</sup>*Phoenix Children's Hospital, Phoenix, AZ;* <sup>6</sup>*The University of Tennessee Health Science Center, Memphis, TN;* <sup>7</sup>*University of Utah, Salt Lake City, UT;* <sup>8</sup>*University of Alabama at Birmingham, Birmingham, AL;* <sup>9</sup>*Protalix Biotherapeutics, Carmiel, Israel;* <sup>10</sup>*Chiesi USA, Inc, Boston, MA;* <sup>11</sup>*Lysosomal & Rare Disorders Research & Treatment Center, Fairfax, VA.*

**Background:** Fabry disease (FD) is a rare genetic disorder caused by deficiency in lysosomal enzyme, alpha-galactosidase A ( $\alpha$ -Gal A), activity. Pegunigalsidase alfa (PA) is a novel PEGylated  $\alpha$ -Gal A enzyme replacement therapy in development for FD. An expanded-access program (EAP) is offered in the US to adults with FD that cannot be adequately managed with approved drugs and who are not eligible for clinical trials. Characterizing patients in an EAP is critical to understanding unmet needs.

**Methods:** We collated baseline characteristics for patients with FD enrolled in the ongoing EAP in the US as of January 1, 2022.

**Results:** At the data cutoff date, 30 patients had enrolled in the EAP; primarily due to worsening disease symptoms and/or poor tolerability of infusions. There was a mean of 12.9 (SD 11.8) years since diagnosis and most patients had received agalsidase beta treatment (mean duration 7.1 [SD 4.7] years). Median (range) baseline eGFR was 91.4 mL/min/1.73m<sup>2</sup> (14.1–131.9) and median concentration (range) of plasma globotriaosylsphingosine was 18.1 nM (0.8–134.6)

**Conclusions:** Assessment of patients in the PA EAP demonstrated gaps in current treatment options for FD. Some patients had experienced persistent symptoms despite treatment and/or poor tolerability of infusions and may benefit from the PA EAP. Follow-up of clinical outcomes from this EAP will be monitored and presented as data become available.

**Funding:** Commercial Support - o This study was sponsored by Protalix Ltd. Medical writing support was provided by Ebony Lai Hing, PhD, of Oxford PharmaGenesis, Newtown, PA, and was funded by Chiesi USA, Inc.

**Fabry Disease Mouse Is Resistant to High-Salt Diet-Induced Hypertension Probably via Dysfunctional Sodium Transporters and Aquaporin 2**  
Junkyu Park, Wonji Jo, Sungjin Chung, Eun Sil Koh. *The Catholic University of Korea, Seoul, Republic of Korea.*

**Background:** Fabry disease is a rare X-linked lysosomal storage disorder resulting from an error in glycosphingolipid metabolism caused by the *GLA* gene mutation. Patients with Fabry disease often have near normal or even low systemic blood pressure although the mechanism underlying such observed finding remains unexplained. This study examined whether a high salt intake could affect transport of sodium and water and induce hypertension in mice with Fabry disease.

**Methods:** Fabry disease model mice (B6;129-Gla<sup>tm1</sup>Kul/J) and wild-type (WT) mice received 8% or normal NaCl salt diet for 2 weeks.

**Results:** A high-salt diet for 2 weeks generated higher blood pressure in WT mice but not in Fabry disease mice. Free water clearance (FWC) and electrolyte free water clearance (EFWC) in groups fed with a high salt diet were lower than those in groups fed with a normal salt diet. Both high salt-fed WT and Fabry disease mice had decreased  $\gamma$ -subunit of epithelial Na channel (ENaC) compared with normal salt-fed groups. In Fabry disease mice fed a high-salt diet, there was an decrease in renal expressions of Na<sup>+</sup>/H<sup>+</sup> exchanger isoform 3 (NHE3) and Na<sup>+</sup>-Cl<sup>-</sup> cotransporter (NCC) compared with WT mice fed a high-salt diet. Although renal expression of vasopressin V2 receptor (V2R) was upregulated in Fabry mice fed with a high salt diet, renal aquaporin 2 (AQP2) level failed to increase up to the level in WT mice fed with a high salt diet.

**Conclusions:** These findings suggest that the decreased expression of NHE3 and NCC and impaired response of AQP2 in kidneys of Fabry disease to a salt load could be one of mechanisms by which Fabry disease could have resistance to the development of hypertension.

FR-PO341

**TFEB Activation by Ceria-Zirconia Antioxidant Nanoparticles Attenuates Kidney Injury in Cellular and Animal Models of Fabry Disease**  
Se-Hee Yoon,<sup>1</sup> Won Min Hwang,<sup>1</sup> Yohan Park,<sup>1</sup> Sung-Ro Yun,<sup>1</sup> Kuk Ro Yoon.<sup>2</sup> <sup>1</sup>*Konyang University College of Medicine, Daejeon, Republic of Korea;* <sup>2</sup>*Hannam University, Daejeon, Republic of Korea.*

**Background:** Fabry disease (FD) is a lysosome storage disease (LSD) characterized by significantly reduced intracellular autophagy function. This contributes to the progression of intracellular pathologic signaling and can lead to organ injury. Phospholipid-polyethyleneglycol-capped Ceria-Zirconia antioxidant nanoparticles (PEG-CZNP) have been reported to enhance autophagy flux. We investigated the signalling pathway of PEG-CZNP associated with autophagy flux function and analyzed whether they suppress kidney injury in both cellular and animal models of FD.

**Methods:** PEG-CZNP with size 2-3nm were synthesized using non-hydrolytic sol-gel reaction. HK-2 cells and conditionally human immortalized podocytes were transfected with shRNA targeting  $\alpha$ -GLA. FD model mice, B6;129-Glatm1Kul/J (known as  $\alpha$ -Gal A KO mice) were used for *in-vivo* study. Mice were sacrificed at 3- and 6-month age for investigation.

**Results:** PEG-CZNP treatments decreased the intracellular globotriaosylceramide (Gb3) accumulation levels in both cellular and animal models of FD by enhancing the autophagy flux. PEG-CZNP enhanced TFEB nuclear translocation by GSK3 $\beta$  inhibition. Activated TFEB by PEG-CZNP restored the blunted ATK/mTOR pathway in cellular models of FD. PEG-CZNP led to decrease of the intracellular oxidative stress, inflammatory response and fibrosis in cellular and animal models of FD.

**Conclusions:** TFEB activation by PEG-CZNP recovered the diminished autophagy flux function in cellular and animal models of FD and showed the potential as a new therapeutic medicine by alleviating the progression of kidney injury in FD.

FR-PO342

**Modeling Fabry Disease in Kidney and Heart Organoids From Patient-Derived Human Induced Pluripotent Stem Cells**  
Sandra D. Laufer,<sup>1</sup> Anna Reinelt,<sup>1</sup> Milagros N. Wong,<sup>1</sup> Linda Blomberg,<sup>2</sup> Christine E. Kurschat,<sup>2</sup> Nicola Wanner,<sup>1</sup> Victor G. Puelles,<sup>1</sup> Tobias B. Huber,<sup>1</sup> Fabian Braun.<sup>1</sup> <sup>1</sup>*Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany;* <sup>2</sup>*Uniklinik Köln, Köln, Germany.*

**Background:** Fabry disease is an inherited lysosomal storage disorder, caused by mutations in the *GLA* gene, resulting in a multisystemic disease. Currently existing animal models fail to mirror the complexity of this clinical & molecular phenotype, specifically Fabry nephropathy and cardiomyopathy. This project aims to establish informative human in vitro systems for Fabry disease to advance our molecular understanding by employing the recent advances in human induced pluripotent stem cells (hiPSC) and organoid differentiation

**Methods:** We collected primary urinary cells (PUCs) of 15 Fabry patients with different mutations (classical, classical and chaperone amenable, late onset, unclear significance). 8 PUC samples were reprogrammed into hiPSC with subsequent creation of respective isogenic control lines by CRISPR Cas9 gene editing. These cell lines were differentiated into kidney and heart organoids as well as engineered heart tissue (EHTs) using published protocols.

**Results:** All patient-derived hiPSC lines and organoids retained decreased enzyme activity and Gb3 accumulation. Fabry mutations did not impair the differentiation into organoids and EHTs. Kidney organoids depicted the presence of marker proteins for different nephron segments, including glomerular structures. Heart organoids showed contractions and contained different cardiac cell types including cardiomyocytes with sarcomeres and Z-Disc formation. EHTs displayed functional abnormalities including decreased contractile force and arrhythmic beating indicative of molecular changes due to GLA deficiency.

**Conclusions:** This project underlines the advantages of novel complex human *in vitro* disease modelling to study Fabry disease. Ongoing experiments focus on the detailed structural assessment and single cell analyses of the established systems in the presence and absence of available therapies.

**Funding:** Commercial Support - Amicus Therapeutics, Government Support - Non-U.S.

## FR-PO343

### Discovery of a Novel Autophagy Activator to Treat Autosomal Dominant Tubulointerstitial Kidney Disease

Yeawon Kim,<sup>1</sup> Chuang Li,<sup>1</sup> Chenjian Gu,<sup>1</sup> Eric Tycksen,<sup>1</sup> Sun-Ji Park,<sup>1</sup> Anuradhika Puri,<sup>1</sup> Terri A. Pietka,<sup>1</sup> Jothilingam Sivapackiam,<sup>1</sup> Kendrah O. Kidd,<sup>2</sup> Bryce G. Johnson,<sup>3</sup> Stanislav Kmoch,<sup>3</sup> Jeremy S. Duffield,<sup>6</sup> Anthony J. Bleyer,<sup>2</sup> Meredith Jackrel,<sup>1</sup> Fumihiko Urano,<sup>1</sup> Vijay Sharma,<sup>1</sup> Maria Lindahl,<sup>4</sup> Ying M. Chen.<sup>1</sup> <sup>1</sup>Washington University in St Louis, St Louis, MO; <sup>2</sup>Wake Forest University, Winston-Salem, NC; <sup>3</sup>Univerzita Karlova, Prague, Czechia; <sup>4</sup>Helsingin yliopisto, Helsinki, Finland; <sup>5</sup>Pfizer Inc, New York, NY; <sup>6</sup>Prime Medicine, Cambridge, MA.

**Background:** Autosomal dominant tubulointerstitial kidney disease due to uromodulin mutations (ADTKD-UMOD) is one of the leading hereditary kidney diseases. UMOD is largely expressed in the thick ascending limb (TAL) tubular cells, and the p.His177\_Arg185del in-frame deletion is one of the most prevalent human mutations. Currently there is no treatment for ADTKD.

**Methods:** CRISPR/Cas9 was utilized to generate an ADTKD-UMOD mouse model carrying *Umod* p.Tyr178\_Arg186del, analogous to human p.His177\_Arg185del. Inducible tubular-specific MANF transgenic and TAL-specific MANF knockout mice were also generated. Meanwhile, stable HEK cell line harboring WT or p.His177\_Arg185del was established. RNA sequencing was performed on isolated primary TAL cells. Immunoblot, q-PCR, immunofluorescence staining and electron microscopy were employed. Mitochondrial function was assessed by Oroboros high resolution respirometry and mitochondrial ROS was monitored by <sup>68</sup>Ga-Galuninox PET/CT in live animals for the first time.

**Results:** We find activated endoplasmic reticulum (ER) stress, severely impaired autophagy/mitophagy and dysfunctional mitochondria in the mutant TAL tubules, and mitochondrial DNA leaking to cytosol leads to activation of the cyclic GMP-AMP synthase-stimulator of interferon genes (cGAS-STING) inflammatory pathway and cell death in the *Umod* Y178-R186del mice. Mesencephalic astrocyte-derived neurotrophic factor (MANF), a novel ER stress-regulated secreted protein is induced in both mutant kidney and kidney biopsies with the mutation. We demonstrate that genetic ablation of MANF in TALs worsens autophagy and mitochondria failure, and exacerbates kidney fibrosis. Conversely, tubular overexpression of MANF after the onset of disease stimulates autophagy/mitophagy through activation of p-AMPK-FOXO3 axis, leading to increased autophagic clearance of mutant UMOD. Moreover, MANF induction promotes mitochondrial biogenesis and oxidative phosphorylation, as well as alleviates cGAS-STING signaling, thereby improving kidney function.

**Conclusions:** Our findings uncover a previously unknown mechanism of MANF action that can activate autophagy and protect mitochondrial function in ADTKD.

**Funding:** NIDDK Support, Other NIH Support - NIBIB and NHLBI, Other U.S. Government Support

## FR-PO344

### Knock-Down of Uromodulin Using Antisense Oligonucleotides as a Potential Treatment for Autosomal Dominant Tubulointerstitial Kidney Disease

Kathy Y. Morgan, Nino Jungels, Ryan A. Oliver, Tushare Jinadasa, Kailash Adhikari, Nicholas L. Kern, Saad Sohail, Stephanie Garcia, Annika Malmberg, Kevin Kim. Sarepta Therapeutics Inc, Cambridge, MA.

**Background:** Autosomal Dominant Tubulointerstitial Kidney Disease-Uromodulin (ADTKD-UMOD) is a genetic disease caused by mutations in the uromodulin (UMOD) or Tamm-Horsfall protein. The misfolded UMOD prevents the secretion of the protein and causes intracellular UMOD to aggregate and accumulate inside the loop of Henle and distal convoluted tubule. This aggregation leads to progressive and irreversible chronic kidney disease. We hypothesized that peptide-conjugated phosphorodiamidate morpholino oligonucleotides (PPMOs) can knock down *UMOD* expression, which can potentially reduce the disease-causing UMOD aggregation inside the cells.

**Methods:** A library of PPMOs was designed to bind to the complementary sequences of the mouse *Umod* gene and induce nonsense-mediated decay. These PPMOs were screened in mIMCD-3 cells, which express endogenous *Umod*, to find the most efficacious sequence. The sequence that caused the largest *Umod* knockdown was then further characterized *in vitro* and *in vivo*.

**Results:** After screening the library of PPMOs, PPMOs that exhibited knockdown of *Umod* expression were further characterized and demonstrated robust knockdown of *Umod* expression in a dose-dependent manner in mIMCD-3 cells. In the high dose group, up to 85% knockdown of *Umod* expression was observed. PPMO was then dosed in wild-type mice where up to 70% knockdown of *Umod* was observed.

**Conclusions:** PPMOs to knockdown *Umod* and have shown their efficacy both *in vitro* and *in vivo*. These findings demonstrate that PPMOs have the potential to preserve renal function in patients with ADTKD.

**Funding:** Commercial Support - Sarepta Therapeutics, Inc.

## FR-PO345

### Pkd2 Re-Expression Can Reverse Liver Cysts and Improve GFR in Mouse Models of Autosomal Dominant Polycystic Kidney Disease

Ke Dong,<sup>1</sup> Mingshen Tham,<sup>1</sup> Adrian Cordido,<sup>1</sup> Yiqiang Cai,<sup>1</sup> Steven Lim Cho Pei,<sup>1</sup> Rishi Bhardwaj,<sup>1</sup> Zemeng Wei,<sup>1</sup> Michael Rehman,<sup>1</sup> Kasturi Roy,<sup>1</sup> Xin Tian,<sup>1</sup> Stefan Somlo.<sup>1,2</sup> <sup>1</sup>Yale University School of Medicine Department of Internal Medicine, New Haven, CT; <sup>2</sup>Yale University School of Medicine Department of Genetics, New Haven, CT.

**Background:** We have previously shown that PKD gene re-expression reverses polycystic kidney disease in inducible, whole nephron Cre mediated mouse models of ADPKD. We now sought to investigate the potential for cyst reversal in the *Pkd2*<sup>WS25</sup> mouse model in which macrocyst formation occurs by stochastic, non-Cre recombinase dependent, second hit events that better resemble the genetic mechanism of human ADPKD and allows determination of the potential to reverse both polycystic kidney and liver phenotypes.

**Methods:** *Pkd2*<sup>WS25/-</sup> and tamoxifen inducible *Pkd2*-BAC re-expression (*Pkd2*<sup>FSF;Rosa26<sup>Flpo</sup>ER</sup>) models previously established in the lab were intercrossed to generate *Pkd2*<sup>WS25/-</sup>; *Pkd2*<sup>FSF;Rosa26<sup>Flpo</sup>ER</sup> mice (*Pkd2*<sup>WS25/Flpo</sup>). *Pkd2* re-expression was induced with 7 daily intraperitoneal tamoxifen injections beginning at 16 weeks. Serial kidney MRI were obtained at 16, 19 and 24 weeks and kidney and liver histology was examined at 24 weeks. In addition, we used our published *Pkd2*<sup>Cre/Flpo</sup> model with doxycycline induced *Pkd2* inactivation at 4-6 weeks and reactivation at 16 weeks to measure serial GFR at 16 and 19 weeks.

**Results:** Compared to 16-week-old *Pkd2*<sup>WS25/-</sup> mice, kidney weight/body weight ratio (1.812% vs 1.333%, *P*=0.0049), liver weight/body weight ratio (5.299% vs 4.371%, *P*=0.0198) and kidney cystic index (22.18% vs 7.164%, *P*=0.0002) were significantly reduced in 24-week-old *Pkd2*<sup>WS25/Flpo</sup> mice following *Pkd2* reactivation at 16 weeks. Moreover, MRI images shows progressive decrease in kidney cystic burden from 16 to 24 weeks. Kidney and liver histology at 24 weeks showed reduced cystic changes but persistent residual fibrosis and focal inflammation compared to 16-week-old *Pkd2*<sup>WS25/-</sup> mice which exhibited multifocal cysts. Separately, *Pkd2*<sup>Cre/Flpo</sup> mice which showed reduced GFR at 16 weeks before *Pkd2* re-expression, had normalization of GFR at 19 weeks age, 3 weeks after *Pkd2* re-expression (0.77 ml/min/100g vs 1.45 ml/min/100g, *P*=0.0032).

**Conclusions:** *Pkd2* re-expression can reverse both kidney and liver cysts in a spontaneous, non-Cre recombinase dependent *Pkd2* model that more closely recapitulates the human ADPKD phenotype with a smaller number of larger macrocysts. Furthermore, our follow-up study to our published data shows that improved GFR accompanies improved histology following Pkd gene re-expression.

## FR-PO346

### A Novel Organoid Model for Autosomal Dominant Polycystic Kidney Disease Based on Mouse Nephron Progenitor Cells (NPCs)

Yu Ishimoto,<sup>1</sup> Toshikazu Araoka,<sup>2</sup> Luis F. Menezes,<sup>1</sup> Tatsuya Shimizu,<sup>2</sup> Shin-ichi Mae,<sup>2</sup> Kenji Osafune,<sup>2</sup> Gregory G. Germino.<sup>1</sup> <sup>1</sup>National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD; <sup>2</sup>Center for iPS Cell Research and Application, Kyoto University, Kyoto, Japan.

**Background:** An *in vitro* cell culture system that accurately recapitulates ADPKD cystogenesis is needed, and a human iPS cell-derived nephron organoid system is one of the options. However, the process takes >20 days, differentiation efficiency varies between cell lines, and long-term methods of induction of differentiation result in higher inter-experiment variability. Moreover, the lack of a mouse-based system means that the results of *in vitro* studies cannot be easily assessed in a whole organism. To overcome these problems, we have established a mouse nephron organoid system from primary NPCs.

**Methods:** We sorted NPCs from mouse E13.5 embryonic kidneys using antibodies that detect kidney lineage differentiation markers. Sorted NPCs were maintained in 3D expansion culture and evaluated for their nephrogenic potential. We modified conditions to assess organoid differentiation using both air-fluid and suspension culture methods. Finally, we used established differentiation protocols to evaluate cystogenesis in nephron organoids derived from NPCs of ADPKD mouse models.

**Results:** Robo2<sup>high</sup>/Pdgfrb<sup>+</sup>/Podocalyxin<sup>+</sup> cells (NPCs) sorted from E13.5 embryonic WT, *Pkd1*<sup>KO/KO</sup>, *Pkd2*<sup>KO/KO</sup>, and *Pkd1*<sup>claculo</sup>; tamoxifen *Cre* kidneys could be cultured for >40 passages and maintain nephrogenic potential, and they could be differentiated into nephron organoids using either air-fluid or suspension culture methods in <10 days. NPCs established from ADPKD models spontaneously formed cyst-like structures without inducers like forskolin in suspension culture but not in air-fluid culture.

**Conclusions:** Mouse primary NPCs could be maintained long term with nephrogenic potential. ADPKD mutants spontaneously make cyst-like structures when grown in suspension. This is the first mouse NPC-based organoid system that appears to make cyst-like structures spontaneously and will be a useful tool to reveal mechanisms of cystogenesis in ADPKD.

**Funding:** NIDDK Support

## FR-PO347

### Novel Missense Mutation in SAMD9L Linked to Autosomal Dominant Cystic Kidney Disease in Mice Associated With Proteostatic Stress and Metabolic Reprogramming

Dorian Kaminski,<sup>1</sup> Yalu Zhou,<sup>1</sup> Dilip K. Deb,<sup>1</sup> Joshua S. Waitzman,<sup>2</sup> Susan E. Quaggin,<sup>1,3</sup> <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>Beth Israel Deaconess Medical Center, Boston, MA; <sup>3</sup>Northwestern Memorial Hospital, Chicago, IL.

**Background:** Genetic cystic kidney syndromes, including polycystic kidney disease and nephronophthisis, are important causes of renal impairment. Here, we present a cystic kidney phenotype in mice carrying a novel missense mutation in *SAMD9L*, a gene that has previously been implicated in congenital autoinflammatory disorders and pediatric myelodysplastic syndrome.

**Methods:** An ENU mutagenesis library was screened for renal phenotypes and mutant mouse strains were established via backcrossing. The candidate gene was identified via mutation mapping, exome capture, high throughput sequencing on the SOLiD 4 platform (Applied Biosystems) and confirmed via whole-genome sequencing on the Illumina XTen machine. The phenotype was characterized via whole-body imaging, histology, immunoblotting, bulk RNAseq, and scRNA-seq on the 10x platform.

**Results:** A mutant with cystic kidneys was identified. While heterozygous mice exhibited a renal-restricted phenotype inherited in an autosomal dominant fashion, homozygous mutants exhibited perinatal lethality due to vascular anomalies and hypoxia. The trait was inherited in Mendelian ratios. Mutation mapping and high throughput sequencing revealed a critical region on Chr6 containing an A→T transversion in the coding region of *SAMD9L*. Kidney histology renal cysts along the entire length of the nephron and collecting system, including glomerulocysts. Bulk and scRNAseq of mutant kidneys revealed differential expression of several hundred genes, but not genes previously implicated in inherited cystic kidney disease. In homozygous mutants, there was marked differential expression of genes involved in the unfolded protein response, c-Myc signaling, and fatty acid oxidation. In heterozygous mutants, a similar but attenuated transcript signature was seen in differentiated nephron progenitors and mature epithelial clusters.

**Conclusions:** We identified a novel missense mutation in *SAMD9L* that resulted in a severe cystic kidney phenotype, with associated perturbations in proteostatic stress pathways and metabolism. Future experiments will include *in vivo* metabolic flux analysis and *in vitro* measurement of translation dynamics in a cell culture model.

## FR-PO348

### Repurposing Calcium-Sensing Receptor Activator Cinacalcet for Autosomal Dominant Polycystic Kidney Disease Treatment

Pattareeya Yottasan, Qi Tiffany Chu, Onur Cil. University of California San Francisco, San Francisco, CA.

**Background:** ADPKD is characterized by progressive cyst formation and enlargement leading to renal failure. Elevated cAMP is a key mechanism of ADPKD progression by promoting cell proliferation, cystogenesis, and cyst enlargement (via Cl<sup>-</sup> and fluid secretion). V2 receptor antagonist tolvaptan is currently the only FDA-approved treatment for ADPKD; however, it can cause serious adverse effects including hepatotoxicity. There remains an unmet clinical need for effective and safe treatments for ADPKD. The extracellular Ca<sup>2+</sup>-sensing receptor (CaSR) is a major regulator of ion transport in kidney tubules and ADPKD cyst epithelia. Cinacalcet is an FDA-approved CaSR activator used for treatment of hyperparathyroidism associated with CKD and renal failure. We recently showed that cinacalcet has marked antisecretory effects in human intestinal cell and mouse models of cholera by activating phosphodiesterases (PDE) that hydrolyze cAMP (*JCI Insight* 2021, 6:e146823). Since elevated cAMP is the key shared pathophysiological mechanism for Cl<sup>-</sup> and fluid secretion in cholera and ADPKD, we hypothesize that cinacalcet can reduce cyst enlargement in ADPKD.

**Methods:** We studied the effects of cinacalcet on Cl<sup>-</sup> secretion, investigated its mechanisms of action; and tested its efficacy on cyst enlargement in MDCK cells and a mouse model of ADPKD.

**Results:** Cinacalcet (30 μM) pretreatment inhibited cAMP-induced Cl<sup>-</sup> secretion and CFTR activity in MDCK cells as suggested by ~70% lower short-circuit current (I<sub>sc</sub>) changes in response to forskolin and CFTR<sub>inh</sub>-172, respectively. Cinacalcet pretreatment inhibited forskolin-induced cAMP elevation by 60% in MDCK cells, and its effect was completely reversed by PDE inhibitor IBMX. In MDCK cells grown in collagen matrix and treated with forskolin, cinacalcet treatment (1-10 μM, Day 6 onward) concentration-dependently reduced cyst enlargement by up to 50% at Day 12 without affecting cell viability (assayed by Alamar blue). In preliminary studies, cinacalcet treatment (30 mg/kg/day for 7 days) reduced renal cyst enlargement in *Pkd1lox;KspCre* mice.

**Conclusions:** Cinacalcet reduces cyst enlargement in cell and mouse models of ADPKD by reducing cAMP via PDE activation. Considering its efficacy shown here, and favorable safety profile including extensive post-approval data, cinacalcet can be repurposed as a novel ADPKD treatment.

## FR-PO349

### Proteomic Analysis of Acutely Injured Kidneys Following Treatment With Mesenchymal Stem Cells

Chris Erickson,<sup>1</sup> Danielle Soranno,<sup>2</sup> <sup>1</sup>University of Colorado, Denver, CO; <sup>2</sup>Indiana University, Bloomington, IN.

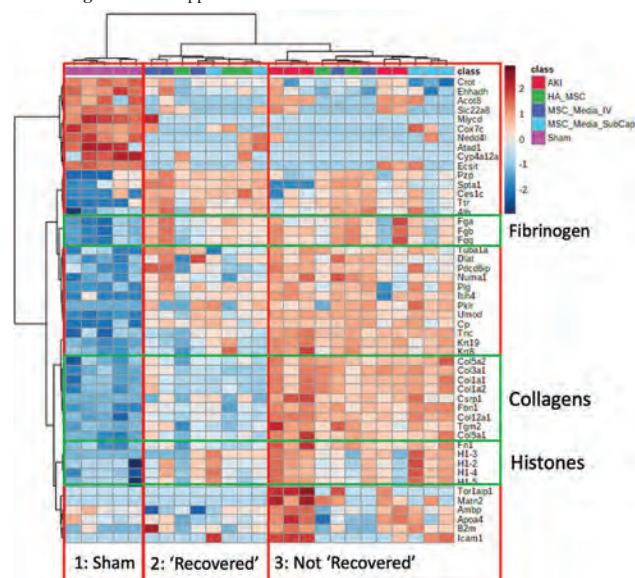

**Background:** Acute kidney injury (AKI) can result in renal fibrosis and kidney disease. Mesenchymal stem cells (MSC) have been studied as a potential treatment to mitigate renal damage from AKI. Proteomics can give insights into cell and tissue response by profiling changes to the extracellular matrix (ECM) following AKI. In this study we investigate changes to the kidney proteome following AKI and treatment with MSCs.

**Methods:** All procedures were IACUC approved. 8 week-old C57BL/6J male mice underwent bilateral ischemia-reperfusion AKI (clamp time 25 min). Animal groups were: AKI treated with: 1) MSC injected under renal capsule (subcap); 2) MSC injected IV; 3) MSC in hyaluronic acid hydrogels injected subcap; 4) No treatment; or 5) Sham AKI. After 3 months, mice were euthanized, kidneys harvested, processed for ECM extraction, and resultant renal tissue (N=5/group) were analyzed for proteomics by LC-MS/MS. Bioinformatics was performed on the resulting dataset. Statistical significance was determined by FDR corrected ANOVA p-value <0.05.

**Results:** MSC-treated mice did not cluster by proteomic analysis according to delivery method. Hierarchical clustering of the most expressed proteins showed three groups: 1) Sham AKI; 2) 'Recovered' treated kidneys (RK); and 3) 'Not Recovered' treated kidneys (NRK), which closely correlated with the untreated AKI group. NRKs showed high expression of fibrinogen, fibrillar collagens, and histones. The RK group showed attenuated expression of fibrinogens, collagens, and histones.

**Conclusions:** Our results showed increases in fibrinogen, fibrillar collagens, and histones in NRKs after AKI; whereas RKs showed lower levels of these proteins, indicating lower levels of fibrosis and preservation of ECM integrity. Further studies will investigate the mechanism of action of MSC therapy.

## FR-PO350

### Uncovering the Podocyte Foot Process Proteome

Gary F. Gerlach, Lori L. O'Brien. The University of North Carolina at Chapel Hill, Chapel Hill, NC.

**Background:** Podocyte foot process integrity is vital for kidney function and health. Disruptions to podocyte architecture, or effacement, is one of the most common clinical observation in kidney disease. However, the full complement of proteins responsible for maintaining podocyte foot process integrity remains unresolved.

**Methods:** The discovery of a proximity-dependent biotin identification (BioID) moiety that utilizes a promiscuous biotin ligase has opened new avenues to discover spatially localized proteomes. Podocin (*Nphs2*), localizing to the slit diaphragm, was employed as a handle to identify the *in vivo* proteome of the podocyte foot process via knock in of the BioID moiety into the murine *Nphs2* locus (Podocin-BioID).

**Results:** We validated our Podocin-BioID model by assessing correct expression and localization of the fusion protein via western blot, immunofluorescence (IF), and localization to the slit diaphragm via electron microscopy. Subcutaneous injection of biotin into Podocin-BioID mice yields a significant enrichment of biotinylated proteins in podocytes. We isolated these biotinylated proteins and performed mass spectrometry (MS) analysis to identify proteins localized to the foot process. *In silico* analysis of the top proteins uncovered from MS identified 'cell junctions', 'actin binding', and 'cytoskeleton organization' as the top gene ontology terms. Our analyses uncovered a novel Immunoglobulin-like domain-containing receptor 2 (Ildr2) protein as highly

expressed within the podocyte foot process. We confirmed Ildr2 expression in mouse podocytes by IF and *in situ* hybridization. Further, publicly available single cell RNA-seq databases detail conserved Ildr2 expression in human podocytes.

**Conclusions:** Ildr2 has documented expression in tricellular tight junctions and roles in immunomodulation with the ability to ameliorate autoimmune disease states in models of multiple sclerosis, type I diabetes, and rheumatoid arthritis. Yet the function of Ildr2 in podocyte development, integrity, and contribution to kidney immune cell modulation remains unknown. At large the podocytes' role in immunomodulation remains a relatively unexplored niche which we aim to test through podocyte specific deletion of Ildr2. In summary our innovative strategy enabled the identification of novel components of the podocyte foot process proteome leading to a new set of biomarkers and candidates for renal disease therapeutics.

## FR-PO351

### Trajectory Analysis of the Kidney Organoid Proteome Extends Its Modelling Potential of Disease

Moritz Lassé,<sup>1</sup> Fatih Demir,<sup>3</sup> Sean Eddy,<sup>2</sup> Jamal El Saghir,<sup>2</sup> Matthew Fischer,<sup>2</sup> Léna L. Bonin,<sup>3</sup> Arvid D. Hutzfeldt,<sup>1</sup> Bernhard Dumoulin,<sup>1</sup> Linda Reinhard,<sup>1</sup> Elion Hoxha,<sup>1</sup> Bodo B. Beck,<sup>4</sup> Matthias Kretzler,<sup>2</sup> Jennifer L. Harder,<sup>2</sup> Markus M. Rinschen,<sup>1,3</sup> <sup>1</sup>Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; <sup>2</sup>University of Michigan, Ann Arbor, MI; <sup>3</sup>Aarhus Universitet, Aarhus, Denmark; <sup>4</sup>Uniklinik Köln, Cologne, Germany.

**Background:** Kidney organoids are a valuable and innovative model to understand genetic diseases, kidney development and transcriptomic dynamics. However, details of proteome organization during organoid development are insufficiently characterized. It is unclear how the organoid proteome changes during differentiation, and if more complex disease processes such as inflammatory tissue responses could be modelled using organoids.

**Methods:** Here, we used proteomics to compare organoids with existing model systems such as native glomeruli and cultured podocytes. We characterize the trajectory of organoid differentiation and delineate innate immune responses in organoids to expand its scope as a model system in nephrology. We also compared our proteomics with bulk and single cell transcriptomic data.

**Results:** Genes involved in Focal segmental glomerulosclerosis (FSGS) and cystic kidney disease were abundantly expressed on protein level, distinguishing organoids from almost every available cell culture model. On their pathway to terminal differentiation, organoids developed increased deposition of extracellular matrix. Single cell transcriptomic analysis suggests that most changes locate to podocytes and early podocyte progenitors. This matrix deposition of organoids during maturation was similar to the matrix deposits found in human FSGS but differed markedly from other *in vitro* and *in vivo* animal disease models. A novel signaling system discovered was the TNF $\alpha$  system, a system also available in podocytes. Incubation of organoids with high concentrations of TNF $\alpha$  led to an activation of NF- $\kappa$ B signaling, and secretion of cytokines and complement components, alongside with extracellular matrix components.

**Conclusions:** We provide a repository of human kidney organoid proteins and show their potential to model pathophysiological pathways beyond genetic diseases. Signaling systems in these organoids link inflammatory signaling, production of cytokines and complement, and production of extracellular matrix.

## FR-PO352

### Development of Molecular Targeting Agents Enables Specific Gene Editing of Human Podocytes in Kidney Organoids

Nicole Vo, Benjamin S. Freedman. Dr. Benjamin Freedman lab *University of Washington, Seattle, WA.*

**Background:** Gene therapy offers many opportunities to treat kidney diseases. Kidney organoids are complex structures that resemble nephrons and can be used to develop gene therapy approaches. Commonly used gene transfer techniques, such as lentivirus and adeno-associated virus, are size limited, transient, or introduce DNA non-specifically into the genome. As in tissues, however, gene editing in organoids remains inefficient and non-specific. There is an unmet need for reporter systems that enable tracking of editing in different cell types. We sought to improve upon these challenges, using kidney organoids as a representative lineage.

**Methods:** To enable detection of genome editing events in different cell types, we developed a fluorescence-on (mCherry) reporter system in human iPS cells. Intact kidney organoids were transfected with CRISPR ribonucleoprotein (RNP) complexes. To improve delivery, we tested candidate surface markers to identify molecular targeting agents (MTAs) specifically recognizing podocytes, proximal tubules, or endothelial cells in live imaging assays. An MTA labeling podocytes (PodoTracker) was tethered to Cas9. Genome editing events were detected by changes in fluorescence in specific cell types, and next generation sequencing at the target locus.

**Results:** Confocal microscopy showed that mCherry+ cells were detected in kidney organoids treated with gRNA targeting fluorescence-on reporter, but not with a scrambled guide. Co-staining of gene edited cultures with nephron markers revealed editing in both proximal tubule cells and podocytes. By imaging analysis, the fluorescence-on editing efficiency in organoids was around 5%. MTAs successfully live-labeled podocytes within kidney organoids. Tethering of Cas9 to podocyte-targeting MTA produced increased rates of podocyte genome editing (mCherry<sup>+</sup>), relative to non-tethered Cas9.

**Conclusions:** Using fluorescence-on organoids, genome editing events can be monitored using individual cell types, showing editing rates consistent with sequencing. Coupling of Cas9 to MTAs is a promising approach to enhance delivery and edit specific cell types of interest. Because the cultures are derived from pluripotent stem cells, the platform may also be readily adapted to detect genome editing in other organ lineages. In the future, we will also test whether our tubule MTAs can selectively enable editing in tubules.

### Podocyte Maturation in Human Kidney Organoids Is Accelerated With Renin-Angiotensin System Activation

Waleed Rahmani,<sup>1,2</sup> Justin Chun.<sup>1,2</sup> <sup>1</sup>Department of Medicine, Cumming School of Medicine, Calgary, AB, Canada; <sup>2</sup>Calvin, Phoebe and Joan Snyder Institute for Chronic Diseases, Calgary, AB, Canada.

**Background:** The global prevalence of chronic kidney disease (CKD) is approximately 10% and rising. Current renal replacement modalities carry a significant socioeconomic burden and will struggle to meet rising demands. Pluripotent stem cell-derived kidney organoids have emerged as a promising alternative for providing functional nephrons to CKD patients. This technology faces many challenges including maturation as they resemble first and second-trimester fetal kidneys. The renin-angiotensin system (RAS) is critical for normal kidney morphogenesis. Indeed, prenatal exposure to RAS inhibitors is associated with kidney dysgenesis and mortality. We hypothesize that Ang II and RAS inhibitors perturb developmental programs within nephron progenitor populations and alter cell fate specification and maturation of glomerular epithelial cells within kidney organoids.

**Methods:** We performed single-cell RNA sequence analyses on human iPSC-derived kidney organoids treated acutely (24hrs) with vehicle, Ang II, losartan, or Ang II and losartan on 28th day of the Takasato protocol.

**Results:** Kidney organoids expressed all major RAS genes (*AGT*, *ACE1*, *ACE2*, *REN*, *AGTR1*, and *AGTR2*) within expected cell populations. *REN* expression was downregulated by Ang II and normalized with losartan pre-treatment suggesting a functioning RAS network. We identified 3 late podocyte (LP) clusters, 1 early podocyte (EP) cluster, 1 parietal epithelial (PEC) cluster, and 2 nephron progenitor (NPC) clusters. The EP and NPC transcriptional profiles were disproportionately sensitive to Ang II as we noted significant upregulation of podocyte differentiation genes such as *BMP7*, *FOXC2*, *PODXL*, and *NPHS2*. Moreover, Ang II depleted the immature populations (NPC and EP) and expanded mature cell states (PEC and LP). Losartan downregulated podocyte differentiation programs and increased the proportion of immature cells (EP and NPC).

**Conclusions:** Human kidney organoids developed a functioning intra-organoid RAS resembling *in vivo* intrarenal RAS. The lineage plasticity observed between NPCs, EPs, PECs, and LPs was sensitive to acute RAS perturbation. Ang II accelerated podocyte maturity while RAS inhibition held podocytes in an immature state. The next steps include testing different Ang II treatment durations, validating findings using immunocytochemistry, and reproducing this analysis on endothelial and tubule cells.

## FR-PO354

### Deep Learning Predicts the Differentiation of Kidney Organoids Derived From Human-Induced Pluripotent Stem Cells

Jong Young Lee,<sup>1</sup> Jinwon Kim,<sup>1</sup> Yong Kyun Kim,<sup>1</sup> Jin Kim,<sup>2</sup> Sun-ah Nam.<sup>1</sup> <sup>1</sup>Catholic University of Korea - Songeui Campus, Seoul, Republic of Korea; <sup>2</sup>Ajou University, Suwon, Gyeonggi-do, Republic of Korea.

**Background:** Kidney organoids derived from human pluripotent stem cells (hPSCs) contain multi-lineage nephrogenic progenitor cells and can recapitulate the development of the kidney. Kidney organoids differentiated from human pluripotent stem cells can be applied in regenerative medicine as well as renal disease modeling, drug screening and nephrotoxicity testing. However, despite culturing under the same conditions, there are differences in the shape and growth level of each kidney organoid, making it difficult for clinical application. We hypothesized that an automated non-invasive method based on deep learning of bright-field images of kidney organoids can predict their differentiation status.

**Methods:** Kidney organoids were differentiated from induced pluripotent stem cells (iPSC). Bright-field images of kidney organoids were collected on day 18 after differentiation. To train the convolutional neural networks (CNNs), we utilized a transfer learning approach: CNNs were trained to predict the differentiation of kidney organoids on bright-field images, based on the mRNA expression of renal tubular epithelial cells as well as podocytes.

**Results:** The best-performing prediction model with DenseNet121 had a total Pearson correlation coefficient score of 0.783 on a test dataset. Furthermore, we focused on the classification of kidney organoids, into two categories: organoids with above-average gene expression (*Positive*) and those with below-average gene expression (*Negative*). Comparing the best-performing CNN with human-based classifiers, the CNN algorithm had a receiver operating characteristic-area under the curve (AUC) score of 0.85, while the experts had AUC score of 0.48. Time needed to classify one organoid by the experts took 1.04 seconds, but 0.014 seconds by CNN.

**Conclusions:** In this study, the CNN model predicts organoid maturity more accurately and rapidly than experts. These results show that the maturity of organoids can be predicted based on the bright-field and that the artificial intelligence algorithm can successfully recognize the differentiation status of kidney organoids.

## FR-PO355

## Tuning Kidney Organoids to Generate High-Fidelity Proximal Tubule Cells

Jack Schnell, Mary Anne A. Achieng, Nils Lindstrom. *University of Southern California Department of Stem Cell Biology and Regenerative Medicine, Los Angeles, CA.*

**Background:** The most abundant cell in the kidney, proximal tubule (PT) cells, are poorly replicated across 3D kidney organoid models. PTs perform the bulk of renal reabsorption via the work of solute carriers and transporters for nutrients, toxins, and substrates. Defects to these cells often manifest as urinary wasting of nutrients. Studies have suggested role for transcription factor Hnf4a in PT maturation by driving the expression of transporters that impart physiological function to the PT, such as *Urat1*. Yet, recapitulating PT maturation in kidney organoids remains a challenge for regenerative therapeutics.

**Methods:** We undertook a stepwise approach that mimics early proximal precursor populations. HNF4A<sup>+</sup> PTs within organoids were increased through a modified protocol for the directed differentiation of a human induced pluripotent stem cell HNF4A reporter line. This was done by transiently treating organoids with a small-molecule inhibitor of PI3K signaling. RNA-sequencing and immunofluorescent validation were performed to assess organoids for PT maturation genes.

**Results:** Treated organoids underwent increases in the abundance of HNF4A<sup>+</sup> PTs. RNA-sequencing of organoids suggests increases in the urate and organic ion transporter *URAT1*, the glucose transporter *SGLT6*, amino acid transporters *SLC3A1* and *EAAC1*, and others (Fig. 1). These data suggest enhanced PT maturation and better recapitulation of normal physiology compared to control samples.

**Conclusions:** These data demonstrate that organoid nephron maturation can be enhanced by modifying differentiation. Promoting proximal precursors within kidney organoids increases the abundance of HNF4A<sup>+</sup> PTs at later stages of differentiation. These organoids exhibit increased expression of vital kidney transporters, suggesting that tuning early patterning can improve organoid functional potential. As such, these studies inform *in vitro* nephrogenesis strategies building regenerative therapeutics.

**Funding:** Other NIH Support - T32 Training Grant from USC Stem Cell and NIH NICHD

Percentage of total read counts from day 18 bulk RNA-seq of whole-organoid samples (n = 2).

## FR-PO356

## Hypoxia Triggers a Signature of Maladaptive Repair in Human Kidney Organoids

Ana B. Nunez Nescolarde,<sup>1</sup> Mehran Piran,<sup>1</sup> David J. Nikolic-Paterson,<sup>1,2</sup> Alexander N. Combes.<sup>1</sup> *<sup>1</sup>Monash University, Clayton, VIC, Australia; <sup>2</sup>Monash Health, Clayton, VIC, Australia.*

**Background:** Reduced oxygen levels during renal ischemia can induce AKI and lead to CKD through maladaptive repair. Tubulointerstitial fibrosis is a chronic and progressive feature of CKD, for which we lack effective treatments. To facilitate therapeutic studies, we develop a human kidney organoid model of hypoxia-induced renal fibrosis.

**Methods:** Human iPSC-derived organoids were generated from 3 different cell lines and cultured for 18 days, then subjected to hypoxia (1%O<sub>2</sub>) or normoxia (21%O<sub>2</sub>) for 48h (d20) followed by 5 days recovery period in normoxia (d25). Organoids were examined by gene expression profiling, immunohistochemistry and immunofluorescence microscopy.

**Results:** Robust hypoxic response was evident on d20 by 5- and 7-fold increases in mRNA levels of hypoxia-inducible genes *VEGFA* and *HK1*, respectively (both p<0.001, Fig 1A). Tubular damage marker *KIMI1/HAVCR1*, stress-response gene *JUN*, and profibrotic signal *TGFBI* were all upregulated (>2 fold p<0.001) in hypoxic organoids on d20, consistent with an AKI response (Fig 1A). Mitochondrial dysfunction was evident in hypoxic organoids on d20 with a 50% decrease (p<0.001) of *PPARGC1A* levels (Fig 1A). On d25, expression of hypoxia-responsive genes and AKI markers returned to control levels. However, proinflammatory cytokine *CCL2* (p<0.05), extracellular matrix components *COL1A1* (p<0.01) and matrix producing cells *ACTA2* were significantly upregulated in hypoxia-treated organoids (Fig 1A). Immunostaining at d25 for *COL1A1* affirmed increased collagen I deposition and reduction in tubular density (PAX8) in hypoxia-treated organoids (Fig 1B). We are currently profiling control and hypoxia-treated organoids from day 20 and 25 timepoints using bulk and single cell RNA-sequencing.

**Conclusions:** Here we show that kidney organoids transiently upregulate markers of AKI in response to hypoxia and later display signatures of maladaptive repair including elevated levels of ECM. These results suggest kidney organoids may aid in disease modelling and drug development for AKI and fibrosis.

**Funding:** Government Support - Non-U.S.

Figure 1. (A) Expression levels of AKI and CKD-related markers in normoxic and hypoxic kidney organoids at day 20 and 25. One-way ANOVA to test differences (p<0.05, \* <0.01, \*\* <0.001, \*\*\*). replicates from two iPSC lines. (B) Representative images of COL1A1 increase and PAX8 decrease from 3 batches of hypoxia-treated organoids at day 25. Scale bar = 100 μm.

## FR-PO357

## Human Collecting Duct Tubuloids of Principal Cells Derived From Ureteric Bud Organoids as Differentiated Cell Models for Physiology and Disease Modelling

Annarita Di Mise,<sup>1</sup> Kyle McCracken,<sup>4</sup> Ankit B. Patel,<sup>2,3</sup> Giovanna Valenti,<sup>1</sup> Takaharu Ichimura,<sup>3</sup> Joseph V. Bonventre.<sup>5</sup> *<sup>1</sup>Universita degli Studi di Bari Aldo Moro, Bari, Italy; <sup>2</sup>Vertex Pharmaceuticals Incorporated, Boston, MA; <sup>3</sup>Brigham and Women's Hospital, Boston, MA; <sup>4</sup>Boston Children's Hospital, Boston, MA; <sup>5</sup>Division of Renal Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

**Background:** 3D kidney cellular models, organoids or tubuloids that recapitulate tissue-specific pathophysiology, including disease phenotypes after genome editing, may represent useful tools for kidney disease modeling and drug screening. We report here the first model of tubuloids originated from 3D culturing of human collecting duct (hCD) cells obtained from pluripotent stem cells-derived ureteric bud organoids. These cells generate functional epithelia characterized by amiloride-sensitive transepithelial potential and high transepithelial resistance when evaluated in two-dimensional transwells. These functional properties of hCD principal cells are unique with no other comparable cell line available in the literature.

**Methods:** To generate hCD cell tubuloids, cells were cultured as monolayer (2D) or grown in Geltrex diluted in 2% serum DMEM/F12. After 1-2 days in Geltrex, hCD cells formed aggregates which developed into more complex 3D tubular structures, which detached from the original aggregates.

**Results:** Both 2D cultures and 3D tubuloid cells expressed *AVPR2* and *AQP2* gene transcripts by qPCR. The water channel, *AQP2*, was poorly expressed in 2D cells as assessed by immunofluorescence with higher expression in tubuloids primarily in the intracellular vesicles. Activation of the V2R with dDAVP induced *AQP2* relocation from the intracellular vesicles to the apical membrane of hCD-tubuloids, but not in 2D cells. Long-term exposure of hCD-tubuloids to dDAVP induced the growth of cysts. In addition, hCD tubuloids expressed *PC2*, a protein which is mutated in ~15% of individuals with Autosomal Dominant Polycystic Kidney Disease (ADPKD).

**Conclusions:** Since the collecting system plays an important role in regulating sodium, potassium, and acid-base homeostasis as well as disease states such as polycystic kidney disease and nephrogenic diabetes insipidus, the generation of hCD-tubuloids with functional properties of hCD principal cells represents a unique model for disease modelling in human cells *in vitro*.

**Funding:** NIDDK Support, Other NIH Support - NCATS, Government Support - Non-U.S.

## FR-PO359

## Vascularization of iPSC-Kidney Organoids In Vitro Is Improved by Co-Culturing With Macrophages

Yulia Kiyan,<sup>1</sup> Ekaterina Chernobryvaia,<sup>1</sup> Nico Lachmann,<sup>1</sup> Hermann Haller.<sup>1,2</sup> *<sup>1</sup>Medizinische Hochschule Hannover, Hannover, Germany; <sup>2</sup>Mount Desert Island Biological Laboratory, Salsbury Cove, ME.*

**Background:** Induced pluripotent stem cells (iPSC) - derived derived kidney organoids represent an attractive model for studying kidney development, disease mechanisms and drug response *in vitro*. Despite the progress achieved in the deciphering the developmental program of the kidney and differentiating iPSC to kidney organoids *in vitro*, our knowledge of the early stages of vascularization is limited. A major limitation is the lack of proper microvascular system to study the growth and development of iPSC organoids. Secondly, during the embryonic kidney development *in vivo* macrophages play an important role in vascularization. We have investigated the role of macrophages in vascular development using iPSC and a novel angiogenesis-on-chip model.

**Methods:** We have used co-culture of organoids and human iPSC-derived macrophages in microfluidic environment. We generated reporter iPSC cell lines expressing secreted Gaussia luciferase under control of CD31-promoter to monitor endothelial differentiation, 3D confocal microscopy, RNA sequencing and biochemical assays.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Results:** Differentiation of iPSC-derived endothelial cells and endothelial-specific function such as permeability, development of glycocalyx, and permeability are significantly improved by microfluidity conditions. In the presence of macrophages the number of endothelial cells is significantly increased. Furthermore, co-culture with macrophages induced lumen formation and capillary capillary growth. Formed capillary show directed growth towards the glomeruli-like nephrin-positive cell clusters and tend to interconnect developing neighboring organoids. The analysis of endothelial cells transcriptome shows advanced differentiation pattern in the presence of macrophages in comparison to the organoids in monoculture.

**Conclusions:** In summary, we firstly demonstrate that co-culturing developing iPSC-kidney organoids with human iPSC-macrophages promotes endothelial differentiation and induces capillary formation. Macrophages may directly or indirectly contribute to the early vascularization in organoids and can improve organoid-derived renal tissue generation.

**Funding:** Private Foundation Support, Government Support - Non-U.S.

## FR-PO360

### Kidney Decellularized Extracellular Matrix Enhanced the Vascularization and Maturation of Human Kidney Organoids

Jinwon Kim,<sup>1</sup> Jong Young Lee,<sup>1</sup> Jin Kim,<sup>2</sup> Yong Kyun Kim,<sup>1</sup> Sun-ah Nam.<sup>1</sup>  
<sup>1</sup>Catholic University of Korea School of Medicine, Seoul, Republic of Korea;  
<sup>2</sup>Ajou University, Suwon, Gyeonggi-do, Republic of Korea.

**Background:** Kidney organoids derived from human pluripotent stem cells have extensive potential for disease modelling and regenerative medicine. However, the limited vascularization and immaturity of kidney organoids have been still remained to overcome. In kidney development, kidney ECM regulate mesenchymal condensation, nephron formation, terminal differentiation of renal tubules, and glomerular basement membrane assembly. Kidney decellularized ECM (dECM) hydrogels contain ECM proteins to provide a microenvironment similar to that of a normal kidney. Our study highlights that kidney dECM hydrogels could be used to more accurately culture kidney organoids.

**Methods:** Porcine kidneys were decellularized to prepare kidney decellularized extracellular matrix hydrogels. Kidney organoids were differentiated using kidney dECM, and VEGF for enhancing the vascular network and SB-431542 for enhancing podocyte differentiation were added.  $\alpha$ -galactosidase A (GLA) mutant iPSCs in which the GLA gene was knocked out were generated using the CRISPR/Cas9. To recapitulate of Fabry Nephropathy with Vasculopathy, GLA-mutant human iPSCs were differentiated into kidney organoids using kidney dECM. We transplanted kidney organoids derived from human iPSCs with kidney dECM beneath the kidney capsule of immunodeficient NOD-SCID mice for engraftment.

**Results:** The vascularization was extensively increased in the kidney organoids generated by using kidney dECM. Single-cell transcriptomics revealed that the vascularized kidney organoids cultured using the kidney dECM had more mature patterns of glomerular development and higher similarity to human kidney than those cultured without the kidney dECM. Differentiation of GLA knock-out hPSC generated using CRISPR/Cas9 into kidney organoids by the culture method using kidney dECM efficiently recapitulated Fabry nephropathy with vasculopathy. Transplantation of kidney organoids with kidney dECM into kidney of mouse accelerated the recruitment of endothelial cells from the host mouse kidney and maintained vascular integrity with the more organized slit diaphragm-like structures than those without kidney dECM.

**Conclusions:** Our data suggest that kidney dECM methodology for inducing extensive vascularization and maturation of kidney organoids can be applied to studies for kidney development, disease modeling, and regenerative medicine.

## FR-PO361

### Developing Methods to Improve Vascularization of Nephron Progenitor Cell Grafts Beneath the Kidney Capsule Through the Use of Pro-Angiogenic Uniformly Porous Templated Hydrogel Scaffolds

Thomas Vincent, Sophie M. Blackburn, Buddy Ratner, Benjamin S. Freedman.  
University of Washington, Seattle, WA.

**Background:** When human kidneys are acutely injured or damaged by underlying chronic conditions, the nephrons are unable to sufficiently repair themselves and will progressively deteriorate to the point of end stage kidney disease. The fairly recent development of stem cell-derived kidney organoids has raised the possibility of achieving regenerative medicine-based therapeutic to restore renal function. However, studies *in vivo* have not yet achieved clinically significant integration of implanted cells with the host kidney. Here we examine the effects of implanting nephron progenitor cells (NPCs) as well as pro-angiogenic uniform porous templated hydrogel scaffolds beneath the kidney capsule as potential methods to achieve highly vascularized grafts.

**Methods:** Human induced pluripotent stem cell-derived NPCs, differentiated kidney organoids, and hydrogel scaffolds were implanted beneath the kidney capsules of 8–10-week-old NOD-SCID mice. Cellular material was collected by manually scraping cells from adherent cultures in a 24-well plate and aggregated through centrifugation. Kidneys were excised after 3-weeks and analyzed through cryosection immunofluorescent staining to look for a variety of cell markers including those that indicate major nephron segments such as podocalyxin, lotus tetragonolobus lectin and e-cadherin.

**Results:** Our data shows that implantation of NPCs beneath the kidney capsule of NOD-SCID mice supports differentiation and leads to the development of renal structures that include podocytes, and proximal and distal tubules. The developing podocytes

interact with host vasculature to form chimeric glomerular structures lined by parietal epithelial cells. Additionally, implanted porous scaffolds allow for ubiquitous cellular infiltration and vascularization while reducing the fibrotic host response compared to similar non-porous implants.

**Conclusions:** Together, the results from these experiments have demonstrated the potential for each of these two technologies to improve kidney regeneration therapies. Next steps will be to optimize cell-seeding methodology and implant combined NPC-seeded scaffolds beneath the kidney capsule to explore potential synergistic effects.

### Utilizing a Patient-Specific iPSC Platform for the Study of Rare Genetic Kidney and Vascular Diseases

Daniel Diatlov,<sup>1,2</sup> Franz Leonard Melzer,<sup>2</sup> Arlette Bohorquez,<sup>2</sup> Alison L. Ma,<sup>4</sup> Christoph Licht.<sup>3,2</sup> <sup>1</sup>University of Toronto Institute of Medical Science, Toronto, ON, Canada; <sup>2</sup>The Hospital for Sick Children Research Institute Cell Biology Program, Toronto, ON, Canada; <sup>3</sup>The Hospital for Sick Children Division of Nephrology, Toronto, ON, Canada; <sup>4</sup>Hong Kong Children's Hospital Department of Paediatric Nephrology, Kowloon City, Hong Kong.

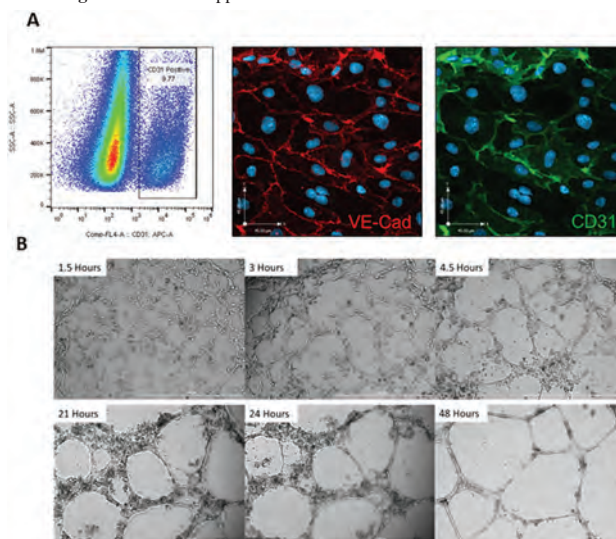

**Background:** The increasing use of induced pluripotent stem cells (iPSCs) to model human genetic diseases *in vitro* has allowed researchers to better understand the pathology of countless disorders, and subsequently develop better treatments for patients. Currently in our lab we use blood-outgrowth endothelial cells (BOECs) to study endothelial cell (EC) dysfunction in kidney diseases and thrombotic microangiopathies. However, isolating patient BOECs is often challenging, as it requires a significant sample of fresh blood which is not always readily available. As such, we are working to utilize a platform that uses patient skin fibroblasts to create patient-specific iPSCs, that can then be differentiated into ECs which capture the genetic conditions of patients.

**Methods:** Patient skin fibroblast-derived iPSCs and healthy control iPSCs were created using a commercially available Sendai virus CytoTune-iPS 2.0 reprogramming kit (Thermo Fisher). These iPSCs were then differentiated into ECs using a directed differentiation protocol in factor-defined media. Following differentiation, CD31 (PECAM1) positive cells were sorted using fluorescence-activated cell sorting (FACS), to isolate a pure population. Isolated ECs were then characterized using immunofluorescence (IF) staining for CD31 and VE-Cadherin, as well as a tubule formation assay.

**Results:** We were able to successfully create the iPSCs and differentiate them into ECs that express the appropriate markers (CD31 and VE-Cadherin) and are able to successfully form robust capillary-like tubes over a 48 hour period.

**Conclusions:** Our iPSC differentiation protocol provides a verified and valuable tool for the study of genetic kidney disorders involving endothelial cells when BOEC isolation is not possible.

**Funding:** Government Support - Non-U.S.

**Figure 1. (A)** Patient iPSC ECs sorted for CD31 using FACS express CD31 and VE-Cadherin (20x). **(B)** Patient iPSC ECs form robust capillary-like tubes over 48 hours (4x).

## FR-PO363

**Transcription Factor 21 Is Required for Normal Vascular Development of the Kidney**

Gal Finer,<sup>1,2</sup> Tomoko Hayashida,<sup>1,2</sup> Susan E. Quaggin,<sup>1,3</sup> Roberto Ariel Gomez,<sup>4</sup> Maria Luisa S. Sequeira Lopez.<sup>4</sup> <sup>1</sup>*Northwestern University Feinberg School of Medicine, Chicago, IL;* <sup>2</sup>*Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL;* <sup>3</sup>*Northwestern Memorial Hospital, Chicago, IL;* <sup>4</sup>*University of Virginia, Charlottesville, VA.*

**Background:** Normal kidney development requires coordinated interactions between multiple progenitor cells. The Foxd1+ cells are a distinct progenitor cell population within the metanephric mesenchyme that gives rise to the stroma, the renal capsule, the mesangium, vascular smooth muscle cells (VSMCs), and pericytes. VSMCs surround larger vessels while pericytes envelop capillaries and establish direct contact with the endothelium. The specification and functional specialization of renal mural cells are poorly understood. We previously showed that the transcription factor 21 (Tcf21) in Foxd1+ cells promotes proliferation and differentiation of interstitial progenitors via enhancement of  $\beta$ -Catenin action on Wnt-target genes. Here, we study the role of Tcf21 in the interaction between mural cells and endothelium during nephrogenesis.

**Methods:** We examined Foxd1Cre;Tcf21f/f kidneys by immunostaining and in-situ hybridization.

**Results:** Foxd1Cre;Tcf21f/f kidneys show distorted centripetal pattern of the arterial tree with disorganized, shorter, and thinner arteries at E15.5. Additionally, Foxd1Cre;Tcf21f/f kidneys show reduced branching and aberrant ramification into the renal capsule. At E18.5, mutant kidneys have fewer vessels globally. Specifically, the mutants have smaller interlobular arteries, fewer simplified glomerular capillary loops, and disorganized peritubular capillaries in the medulla. Examination of mural cells revealed fewer layers of smooth muscle cells, fewer PDGFR $\beta$ + CD146+ mesangial cells, and fewer CD146+ pericytes in the peritubular capillaries in mutants. These findings suggest that Tcf21 expression in Foxd1+ cells is required for normal differentiation of the mural cells hence for normal development of the kidney vasculature. Renin progenitors are a subset of the Foxd1+ cells that control renal vascular development. We next examined renin expression in Foxd1Cre;Tcf21f/f kidneys. Renin mRNA and protein were significantly reduced in mutants compared to controls. Specifically, CD146+Renin+ pericytes at the afferent arteriole of the glomerulus and around the peritubular capillaries were markedly reduced.

**Conclusions:** Together, our findings suggest that Tcf21 in Foxd1+ cells directs the differentiation of kidney mural cells thereby controlling the normal development of the endothelium and the overall arterial tree of the kidney.

## FR-PO364

**Defining Gene Regulatory Networks in Human Kidney Organoids by Single Cell Multiomic Analysis**

Yasuhiro Yoshimura, Yoshiharu Muto, Kohei Omachi, Nicolas Ledru, Jeffrey H. Miner, Benjamin D. Humphreys. *Washington University School of Medicine, St. Louis, MO.*

**Background:** During development, changes in chromatin structure regulate gene expression dynamics. A detailed understanding of gene regulatory networks will improve our understanding of organogenesis and disease mechanisms. Kidney organoids derived from pluripotent stem cells provide unique opportunities to study kidney development *in vitro*. However, whether the epigenetic landscape during organoid differentiation is similar to that during nephrogenesis has not been elucidated.

**Methods:** We performed single nucleus RNA sequencing (snRNA-seq) and assay for transposase-accessible chromatin with sequencing (snATAC-seq) and cleavage under targets and release using nuclease (CUT&RUN) sequencing to map the epigenetic and gene expression signatures of human kidney organoids during the organoid differentiation time course.

**Results:** We identified cell type-specific chromatin accessibility and predicted cis-regulatory links between ATAC peaks and target genes. Gene body ATAC peaks correlated highly with gene expression levels. Putative enhancers were identified by examining peaks in intergenic and intronic regions through integration with genome-wide histone marks identified by CUT&RUN sequencing. Direct comparison with human adult kidney multiome datasets revealed that kidney organoids had fewer distinct cell-specific chromatin accessibility patterns in the gene regulatory elements of maturation-related genes, indicating organoid cell immaturity. Time-course analysis of organoid differentiation showed changes in transcription factor expression varied directly with enrichment of their corresponding DNA binding motifs in ATAC peaks and target gene expression. For validation, we applied CRISPR interference against the promoter and putative enhancer regions of the HNF1B gene, a critical transcription factor for proximal tubule differentiation. We observed decreased HNF1B expression in the proximal tubule cells by suppressing either promoter or distal enhancer activity, validating this gene regulatory network elucidated by multiome analysis.

**Conclusions:** We defined the cell-specific epigenetic landscape during organoid differentiation and validated select gene regulatory mechanisms in human kidney organoids. This study provides a new benchmark against which to judge the cell-specific maturation state of human kidney organoids.

**Funding:** Private Foundation Support, Government Support - Non-U.S.

## FR-PO365

**Single-Nucleus RNA Sequencing Identifies Sex-Specific Proximal Tubular Cell Differentiation Pathways**

Yuehan Lu,<sup>1,2</sup> Chia-Te Liao,<sup>3</sup> Bnar Talabani,<sup>1</sup> Tanya A. Smith,<sup>1</sup> Robert Andrews,<sup>1</sup> Sumukh Deshpande,<sup>1</sup> Timothy Bowen,<sup>1</sup> Philip Taylor,<sup>1</sup> Donald Fraser.<sup>1</sup> *Wales Kidney Research Unit* <sup>1</sup>*Cardiff University, Cardiff, United Kingdom;* <sup>2</sup>*Chang Gung Medical Foundation, Taipei City, Taiwan;* <sup>3</sup>*Taipei Medical University, Taipei, Taiwan.*

**Background:** Postpartum kidney growth is substantial but proliferation and differentiation pathways underpinning nephron elongation are not well defined. Here we performed sequential characterization of mouse kidney transcriptomics at the single cell level to address this.

**Methods:** Single nuclear RNA sequencing (snRNAseq) was performed on freshly harvested kidney tissue from male and female mice at age 1, 2, 4, 12 weeks of age (n=2, a total of 16 mice) using the 10x platform. Sequencing employed the Illumina Novaseq platform and downstream analysis was conducted in R using Seurat and associated packages.

**Results:** Unbiased clustering was performed on 68,775 nuclei. All expected cell types were identified. High levels of proliferation were evident at early time points in some (eg. Tubular) but not other (eg. Podocyte) clusters. Proliferation was especially evident in Proximal Tubular Cells (PTC's) which are the most abundant cell type in the adult kidney. Uniquely when compared to other kidney cell types, PTC's demonstrated sex-specific expression profiles at 4 and 12 weeks. Mapping of PTC differentiation pathways using techniques including trajectory and RNA Velocity analyses delineated increasing PTC specialization and sex-specific phenotype specification. Ligand-receptor analysis identified key cues.

**Conclusions:** Our single-cell transcriptomics data provide a library of cellular states observed during kidney growth. We have identified PTC differentiation pathways that lead to sex-specific tubular cell phenotypes.

## FR-PO366

**Centrosome Dysfunction Disrupts Nephrogenesis and Causes Cystic Kidney Disease**

Tao Cheng,<sup>1</sup> Chidera Agwu,<sup>1</sup> Kyuwan Shim,<sup>1</sup> Baolin Wang,<sup>2</sup> Sanjay Jain,<sup>1</sup> Moe Mahjoub.<sup>1</sup> *Washington University in St Louis, St Louis, MO;* <sup>2</sup>*Weill Cornell Medicine, New York, NY.*

**Background:** Nephrogenesis requires coordinated signaling between progenitors of the metanephric mesenchyme (MM) and ureteric bud (UB) epithelium. Many of these pathways are organized by the centrosome, the main microtubule-organizing center, and its associated structure the cilium. Mutations in centrosomal genes cause congenital renal dysplasia and cystic-fibrotic pathologies, found in patients with Nephronophthisis, Joubert and Jeune syndromes. Yet, how these mutations impact renal development and physiology is unknown. Here, we examined the consequences of centrosome dysfunction on nephron progenitor growth, fate determination and tubule formation in mice, and compared outcomes with those caused by ciliary defect.

**Methods:** Conditional deletion of Cep120, critical for centrosome duplication, was induced by crossing *Cep120*<sup>fl/fl</sup> mice with *Six2-Cre* or *Hoxb7-Cre* strains. Loss of PKD1 (which causes ADPKD) was similarly induced in the two progenitors. Kidney morphology and function were tested at various stages. To identify pathways impacted by centrosome loss, we performed RNAseq of embryonic and adult kidneys from Cep120- and PKD1-null mice.

**Results:** Loss of Cep120 blocked centrosome biogenesis in the respective progenitor niches and led to reduced abundance of each population. This was due to delayed mitosis, activation of a mitotic surveillance pathway and apoptosis. Centrosome loss also caused premature formation of pre-tubular structures and low nephron branching morphogenesis. These defects resulted in dysplastic kidneys with low nephron endowment at birth, which mimic the human disease phenotypes. In contrast, loss of PKD1 in the MM or UB did not impact these processes, highlighting differences between centrosome and ciliary dysfunction. RNAseq of embryonic Cep120-null kidneys identified changes in signaling pathways including Wnt7-Wnt11, TGF- $\beta$  and RET-MAPK. Remarkably, a developmental switch occurred postnatally whereby centrosome-less kidneys rapidly formed cysts with fibrosis and corresponding decline in kidney function. Finally, RNAseq of adult Cep120-null kidneys identified unique pathways involved in cystogenesis and fibrosis upon centrosome dysfunction compared to ADPKD.

**Conclusions:** Our study defines the developmental defects caused by centrosome dysfunction in nephrogenesis and identifies new therapeutic targets in patients with renal "centrosomopathies".

## FR-PO367

**Consequences of Centrosome Dysfunction in Stromal Progenitors During Kidney Development and Repair**

Ewa Langner,<sup>1</sup> Tao Cheng,<sup>1</sup> Eirini Kefalogianni,<sup>1</sup> Baolin Wang,<sup>2</sup> Moe Mahjoub.<sup>1</sup> *Washington University in St Louis, St Louis, MO;* <sup>2</sup>*Cornell University, Ithaca, NY.*

**Background:** Reciprocal signaling between progenitor cells of the cap mesenchyme, ureteric bud epithelium and stromal mesenchyme (SM) is critical for mammalian kidney morphogenesis. Several signaling pathways involved in the growth and differentiation

of these progenitors are regulated by the centrosome, the main microtubule-organizing center, and its associated structure the cilium. Mutations in genes that disrupt centrosome biogenesis or function cause congenital renal dysplasia and cystic-fibrotic pathologies. However, it is unknown how defects in centrosome biogenesis impact renal interstitial progenitor cells. Here, we examined the consequences of defective centrosome biogenesis on SM progenitor cell growth, fate determination, formation of SM-derived lineages, and overall kidney development in mice.

**Methods:** Deletion of Cep120, the ciliopathy gene essential for centrosome duplication, was induced in the SM by crossing Cep120<sup>fl/fl</sup> mice with the FoxD1-Cre strain. Changes in kidney morphology and function upon centrosome loss were assessed at embryonic and postnatal time points and following unilateral ureteral obstruction (UUO) injury.

**Results:** Ablation of Cep120 blocked centrosome biogenesis in FoxD1-derived cells and led to reduced abundance of pericytes, peritubular fibroblasts and mesangial cells at birth. This was caused by delayed mitosis, abnormal Wnt and Hedgehog signaling leading to reduced proliferation. There was a concomitant delay in maturation of nephron tubular structures resulting in small, dysplastic kidneys by P15. Mutants differed in phenotypic severity, with survival rates between 1-5 months of age. Remarkably, mutants showed no change in kidney function nor developed spontaneous fibrosis. In contrast, loss of centrosomes caused increased proliferation of pericytes and fibroblasts following UUO injury, and led to elevated levels of profibrotic signaling factors.

**Conclusions:** Our results indicate that centrosome loss in the SM disrupts kidney morphology but not function during embryonic development. In contrast, centrosome loss sensitizes the kidneys leading to accelerated fibrosis following injury. These data highlight the contribution of defective centrosome biogenesis in the developing renal interstitium, and identify possible pathways as targets for therapy.

## FR-PO368

### **$\alpha$ -Parvin, an Integrin-Related Scaffold Protein, Regulates Actin Turnover to Facilitate Kidney Ureteric Bud Development**

Xinyu Dong,<sup>1,2</sup> Fabian Bock,<sup>2</sup> Nada M. Bulus,<sup>2</sup> Olga Viquez,<sup>2</sup> Ambra Pozzi,<sup>2</sup> Roy Zent.<sup>2,1</sup> <sup>1</sup>Vanderbilt University, Nashville, TN; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN.

**Background:** The kidney collecting duct develops by iterative branching of the ureteric bud (UB), a process that requires cell migration that is tightly regulated by actin dynamics.  $\alpha$ -Parvin is a scaffold protein associated with integrins, the major extracellular matrix (ECM) receptors. Parvin controls actin dynamics by binding to the actin filaments and by regulating the activation of the Rho family of GTPases (Rho, Rac, and Cdc42), which restructure the actin cytoskeleton during key cell activities such as cell migration. The Rho GTPases function in part by depolymerizing filamentous actin (F-actin) via the ADF/cofilin proteins. We previously showed  $\alpha$ -Parvin is critical for mouse kidney development because global  $\alpha$ -Parvin knockout led to kidney agenesis. In this study, we defined the mechanism of how  $\alpha$ -Parvin regulates UB branching.

**Methods:** We deleted  $\alpha$ -Parvin at the initiation of UB development (E10.5) by crossing the  $\alpha$ -Parvin<sup>fl/fl</sup> with a HOXB7<sup>Cre</sup> mice. To study the molecular function of  $\alpha$ -Parvin, we generated  $\alpha$ -Parvin-null collecting duct (CD) cells by deleting  $\alpha$ -Parvin using adenoviral-mediated delivery of plasmids encoding Cre recombinase from isolated CDs of the  $\alpha$ -Parvin<sup>fl/fl</sup> mice.

**Results:** The  $\alpha$ -Parvin<sup>fl/fl</sup>:HoxB7<sup>Cre</sup> mice were born with severely dysmorphic kidneys leading to death by 3 months. The kidneys showed a significant UB branching defect by E11.5. In addition to the decreased branching, the UB branches were abnormally shaped, with a larger tubular diameter and an increased number of cells around the circumference. There was excessive basal F-actin in the UB and prominent F-actin formation in  $\alpha$ -Parvin-null CD cells, suggesting a loss of actin depolymerization. Mechanistically, the  $\alpha$ -Parvin-null CD cells and kidneys had a profound increase in RhoA and Cdc42 activity. The major actin-depolymerizing factor downstream of the Rho GTPases, cofilin, was also inactivated in both the papilla of  $\alpha$ -Parvin-null kidneys and CD cells. Consequently, the  $\alpha$ -Parvin-null CD cells showed increased cell adhesion and spreading but impaired migration on ECM. Finally, inhibition of RhoA and Cdc42 was sufficient to reverse the inactivation of cofilin and rescue the  $\alpha$ -Parvin-null phenotypes.

**Conclusions:**  $\alpha$ -Parvin is required for UB development and it exerts its function by regulating the Rho/cofilin pathway that finetunes the actin dynamics.

**Funding:** NIDDK Support, Veterans Affairs Support

## FR-PO369

### **Rac1 Promotes Epithelial Collecting Duct Repair by Maintaining Mitotic Morphology**

Fabian Bock, Olga Viquez, Eric Sha, Xinyu Dong, Ambra Pozzi, Roy Zent. Vanderbilt University Medical Center, Nashville, TN.

**Background:** The kidney collecting duct (CD) is a major source of inflammation and fibrosis after injury but how it repairs is not known. The actin cytoskeleton is critical to restore cellular morphology and for normal cell cycle progression during epithelial repair. We have recently shown that the small Rho GTPase Rac1 is a key regulator maintaining the CD actin cytoskeleton at baseline. We thus hypothesize that Rac1 is required for CD repair after injury.

**Methods:** We crossed Rac1<sup>fl/fl</sup> with AQP2-Cre mice deleting Rac1 in the collecting system and performed reversible unilateral ureteral obstruction (rUUO). Furthermore, we performed cell cycle synchronization *in vitro* and investigated the role of Rac1 in regenerating epithelial monolayers, utilizing isolated Rac1 null CD cells.

**Results:** AQP2:Rac1<sup>fl/fl</sup> mice show impaired fibrosis regression after reversal of obstruction and were unable to normally restore epithelial and actin cytoskeletal integrity and polarity. Rac1 deletion decreased post-injury CD cell turnover with less proliferation and more apoptosis. *In vivo* cell cycle characterization by flow cytometry revealed a G2/M cell cycle defect. Upon *in vitro* cell cycle synchronization using a double thymidine block we found abnormal mitotic entry, delayed mitotic progression and mitotic cell death in the Rac1 null CD cells. High-resolution confocal microscopy *in vivo* and *in vitro* demonstrated that Rac1 is required for normal metaphase rounding, a critical mitotic morphological transformation. Furthermore, Rac1 null CD cells were unable to maintain mechanical G2/M checkpoint integrity thus allowing morphologically abnormal cells with a disrupted actin cytoskeleton to enter mitosis.

**Conclusions:** We find that Rac1 promotes kidney CD repair and Rac1 is required for both, morphological reconstitution, and post-injury cell cycle progression. Specifically, Rac1 promotes normal mitotic morphology likely by maintaining mechanical G2/M checkpoint integrity. We thus propose that Rac1 promotes repair by preventing morphologically abnormal cells from entering cell division.

**Funding:** NIDDK Support, Veterans Affairs Support, Private Foundation Support

## FR-PO370

### **Drosophila Nephrocytes as a Personalized Platform for Validation of Variants in TBC1D8B-Associated Focal Segmental Glomerulosclerosis**

Julian Milosavljevic,<sup>1</sup> Camille Lempicki,<sup>1</sup> Konrad Lang,<sup>1</sup> Helena Heinkele,<sup>1</sup> Minxian Wang,<sup>2,3</sup> Andrea Knob,<sup>2</sup> Martin Pollak,<sup>2,3</sup> Tobias F. Hermle,<sup>1</sup> <sup>1</sup>Renal Division, Department of Medicine, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany; <sup>2</sup>Division of Nephrology, Department of Medicine, Beth Israel Deaconess Medical Center, Boston, MA; <sup>3</sup>Department of Medicine, Harvard Medical School, Boston, MA.

**Background:** Mutations in *TBC1D8B* have been discovered as a monogenic cause of nephrotic syndrome and functional studies in *Drosophila* support a role in nephrin trafficking. Nevertheless, the role of *TBC1D8B* remains incompletely understood. Frequency of *TBC1D8B* mutations among patients with hereditary FSGS is unclear while functional characterization of novel genetic variants continues to be challenging.

**Methods:** We tested evolutionary conservation of *TBC1D8B* through expression of murine *Tbc1d8b* in the background of a stable null allele of fly *Tbc1d8b*. We exploited the accessibility of slit diaphragms in podocyte-like *Drosophila* nephrocytes to assess Nephrin turnover in a *Tbc1d8b* loss-of-function. Novel *TBC1D8B* mutations were detected by whole exome sequencing within an FSGS cohort. Transgenesis of mammalian *Tbc1d8b* harboring patient mutations was used for validation in *Drosophila in vivo*.

**Results:** Fly Tbc1d8b was required for rapid nephrin turnover in nephrocytes and nephrin endocytosis induced by excessive function of Rab5. Accumulation of LAMP-GFP upon *Tbc1d8b* loss-of-function confirmed a role for endolysosomal degradation. Low level expression of murine *Tbc1d8b* rescued loss of the *Drosophila* gene demonstrating evolutionary conservation. We previously showed that excessive overexpression induces nephrin vesicles. To examine if this effect is linked to TBC/GAP function, we generated a transgene harboring a R537K mutation which targets the catalytic arginine finger. Expression of this transgene still entailed nephrin vesicles, but these were of a reduced size. This suggests that TBC1D8B function is partially GAP-independent. Finally, we discovered four novel *TBC1D8B* mutations within a cohort of 363 FSGS patients and validated a functional impact for three of these mutations in *Drosophila* studying nephrin vesicles in podocyte like nephrocytes.

**Conclusions:** The podocyte-like nephrocytes of *Drosophila melanogaster* are suitable for validation of novel variants and further functional characterization of the nephrotic syndrome gene *TBC1D8B*, establishing a personalized platform for *TBC1D8B*-associated FSGS.

**Funding:** Other NIH Support - Grant / Award Number: 'RC2-DK122397', Government Support - Non-U.S.

## FR-PO371

### **Genetic Studies of Paired Metabolomes Reveal Enzymatic and Transport Processes at the Interface of Plasma and Urine**

Pascal Schlosser,<sup>1,2</sup> Nora Scherer,<sup>1,3</sup> Franziska Grundner-Culemann,<sup>1</sup> Yong Li,<sup>1</sup> Anna Kottgen,<sup>1,2</sup> <sup>1</sup>Institute of Genetic Epidemiology, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany; <sup>2</sup>Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; <sup>3</sup>Spemann Graduate School of Biology and Medicine (SGBM), University of Freiburg, Freiburg, Germany.

**Background:** The kidneys operate at the interface of plasma and urine by clearing molecular waste products from the body while retaining valuable solutes. We hypothesized that a genetic study of paired plasma and urine metabolomes facilitates the identification of transport proteins and enzymes involved in this process.

**Methods:** We performed genome-wide association studies of 1,916 metabolites, of which 779 were quantified in plasma and urine from 5,023 participants of the German Chronic Kidney Disease study. Identified associations were integrated with orthogonal datasets, including colocalization with expression and protein quantitative trait loci to prioritize the underlying genes, and with complex traits and diseases to identify potential consequences. ATAC- and RNA-seq data from primary human kidney was used to annotate regulatory variants.

**Results:** We found 1,299 significant associations between genetic variants and metabolite levels, including examples related to the kidneys' role in metabolite handling. Of note, studying either plasma or urine alone would have missed associations with 40%

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

of the underlying metabolites. The major genes and metabolite pathways shaping the plasma and the urine associations were clearly distinct. Insights only enabled through the study of urine included the identification of a missense variant in *AQP7* resulting in reduced tubular glycerol reabsorption. The kidney-enriched transporter *SLC13A3* left different metabolomic footprints in plasma and urine, consistent with its function in mitochondrial energy generation. The prioritized underlying variant is predicted to specifically alter binding of major cell type-relevant transcription factors. Shared genetic determinants of 7,515 metabolite-biomarker/disease combinations provided mechanistic hypotheses for complex and monogenic diseases and allowed for the characterization of yet undescribed systemic roles of renal dipeptidase 1.

**Conclusions:** This genetic study of plasma and urine metabolomes emphasizes the role of multi-matrix studies to gain insights into *in vivo* metabolic processes, and particularly into kidney functions. The results provide a rich resource of yet unknown enzymatic and transport processes that represent a molecular link to human diseases.

### Single-Cell RNA Sequencing Reveals Renal Endothelium Heterogeneity During Injury and Regeneration in a Murine Model of Renal Thrombotic Microangiopathy

Jan Sradnick, Anika Wirth, Hannah Kroeger, Patrick Arndt, Vladimir T. Todorov, Christian Hugo. *Division of Nephrology, Department of Internal Medicine III, University Hospital CGC, Dresden, Germany.*

**Background:** Analyses of the marker genes, pathways, and biological functions revealed that endothelial cells (EC) are highly heterogeneous showing plasticity both in normal and pathophysiological conditions. However, the heterogeneity and cellular responses of renal endothelial cells during injury and regeneration have not been well characterized.

**Methods:** Endothelial specific injury was induced in Tie2 eGFP mice (n=48) by renal arterial perfusion with ConcanavalinA (ConA)/anti-ConA. Nineteen mice served as sham operated controls. Kidneys were harvested 24h, 48h, 3 days 4 days and 7 days after injury induction. For 10x single-cell RNA sequencing, cells were isolated from glomerular and extraglomerular renal tissue. Tie2 eGFP<sup>+</sup>CD102<sup>+</sup>CD105<sup>+</sup>CD45<sup>+</sup> endothelial cells were further separated using FACS cell sorting. After 10x single cell sequencing, Seurat clustering analysis was performed to identify EC cell clusters. Endothelial cell damage was evaluated using periodic acid-Schiff staining and histology in zinc fixed paraffin embedded slices.

**Results:** Endothelial cell loss was observed 24h following injury, while the EC number already markedly increased on day 3 and was back to baseline levels after 4–7 days. 10x single-cell RNA sequencing was performed on 42,000 sorted renal cells. Following quality control measurements almost all sequenced cells expressed endothelial specific genes. In glomerular and peritubular ECs, different cluster (17 and 7, respectively) could be identified following t-distributed stochastic neighbour embedding (t-SNE). In both glomerular and peritubular EC transcriptomics, cell clusters demonstrating predominant regulation of cellular injury genes was seen 24h but also 48h after model induction. Gene clusters consistent with cell remodeling and differentiation were mostly identified on days 4–7.

**Conclusions:** In summary, our study provides a high-resolution atlas of the renal endothelium during EC specific injury and regeneration. Our data highlight the phenotypic heterogeneity and changes of endothelial subtypes which were potentially involved during EC injury and regeneration after selective renal endothelial cell injury.

## FR-PO373

### Multi-Omic Analyses of Primary Kidney Tissue Identifies Medulla-Specific Genes and Transcriptional Regulators

Stefan Haug,<sup>1</sup> Yong Li,<sup>1</sup> Selvaraj Muthusamy,<sup>3</sup> Anna Kottgen,<sup>1</sup> Shreeram Akilesh,<sup>2</sup> <sup>1</sup>*Institute of Genetic Epidemiology, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany;* <sup>2</sup>*Department of Laboratory Medicine and Pathology, University of Washington, Seattle, WA;* <sup>3</sup>*Department of Pathology, Virginia Commonwealth University, Richmond, VA.*

**Background:** The kidney medulla is a key regulator of salt and water balance. Despite this vital function, it is relatively understudied, including its contribution to inherited or acquired kidney disease. To fill this gap, we generated and analyzed gene expression (RNA-seq), chromatin accessibility (ATAC-seq) and chromatin conformation (HiC) data derived from human cortex and medulla tissue in order to identify patterns of medulla-specific gene expression and regulation.

**Methods:** Macrodissected matched pairs of healthy cortex and medulla tissue were sampled from kidneys of four adult tumor nephrectomy patients. RNA-seq, ATAC-seq and HiC data were generated and analyzed to identify differentially expressed genes, differentially accessible regions and differential loops between cortex and medulla. We also analyzed our data together with publicly available single nucleus RNA-seq data and the GTEx database to calibrate and extend our findings.

**Results:** Over 2,300 genes were differentially expressed (padj < 0.01, log2-fold change > 1) between cortex and medulla. Our carefully annotated samples and gene expression analysis helped to re-assign mislabeled samples in the GTEx database. Medulla-specific genes expressed in the adult were overrepresented among kidney development pathways and included many genes relevant for kidney disease like *UMOD*, *SLC12A1* and *EGF*. By incorporating genome-wide maps of chromatin accessibility and conformation, we defined the regulatory landscape around exemplar medullary genes (*SLCO3A1*, *CLDN14*

and *WNT7B*). Next, we examined transcription factor (TF) motifs in accessible chromatin regions and predicted an important role for POU3F3 in the medulla, which we confirmed by immunohistochemistry. POU3F3 has been previously shown to be important in mouse kidney development, but here we show that it is also expressed in the adult human medulla, where it may direct expression of ~17% of medulla-specific genes.

**Conclusions:** The reference-quality functional genomic datasets generated in this study elucidate the regulatory differences between human kidney cortex and medulla. This valuable resource will help us better understand diseases and conditions originating in the medullary portion of the human kidney.

**Funding:** Government Support - Non-U.S.

## FR-PO374

### Generation of Mouse/Human Chimeric Organoids by Renal Fetal Dissociated Cell and Induced Nephron Progenitor Cells

Naoto Matsumoto, Shuichiro Yamanaka, Kenji Matsui, Yatsumu Saito, Kei Matsumoto, Eiji Kobayashi, Takashi Yokoo. *Tokyo Jikeikai Ika Daigaku Igakubu Igakuka, Minato-ku, Japan.*

**Background:** Several aspects of renal development are still unclear. Consequently, not all component cells of the kidney can be made from induced pluripotent stem cells (iPSCs). For example, human stromal progenitor cells cannot be artificially produced. Thus generating a completely functional kidney from iPSCs is still difficult. Hence attempts have been made to compensate for this limitation using xenogeneic cells. Renal progenitor cells self-organize into nephrons by aggregation. We hypothesized that taking advantage of this reorganization mechanism, high concentration of human nephron progenitor cells (NPCs) and low of mouse dissociated single cells (DSCs) could increase cell to cell the contact chance efficiently for generating chimeric nephrons. Therefore, we examined whether higher-order chimeric structures could be obtained by mixing human NPCs with mouse renal progenitor cells to generate heterologous renal chimeric organoids.

**Methods:** NPCs were selectively induced from human iPSCs using the method reported by Taguchi and Nishinakamura et al., and spheres were created by mixing the induced NPCs with renal progenitor cells extracted from B6 mice kidneys at E13.5 and at a 1:3 ratio. The combined cells were cultured with spinal cord cells in Transwell plates. The resulting tissue was collected on day 6 and histological evaluation of differentiation was performed by immunostaining.

**Results:** On day 6, human NPCs aggregated on mouse ureteric bud (UB) tips and exhibited a chimeric CM structure. All NPCs were derived from human cells, and all UB tips were derived from mouse cells. The spinal cord cocultures revealed human-derived distal tubules (DTs), which were derived exclusively from human cells, connected to mouse collecting ducts (CDs).

**Conclusions:** Using NPCs derived from human iPSCs, we have successfully generated higher-order interspecies renal chimeric organoids with connected human CM and mouse tubular structures. This new chimeric organoid is expected to provide new insights into induced renal cells and contribute substantially to the production of kidneys for regenerative medicine.

## FR-PO375

### Modeling ST2/IL-33 “Alarmin” Signaling Through Kidney Organoid-Immune Cell Co-Culture System

Vikram Sabapathy, Gabrielle Costlow, Saleh Mohammad, Rahul Sharma. *University of Virginia, Charlottesville, VA.*

**Background:** Renal diseases are a major cause of morbidity and mortality worldwide. Inflammation elicited by a variety of cytokines and chemokines is a major player in the initiation and progression of the disease. Interleukin 33 (IL-33) belongs to the IL-1 family of cytokines, which acts as an ‘alarmin’ that regulates the immune response during injury. Released during injury-response, cytokine IL-33 acts in an autocrine/paracrine manner through membrane receptor (ST2) aka IL33R or IL-1 receptor-like 1 (IL1RL1), triggering an inflammatory response. ST2 is widely expressed in many cells including regulatory T cells (Tregs), which constitute a major anti-inflammatory mechanism. Although, it’s been demonstrated in various studies that Tregs play a crucial role in mitigating renal injury. There is no evidence determining the role of the ST2/IL33 axis in Tregs during kidney injury.

**Methods:** In this study, we attempt to delineate the role of the ST2 pathway in Tregs using murine renal injury model and kidney organoids.

**Results:** By RNA sequencing analysis it was observed that ST2-high Tregs had higher expression of regenerative factors such as amphiregulin (AREG) and Growth/differentiation factor (GDF15). The *in vivo* ischemic renal injury experimental data indicated that loss of ST2/IL33 signaling from Tregs resulted in exacerbation of renal injury leading to worsening of renal function. Co-culture of kidney organoids with ST2+ Tregs protected cellular viability under *in vitro* ischemia-reoxygenation conditions compared to ST2- Tregs. We observed that the addition of secretome from ST2+ Tregs in kidney organoid cultures improves cellular viability during *in vitro* hypoxic injury. Secretome analysis indicated elevated levels of AREG in spent media of ST2+ Tregs cultures. Our data shows that AREG treatment protected kidney organoids from cisplatin-induced apoptosis in a dose-dependent manner and mediates tubular cell plasticity.

**Conclusions:** Activation of IL-33/ST2 signaling axis in Tregs is essential for the regulation of inflammation, apoptosis, and repair in renal tissue during inflammation and injury.

## FR-PO376

**Effects of Re-Expression of Renal Progenitor Genes in Mature Human Kidney Cells**

Naomi Pode Shakked,<sup>1,2</sup> Benjamin Dekel,<sup>4,3</sup> Oren Pleniceanu,<sup>5,6</sup> <sup>1</sup>*Shena Medical Center, Pediatric Stem Cell Research Institute and Sackler Faculty of Medicine Tel Aviv University, Tel Hashomer, Israel;* <sup>2</sup>*Cincinnati Children's Hospital Medical Center, Cincinnati, OH;* <sup>3</sup>*Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel;* <sup>4</sup>*Sheba Medical Center, Safra Children's Hospital, Division of Pediatric Nephrology, Pediatric Stem Cell Research Institute, Tel Hashomer, Israel;* <sup>5</sup>*Sheba Medical Center, Pediatric Stem Cell Research Institute, Tel Hashomer, Israel;* <sup>6</sup>*Sheba Medical Center, the Nephrology Research Lab and Sackler Faculty of Medicine Tel Aviv University, Tel Hashomer, Israel.*

**Background:** During human nephrogenesis, fetal renal progenitors give rise to approximately 10<sup>6</sup> nephrons. It is currently believed that this progenitor pool is abolished postnatally due to the silencing of renal progenitor genes, depriving the mature kidney of the ability to generate new nephrons. At the same time, the incidence of end-stage renal disease is constantly growing, underscoring the need for new kidney regeneration strategies.

**Methods:** Here, we used lentiviral vectors to evaluate the effects of ectopic induction of two major renal progenitor genes (*OSR1* and *SIX2*) in primary adult kidney (AK) cells.

**Results:** OSR1 over-expression resulted in a transient change in cellular morphology into a cuboidal, mesenchymal-like phenotype, accompanied by upregulation of renal developmental transcription factors PAX2, SIX2, CITED1 and GDNF, while maintaining the expression of the GDNF protein, the major factor secreted from kidney stem cells and thus a marker of their functionality. However, no change in clonal efficiency or proliferation rate was noted in OSR1-expressing AK cells. In contrast, SIX2 over-expression led to significantly higher clonal efficiency and enhanced proliferation compared to control cells, consistent with its role as a regulator of self-renewal in renal stem cells. Surprisingly, although SIX2 induction resulted in elevated OSR1 levels, other renal progenitor genes (PAX2, SALL1 and GDNF) showed significantly lower expression levels. When injected subcutaneously into immunodeficient mice, SIX2-expressing cells demonstrated robust tubulogenic potential, giving rise mostly to CD13<sup>+</sup>EMA<sup>+</sup> proximal tubule cells, but were unable to integrate into developing renal tubules when co-cultured with embryonic mouse kidney cells. Importantly, cells over-expressing both OSR1 and SIX2 were both tubulogenic and showed distinct capacity of integrating into developing fetal renal structures.

**Conclusions:** Taken together, our results demonstrate that OSR1 induction in AK cells activates several other renal progenitor genes while SIX2 induction endows the cells with enhanced proliferation and colony formation potential, which could serve as a basis for generating an expandable *in-vitro* population of renal progenitor cells.

## FR-PO377

**CXCL12 and WNT5A Control Nephron Number in the Normal and Hypodysplastic Kidney**

Robert D'Cruz, Nan Jiang, Norman D. Rosenblum. *The Hospital for Sick Children, Toronto, ON, Canada.*

**Background:** Renal hypodysplasia, defined by abnormally small kidneys with low nephron number and expanded stromal tissue, is the major cause of childhood renal failure. While molecular mechanisms controlling nephrogenesis have been elucidated, factors that control the number of nephrons is largely unknown and important as low nephron number is critical to kidney function in childhood and as an antecedent cause of adult-onset kidney and cardiovascular disease. Nephrons and stromal cells arise during embryonic development from *Osr1*-derived *Six2*<sup>+</sup> and *Foxd1*<sup>+</sup> progenitors, respectively. Previous work demonstrated that increased Hedgehog (Hh) signaling in *Osr1*<sup>+</sup> kidney progenitor cells disrupts normal stromal patterning (Sheybani et al., 2018). Here, we investigate the functional contribution of the embryonic renal stroma in determining nephron number.

**Methods:** Constitutive active Hh signaling in *Foxd1*<sup>+</sup> stromal cells was generated by deletion of *Ptch1*, a Hh cell surface receptor, in a *Cre*-dependent manner. Compound mutant mice with *Foxd1Cre*-dependent deficiency of *Cxcl12* or *Wnt5a* together with *Ptch1*, and mice with *Foxd1Cre*-dependent deletion of *Cxcl12*, were generated. Kidney tissue was analyzed by histology, single-cell (sc) and bulk RNA sequencing.

**Results:** Stromal *Ptch1*-deficient kidneys exhibited renal hypodysplasia characterized by a 41% reduction in nephron number (P<0.01, n=4) and expansion of *Foxd1*-derived PDGFRB<sup>+</sup> medullary stromal cells at E18.5. Complementary scRNA-seq and bulk RNA sequencing (n=3) identified increased expression of medullary stromal *Cxcl12* (P<0.001) and *Wnt5a* (P<0.01) ligands. *Foxd1Cre*-dependent deficiency of *Cxcl12* or *Wnt5a* together with *Ptch1* rescued nephron number by 32% (P<0.001, n=4) or 31% (P<0.05, n=3), respectively. Analysis of stromal *Cxcl12*-deficient kidneys demonstrated renal hypodysplasia characterized by a 28% reduction in nephron number (P<0.01, n=4) at P4 due to impaired nephron epithelialization. Bulk RNA sequencing of stromal *Cxcl12*-deficient kidneys (n=3) showed dysregulation of genes associated with retinoic acid signaling, such as *Crabp1/2* (P<0.01) and *Aldh1a2* (P<0.05), and genes associated with Hippo signaling, such as *Cdc42* (P<0.05) and *Taz* (P<0.05).

**Conclusions:** Increased stromal *Cxcl12* and *Wnt5a* signal non-autonomously to drive low nephron number in renal hypodysplasia. Stromal *Cxcl12* functions physiologically to regulate nephron number.

**Funding:** Government Support - Non-U.S.

## FR-PO378

**Wilms Tumor: Insights Into the Role of Integrins Driving Cancer Stem Cells Self-Renewal vs. Differentiation**

Laura Perin,<sup>1</sup> Astgik Petrosyan,<sup>1</sup> Valentina Villani,<sup>1</sup> Paola Aguiari,<sup>1</sup> Min Mahdi,<sup>1</sup> Matthew E. Thornton,<sup>2</sup> Brendan Grubbs,<sup>1</sup> Roger E. De Filippo,<sup>1</sup> Kevin V. Lemley,<sup>1</sup> Sargis Sedrakyan,<sup>1</sup> Gregory M. Shackleford,<sup>1</sup> Anat Erdreich-Epstein,<sup>1</sup> Stefano Da Sacco.<sup>1</sup> <sup>1</sup>*Children's Hospital Los Angeles, Los Angeles, CA;* <sup>2</sup>*University of Southern California, Los Angeles, CA.*

**Background:** Wilms Tumor (WT) is the most common pediatric renal cancer. Growing evidence links WT to aberrant nephrogenesis. While studies highlighted the genetic complexity of WT, little is known about the molecular mechanisms that regulate WT development. Here we report that uncommitted nephrogenic progenitors (NPs) expressing SIX2 and CITED1 (the master regulators of renal development) present characteristics of cancer stem cells (CSCs) and are the ones driving WT. We have also studied the role of integrins in these NPs in regulating WT development.

**Methods:** WT and human fetal kidney (hFK) samples were histologically analyzed, digested to single-cell suspension, incubated with Smartflare-probe to isolate SIX2+CITED1<sup>+</sup> cells, and processed for RNA-seq, single-cell RNA-seq and spatial transcriptomics. Xenografts of WT-NPs and hFK-NPs were generated and tumor formation was assessed. Analyses of mechanisms that regulate self-renewal vs. differentiation were performed *in vitro* and *in vivo*. Knockdown with miRNAs against SIX2 and CITED1 was performed on WT-NPs and processed for RNA-seq.

**Results:** By comparing NPs from different WT subtypes and NPs from hFK we identified that cells expressing SIX2 and CITED1 fulfill CSC criteria, reliably recapitulating WT in transplantation studies. We showed that self-renewal vs. differentiation of SIX2+CITED1<sup>+</sup> WT CSCs is regulated by the interplay between integrins ITGB1 and ITGB4. WT transplantation studies show that blocking ITGB1 or ITGB4 leads to higher number of SIX2+CITED1<sup>+</sup> cells in the xenografts. Knockdown of SIX2 and CITED1 increased expression of kidney differentiation markers LHX1, WNT7B, PODXL, MECOM, reduced expression of nephrogenic markers MEOX1, TMEM100, EYA1, MAYFB, and increased expression of ITGB1, ITGB4, and LAMA5.

**Conclusions:** These studies define SIX2+CITED1<sup>+</sup> cells as the nephrogenic CSCs of WT, where ITGB1 and ITGB4 interplay may play a role in self-renewal vs. differentiation and serve as a potential target for new strategies to treat WT.

## FR-PO379

**Indian Hedgehog Signalling in Kidney Development**

Lauren G. Russell,<sup>1</sup> Christopher Rowan,<sup>2</sup> Norman D. Rosenblum,<sup>2</sup> Paul Winyard,<sup>1</sup> David A. Long.<sup>1</sup> <sup>1</sup>*University College London Institute of Child Health, London, United Kingdom;* <sup>2</sup>*SickKids Research Institute, Toronto, ON, Canada.*

**Background:** Hedgehog (Hh) signalling is critical in the development of the kidney, with genetic alterations of Hh pathway components leading to defects in nephron formation. Indian hedgehog (Ihh) is one of three ligands that activate the Hh pathway, however the cellular sources and functional role of Ihh in kidney development is not well understood.

**Methods:** We utilised a novel 3D imaging technique, combining wholemount fluorescence in situ hybridisation, immunolabelling and optical clearing to visualise *Ihh* mRNA localisation in 3D in the developing mouse embryonic kidney at cellular resolution. Furthermore, we have utilised a total *Ihh* knockout mouse model and *Cre* recombinase-based techniques to conditionally delete *Ihh* in the intermediate mesoderm, using the inducible *Osr1-Cre<sup>ERT2</sup>*, to begin to interrogate the functional role of *Ihh* in the developing kidney.

**Results:** *Ihh* mRNA was detected in the developing mouse kidney from embryonic day (E)16.5; during the maturation of tubules and glomeruli and maintained at E18.5 and the first day postnatally. Double labelling with Lotus tetragonolobus lectin revealed that *Ihh* primarily localised to the proximal tubule. As *Ihh* is detected as the mature nephron is developing, we hypothesise that *Ihh* will be important in nephrogenic development. We observed that *Ihh*<sup>-/-</sup> kidneys are smaller at E16.5 with some observed displaying highly disorganised, abnormal morphology. Additionally, *Ihh*<sup>-/-</sup> kidneys have a significantly reduced total glomerular number (p=0.0297) and a reduction in SIX2<sup>+</sup> nephron precursor cells in around 40% of *Ihh*<sup>-/-</sup> kidneys compared with wild-type littermates, overall suggesting defects in kidney development in *Ihh*<sup>-/-</sup> mice. Conditional deletion of *Ihh* in the *Osr1*<sup>+</sup> intermediate mesoderm, results in a significantly decreased kidney/bodyweight ratio at E18.5 (p=0.0089), providing initial evidence of an importance for *Ihh* in intermediate mesoderm derived cells in the development of the kidney.

**Conclusions:** In summary, using a novel imaging technique we identified the onset of *Ihh* expression in maturing proximal tubules of the mouse embryonic kidney. Further, we observed defects in the development of *Ihh* total knockout kidneys and initial data indicates a function for *Ihh* in intermediate mesoderm derived cells.

## Conditional Ablation of Nephrons in Fetal Mice

Yuka Inage, Kei Matsumoto, Shuichiro Yamanaka, Kenji Matsui, Naoto Matsumoto, Yatsumu Saito, Daishi Hirano, Kimihiko Oishi, Eiji Kobayashi, Takashi Yokoo. *Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan.*

**Background:** In humans, nephron number can vary up to ten-folds and a low nephron number is associated with an increased risk of hypertension and chronic kidney disease. Although low oxygen exposure and maternal nutritional restriction are already reported as animal models of low nephron number, these methods can also affect the development of other organs. Thus far, factors to determine the number of nephrons in a fetus remain to be clarified. Here, we established a low nephron number model, using genetically modified mice, without affecting the development of other organs.

**Methods:** Six2-GFP-Cre transgenic mice were crossed with C57BL/6-Gt (ROSA) 26Sor [tm1(HBEGF)Awai]/J mice (iDTR) to obtain bigenic (Six2-GFP +/+ iDTR-mice) and control offspring (Six2-GFP -/- iDTR-mice). Diphtheria toxin was injected (0.5 ng) via the intra-amniotic route at E13.5. Subsequently, at E19.5, caesarean delivery was performed and offspring were placed in foster care. We assessed body weight, blood pressure, and nephron number and also conducted blood and urine tests.

**Results:** Both bigenic and control offspring displayed adequate development. Although blood pressure was not significantly different at the 12-weeks timepoint, nephron number per area in bigenic offspring decreased by approximately 50% compared to that in control offspring. Furthermore, bigenic offspring displayed higher blood urea nitrogen levels than control offspring.

**Conclusions:** We successfully ablated nephrons in fetal mice, approximately 50% per area. While these mice grew normally, showing no-hypertension using this protocol, additional salt loading experiments are ongoing to further refine this low nephron number model.

## FR-PO381

## Interplay Between Pparg1a and Esrrya Regulates Nephron Segmentation and Ciliogenesis

Hannah M. Wesselman, Rebecca A. Wingert. *University of Notre Dame, Notre Dame, IN.*

**Background:** Cilia, hair-like projections that facilitate mechano- and chemo-sensing, are nearly ubiquitous in mammalian cells. Broadly speaking, ciliopathies present phenotypes in numerous tissues, including auditory, central nervous, and renal systems. Previous research has found *ppar gamma coactivator 1a* (*pparg1a*) as an essential regulator of renal and cilia formation, and we sought to identify cooperative factors that regulate these developmental pathways. *estrogen-related receptor gamma a* (*esrrya*) was of interest, as it interacts with *Pparg1a* in regulating other tissues, and has been independently linked to decreased kidney function.

**Methods:** We confirmed that *esrrya* independently affects nephron development in the zebrafish embryonic kidney using whole mount in situ hybridization to characterize distinct cell types. Through immunofluorescence, we quantified aberrant cilia formation, cell polarity, and cell turnover in the kidney, ear, and node. Through dual heterozygosity models, we evaluated the relationship between *esrrya* and *pparg1a* in cilia and nephron development. Additionally, we used ELISA and qRT-PCR to evaluate potential downstream targets of this genetic cascade.

**Results:** *esrrya* deficient animals exhibited nephron composition defects including expanded proximal and reduced distal segments. Similarly, we detected defects in cilia formation, where ciliated basal bodies and cilia length were significantly reduced. These phenotypes were not isolated to renal cilia, and aberrant cilia were also observed in the node and ear. By modelling heterozygosity, we found that *esrrya* cooperates with *pparg1a* in ciliogenesis. Specifically, both of these factors work upstream of PGE2 production by regulating Cox1.

**Conclusions:** These data position *Esrry* as a critical component of nephron development and cilia formation where it cooperates with *Pparg1a* to modulate prostaglandin signaling. These novel findings may have clinical relevance for understanding the pathogenesis of ciliopathies or other renal conditions.

## FR-PO382

## The Regulatory Program of the Distalizing Mammalian Nephron

Mary Anne A. Achieng, Jack Schnell, Connor Fausto, Nils Lindstrom. *University of Southern California Keck School of Medicine, Los Angeles, CA.*

**Background:** During development, nephron progenitors differentiate into over 24 cell types that become positioned along the nephron proximal-distal axis. To improve distal cell differentiation in the *in vitro* organoid model, we are delineating the developmental programs generating distal nephrons *in vivo* by analyzing scRNAseq data capturing human nephrogenesis. Comparisons of organoid scRNAseq data to the *in vivo* benchmark highlight dissimilarities between organoids and nephron cells, notably that organoids lack mature distal nephron markers. We present a scalable platform for synchronized nephrogenesis for studying patterning programs and forming functionally competent distal-like cells.

**Methods:** To correct patterning abnormalities *in vitro*, we generated a synchronized kidney organoid system for tuning differentiation of specific nephron cell fates.  $\beta$ -catenin signaling plays a role in expanding the distal domain and is required for distal tubule formation. Thus, we pulsed small molecule WNT agonists and quantified expression of early distal transcription factors to test whether  $\beta$ -catenin signaling plays a conserved role.

**Results:** Through early modulation of  $\beta$ -catenin signaling, we increased abundance of distal precursors and partially normalized patterning. Expression of transcription factors HNF1 $\beta$  and TFAP2A, which demarcate distal precursors in the comma- and S-shaped body of the mammalian nephron, is faithfully replicated in these treated organoids, with more elongated distal domains.

**Conclusions:** The synchronicity of our organoids enables manipulation of cohorts of nephron-like structures in a narrow developmental stage. In this system,  $\beta$ -catenin signaling manipulation in early organoids alters differentiation and morphogenesis, consistent with our model of  $\beta$ -catenin regulating positional identities along the nephron proximal-distal axis.

In CHIR-treated organoids, HNF1B+, TFAP2A+ distal domains are significantly increased compared to control, with more elongated tubules.

## FR-PO383

Effect of Stromal Cell-Derived Factor 1 $\alpha$  Bio-Functionalization on Tissue Formation of Vascular In Situ Tissue Engineered Grafts in Rats With CKD

Merle M. Krebber,<sup>1</sup> Paul J. Besseling,<sup>1</sup> Joost O. Fledderus,<sup>1</sup> Patricia Y. Dankers,<sup>2</sup> Carlijn V. Bouten,<sup>2</sup> Marianne C. Verhaar.<sup>1</sup> <sup>1</sup>Valve, Materials Driven Regeneration <sup>1</sup>Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; <sup>2</sup>Technische Universiteit Eindhoven, Eindhoven, Netherlands.

**Background:** *In situ* tissue engineering (TE) offers cell-free scaffolds that transform into living grafts. However, the pro-inflammatory chronic kidney disease (CKD) environment might influence neo-tissue formation. Stromal cell-derived factor 1 $\alpha$  (SDF-1 $\alpha$ ) bio-functionalization may attract and guide host cells with anti-inflammatory and neo-tissue-stimulating properties. Therefore, we studied the role of SDF-1 $\alpha$  on initial inflammation and remodeling of vascular grafts in CKD and healthy rats.

**Methods:** CKD was induced in female rats (n=53) by 5/6<sup>th</sup> nephrectomy. Upon 50mg/24h proteinuria, CKD or sham-operated rats underwent abdominal aorta-replacement with an electrospun biodegradable supramolecular polyurethane-131-bisurea (PCU-131-BU) graft, bare or SDF-1 $\alpha$  bio-functionalized. Explantation was performed at 2 weeks (preliminary: sham + bare n=4, CKD + bare n=4, sham + SDF-1 $\alpha$  n=4, CKD + SDF-1 $\alpha$  n=7) or during remodeling (12 weeks, preliminary: sham + bare n=2 and Sham + SDF-1 $\alpha$  n=6). Explants were checked for inflammation, tissue formation and graft integrity.

**Results:** At 2 weeks, immunohistochemistry (IHC) on explants showed that CKD decreased anti-inflammatory macrophage (CD163) presence. The combined presence of CKD and SDF-1 $\alpha$  determined Elastin, pan-macrophage inflammation (CD68) and smooth muscle cell Calponin. Fibroblast marker Vimentin was similar in all conditions. Due to progressive proteinuria in n=11 animals, no 12 weeks explants were included for CKD. Vascular rupture and sudden death occurred in 4/15 sham from 3 weeks onwards (2 bare and 2 SDF-1 $\alpha$ ), possibly related to premature graft resorption. With IHC we indeed found PCU-131-BU fibers in 2-but not in 12 weeks explants. In sham at 12 weeks, SDF-1 $\alpha$  led to a non-significant increase of Elastin but no other differences. While patent, all n=9 explants at 12 weeks showed severe vascular dilatation.

**Conclusions:** *In situ* TE with PCU-131-BU led to a remodeling response, replacing the synthetic material by vascular tissue. Resorption and mechanical stability may dictate outcomes at least in equal amount to disease and bio-functionalization. SDF-1 $\alpha$  may mediate inflammation and tissue-formation in CKD at 2 weeks but during later remodeling under healthy conditions, function appears limited.

**Funding:** Government Support - Non-U.S.

## FR-PO384

**Malnutrition During Pregnancy Impairs Nephrogenesis by Modifying Epigenetic Regulation in Nephron Progenitor Cells**

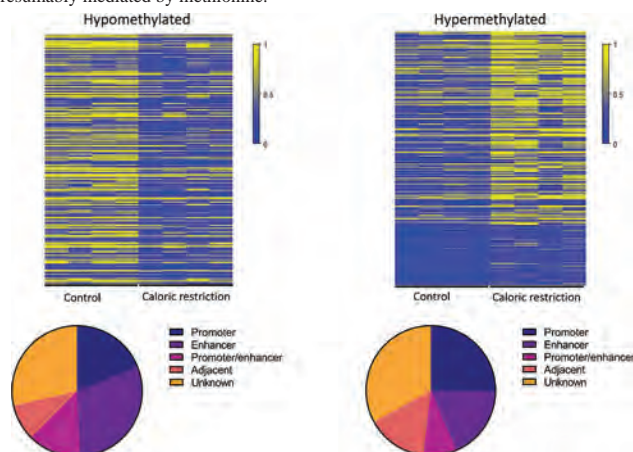

Oded Volovelsky, Yaniv Makayes, Morris Nechama. *Hadassah University Medical Center, Jerusalem, Israel.*

**Background:** Poor intrauterine environment, such as maternal malnutrition, impairs nephron endowment and increases the risk of chronic kidney disease in adulthood in the next generation. We have previously demonstrated that methionine metabolism has an important role in mediating the negative effects of caloric restriction during pregnancy on nephron endowment. As methionine has an important role in epigenetic control of gene expression, we examined the effects of malnutrition on gene methylation in nephron progenitor cells.

**Methods:** The caloric intake of pregnant mice was limited to 70% of daily intake. Nephron progenitor cells (NPCs) were sorted using transgenic mice with specific GFP labeling. DNA from NPCs was extracted, and the methylation pattern was characterized and analyzed using reduced representation bisulfite sequencing. The data acquired was cross-referenced with chromatin accessibility and histone modification data of nephron progenitor cells. The findings were validated using RT-qPCR. In addition, the effects of methionine on methylation patterns were evaluated using Bisulfite Amplicon Sequencing.

**Results:** Caloric restriction during pregnancy leads to a global decrease in DNA methylation in nephron progenitor cells compared to control. Specific changes in DNA methylation were localized to gene promoters, enhancers, and transcription factor binding sites. These effects were present throughout the genome, including genes involved in nephrogenesis and pivotal intracellular signaling pathways, in accordance with the changes in expression profile.

**Conclusions:** This study is the first evidence that maternal malnutrition during pregnancy impairs nephrogenesis by modifying epigenetic remodeling in NPCs, presumably mediated by methionine.

Heatmaps of differentially methylated regions in DNA of NPCs extracted from embryonic kidneys subjected to caloric restriction during pregnancy. Pie charts representing the anticipated distribution of differentially methylated regions.

## FR-PO385

**Altering Maternal Macronutrient Supply Can Extend Nephrogenesis and Rescue Nephron Endowment**

John F. Bertram,<sup>1</sup> Sarah E. Gazzard,<sup>1</sup> Julie L. Moreau,<sup>1</sup> Joel A. Eliades,<sup>3</sup> Alexander N. Combes,<sup>1</sup> Stephen J. Simpson,<sup>2</sup> Luise A. Cullen-McEwen.<sup>1</sup> <sup>1</sup>Department of Anatomy and Developmental Biology, Monash Biomedicine Discovery Institute, Monash University, Melbourne, VIC, Australia; <sup>2</sup>Charles Perkins Centre Research and Education Hub, The University of Sydney, Sydney, NSW, Australia; <sup>3</sup>Department of Biochemistry and Molecular Biology, Monash Biomedicine Discovery Institute, Monash University, Melbourne, VIC, Australia.

**Background:** Human and animal studies have linked low nephron endowment with increased risk of chronic kidney disease and hypertension in later life. Strategies to increase nephron endowment in those at risk of a nephron deficit are therefore sought. We have previously shown that feeding pregnant mice a low carbohydrate high fat diet (LCHFD) boosts offspring nephron endowment. The present study investigated the mechanism behind this increased nephron endowment and whether the maternal LCHFD could rescue a programmed nephron deficit.

**Methods:** To examine the mechanism behind the increased nephron endowment C57Bl6 pregnant mice were fed a normal diet (ND) or LCHFD until postnatal day (PN) 0 (to assess numbers of Six2+ nephrogenic niches) or PN2-7 (to assess the timing of cessation of nephrogenesis). To examine whether the LCHFD could rescue a programmed nephron deficit, a cohort of pregnant mice were fed either a ND, LCHFD or a low protein diet (LPD) from mating and throughout gestation and lactation, or LPD from mating and throughout gestation and then switched to the LCHFD at birth. At PN21 we estimated

nephron endowment using unbiased stereology. Food intakes were measured throughout pregnancy and lactation to assess total caloric intake.

**Results:** At birth, the number of nephrogenic niches and nephrons in LCHFD offspring was similar to ND offspring indicating the augmentation of nephron number occurs postnatally during lactation. At PN3, nephron induction was complete in ND mice, however in LCHFD offspring Six2+ nephron progenitor cells were still present. Similarly, at PN6 the nephrogenic zone was absent in ND offspring but remained in LCHFD offspring indicating a prolonged nephrogenic period. At PN21, LPD mice contained 9770±417 nephrons per kidney while ND mice contained 13143±270 nephrons per kidney (p<0.0001). Offspring of mothers fed the LPD diet and then switched to the LCHFD contained 13455±403 nephrons (p<0.0001 compared with LPD) demonstrating the diet switch at birth prevented the nephron deficit. Food intake analyses indicated the increased caloric density of the LCHFD was not responsible for the augmentation of nephron number.

**Conclusions:** These findings indicate that maternal nutrition, via lactation, can rescue nephron endowment in mice destined to develop kidneys with a nephron deficit.

## FR-PO386

**SGLT2 Inhibition Promotes Intrinsic Kidney Regeneration by Cells of the Renin Lineage**

Lois van der Pluijm,<sup>1</sup> Angela Koudijs,<sup>1</sup> Wendy Stam,<sup>1</sup> Joris I. Rotmans,<sup>1</sup> Kenneth W. Gross,<sup>2</sup> Michael P. Pieper,<sup>3</sup> Anton J. Van Zonneveld,<sup>1</sup> Roel Bijkerk.<sup>1</sup> <sup>1</sup>Leids Universitair Medisch Centrum, Leiden, Netherlands; <sup>2</sup>Roswell Park Comprehensive Cancer Center, Buffalo, NY; <sup>3</sup>CardioMetabolic Diseases Research, Boehringer Ingelheim Pharma GmbH & Co KG, Biberach an der Riss, Germany.

**Background:** With chronic kidney disease (CKD) prevalence rapidly increasing, the need for novel therapies rises. Sodium glucose co-transporter-2 (SGLT2) inhibitors were initially developed to treat hyperglycemia in diabetes type 2. Clinical trials with the SGLT2 inhibitor Empagliflozin (EMPA) revealed a remarkable renal protective effect in patients with (non-) diabetic CKD, but the molecular mechanism behind this remains to be clarified. Interestingly, the cells of renin lineage (CoRL) in the juxtaglomerular apparatus have been demonstrated to harbor a progenitor potential. Upon injury or aging, CoRL are able to migrate into the glomerular tuft where they start expressing different glomerular cell markers in several CKD mouse models. Considering that EMPA treatment affects renin plasma levels and electrolyte balance in patients, we hypothesized that SGLT2 inhibition might have an effect on CoRL-induced glomerular regeneration.

**Methods:** Experiments were performed in a Ren1cre;tdTomato lineage-trace mouse strain that expresses a tomato fluorescent label in cells derived from renin lineage. Two kidney injury models were applied; bilateral ischemia reperfusion injury (bIRI) and 5/6 nephrectomy (5/6NTx). EMPA (10 mg/kg) was administered daily by oral gavage for 14 days. Subsequently, kidneys were harvested for histological analysis.

**Results:** In both the bIRI and 5/6NTx model, EMPA intake led to an increase (>2 fold) of CoRL found in intraglomerular regions compared to vehicle control. These CoRL differentiated selectively towards different glomerular cell types per model: bIRI combined with EMPA administration resulted in an increase of claudin- (10 fold) and integrin-α8- (1.5 fold) tomato double positive cells, suggesting favored differentiation from CoRL to respectively a parietal epithelial or mesangial cell type. In contrast, in the EMPA treated 5/6NTx model, an increase (1.5 fold) in tomato-podocyn double positive cells was observed, implying more restocking of podocytes by CoRL in this model.

**Conclusions:** SGLT2 inhibition by EMPA treatment leads to increased CoRL-mediated intrinsic regeneration potential and provides the kidney with different replenished cell types in different kidney disease models. Our findings demonstrate a novel mechanism via which SGLT2 inhibition might protect against kidney injury.

**Funding:** Commercial Support - Boehringer Ingelheim

## FR-PO387

**A New Quantifiable View of the Renin Cell Niche in Longitudinal 3D Intravital Microscopy Reveals a Response to Glomerular Injury Feedback System**

Patrick Arndt,<sup>1</sup> Jan Sradnick,<sup>1</sup> Hannah Kroeger,<sup>1</sup> Stefan Holtzhausen,<sup>2</sup> Michael Gerlach,<sup>1</sup> Vladimir T. Todorov,<sup>1</sup> Christian Hugo.<sup>1</sup> <sup>1</sup>Universitätsklinikum Carl Gustav Carus, Dresden, Germany; <sup>2</sup>Technische Universität Dresden, Dresden, Germany.

**Background:** Renin cells (RC) reside in the juxtaglomerular apparatus and function as progenitors capable of migrating into the glomerulus after injury. While regulation of these repair processes is poorly understood, the authors propose the hypothesis that glomerular repair processes in adults underlie an individual intraglomerular-juxtaglomerular feedback mechanism. Using longitudinal intravital microscopy and a laser injury model that induces local damage in individual glomeruli, enables controlled observations of repair processes. Using virtual ray tracing, an optical object characterization technique, a new method of quantification in longitudinal 3D intravital imaging, especially a detailed characterization of the renin cell niche, was established.

**Methods:** Renin reporter mice underwent doxycycline pulse induction. Intravital microscopy was performed through an implanted body window under an upright Leica SP8 LSM for 3 hours on up to 7 days. Laser injury was induced by focusing 100% laser power for 5 seconds at 48x zoom on one Z-plane. 3D processing was performed with Bitplane Imaris 9.7 and novel 3D image quantification was realized by the Marching Cubes algorithm. The calculation of the directional thickness of RC was based on an adapted ray tracing method.

**Results:** Targeted use of laser irradiation established an inducible, selective and reproducible intraglomerular injury model. Migrating RC extended during 3 hours towards the injury area, infiltrating this areas vicinity without losing contact to the juxtaglomerular RC. During these processes the RC volume first increased outside the glomerulus and then showed an up to threefold increased area of dynamic migration with up to 344% compared to their niche of origin.

**Conclusions:** Longitudinal intravital microscopy combined with laser-induced intraglomerular injury and 3D image analysis of injury directed renin cell migration in transgenic mice was assessed in a quantifiable manner. The combination of these technologies provides a new powerful tool for studying the juxtaglomerular feedback system of renin cell recruitment/migration and transdifferentiation as a site-specific response to intraglomerular injury and may promise viable targets for further glomerular research.

## FR-PO388

### Tet2 and Tet3 Mediated Active Cytosine Hydroxymethylation in Six2 Progenitor Cells Is Critical for Nephron Progenitor Differentiation and Nephron Endowment

Xiujie Liang, Tamas Aranyi, Jianfu Zhou, Yuting Guan, Hailong Hu, Hongbo Liu, Katalin Susztak. Susztak lab *University of Pennsylvania, Philadelphia, PA*.

**Background:** Nephron endowment is a key determinant of later life hypertension and kidney disease. Epigenetic changes are key regulators of gene expression. Here we studied whether epigenetic changes, specifically the ten-eleven translocation (*Tet*) DNA demethylase family, *Tet1*, *Tet2*, and *Tet3*-mediated active DNA hydroxymethylation is necessary for gene expression regulation and kidney differentiation.

**Methods:** We generated mice with deletion of *Tet1*, *Tet2* or *Tet3* in Six2 positive nephron progenitors (NP) and performed unbiased omics profiling, whole genome bisulfite sequencing on isolated Six positive NP and single cell RNA sequencing on newborn kidneys.

**Results:** We did not observe changes in development or kidney function in mice with nephron progenitor-specific deletion of *Tet1*, *Tet2*, *Tet3* or *Tet1/Tet2* or *Tet1/Tet3*. On the other hand, mice with combined *Tet2* and *Tet3* loss in Six2-positive NPCs failed to form nephrons leading to kidney failure and perinatal death. *Tet2* and *Tet3* loss in Six2-positive NPs resulted in defect in mesenchymal to epithelial transition and renal vesicle differentiation. Whole genome bisulfite sequencing, single cell RNA sequencing, and gene and protein expression assay identified a defect in expression in genes in the WNT- $\beta$ -catenin signaling pathway in absence of *Tet2* and *Tet3* due to a failure in demethylation of these loci.

**Conclusions:** Our results indicate the key role of *Tet2* and *Tet3*-mediated active cytosine hydroxymethylation in NPs in kidney development and nephron endowment.

### Inducing Kidney Lymphangiogenesis in Development and Disease

Michael D. Donnan,<sup>1</sup> Dilip K. Deb,<sup>1</sup> Eric Ni,<sup>2</sup> Yalu Zhou,<sup>1</sup> Valentin David,<sup>1</sup> Susan E. Quaggin.<sup>1</sup> <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>Lake Erie College of Osteopathic Medicine, Erie, PA.

**Background:** Expansion of the lymphatic vasculature, or lymphangiogenesis, is observed in a number of kidney pathologies including AKI, diabetes, and transplant rejection. Additionally, lymphangiogenesis in these settings appears to be protective against injury and the progression of kidney fibrosis. As lymphangiogenesis is primarily driven by the secreted ligand vascular endothelial growth factor C (VEGF-C) through the receptor VEGFR-3, this signaling pathway is a potential target for future kidney therapeutics.

**Methods:** We generated a new transgenic mouse model to investigate the role of VEGF-C induced lymphangiogenesis in kidney development and response to injury. VEGF-C was overexpressed in nephron progenitor cells and the renal tubular compartment using the Six2Cre (*Six2Vegf-C*) and Pax8-CreERT2 (*Pax8Vegf-C*) driver strains respectively. We characterized the consequences of VEGF-C overexpression during development (*Six2Vegf-C* and *Pax8Vegf-C*) as well as adult mice after 1 week of induction (*Pax8Vegf-C*). Mice underwent a detailed phenotypic evaluation. Whole kidneys were processed for micro-CT 3D imaging and histology with kidney lymphatics distinguished by co-immunofluorescence for the markers PDPN and VEGFR-3.

**Results:** Developmental overexpression of VEGF-C was detrimental to pup growth with increased mortality. Gross evaluation revealed enlarged kidneys with increased kidney-to-mouse weight ratio. Kidney histology and micro-CT imaging demonstrated large cystic lesions within the kidney hilum with marked expansion of the lymphatic capillary network throughout the kidney cortex. Inducing VEGF-C expression for 1 week in 4-week-old *Pax8Vegf-C* mice also resulted in an expansion of cortical lymphatic vessels, however without disruption of gross kidney architecture or reduced mouse viability. Single-cell RNA-seq of this model is currently pending.

**Conclusions:** Developmental and post-natal lymphangiogenesis is promoted by overexpression of VEGF-C. While developmental overexpression resulted in a more severe phenotype suggestive of cystic renal lymphangioma with increased mortality, augmenting VEGF-C expression in adult mice increased the lymphatic capillary density in the kidney without overt phenotypic consequence. This model enables further investigation into the function of lymphatic vessels during kidney injury.

### Role of P2X Receptors on Endothelial Cell Injury Mediated by Complement Activation

Arlette Bohorquez, Carolina G. Ortiz-Sandoval, Daniel Diatlov, Christoph Licht. CL Lab *The Hospital for Sick Children, Toronto, ON, Canada*.

**Background:** The complement system is critical for to innate immunity. The complement system consists of over 50 proteins, provides defense against microbes, mediates inflammatory responses. The final step of complement activation is formation of the membrane attack complex (MAC, C5b-9). Complement over-activation is implicated in the pathophysiology of numerous diseases, yet the mechanisms underlying host cell damage are not fully elucidated. The P2X receptors, are transmembrane cationic channels gated by adenosine triphosphate (ATP) which are present in the plasma membrane (PM) of most excitable and non-excitabile cells including all segments of the nephron, and renal cells. Recently, a link between complement system and P2X receptors has been established, showing that inhibition of P2X activation decreases complement mediated cell damage. The aim of this study is to determine the role of P2X receptors activity in complement activation on primary endothelial cells.

**Methods:** Complement was activated on blood outgrowth endothelial cells (BOECs) using an established protocol, first sensitizing the cells using a specific antibody to CD59, followed by treatment with normal human serum. Complement activity was assessed by measuring the deposition of C3b and C5b-9 on BOEC PM via immunofluorescence using specific antibodies. Intracellular Ca<sup>2+</sup> levels were measured using a fluorescent calcium indicator (Invitrogen). ATP release was measured using a commercial ATP luminescence assay (Promega).

**Results:** Complement activation caused C3b and C5b-9 deposition on the PM of BOECs, followed by Ca<sup>2+</sup> influx and ATP release. Cells treated with P2X receptor antagonists, showed a significant decrease in C5b-9 deposition compared to untreated controls. In addition, P2X antagonist treatment significantly ameliorated Ca<sup>2+</sup> influx as well as ATP release.

**Conclusions:** The finding of reduced C5b-9 deposition on BOECs in the presence of P2X receptor antagonists suggests an important functional link between the complement system and purinergic system. While more research is required to fully elucidate the interactions between these critical, ubiquitous biological systems, our results contribute to a better understanding of the consequences of complement activation on endothelial cells and suggest new therapeutic targets for disease related to dysregulated complement system.

## FR-PO391

### mTORC1 Activity Promotes an Intercalated Cell State Which Is Suppressed by Hes1 to Maintain Principal Cells in a Mature State

Jennifer DeRiso,<sup>1</sup> Malini Mukherjee,<sup>1</sup> Madhusudhana R. Janga,<sup>1</sup> Morgan J. Rothschild,<sup>3</sup> Sabdi Bravo,<sup>1,4</sup> Alicia L. Simmons,<sup>3</sup> Brook W. Busselman,<sup>3</sup> Indra Chandrasekar,<sup>1,2</sup> Kameswaran Surendran.<sup>1,2</sup> <sup>1</sup>Sanford Research, Sioux Falls, SD; <sup>2</sup>University of South Dakota Sanford School of Medicine, Sioux Falls, SD; <sup>3</sup>University of South Dakota, Vermillion, SD; <sup>4</sup>Augustana University, Sioux Falls, SD.

**Background:** Notch signaling via Hes1 is required to maintain Aquaporin-2 expressing principal cell types in the distal convoluted tubule, connecting tubule and collecting duct segments of the adult mouse kidney in a non-intercalated cell state. Lineage tracing of Hes1-deficient principal cells revealed that Notch signaling suppresses intercalated programs from turning on in mature principal cells. Here we attempt to identify intercalated cell state promoting signals by using unbiased genomic approaches to determine signaling pathways suppressed by Hes1 in principal cells.

**Methods:** We identified differentially expressed genes in adult mouse kidneys from control littermates (n=9) versus mice with one week of *Hes1* inactivation within the kidney epithelial cells (n=7). RNA-sequencing of total kidney RNA was performed to identify differentially expressed genes. Also, we performed chromatin immunoprecipitation (ChIP) using anti-FLAG antibody to identify loci visited by *Hes1* in a mature principal cell line expressing *Hes1* fused with 3xFLAG. We validated direct targets of *Hes1* by ChIP-qPCR. We detected mTORC1 activity by staining for phosphorylated S6 along with principal and intercalated cell markers. We also traced the fate of wild type versus *Tsc2*-deficient mature principal cells by genetically labeling them in adult mouse kidneys.

**Results:** Our results reveal that multiple signaling pathways components, including Wnt, BMP, Hh and mTOR are upregulated soon after inactivation of *Hes1*. *Hes1* suppresses *insulin receptor substrate 1* (*irs1*), a component that mediates mTORC1 activation. Consistent with mTORC1 activity promoting intercalated cell state we observed an increase in phosphorylated S6 ribosomal protein soon after inactivation of *Hes1* in principal cells of adult mouse kidneys. Additionally, inactivation of *Tsc2*, an inhibitor of mTORC1, is sufficient to initiate conversion of principal cells towards a type A intercalated cell state in adult kidneys.

**Conclusions:** These studies reveal a role for mTORC1 activity in promoting an intercalated cell state which is suppressed by Notch signaling to maintain principal cells in a mature state.

### Evidence for Post-Branching Nephrogenesis and Novel Ureteric Bud/Nephron Progenitor Interaction in the Postnatal Rabbit

Meredith P. Schuh, Sunitha Yarlagadda, Lyan Alkhudairy, Raphael Kopan. Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

**Background:** While all vertebrates undergo branching nephrogenesis, humans proceed in two additional post-branching nephrogenesis (PBN) periods: arcading and lateral branch nephrogenesis (LBN). This process is completed at 34-36 weeks gestation, with 60% of nephrons forming in the third trimester. Infants born before 30 weeks undergo nephrogenesis for no more than 40 days postnatally, resulting in low nephron endowment and increased risk for chronic kidney disease (CKD) later in life. Identifying a model that simulates human postnatal nephrogenesis is critical in order to reduce risk of CKD in this population. The rabbit continues nephrogenesis postnatally but whether it has PBN has not been determined. Without this knowledge, its utility as a model of preterm human remains unknown.

**Methods:** To address this, we performed morphologic assessments of rabbit nephrogenesis from post conceptual day (PC) 31 (birth) to PC49 using H&E and immunofluorescence to localize *SIX1*, *SIX2*, *WT1*, *ZO-1*, and *JAG1* in the postnatal period. We performed 3D rendering of the nephrogenic niche to assess for PBN, and applied RNAScope to localize the nephrogenic niche by expression of *Six1* (nephron progenitors, NPC) and *Ret* (ureteric bud (UB) tip) transcripts.

**Results:** Using molecular markers, *SIX1* and *SIX2* were identified in the NPC throughout nephrogenesis. 3D morphologic assessments identified an elongated tubule with attached glomeruli extending below the UB tip, consistent with PBN arcades. Above these arcades, the UB tip contained a horn-like protrusion interacting with an immature *WT1*+ NPC population (fig 1). The *Ret*+ UB horns were present until PC38, while the arcades were *Cdh1*+*Ret*-.

**Conclusions:** We conclude that the rabbit shows morphologic and molecular evidence of PBN continuing postnatally. Furthermore, we identified a novel UB/NPC interaction during the arcading period.

### The Scattered Tubular Cell Phenotype Is Induced in Cultured Primary Human Tubular Cells and Correlates With Loss of HNF4A Expression

Michelle Kha,<sup>1</sup> Gülay Altıparmak,<sup>1</sup> Karl Swärd,<sup>2</sup> Martin E. Johansson,<sup>1,3</sup> <sup>1</sup>Göteborgs universitet Sahlgrenska Akademien, Göteborg, Sweden; <sup>2</sup>Lunds Universitet, Lund, Sweden; <sup>3</sup>Sahlgrenska universitetssjukhuset, Göteborg, Sweden.

**Background:** Scattered tubular cells (STCs) are found in the proximal tubules (PTs) of healthy human kidneys. The STCs differ from the PT cells by having less cytoplasm, fewer mitochondria and reduced brush border. Furthermore, several markers have been identified for the STCs. Shown to be involved in injury and regeneration, their phenotype is believed to be induced by injury or more controversially to represent a putative progenitor cell population. HNF4A is a transcription factor controlling the mature PT phenotype, including brush border formation and regulation of genes associated with transport and metabolism. We aimed to study if primary tubular cell cultures model induction of the STC phenotype by loss of HNF4A.

**Methods:** Primary PT cells were obtained from dissociated human kidney tissue. Histological material was collected from tissue and primary cells at consecutive passages. In parallel, we developed a method for correlative light and electron microscopy (CLEM) to seamlessly detect the STCs in light microscopy and study the ultrastructure of these cells in electron microscopy using the same tissue sample. Finally, *HNF4A* adenoviral transduction was used to reintroduce the PT phenotype in primary cells, followed by RNA sequencing.

**Results:** Colocalization of HNF4A and the STC marker VIM in human kidney tissue revealed two STC populations. A minority of VIM+ cells had complete loss of HNF4A expression. Most of the STCs were VIM+/HNF4A+, indicating an intermediate form between the PT and STC phenotype. CLEM showed reduced brush border and fewer mitochondria in most VIM+ cells, while a subset had complete loss of brush border and considerably less cytoplasm corresponding to the VIM+/HNF4A+ population. Primary cells showed rapid reciprocal HNF4A loss and VIM induction following tissue dissociation. By reexpressing HNF4A using viral transduction, the PT phenotype was regained, including expression of HNF4A target genes associated with metabolism and brush border formation.

**Conclusions:** Collectively, this study suggests that HNF4A loss is a major event during development of the STC phenotype. *In vitro* culture of PT cells represents an induced STC model rather than a PT model, a process reversed by reintroduction of HNF4A. Loss of HNF4A is a gradual process possibly triggered by injurious events.

### Selected Renal Cells Self-Organize to Form Neo-Nephrons and Attenuate Kidney Disease

Prakash Narayan,<sup>1</sup> Elias A. Rivera,<sup>2</sup> Deepak Jain,<sup>1</sup> Tim A. Bertram,<sup>1</sup> John W. Ludlow,<sup>1</sup> Joydeep Basu.<sup>1</sup> <sup>1</sup>ProKidney, Winston-Salem, NC; <sup>2</sup>Infinium Pathology Consultants, Oak Ridge, NC.

**Background:** Selected renal cells (SRC), a renal epithelial cell-enriched platform, is being advanced as autologous cell-based therapy for treatment of chronic kidney disease (CKD). In the present study, we tested the hypothesis that SRC forms organoids which self-organize into neo-nephrons, and its implantation into the diseased kidney induces repair and ameliorates organ dysfunction.

**Methods:** Rodent and human SRC were generated from kidney tissue using buoyant density gradient centrifugation. SRC cultures ± hydrogel were examined using light and immunofluorescence microscopy. SRC retention *in vivo* and bioactivity were examined in rodent models of CKD (ZSF1 rat and subtotal nephrectomy).

**Results:** In culture, both rodent and human SRC formed organoids (Figure 1A) that expressed renal markers including the Na-K-2Cl cotransporter, gamma-glutamyltransferase type 1, megalin, and cubilin. In the presence of hydrogel, these SRC-derived organoids self-organized into tubules (Figure 1B), and other neo-nephron structures. Seeding SRC into diseased kidneys resulted in its incorporation into the renal parenchyma, evident even 4 months post-implantation, and formation of glomerular capillary loops and neo-nephrons. In subtotal nephrectomized rats, SRC implantation was associated with improvement in both survival and renal function (BUN, Scr, UPCr; p<0.05 vs. sham).

**Conclusions:** SRC forms organoids that express renal markers, and in the presence of hydrogel, self-organize into neo-nephrons. When introduced into diseased kidneys SRC exhibits reparative and restorative activity inducing neo-nephrogenesis, and improving survival and renal filtration. SRC-based Renal Autologous Cell Therapy (REACT) is in late-stage clinical trials for CKD, and has been granted Regenerative Medicine Advanced Therapy designation by Food and Drug Administration.

**Funding:** Commercial Support - ProKidney

Figure 1. Organoids (A, arrows, 20X) formed from cultured SRC self-organize into tubules and neo-nephrons (B, arrow, 20X) in the presence of hydrogel.

## FR-PO395

### Hypoxic Mesenchymal Stem Cells-Derived Extracellular Vesicles Suppress Renal Fibrosis by Downregulating Rheb/mTOR Signaling

Wei-Cheng Tseng,<sup>1,2</sup> Der-Cherng Tarn,<sup>1,2</sup> <sup>1</sup>Division of Nephrology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; <sup>2</sup>School of Medicine; Center for Intelligent Drug Systems and Smart Bio-devices (IDS2B), National Yang Ming Chiao Tung University, Hsinchu, Taiwan.

**Background:** Renal interstitial fibrosis, characterized by overactivated myofibroblasts and excessive deposition of extracellular matrix, is the final common pathway of all kinds of renal diseases. Recent evidence suggests that Rheb/mTOR signaling may activate renal fibroblasts and promote renal fibrosis. Till now, specific treatment targeting the pathophysiology of renal fibrosis remains an unmet medical need. Hypoxic mesenchymal stem cells (HMSC) represent novel frontiers in treating organ fibrosis. HMSCs can confer their paracrine therapeutic effects through the secreted extracellular vesicles (EVs), which are small membrane vesicles as a novel form of intercellular communication. Nevertheless, the detailed mechanisms that underlie the therapeutic effect of HMSC-EVs remain to be investigated.

**Methods:** HMSC-EVs were first isolated and characterized by transmission electron microscopy, nanoparticle tracking analysis, immunoblotting, and flow cytometry. After subjected to unilateral ureteral obstruction (UUO), 6-week-old male C57BL/6 mice were administered HMSC-EVs intravenously. In vitro, renal proximal NRK-52E epithelial cells were treated with transforming growth factor-beta 1 in the presence or absence of HMSC-EVs. The extent of renal fibrosis and the relevant pathomechanism of Rheb/mTOR signaling were investigated by histology, immunoblotting, and immunohistochemistry.

**Results:** We found the injured renal tubular cells can incorporate the HMSC-EVs, which further reduced renal fibrosis both in vivo and in vitro. HMSC-EVs not only effectively reduced UUO-induced renal interstitial fibrosis but also suppressed the expression of alpha-smooth muscle actin and fibronectin expression in vitro. Notably, HMSC-EVs decreased the expression of profibrotic Rheb in the UUO-injured renal tubular epithelial cells. Moreover, HMSC-EVs also inhibited mTOR and p70S6K expression in the obstructed kidneys.

**Conclusions:** The present study was the first to uncover the anti-fibrotic role of HMSC-EVs by suppressing Rheb-mTOR-p70S6K signaling in renal fibrosis. Our findings shed new light on the therapeutic effect of HMSC-EVs, and provide the bench evidence for applying the HMSC-EVs to treat patients with fibrotic kidney diseases.

## FR-PO396

### Urine-Derived Stem Cell Attenuated Renal Fibrosis via Klotho Activation in Mice

Hojoon Ko,<sup>1</sup> Dae Eun Choi,<sup>2,1</sup> Hyunsu Choi,<sup>3</sup> Yoon-Kyung Chang,<sup>3</sup> Eu Jin Lee,<sup>1</sup> Youngrok Ham,<sup>1</sup> Kiryang Na,<sup>2,1</sup> Kang Wook Lee,<sup>2,1</sup> Moo Jun Kim,<sup>1</sup> Suyeon Han,<sup>1</sup> <sup>1</sup>Chungnam National University Hospital, Daejeon, Republic of Korea; <sup>2</sup>Chungnam National University, Daejeon, Republic of Korea; <sup>3</sup>Catholic University of Korea Daejeon St Mary's Hospital, Daejeon, Republic of Korea.

**Background:** After renal IRI, regeneration and recovery of the renal tubular cell occurs. However, if the renal repair process is maladaptive, it progresses to renal fibrosis. The role of stem cells in kidney regeneration or fibrosis has not been fully elucidated. We evaluated the urine derived stem cells (UDSC) for renal inflammation and fibrosis after renal ischemia reperfusion (IR).

**Methods:** 10 week old balb/c nude male mice were used. sham, sham with UDSC, IR, IR with UDSC. UDSC were infused 3 times via tail vein at 6,7,8th day after renal IR. Urine NGAL/creatinine (Cr) were checked. The kidneys tissue were harvested at day 14 day. In vitro, TGF- $\beta$  treated HK2 cell were co-cultured with UDSC. Klotho siRNA silencing was performed in UDSC.

**Results:** Urinary NGAL/Cr were significantly increased in IR mice after 14 day IR, compared to sham mice. Urinary NGAL/Cr significantly decreased in UDSC treated IR mice, compared to IR mice. In H&E stain, renal tubulo-interstitial injury were significantly decreased in UDSC treated IR mice, compared to IR mice. In masson trichrom stain, renal fibrosis area were were significantly decreased in UDSC treated IR mice, compared to IR mice. The renal expression of MCP-1, osteopontin, TGF- $\beta$ ,  $\alpha$ -SMA, collagen IV, and F4/80 positive cells were significantly decreased in UDSC treated IR mice, compared to IR mice. The renal expression of Klotho were increased in UDSC treated IR mice, compared to IR mice. In vitro, UDSCs were stem cells that expressed Klotho protein more strongly than other mesenchymal stem cells (MSCs). UDSCs also suppressed fibrosis

by inhibiting transforming growth factor (TGF)- $\beta$  in HK-2 human renal proximal tubule cells in an in vitro model. Klotho siRNA silencing reduced the TGF- $\beta$ -inhibiting ability of UDSCs.

**Conclusions:** UDSC attenuate renal fibrosis after renal IR. Klotho-secretion of UDSC play a role in these anti-fibrotic effects.

**Funding:** Government Support - Non-U.S.

## FR-PO397

### Phenotypic Characterisation of Novel Immortalised Human Distal Convoluted Tubule Cells

Chutong Zhong, Keith Siew, Stephen B. Walsh. University College London, London, United Kingdom.

**Background:** The distal convoluted tubule (DCT) is responsible for fine-tuning the final excretion of sodium, potassium, calcium and magnesium in the urine. The study of rare monogenic diseases (namely Gordon and Gitelman syndromes) have highlighted the physiological importance of the DCT in blood pressure control. However, the most commonly used cellular models of this segment are either not truly kidney cells (e.g. studies have shown HEK293 are more likely of neuronal lineage) or of murine origin, and thus there is need for advanced human DCT (hDCT) models. Recently, 4 immortalised hDCT models isolated from human urine have been created by Dr Tetsuro Kusaba, but have not been biochemically or functionally characterized.

**Methods:** Western blot analysis on total cellular lysates by using NCC antibody detected three different states of NCC in all four hDCT cell lines. qPCR detected the presence of NCC mRNA at Cq 29.57-32.18 across all four samples (Human kidney positive control Cq 27, and HEK293 negative control Cq 45).

**Results:** Western blot analysis on total cellular lysates by using NCC antibody detected three different states of NCC in all four hDCT cell lines. qPCR detected the presence of NCC mRNA at Cq 29.57-32.18 across all four samples (Human kidney positive control Cq 27, and HEK293 negative control Cq 45).

**Conclusions:** The preliminary western blot and qPCR results confirmed NCC expression in all four hDCT cell lines and the position of bands agreed with previous studies (de Jong et al., 2003; DOI 10.1074/jbc.M303101200. Zhang et al., 2015. doi: 10.1093/hmg/ddv185.). Further experiments will be performed using other key markers expressed in DCT, including TRPM6 and parvalbumin, Calbindin, KS-WNK1, WNK4, human isoforms of SPAK and NCC. These cell lines could be the first validated hDCT cellular models which reflect the human DCT physiology and can be adapted to 3D cell culture system for functional experiments

## FR-PO398

### Hypoxia Preconditioning Improves Angiogenic and Inflammatory Gene Profile of Adipose Derived Mesenchymal Stem Cells in Hypertensive Kidney Disease

Naba Farooqui,<sup>1</sup> Arjunmohan Mohan,<sup>1</sup> Eram Ahsan,<sup>1,2</sup> Leticia A. Sandoval,<sup>1</sup> Alfonso Eirin,<sup>1</sup> Lilach O. Lerman,<sup>1</sup> Sandra Herrmann,<sup>1</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Jersey Shore University Medical Center, Neptune City, NJ.

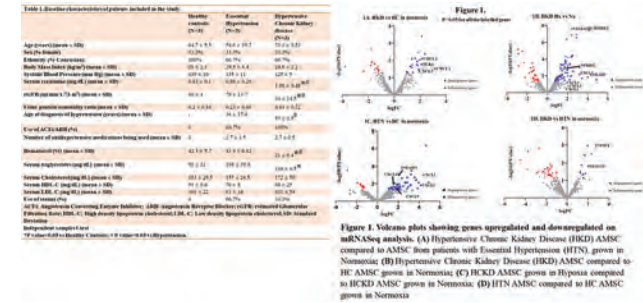

**Background:** Hypertensive kidney disease (HKD) in the setting of uremic milieu may alter the reparative potential of autologous adipose derived mesenchymal stem cells (AMSC) but might be improved by hypoxic preconditioning (HPC). We hypothesize that the state of HKD and not hypertension per se worsens the gene expression profile of AMSC compared to AMSC from patients with essential hypertension without CKD (HTN) as well as healthy controls (HC) and we examined if HPC attenuates that.

**Methods:** We cultured human AMSC (P3-4) isolated from healthy kidney donors (HC), HTN and HKD (n=3 each) under normoxia (20% O<sub>2</sub>) and hypoxia (1% O<sub>2</sub>). mRNA sequencing was performed on AMSC cell pellets and counts were normalized using edgeR software (v3.28.1). Genes with significant log fold change (p<0.05 and >1.4 for up- or down-regulation) were grouped based on gene sets available on Mouse Genome Informatics database.

**Results:** The baseline characteristics of the patients are shown in Table 1. On comparing HKD vs HC, inflammatory genes TLR3, CXCL1, CXCL2, and CXCL3 were significantly upregulated and a greater % of angiogenic genes are downregulated than upregulated (Fig. 1A). HPC promoted upregulation of angiogenic genes including vascular endothelial growth factor A (VEGF A), anti-inflammatory genes like Interleukin-1 receptor antagonist protein and nuclear factor kappa-B (NF- $\kappa$ B) inhibitors (Fig. 1C). Similarly, in HTN the inflammatory genes CXCL1, CXCL2, CXCL5, CXCL12, and TNF alpha-induced proteins were upregulated versus HC (Fig. 1B), and HPC abolished their upregulation. HKD showed a greater percentage downregulation of angiogenic genes compared to HTN which was reversed by HPC (Fig. 1D).

**Conclusions:** HKD and HTN are associated with upregulation of RNA levels of inflammatory genes in AMSC as compared to HC, with HKD showing decreased angiogenic gene profile compared to HTN. HPC may serve as a strategy to attenuate this response and enhance the angiogenic and anti-inflammatory gene expression profile of these AMSC.

**Funding:** NIDDK Support

FR-PO399

Renal Tubular Epithelial Cells From Urinary Samples of Renal Transplanted Recipients: Phenotypic Characterization, Stemness, and Immunomodulatory Properties

Valeria Pizzuti,<sup>1,2</sup> Chiara Donadei,<sup>1</sup> Elisa Gessaroli,<sup>1</sup> Giorgia Comai,<sup>1</sup> Gaetano La Manna,<sup>1</sup> <sup>1</sup>Nephrology, Dialysis and Renal Transplant Unit, IRCCS-Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; <sup>2</sup>Unit of Histology, Embryology and Applied Biology, Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, Italy.

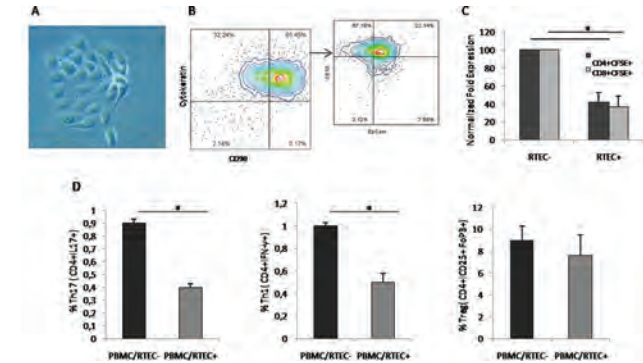

**Background:** The isolation of cells from urine samples represents a non-invasive approach to expand and characterize different cell populations. Renal Tubular Epithelial Cells (RTEC) are released into urines, and their amount can increase in the presence of kidney damage and transplant rejection. The aim of the present study was the isolation and phenotype characterization of RTEC in urinary samples from kidney transplant recipients, focusing on their stemness and immunomodulatory potential.

**Methods:** Urine derived RTEC, were then analyzed by cytometry for Cytokeratin, EpCAM and CD13 to confirm their epithelial features. The expression of CD90, CD73, CD44, CD105, CD24 and CD133 markers was also assayed. For the evaluation of their immunomodulatory properties, RTEC were cultured with PBMCs derived from healthy donors and the proliferation of CD4 and CD8 was analyzed with CFSE. After co-culture, T-cell subsets were quantified through flow cytometry for Th17 (CD4<sup>+</sup>, IL17<sup>+</sup>), Th1 (CD4<sup>+</sup> IFN-γ<sup>+</sup>) and Treg (CD4<sup>+</sup>CD25<sup>+</sup>, FoxP3<sup>+</sup>).

**Results:** The analysis of RTEC markers confirmed their epithelial features, with a high percentage of Cytokeratin positive cells. The expression of proximal and distal RTEC marker, CD13 and EpCam was observed (Fig.A,B). Most of the cells were positive for CD90, CD73, CD44, CD105, CD24 and CD133, which are typically associated with stem or progenitor populations. The co-culture with PBMCs activated with anti-CD3/CD28 showed a suppression in CD4<sup>+</sup> and CD8<sup>+</sup> proliferation (fig.C). Moreover, there was a reduction in Th17 and Th1 populations, while Treg subset remained stable (Fig.D).

**Conclusions:** The RTEC retain their epithelial characteristics after isolation and in vitro expansion. The expression of markers associated with stemness suggests the presence of not terminally differentiated subpopulations. The ability of RTEC to modulate the proliferation of immune cells could play an essential role in immune-mediated disorders.

**Funding:** Government Support - Non-U.S.

FR-PO400

Chimeric Nephrons in Neonatal Mice for Repeated-Dose Toxicity Evaluation

Kenji Matsui, Shuichiro Yamanaka, Naoto Matsumoto, Yatsumu Saito, Kei Matsumoto, Eiji Kobayashi, Takashi Yokoo. Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan.

**Background:** The detailed molecular mechanisms of drug-induced nephrotoxicity (DIN) have not been established to date. It is difficult to examine multiple target molecules comprehensively *in vivo* because mice genetic modification requires time. Cultured kidney cells that lose polarity do not accurately reproduce toxicity. Renal organoids are

not suitable to validate the recovery process and chronic toxicity because they cannot be cultured for a long time. In this study, we have generated a new evaluation model using chimeric mice.

**Methods:** 1. Renal progenitor cells (RPCs) extracted from EGFP-labeled mouse fetuses were incubated to form spheres. The spheres were then transplanted under the renal capsules of adult C57BL/6 (B6) and NOG mice. 2. RPCs cell suspension was injected into neonatal B6 renal capsules. The mice were treated with repeated-dose cisplatin and were harvested 2 months after the injection for an evaluation with immunostaining and scRNA-seq.

**Results:** 1. The RPCs spheres in adult B6 showed a marked T-cell infiltration, suggesting an EGFP proteins rejection. Those transplanted into NOG formed nephrons, but their tubules became markedly dilated after 2 months. 2. The RPCs injected into the neonatal B6 were integrated into the host nephrogenic region without rejection. Subsequently, they formed mature chimeric nephrons from the glomeruli to the distal tubules that were retained for 4 months. Their function was confirmed by the presence of systemically administered dextran in their lumens. The repeated cisplatin administration caused them to express injury markers equivalent to the host nephrons.

**Conclusions:** We have developed a method to generate chimeric nephrons from the RPCs in neonatal mice that reproduced repeated-dose toxicity. The advantages of this model are as follows: 1, chimeric mice were generated easily; 2, chimeric nephrons showed a similar maturity and drug response to the host; 3, they survived for a longer time than the spheres in adults with connection to the host excretory tract; 4, immunocompetent neonates were tolerant to EGFP antigens, thus, traceable chimeric nephrons were formed; 5, scRNA-seq could be used to compare the nephron behavior of different origins. Furthermore, this model provided the potential to easily change tubular phenotypes by gene-editing RPCs and may be applied to elucidate the DIN mechanism.

Metabolomics and In Vitro Validation Study to Identify the Preventive Effect of Sodium-Glucose Cotransporter 2 Inhibitor on the Progression of Diabetic Nephropathy

Hyung Ah Jo,<sup>1</sup> Seung Hee Yang,<sup>2</sup> <sup>1</sup>Inje University Ilsan Paik Hospital, Goyang, Republic of Korea; <sup>2</sup>Seoul National University College of Medicine, Seoul, Republic of Korea.

**Background:** We aimed to determine the metabolic profile of kidney resident cells under hyperglycemic conditions and following SGLT2 inhibitor treatment. The targeted metabolomics using the Absolute IDQ-p180 kit was applied to quantify metabolites in the kidney resident cells stimulated by high glucose (25, 50 μM) and following SGLT2 inhibitor, dapagliflozin treatment.

**Methods:** The primary cultured human tubular epithelial cells (TECs), podocytes, and glomerular endothelial cells (GECs) were used to identify metabolomic patterns according to hyperglycemic conditions following dapagliflozin treatment.

**Results:** The metabolomic pattern of kidney resident cells is distinctly depicted in the hyperglycemic stimuli compared to control (Figure 1). The levels of Asparagine, PC aa C38:4, and PC ae C34:1 were elevated in the TECs stimulated with 50 μM of glucose and significantly decreased after dapagliflozin treatment. The metabolite level of PC aa C28:1 was decreased in the TECs according to 50 μM of glucose treatment, and dapagliflozin treatment elevated its level. The level C18:1-OH was significantly decreased after 50 μM of glucose compared with control and its level was significantly increased after dapagliflozin treatment in podocytes. The level of C12 in the GECs was decreased after treatment with 50 μM of glucose, whereas dapagliflozin treatment significantly elevated its level. *In vitro* analysis showed that the treatment with glucose significantly increased the expression of fibronectin dose-dependently assessed by Western blot in the TECs, podocytes, and GECs. Dapagliflozin treatment significantly abrogated the high-gl

**In Utero Exposure to Maternal Diabetes Reprograms Nephron Formation and Predisposes to Hypertension and CKD**

Debora Malta C.S Santos, Takuto Chiba, Ariane Bruder do Nascimento, Andrew S. Clugston, Maliha Tayeb, Andrew J. Bodnar, Dennis Kostka, Thiago Bruder do Nascimento, Sunder Sims-Lucas, Jacqueline Ho. *University of Pittsburgh School of Medicine, Pittsburgh, PA.*

**Background:** The prevalence of diabetes has markedly increased among pregnant women worldwide and infants who are exposed to maternal diabetes *in utero* are at increased risk of congenital anomalies of the kidney and urinary tract (CAKUT). These anomalies can result in a reduction in the number of nephrons formed during kidney development, which is linked to hypertension and chronic kidney disease (CKD). However, it remains unclear how exposure to maternal diabetes *in utero* reprograms the developing kidney, predisposing to hypertension and CKD later in life.

**Methods:** We used the *Ins2<sup>+/-C96Y</sup>* mouse as a genetic model of maternal type 1 diabetes. Diabetic *Ins2<sup>+/-C96Y</sup>* females were bred with wildtype *C57BL/6J* males, and the wildtype offspring (DM\_Exp) were compared to wildtype offspring from *C57BL/6J* dams (=Control). Nephron numbers were estimated using the gold-standard physical dissector/fractionator method. scRNA-seq was performed on postnatal day 2 (P2) kidneys. Renal ischemia reperfusion injury was performed in male 3-month-old mice, and renal function was examined by BUN and sCr levels. Radio-telemetry was utilized to measure continuous blood pressure in male 6-month-old mice.

**Results:** Adult DM\_Exp mice exhibited a nephron deficit of approximately 20% with no associated growth restriction. The expression of the nephron progenitor markers, *Six2* and *Cited1*, was increased in DM\_Exp kidneys, while the number of developing nephrons was significantly reduced at postnatal day 2 (P2). This was accompanied by reduced levels of the *miR-200* family and increased expression of their target genes, *Zeb1/2*. Moreover, increased *DNMT3a* expression was observed in DM\_Exp kidneys. scRNA-seq indicated that the majority of significantly differentially expressed genes occur in the distal tubules and many of them encode solute transporters. Finally, adult DM\_Exp mice exhibited increased susceptibility to acute kidney injury and salt-sensitive hypertension.

**Conclusions:** Together, these data suggest that the diabetic intrauterine environment reprograms nephron formation and function via epigenetic mechanisms, predisposing to hypertension and CKD later in life.

## FR-PO403

**Development of Clinically Applicable In Vivo Tracking of Extracellular Vesicles Using Magnetic Resonance Imaging (MRI)**

Sargis Sedrakyan,<sup>1,2</sup> Johnny C. Akers,<sup>3</sup> Hasmik Soloyan,<sup>1</sup> Paola Aguiari,<sup>1</sup> Roger E. De Filippo,<sup>1,2</sup> Mya S. Thu,<sup>3</sup> Laura Perin.<sup>1,2</sup> <sup>1</sup>*Children's Hospital Los Angeles, Division of Urology, Los Angeles, CA;* <sup>2</sup>*University of Southern California Keck School of Medicine, Los Angeles, CA;* <sup>3</sup>*VisiCell Medical Inc, San Diego, CA.*

**Background:** Extracellular vesicles (EVs) derived from amniotic fluid stem cells (AFSC) hold great potential for the treatment of chronic kidney diseases (CKD). We demonstrated that AFSC-EVs are renoprotective in a mouse model of CKD, Alport syndrome. However, there is an unmet need for real-time *in vivo* monitoring of these therapeutic EVs to understand their safety, targeting, and effectiveness. While current optical imaging solutions are useful for EV tracking studies in animal models, there is limited utility in clinical applications. Here we present a novel *in vivo* tracking solution for our therapeutic EVs in Alport mice, utilizing clinically applicable MRI technology.

**Methods:** To generate trackable EVs, AFSC were labeled with a novel magnetic agent (VMI-Trac). EVs secreted by the labeled AFSC were isolated by ultracentrifugation. The viability and morphology of labeled-cells were evaluated, and the *in vitro* MR properties were analyzed by magnetometer. Purity, potency and identity was compared to non-labeled EVs. *In vivo* biodistribution of labeled EVs was evaluated in WT and Alport mice by MRI at 20 min post injection, and retro-orbital and intra-cardiac routes of delivery were compared.

**Results:** VMI-Trac did not affect the physiological characteristics of the cells and did not change identity, purity and potency of EVs. MRI phantom studies confirmed the *in vitro/ex vivo* detectability of labeled-EVs. Importantly, MRI studies showed that EV homing to the kidney injected intra-cardiacally into Alport mice was more efficient vs the retro-orbital route, and Prussian blue staining of sections confirmed EV homing to the kidney.

**Conclusions:** We have developed a clinically applicable novel magnetic nanoparticle agent that can be used to label and track the biodistribution of EVs in the kidney and other organs using non-invasive, safe, and effective MRI technology that's widely available. This technology is highly adaptable and can be deployed in both preclinical and clinical settings.

## FR-PO404

**Characterization of TRIM72 Immune Modulatory Functions**

Pu Duann, Brad H. Rovin, Pei-Hui Lin. *The Ohio State University, Columbus, OH.*

**Background:** TRIM72 (MG53) is a myokine that appears to confer protection to the kidney in ischemia-reperfusion (I/R) injury and kidney fibrosis. We recently discovered the functional duality of TRIM72 as a membrane repair protein and immune system

regulator in kidney protection. We conducted experiments to identify whether TRIM72 is expressed within the immune system, and further investigated whether TRIM72 affected inflammatory cytokine profiles.

**Methods:** Spleen and bone marrow from wildtype (*mg53/+*) or *trim72*-null (*mg53/-*) age and gender-matched young adult mice were harvested. Thymus from pups at postnatal days 8, 18, and 24 were harvested and separated into thymic stroma and thymocytes. Tissue TRIM72 expression was analyzed by western blot and quantitative RT-PCR (qRT-PCR). Thymocyte and splenocyte immune phenotypes were further analyzed with anti-CD3, -CD4, -CD25 and -FoxP3 flow cytometry. In addition, we profiled serum from wildtype and *trim72*-null mice for pro-inflammatory cytokines using the V-PLEX Plus pro-inflammatory panel 1 (MSD company). The V-PLEX measures 10 cytokines (INF $\gamma$ , IL-1b, IL-2, IL-4, IL-5, IL-6, CXCL1, IL-10, IL-12p70 and TNF $\alpha$ ).

**Results:** We detected TRIM72 expression in thymus, spleen and bone marrow. TRIM72 is expressed in the thymic stroma, a tissue that regulates T cell tolerance early in life. Thymic expression was moderate, roughly 3% that of skeletal muscle. Wildtype pups had a higher proportion of thymocytes that were CD4+, CD25+, FoxP3+ (Tregs, 4.71%) than thymocytes from *trim72*-null pups (3.27%,  $p^* < 0.05$ ). Bone marrow and spleen expressed lower levels of TRIM72 than the thymus. Of the 10 cytokines examined from serum, CXCL1, IL-2, IL-5, IL-10 and TNF $\alpha$  were significantly elevated in *trim72*-null mice.

**Conclusions:** TRIM72 may facilitate the development of thymic Tregs, and provide basal inhibition of proinflammatory cytokines. Taken together, these findings suggest TRIM72 has anti-inflammatory and pro-tolerogenic immunomodulatory functions.

## FR-PO405

**Evidence for NF- $\kappa$ B/Inflammatory Cytokine Signaling in New Nephron Formation After AKI in Adult Zebrafish**

Heiko J. Schenk,<sup>1,2</sup> Caramai N. Kamei,<sup>1</sup> Samuel M. Hughes,<sup>1</sup> Amber M. Wolf,<sup>1</sup> Iain A. Drummond.<sup>1</sup> <sup>1</sup>*Mount Desert Island Biological Laboratory, Salsbury Cove, ME;* <sup>2</sup>*Medizinische Hochschule Hannover, Hannover, Germany.*

**Background:** Adult progenitor cells in the mesonephric zebrafish kidneys are required during neo-nephrogenesis replacing injured tubules by forming new nephrons. Single-cell RNA transcriptomes of adult kidney progenitor cells point to components of NF- $\kappa$ B and inflammatory cytokine receptors that may initiate stem cell-based nephrogenesis. Here, we present evidence that gentamicin induces inflammation-associated injury, which potentially stimulates stem cell-based nephrogenesis, while the stimulatory effect on the progenitor cells to form new nephrons can be recapitulated by LPS injection.

**Methods:** Adult zebrafish were injected *i.p.* with gentamicin or LPS at day 0. NF- $\kappa$ B signaling was determined 4 days post-injection (dpi) by NF- $\kappa$ B:GFP detection of the NF- $\kappa$ B reporter line *Tg(NF- $\kappa$ B:EGFP)* and NF- $\kappa$ B-associated gene expression using qRT-PCR. The requirement of NF- $\kappa$ B signaling during regeneration was evaluated by pharmacological NF- $\kappa$ B inhibition. Bulk RNAseq from positive selected GFP+ and mcherry+ single cells by FACS was performed from kidneys 7 dpi by gentamicin injection using *Tg(lhx1a:EGFP;cdh17:mCherry)* fish.

**Results:** Gentamicin-induced kidney injury leads to increased tubular NF- $\kappa$ B reporter expression at 4 dpi and is associated with an upregulation of NF- $\kappa$ B target gene expression detected by qRT-PCR. Gentamicin also causes GH receptors mRNA upregulation at 7 dpi along with the kidney progenitor markers *osr1* and *eya4*, while the formation of new nephron aggregates as marked by *Tg(lhx1a:GFP)* expression is increased. NF- $\kappa$ B pharmacological inhibition reduces mRNA expression of kidney progenitor markers, while LPS injection induces mRNA upregulation of kidney progenitor markers. Bulk RNAseq from positive selected GFP+ Lhx1a+ cells 7 dpi with gentamicin confirmed the induction of cytokine receptors in the kidney progenitor cells.

**Conclusions:** Multiple pathways may converge on adult kidney stem cells to activate new nephron formation. We conclude that DAMP and NF- $\kappa$ B signaling is required and sufficient to induce neo-nephrogenesis. Further experiments are required to determine whether cytokine stimulation of neo-nephrogenesis is a direct or indirect effect.

## FR-PO406

**Self-Complementary Adeno-Associated Viral Gene Delivery in the Metanephric Organ Culture Identifies Pvt1 as Modulator of Cystogenesis**

Karam S. Aboudehen, Kara Eckberg, Ivan D. Weissner, Daniel J. Buttram, Nikunj Somia, Peter Igarashi. *University of Minnesota Twin Cities, Minneapolis, MN.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is a monogenic disorder characterized by the formation of kidney cysts, which originate from the epithelial tubules of the nephron. The metanephric organ culture (MOC) is an *ex vivo* system wherein explanted embryonic kidneys undergo tubular differentiation and renal development. The MOC has been previously used to study PKD; however, difficulty in manipulating gene expression has impeded its effectiveness in identifying genes and pathways that are involved in cystogenesis.

**Methods:** We tested the ability of different viruses as a gene-delivery tool by comparing the transduction efficiency of three serotypes scAAV vectors. We then utilized scAAV serotype DJ to deliver shRNA to knockdown *Pvt1*, a long non-coding RNA (lncRNA), which was upregulated in cystic MOCs, in *Pkd1* and *Pd2* mutant mice, and humans with ADPKD. E14.5 metanephroi from wild type CD-1 and *Pkd1*-null embryos

were incubated with scAAV-DJ/shRNA for 4 hours and cultured on a transwell dish between 24 and 96 hours. Semi quantitative qRT-PCR, western blot, and cyst index analysis were performed at 96 hours.

**Results:** scAAV/DJ displayed robust transduction efficiency of the epithelial cells of the MOC by 67%. shRNA delivery by scAAV/DJ downregulated the expression of *Pvt1* by 45% and reduced cyst index by more than 50% in explanted wild-type and *Pkd1*-mutant MOCs treated with cAMP. Mechanistically, knockdown of *Pvt1* decreased the expression of c-MYC protein by up to 60% without affecting *Myc* mRNA.

**Conclusions:** Data from this study suggest that *Pvt1* modulates cystogenesis and targeting *Pvt1* could provide therapeutic benefits for patients with ADPKD. scAAV/DJ could be utilized to rapidly and inexpensively screen and identify genes and pathways that are involved in cystogenesis.

## FR-PO407

### Comprehensive Characterization of 47 Adeno-Associated Virus Serotypes and Mutants for Renal Gene Transfer

Taisuke Furusho, Mia S. Galbraith-Liss, Anusha Sairavi, Hiroyuki Nakai. Oregon Health & Science University, Portland, OR.

**Background:** With the advent of the NGS-based clinical diagnostics, a number of genetic causes have been identified in CKD whose etiology was previously unknown. Such increasing knowledge about genetic etiology of CKD and the relatively high prevalence of monogenic kidney diseases in both pediatric and adult CKD patients have made CKD an attractive target for AAV vector-mediated in vivo gene therapy. However, gene delivery to the kidney has been challenging and there has been no study that compared renal transduction efficiencies of many AAV serotype and mutant capsid-derived vectors in a head-to-head setting. In addition, route of administration (ROA)-dependent differences in renal transduction profiles among different AAV capsids have yet to be investigated. Thus, the development of AAV vector-mediated renal gene therapy has been impeded so far.

**Methods:** We comprehensively characterized renal transduction profiles of 47 different AAV capsids (serotypes and mutants) following vector administration in mice using two ROAs (intravenous injection, IV; and renal vein injection, RV). To this end, we employed AAV DNA/RNA Barcode-Seq, an NGS-based high-throughput method. A barcoded AAV vector library was administered into C57BL/6J mice via IV or RV, kidneys were harvested 6 weeks post-injection, and transduction efficiency of each AAV capsid for each ROA was assessed by Barcode-Seq. Select AAV capsids were then individually vectorized and validated in mice.

**Results:** AAV9 showed the highest renal transduction by IV among the 47 AAV capsids but AAV9 was outperformed by a set of AAV capsids including AAVmt when administered by RV. AAVmt was found to transduce the kidney >30 times better than AAV9. AAV9 transduced only mesangial cells and interstitial cells and transduction patterns by IV and RV remained the same. In contrast, AAVmt transduced only mesangial cells by IV while cortical renal tubule epithelial cells, mostly proximal tubules, were efficiently transduced by RV.

**Conclusions:** Our high-throughput approach using Barcode-Seq identified AAV capsid - ROA combinations that can mediate renal transduction at levels that were not attainable by previous approaches. In addition, our study underscores the importance of carefully selecting AAV capsid and ROA as a combination depending on target cells of interest.

### Plasma Metabolome Differences Across Time in Pediatric CKD

Arthur Lee,<sup>1</sup> Yunwen Xu,<sup>2</sup> Jian Hu,<sup>8</sup> Rui Xiao,<sup>1</sup> Stephen R. Hooper,<sup>3</sup> Erum A. Hartung,<sup>1</sup> Josef Coresh,<sup>2</sup> Eugene P. Rhee,<sup>4</sup> Vasan S. Ramachandran,<sup>7</sup> Paul L. Kimmel,<sup>6</sup> Bradley A. Warady,<sup>5</sup> Susan L. Furth,<sup>1</sup> Michelle Denburg.<sup>1</sup> CKD Biomarkers Consortium <sup>1</sup>The Children's Hospital of Philadelphia, Philadelphia, PA; <sup>2</sup>Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; <sup>3</sup>University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; <sup>4</sup>Massachusetts General Hospital, Boston, MA; <sup>5</sup>Children's Mercy Hospitals and Clinics, Kansas City, MO; <sup>6</sup>National Institutes of Health, Bethesda, MD; <sup>7</sup>Boston University, Boston, MA; <sup>8</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.

**Background:** Studies of longitudinal metabolomics in CKD are lacking. Baseline metabolite levels have been associated with risk of future CKD progression (PMC8455058). The relations of change in metabolite levels and eGFR over time are unknown in children with CKD.

**Methods:** The Chronic Kidney Disease in Children study is a prospective multicenter cohort of children aged 0.5-16 years with eGFR 30-90ml/min/1.73m<sup>2</sup> at entry. Untargeted plasma metabolomics profiling was performed on baseline, year 2, and year 4 samples. Linear mixed effects regression (adjusted for sex and baseline age) was used to evaluate eGFR-metabolite associations and metabolite differences over time. Linear regression evaluated association of changes in metabolite level and eGFR. Significance was based on false discovery rate <0.05.

**Results:** Median (IQR) age=11.6 (8.1-15.1) years and eGFR=49.9 (36.6-64.2). 1156 person-visits (n baseline=626, follow-up=530) were included. **Figure** shows how metabolites associated with eGFR and time. Changes in 70 metabolite levels associated

with change in eGFR. 5 of those increased over time and previously associated with risk of CKD progression: n-acetyl-1-methylhistidine, hydroxyasparagine, homocitrulline, N6-carbamoylthreonyl-adenosine, and 2,3-dihydroxy-5-methylthio-4-pentenol.

**Conclusions:** We described plasma metabolomic patterns in relation to eGFR and time in pediatric CKD. There are likely many drivers of metabolite changes over time (eGFR decline, linear growth, pubertal maturation). Longitudinal data corroborated published baseline metabolites associated with future CKD progression. N-acetyl-1-methylhistidine has been associated with risk of kidney failure and *NAT8* gene variation in adults. N6-carbamoylthreonyl-adenosine is a post-transcriptional breakdown product that is gaining interest as a potential uremic toxin.

**Funding:** NIDDK Support, Other NIH Support - NIH R38 HL143613-03

### Figure: how 622 metabolites relate to time and eGFR

### Longitudinal Metabolite Associations With Cardiovascular Comorbidity in Pediatric CKD

Arthur Lee,<sup>1</sup> Yunwen Xu,<sup>2</sup> Mark Mitsnefes,<sup>3</sup> Jian Hu,<sup>8</sup> Rui Xiao,<sup>1</sup> Erum A. Hartung,<sup>1</sup> Josef Coresh,<sup>2</sup> Eugene P. Rhee,<sup>4</sup> Vasan S. Ramachandran,<sup>5</sup> Paul L. Kimmel,<sup>6</sup> Bradley A. Warady,<sup>7</sup> Susan L. Furth,<sup>1</sup> Michelle Denburg.<sup>1</sup> CKD Biomarkers Consortium <sup>1</sup>The Children's Hospital of Philadelphia, Philadelphia, PA; <sup>2</sup>Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; <sup>3</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH; <sup>4</sup>Massachusetts General Hospital, Boston, MA; <sup>5</sup>Boston University, Boston, MA; <sup>6</sup>National Institutes of Health, Bethesda, MD; <sup>7</sup>Children's Mercy Hospitals and Clinics, Kansas City, MO; <sup>8</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.

**Background:** Children with CKD have high prevalence of left ventricular hypertrophy (LVH) and ventricular dysfunction. We evaluated metabolite associations with cardiovascular comorbidities (CV) leveraging baseline and longitudinal follow-up samples from the Chronic Kidney Disease in Children (CKiD) study.

**Methods:** CKiD is a prospective multicenter cohort of children aged 0.5-16 years with estimated glomerular filtration rate (eGFR) 30-90ml/min/1.73m<sup>2</sup> at entry. Plasma untargeted metabolomic profiling was available at baseline and years 2 and 4, and echocardiograms at years 2, 4, and 6. LVH and ventricular dysfunction are defined the **Figure**. Logistic regression identified CV-metabolite associations at baseline. Generalized linear mixed models identified CV-metabolite associations in follow-up. Significance was defined by p<0.05 in both baseline discovery and follow-up replication analyses.

**Results:** Baseline: n=556, median [IQR] age=11.5 [8.2-15.1] years, eGFR=49.8 [36.6-64.4], LVH 10.9%, and ventricular dysfunction 16.5%. Follow-up: n=328, LVH 9.1%, and ventricular dysfunction 18.4%. **Figure** shows significant CV-metabolite associations. 4-guanidino-butanate was the only metabolite that was not associated with eGFR, urine protein:creatinine, FGF23, or dyslipidemia. In a sensitivity analysis with 24-hour ambulatory blood pressure monitoring data: N6-carbamoylthreonyl-adenosine, 1-methyl-4-imidazoleacetate, and 3-hydroxylaurate remained significantly associated with LVH.

**Conclusions:** This is one of the first studies to utilize longitudinal metabolomics assessments to replicate cross-sectional CV-metabolite associations in CKD. 4-guanidino-butanate has been previously associated with the *AGMAT* gene, reflecting a potential novel genetic-metabolic-CV axis in pediatric CKD. N6-carbamoylthreonyl-adenosine is interesting in that baseline levels were previously associated with risk of CKD progression.

**Funding:** NIDDK Support, Other NIH Support - NIH R38 HL143613-03

Table: metabolites associated with CV outcomes in BOTH baseline and longitudinal analyses

Adjusted covariates were: age, sex, proteinuria, casual hypertension, glomerular diagnosis, CKD duration, BMI z-score, and ACEi/ARB usage. Significance was defined by p<0.05 in both discovery and longitudinal replication analyses.

FR-PO410

**Urine Eicosanoids as Markers of Hyperfiltration-Mediated Injury in the Chronic Kidney Disease in Children (CKiD) Study**  
Tarak Srivastava,<sup>1,2</sup> Vincent S. Staggs,<sup>1</sup> Ginger Milne,<sup>4</sup> Bradley A. Warady,<sup>1</sup> Susan L. Furth,<sup>3</sup> Mukut Sharma.<sup>2</sup> <sup>1</sup>Children's Mercy Hospitals and Clinics, Kansas City, MO; <sup>2</sup>Kansas City VA Medical Center, Kansas City, MO; <sup>3</sup>The Children's Hospital of Philadelphia, Philadelphia, PA; <sup>4</sup>Vanderbilt University, Nashville, TN.

**Background:** Our work on hyperfiltration-mediated injury in animal models identified upregulated cyclooxygenase-2-Prostaglandin E<sub>2</sub> (PGE<sub>2</sub>)-Prostanoid receptor EP2 pathway. We found increased urine PGE<sub>2</sub>/Creatinine levels in children with a solitary kidney. Our long-term goal is to identify urinary biomarkers for hyperfiltration-mediated injury. Presently, we compared urinary eicosanoid metabolite levels between controls and children with CKD Stage 2, 3a and 3b in the CKiD cohort.

**Methods:** Urine samples from 318 CKiD children with glomerular (Glom; n=92) and non-glomerular (N-Glom; n=226) CKD. Enuretic children (n=72) served as controls. Urine PGE<sub>2</sub>, PGD<sub>2</sub>, Prostacyclin (PGI<sub>2</sub>), leukotriene E4 (LTE<sub>4</sub>), Thromboxane (TxB<sub>2</sub>), 9,10-Dihydroxy-12-octadecenoic acid (9,10-DiHOME), 12,13-dihydroxy-9-octadecenoic acid (12,13-DiHOME), 8,9-dihydroxyicosatrienoic acid (8,9-DHET), 11,12-DHET, and 14,15-DHET were measured by liquid chromatography-tandem mass spectrometry. Brunner-Munzel test and Spearman correlation were used for statistical analysis.

**Results:** Urine PGE<sub>2</sub>, PGD<sub>2</sub>, LTE<sub>4</sub>, TxB<sub>2</sub>, 8,9-DHET, 11,12-DHET, 14,15-DHET and 12,13-DiHOME were significantly increased in CKD; PGI<sub>2</sub> and 9,10-DiHOME were significantly decreased (Tables). These metabolites changed incrementally from CKD Stage 2 to 3a to 3b (data not shown). TxB<sub>2</sub>, 12,13-DiHOME, 11,12-DHET and 14,15-DHET were significantly higher in N-Glom vs. Glom. eGFR correlated significantly with PGE<sub>2</sub> (p<0.001), PGI<sub>2</sub> (p<0.001), and 9,10-DiHOME (p<0.001).

**Conclusions:** Urine PGE<sub>2</sub>, PGI<sub>2</sub>, and 9,10-DiHOME are good biomarkers for hyperfiltration-mediated injury as they incrementally change with CKD stages, are comparable in Glom and N-Glom disease, and correlate with eGFR.

**Funding:** NIDDK Support

Table 1: Table shows the median [interquartile range] [range] for urine metabolites from metabolism of arachidonic acid by cyclooxygenase and lipoxygenase enzymes corrected for urine creatinine. p-values <0.05 are highlighted in the Table.

FR-PO411

**Prevalence of Pediatric CKD by ICD-10 Coding in the US Military Health System (MHS)**  
James D. Oliver,<sup>1,2</sup> Robert Nee,<sup>1,2</sup> Hava Marneweck,<sup>5</sup> Amanda Banaag,<sup>5</sup> Meda E. Pavkov,<sup>3</sup> Nilka Rios Burrows,<sup>3</sup> Alain Koyama,<sup>3</sup> Susan R. Mendley,<sup>4</sup> Gregory H. Gorman,<sup>2</sup> Tracey L. Koehlmoos.<sup>2</sup> <sup>1</sup>Walter Reed National Military Medical Center, Bethesda, MD; <sup>2</sup>Uniformed Services University of the Health Sciences, Bethesda, MD; <sup>3</sup>Centers for Disease Control and Prevention, Atlanta, GA; <sup>4</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>5</sup>Henry M Jackson Foundation for the Advancement of Military Medicine Inc, Bethesda, MD.

**Background:** CKD is a major health problem, but its epidemiology in pediatric populations is not well-characterized. We report on CKD prevalence in a large cohort from the MHS Data Repository (MDR), a database of the universal health system for US active-duty military, retirees, and family members, with demographics similar to that of the US general population.

**Methods:** Patient data for age ≤17 from Fiscal Years (FY) 2016-19 were extracted from the MDR. CKD was defined from relevant ICD-10/CPT codes used in previous studies. Prevalence was defined as the percentage with ≥2 outpatient CKD codes during 2016-19 among all children enrolled during this time.

**Results:** 1,646,049 unique children were included over the period. 49% were female and median age (IQR) was 8 (4, 12). Overall prevalence (see Table) was 0.68%, varied by age, and was lowest in males, in Asian/Pacific Islanders (A/PI) and Blacks, and highest in American Indian/Alaskan Natives (AI/AN) and Whites. 72% of the diagnoses were congenital anomalies of the kidney/urinary tract (CAKUT) and 27% were non-specific CKD codes. CAKUT was more prevalent in males (77% vs. 66%), age 0-4 (85% vs. 64% ages 5-17) and in non-Black race groups (73% vs. 65% Black). Non-specific CKD was more prevalent in females (32% vs. 22%), age 14-17 (38% vs. 25% ages 0-13), and Black race (34% vs. 26% all other races).

**Conclusions:** In this universally-insured population, pediatric CKD prevalence by diagnostic coding is higher than previous estimates. Prevalence was higher in females and in AI/AN and White children. *The views expressed in this abstract are those of the authors and do not reflect the official position of the Henry M. Jackson Foundation, the Departments of Army/Navy/Air Force, Department of Defense, Department of Health and Human Services, or the US Government.*

**Age and Kidney Function Are Significantly Associated With Urine Uromodulin Levels in Children With CKD**  
Christine Y. Bakhoun,<sup>1</sup> Matthew Matheson,<sup>2</sup> Susan L. Furth,<sup>3</sup> Joachim H. Ix.<sup>4</sup> <sup>1</sup>Yale University, New Haven, CT; <sup>2</sup>Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; <sup>3</sup>The Children's Hospital of Philadelphia, Philadelphia, PA; <sup>4</sup>University of California San Diego, La Jolla, CA.

**Background:** Uromodulin, or Tamm-Horsfall protein, is the most abundant protein in the urine of healthy adults, and higher urine concentrations mark better tubular health. Greater kidney size and function are predictors of higher uromodulin levels in adults. Urine uromodulin has not yet been studied in children with chronic kidney disease (CKD). Here, we sought to determine the relationship between age and kidney function with urine uromodulin levels in children with CKD.

**Methods:** In the CKD in Children (CKiD) cohort, we utilized multivariable linear regression to evaluate the relationship of age and eGFR with urine uromodulin levels. The primary outcome was urine uromodulin concentration (Umod, mcg/ml). The secondary outcome was uromodulin indexed to urine creatinine (Umod/Cr, mg/g). Both variables were log<sub>2</sub>-transformed given skewed distribution.

**Results:** Among 436 participants, median [IQR] age was 12.4 years [8.9, 15.2], median eGFR was 50 ml/min/1.73 m<sup>2</sup> [36, 62], and 27% had glomerular disease as etiology. The median Umod/Cr level was 0.118 mg/g [IQR 0.048, 0.225]. Each one-year older age was associated with 0.06 lower log<sub>2</sub>(Umod) (i.e., 4% lower Umod) and 0.18 lower log<sub>2</sub>(Umod/Cr) level (i.e., 12% lower Umod/Cr; **Table 1**). Each 10% lower eGFR was associated with 0.10 lower log<sub>2</sub>(Umod) (i.e., 7% lower Umod) but was not significantly associated with log<sub>2</sub>(Umod/Cr) (**Table 1**).

**Conclusions:** Among children with CKD, older age is significantly associated with lower urine uromodulin and Umod/Cr, independent of eGFR. Lower eGFR is significantly associated with lower urine uromodulin but not when it is indexed to urine creatinine. Further studies are needed to comprehensively evaluate age specific reference ranges for urine uromodulin and to evaluate the longitudinal relationship between uromodulin with both age and eGFR in children with CKD.

**Funding:** NIDDK Support, Private Foundation Support

**Table 1.** Multivariable linear regression models evaluating the relationship of age and eGFR with urine uromodulin concentration (model 1) and urine uromodulin indexed to creatinine (model 2).

**Relationships Between BSA-Adjusted Total Kidney Volume and Estimated Glomerular Filtration Rate in Pediatric CKD: Data From the KNOW-Ped CKD Study**

Ji hyun Kim,<sup>1</sup> Yo Han Ahn,<sup>2</sup> Eun mi Yang,<sup>3</sup> Hee Gyung Kang,<sup>2</sup> Min Hyun Cho,<sup>4</sup> Kyoung Hee Han.<sup>5</sup> <sup>1</sup>Seoul National University Bundang Hospital, Seongnam, Republic of Korea; <sup>2</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>3</sup>Chonnam National University Medical School, Gwangju, Republic of Korea; <sup>4</sup>Kyungpook National University Hospital, Daegu, Republic of Korea; <sup>5</sup>Jeju National University Hospital, Jeju, Republic of Korea.

**Background:** The purpose of this study was to investigate the relationship between the estimated glomerular filtration rate (eGFR) and the renal volume adjusted for the body surface area through renal ultrasound in pediatric chronic kidney disease (CKD) in Korea.

**Methods:** Among the subjects enrolled in the KNOW-ped CKD cohort, 336 patients who underwent renal ultrasonography were investigated for renal lengths and widths on the longitudinal plane and the depth on the transverse plane. The formula to calculate the kidney volume was used with 0.523\*length\*width\*depth and was corrected for the body surface area(BSA). The relationship between renal volume and the eGFR at the time of ultrasound measurement was analyzed. In addition, a survival analysis between the renal volume and medical events including renal replacement therapy was performed.

**Results:** The eGFR and BSA-adjusted kidney volume showed a significant correlation (R=0.209, P=0.000) in pediatric CKD with congenital anomalies of the kidney and urinary tract (CAKUT). Kaplan-Meier analysis showed a significantly higher proportion of a 2-fold increase of serum creatinine or medical events of end-stage renal disease (ESRD) according to BSA-adjusted kidney volume (log-rank test,  $\chi^2=17.901$ , P<0.001).

**Conclusions:** The BSA-adjusted kidney volume through renal ultrasound is a marker for kidney survival in pediatric CKD, especially with CAKUT.

FR-PO414

**APOL1 and suPAR on Time to CKD in Children With Sickle Cell Anemia**  
Rima S. Zahr,<sup>1</sup> Sara R. Rashkin,<sup>2</sup> Laila Elsherif,<sup>1</sup> Kenneth I. Ataga,<sup>1</sup> Jeffrey Lebensburger.<sup>3</sup> <sup>1</sup>The University of Tennessee Health Science Center, Memphis, TN; <sup>2</sup>St Jude Children's Research Hospital, Memphis, TN; <sup>3</sup>The University of Alabama at Birmingham, Birmingham, AL.

**Background:** The incidence of CKD increases with time in patients with sickle cell anemia (SCA). Adult SCA patients with high risk *APOL1* variants have an increased risk of developing CKD earlier in life, though this finding has not been explored in children. Biomarkers may further aid in predicting kidney injury and disease progression. Elevated levels of the soluble urokinase-type plasminogen activator (suPAR) is linked to the pathogenesis of CKD in *APOL1* kidney disease. Elevated podocin, is found in urine of individuals with nephrosis. We aimed to identify the association of elevated suPAR, podocin, and high risk *APOL1* on time to develop CKD in pediatric SCA patients.

**Methods:** Participants <18 years (y) with SCA enrolled in the Sickle Cell Clinical Research and Intervention Program (SCCRIP) participants were examined. Time to CKD ( $t^{CKD}$ ) was defined as the age at first instance of estimated glomerular filtration rate (eGFR, modified Schwartz formula) <90 ml/min/1.73m<sup>2</sup> for patients with > or = 3 consecutive instances. Controls (no instances) were censored at last eGFR. Urine podocin and plasma

suPAR were measured using Elisa kits, following manufacturer recommendations. We compared individuals with high biomarker levels (4<sup>th</sup> quartile) to those with lower levels. High risk *APOL1* was defined as homozygous G1 or G2 or double heterozygous. Cox proportional hazards regression was used to test the association of *APOL1*, podocin, and suPAR with  $t^{CKD}$ , adjusted for sex, hydroxyurea use, chronic transfusion use, and five principal components.

**Results:** We identified 29 cases and 220 controls; 52% of the cohort was female. The mean age at first eGFR assessment was 4.1±3.5y, mean follow-up time of 9.8±3.3y and 26% of children had high risk *APOL1*. *APOL1* was associated with  $t^{CKD}$  (hazard ratio (HR)=4.1; P=0.0037). High suPAR was associated with  $t^{CKD}$  (HR=2.8; P=0.040), but high podocin was not (HR=1.5; P=0.39). In a joint model, high risk *APOL1* (HR=4.4; P=0.028) and high suPAR (HR=2.9; P=0.038) were independently associated with  $t^{CKD}$ .

**Conclusions:** High risk *APOL1* and elevated suPAR were associated with earlier diagnosis of CKD in children with SCA. Larger prospective studies are needed to assess the clinical utility for *APOL1* and suPAR in predicting and monitoring SCA CKD progression throughout the lifespan and if therapeutic interventions can ameliorate disease progression.

FR-PO415

**Risk Factors for Long-Term Kidney Outcomes in Childhood Cancer Survivors**  
Anshika Jain,<sup>1,2</sup> Hayton Chui,<sup>1,3</sup> Sophia Nunes,<sup>1,2</sup> Simrandeep Farma,<sup>1</sup> Michael Zappitelli.<sup>1,2</sup> The first and second authors contributed equally to this work. <sup>1</sup>The Hospital for Sick Children, Toronto, ON, Canada; <sup>2</sup>University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; <sup>3</sup>Queen's University Faculty of Health Sciences, Kingston, ON, Canada.

**Background:** Childhood cancer survivor (CCS) follow-up guidelines are unclear on how to risk-stratify for and ascertain long-term kidney outcomes (KO). We evaluated the relation of patient/treatment factors with KO in CCS up to 4 years post-therapy.

**Methods:** Prospective, national data (secondary use: Cancer in Young People in Canada database; CCS, ≤15-years-old at cancer diagnosis post Jan 1, 2001; 17 centers). Excluded: no birth date/sex; died on treatment. Outcome: KO (included hypertension, nephritis, Fanconi syndrome, CKD, AKI, fluid retention, kidney atrophy, high creatinine, low GFR, kidney stone/abscess, thrombotic microangiopathy; selection adjudicated by two authors). Univariable and multivariate logistic regression was used to evaluate independent risk factors for KO.

**Results:** 18,065 CCS included (178 with KO [1%] vs. 17,818 no KO). Age(p=0.42), sex(p=0.96), ethnicity(p=0.41), income quintile(p=0.46), main cancer diagnosis(p<0.001), abdominal radiation during therapy p=0.66), graft vs. host disease (GVHD) (p<0.004), number of hematopoietic stem cell transplants (HSCT)(p<0.001), center geography(p<0.001) and home distance from center(p=0.54) were evaluated in univariable analyses for association with KO. Adjusted analyses(Fig): More HSCT and kidney or hepatic tumor (vs. leukemia/lymphoma) were associated with higher adjusted odds of KO; East/West Canada (vs. Central) and other cancer diagnoses (shown, Fig) were associated with lower adjusted odds of KO.

**Conclusions:** Number of HSCT and cancer type are associated with KO in CCS. KO recording is suboptimal, speaking to lack of awareness and unclear CCS kidney health guidelines. We will use our data to initiate knowledge translation with child oncology stakeholders, explore barriers/facilitators to kidney health monitoring and improve current follow-up guidelines.

## Body Mass Index as a Risk Factor for Kidney Health in Childhood Cancer Survivors

Hayton Chui,<sup>1,2</sup> Anshika Jain,<sup>1,3</sup> Sophia Nunes,<sup>1,3</sup> Simrandeep Farma,<sup>1</sup> Michael Zappitelli.<sup>1</sup> The first and second authors contributed equally to this work. <sup>1</sup>The Hospital for Sick Children, Toronto, ON, Canada; <sup>2</sup>Queen's University Faculty of Health Sciences, Kingston, ON, Canada; <sup>3</sup>University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada.

**Background:** Childhood Cancer (CC) survivors are at risk for kidney outcomes (KO). High Body Mass Index (BMI) is a risk factor for kidney disease. We evaluated the relation between BMI in CC therapy with KO.

**Methods:** Secondary use of national prospective data (Cancer in Young People in Canada database:  $\leq 15$ -yrs-old diagnosed with cancer at 17 Canadian centers after Jan 1, 2001; followed up to 6 yrs). Excluded: no birth date/sex; died during therapy; no BMI. Exposures: first BMI (within 6 mths of diagnosis); last BMI; last vs. first percent change BMI percentile. Outcomes: any kidney or BP outcome after CC therapy. Multivariate logistic regression used to evaluate exposure-KO relations, adjusted for location, cancer diagnosis, graft vs. host and number of hematopoietic transplants.

**Results:** 9805 children included; n=90 (0.92%) had KO recorded. Patients with vs. without KO had higher first BMI, lower last BMI and BMI %change (only significant for first BMI, Fig 1). Adjusted analyses: first BMI was associated with higher adjusted odds for post-therapy KO (adjusted OR 1.01 [1.00-1.02], p<0.02, Table 1).

**Conclusions:** Higher adiposity early in CC therapy is associated with kidney and BP conditions. It is unclear if this is due to higher risk of recurrent AKI or underlying long-term risk. Children with high BMI at CC therapy start may be targeted for closer kidney health follow-up post-therapy.

## FR-PO417

## Feasibility of the NIH Toolbox Cognitive Battery for Children With Mild to Moderate CKD

Stephen R. Hooper,<sup>1</sup> Rebecca J. Johnson,<sup>3</sup> Marc Lande,<sup>2</sup> Joann M. Carlson,<sup>4</sup> Lyndsay Harshman,<sup>5</sup> Camille Wilson,<sup>6</sup> Anne E. Dawson,<sup>6</sup> Matthew Matheson,<sup>7</sup> Bradley A. Warady,<sup>3</sup> Susan L. Furth.<sup>8</sup> <sup>1</sup>University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; <sup>2</sup>University of Rochester Medical Center, Rochester, NY; <sup>3</sup>Children's Mercy Hospitals and Clinics, Kansas City, MO; <sup>4</sup>Robert Wood Johnson University Hospital, New Brunswick, NJ; <sup>5</sup>The University of Iowa Stead Family Children's Hospital, Iowa City, IA; <sup>6</sup>Nationwide Children's Hospital, Columbus, OH; <sup>7</sup>Johns Hopkins University Center for Teaching and Learning, Baltimore, MD; <sup>8</sup>The Children's Hospital of Philadelphia, Philadelphia, PA.

**Background:** Children with CKD show cognitive difficulties in attention, working memory, and executive functions (EF). There is a need for neurocognitive surveillance in clinical research to detect these challenges, but availability of traditional neurocognitive assessments remains elusive. Computerized assessment batteries have promise to assist in this process. The NIH Toolbox Cognitive Battery (NIH-TCB) provides the opportunity to: collect assessment data in a standardized, replicable fashion; use common data elements; employ electronic scoring to reduce examiner error; and allow for increased cross-site collaborations. Its feasibility has not been tested in pediatric CKD.

**Methods:** The NIH-TCB has been administered over the past 3 years by trained Research Coordinators. Analyses examined level of functioning and explored the associations between cognitive outcomes, sociodemographic (age, sex, maternal education), and CKD variables (glomerular diagnosis, U25eGFR, Urine Pr/Cr, blood pressure stage).

**Results:** The CKiD study is a multi-site, prospective cohort of children with eGFR 30-90ml/min/1.73m<sup>2</sup> at entry. The sample included 110 cases, median age=16.8 yrs., 58% males, and 28% Glomerular diagnoses. Primary outcomes from the NIH-TCB included: Working Memory (active recall), Executive Functions (regulatory abilities), and Crystallized Reasoning (academic knowledge). Scores placed in the average range with mild problems present in EF. Linear regressions for EF showed better scores were associated with higher maternal education (p<.03) and less proteinuria (p<.10). For working memory, better scores were associated with less proteinuria (p<.06) and older chronological age (p<.10). For Crystallized Reasoning, better scores were associated with higher maternal education (p<.03). None of the other sociodemographic or CKD factors were associated with the cognitive outcomes.

**Conclusions:** This study is the first to utilize the NIH-TCB for children with mild to moderate CKD. Findings from NIH-TCB had good applicability in the clinical research setting to detect and describe emerging cognitive concerns. Associations between selected cognitive abilities, maternal education, and proteinuria were noted. These findings show the promise of using the NIH-TCB for clinical research in pediatric CKD.

**Funding:** NIDDK Support

## FR-PO418

## Pediatric to Adult Nephrology Transition Program: The Northwestern Experience

Jay H. Kang,<sup>1</sup> Laura Nishi,<sup>2</sup> Cybele Ghossein.<sup>1</sup> Northwestern Nephrology <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>Northwestern Medicine, Chicago, IL.

**Background:** Young adults (YA) with chronic kidney disease (CKD) transitioning care from pediatric to adult medical facilities face many obstacles. Six years ago, the Nephrology division at Northwestern Medicine (NM) implemented a transition program for YA with CKD. The initial transfer visit was led by an adult nephrology team in the pediatric nephrology clinic at Lurie Children's Hospital. Follow up care then occurred in the adult nephrology clinic at NM. Here we report on our outcomes.

**Methods:** All patients that were seen in transition clinic between 2016-2021 were included. Successful transfer of care was defined as a completed transition clinic appointment. Successful transition was defined as one or more completed appointments in the NM adult nephrology clinic. An enhanced communication protocol of phone calls, texts, and emails from the adult nephrology team would be triggered for any patients who failed to show up for their follow up appointment.

**Results:** There were 141 patients who completed their transfer visits. 67 (47%) were female and 74 (53%) were male, with the most common diagnoses being congenital kidney disease (30%) and glomerular disease (24%). 82 patients (58%) were insured with private insurance, 54 (38%) with government insurance, and 5 (4%) had no insurance. Five patients were discharged from nephrology care at the initial transition clinic appointment. Six patients transitioned to external nephrology providers. Successful transition initially occurred in 93 patients (74%) with 32 (26%) patients missing their follow up appointment. Sixteen patients (13%) subsequently successfully transitioned after the enhanced communication protocol was activated, increasing our successful transition rate to 87%. Sixteen patients (13%) were lost to follow up.

**Conclusions:** Based on our experience, successful pediatric to adult transition can be achieved with a dedicated transition program. Enhanced communication protocols for those missing their first adult nephrology clinic appointment can improve successful transition.

## FR-PO419

**Impact of Psychology Integration on Pre-ESKD Care of Children With Congenital Anomalies of the Kidney and Urinary Tract (CAKUT)**

Anne E. Dawson,<sup>1,2</sup> Camille Wilson,<sup>1</sup> Jennifer Cass,<sup>1</sup> Daryl J. Mcleod,<sup>3,2</sup> Brian Becknell,<sup>4,2</sup> Kidney and Urinary Tract Center <sup>1</sup>Department of Pediatric Psychology and Neuropsychology, Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>Kidney and Urinary Tract Center; Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; <sup>3</sup>Department of Pediatric Urology, Nationwide Children's Hospital, Columbus, OH; <sup>4</sup>Division of Pediatric Nephrology and Hypertension, Nationwide Children's Hospital, Columbus, OH.

**Background:** Children with congenital disorders of the kidney and urinary tract (CAKUT) require laboratory monitoring, invasive tests, surgical interventions, and multiple medications. These stressors are associated with anxiety, nonadherence and quality of life concerns. Moreover, CAKUT and associated kidney disease can impact neurodevelopmental outcomes. The role of psychology in caring for these children has been historically reserved for later stages of kidney disease. This study examines rates and outcomes of psychology referrals before and after integration of a psychology provider in the multidisciplinary urology/nephrology clinic, which follows children with all pre-ESKD stages of kidney disease with CAKUT.

**Methods:** A retrospective chart review identified psychology referrals placed from the Urology/Nephrology Clinic at Nationwide Children's Hospital (pre- and post-psychology integration). Number of referrals placed, adherence to follow-up recommendations, common diagnoses and results of evaluations were recorded.

**Results:** From 2014-2018 (pre-integration), no patients were referred to pediatric psychology/neuropsychology (PPNP). In 2020, once psychology was integrated fully, referrals increased 10 fold, which was sustained in 2021 with 12% of patients referred and the majority successfully scheduling an appointment. Most common medical diagnoses of referred patients included prune belly syndrome, posterior urethral valves, and solitary kidney. PPNP evaluations identified low cognitive functioning, risk for attention disorders, and areas of specific learning deficits in the majority of patients and provided recommendations for intervention, including behavioral health supports and school accommodations.

**Conclusions:** Integration of psychology into a multidisciplinary urology/nephrology clinic allows for a holistic assessment of patient and family. Without psychology support, patients may go undiagnosed and/or miss the opportunity for early intervention. By intervening early, patients may benefit from interventions to promote disease self-management and engagement, ease learning burdens in school, address mental health concerns and enhance quality of life. Future studies are necessary to evaluate the potential impact of early psychology involvement on disease progression by enhancing patient compliance and adherence to interventions related to disease mitigation.

## FR-PO420

**Uremic Toxins and Extracellular Vesicles as Drivers of Cardiovascular Disease in CKD**

Felix Behrens,<sup>1,2</sup> Johannes Holle,<sup>2,3</sup> Chia-Yu Chen,<sup>3,4</sup> Benjamin C. Krause,<sup>5</sup> Fabian L. Kriegel,<sup>5,10</sup> Lisa Peters,<sup>1,9</sup> Laura F. Ginsbach,<sup>1</sup> Toralf Kaiser,<sup>7</sup> Pawel Durek,<sup>7</sup> Katrin Lehmann,<sup>7</sup> Laura Michalick,<sup>1,8</sup> Jennifer A. Kirwan,<sup>6,4</sup> Sofia K. Forslund,<sup>3,4</sup> Nicola Wilck,<sup>3,12</sup> Mir-Farzin Mashreghi,<sup>7,6</sup> Dominik Müller,<sup>2</sup> Ulrike Löber,<sup>3,4</sup> Wolfgang M. Kuebler,<sup>1,11</sup> Szandor Simmons,<sup>1,8</sup> <sup>1</sup>Institute of Physiology, Charité – Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>Department of Pediatric Gastroenterology, Nephrology and Metabolic Diseases, Charité – Universitätsmedizin Berlin, Berlin, Germany; <sup>3</sup>Experimental and Clinical Research Center (ECRC), a cooperation of Charité – Universitätsmedizin Berlin and Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany; <sup>4</sup>Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany; <sup>5</sup>Department of Chemical and Product Safety, German Federal Institute for Risk Assessment (BfR), Berlin, Germany; <sup>6</sup>Berlin Institute of Health (BIH) at Charité – Universitätsmedizin Berlin, Berlin, Germany; <sup>7</sup>German Rheumatism Research Centre (DRFZ), Berlin, Germany; <sup>8</sup>German Centre for Cardiovascular Research (DZHK), Berlin, Germany; <sup>9</sup>Institute of Biology, Department of Biology, Chemistry and Pharmacy, Freie Universität Berlin, Berlin, Germany; <sup>10</sup>Nuvisan, Innovation Campus Berlin, Berlin, Germany; <sup>11</sup>Departments of Physiology and Surgery, University of Toronto, Toronto, ON, Canada; <sup>12</sup>Department of Nephrology and Intensive Medical Care, Charité – Universitätsmedizin, Berlin, Germany.

**Background:** Cardiovascular disease (CVD) is the main cause of death in chronic kidney disease (CKD). However, the pathogenesis of CVD in CKD remains incompletely understood. We hypothesized that microbiome-derived uremic toxins (UTs) trigger the release of endothelial (EC-) and immune cell (IC)-derived extracellular vesicles (EVs), promoting endothelial damage and CVD.

**Methods:** We recruited a cohort of 94 children (mean age 10.9 years) at different stages of CKD, including patients on dialysis and after kidney transplantation (KTx), and age-matched healthy donors, offering the unique opportunity to analyze cardiovascular effects of CKD and metabolite-EV interaction in the absence of age-related confounders like diabetes and metabolic syndrome. Plasma metabolomics for 31 tryptophan-derived UTs were performed. Plasma EVs were analyzed by nanoparticle tracking analysis, flow cytometry and small RNA sequencing. EV release from PBMCs was assessed upon UT exposure.

**Results:** UTs of indole and kynurenine pathways were stage-dependently increased in children with CKD. Indoxyl sulfate (IS) increased 21-fold in peritoneal dialysis (PD) patients compared to healthy donors. Similar trends were seen in hemodialysis (HD), while more subtle increments were seen in CKD without dialysis and UT levels after KTx were almost normal. PD patients had elevated levels of total plasma EVs compared to healthy donors and KTx patients. Macrophage- (3-fold) and T-cell-derived EVs (6-fold) were increased in CKD without dialysis compared to healthy donors, while EC-EVs were reduced after KTx in longitudinal follow-ups and cross-sectionally comparing HD and KTx (3-fold). Sequencing revealed several differentially regulated microRNAs in EVs from CKD patients, including miR-16-5p, miR-19b-3p, miR-106a-5p, miR-451a and miR-4485. *In vitro*, IS dose-dependently increased EV release from PBMCs.

**Conclusions:** Increased levels of microbiome-derived UTs and subsequent EV release from ICs and ECs may present both a biomarker and a pathomechanism in CKD that may drive or contribute to long-term CVD.

**Funding:** Government Support - Non-U.S.

## FR-PO421

**Idiopathic Infantile Hypercalcemia in Children With CKD due to Kidney Hypodysplasia**

Evgenia Gurevich,<sup>1,2</sup> Yael Borovitz,<sup>1</sup> Shelly S. Levi,<sup>1</sup> Sharon Perlman,<sup>3,4</sup> Daniel Landau,<sup>1,4</sup> <sup>1</sup>Schneider Children's Medical Center of Israel, Petach Tikva, Israel; <sup>2</sup>Bazilial Medical Centre Ashkelon, Ashkelon, Israel; <sup>3</sup>Rabin Medical Center, Petach Tikva, Israel; <sup>4</sup>Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.

**Background:** Idiopathic infantile hypercalcemia (IIH) etiologies include mutations in CYP24A1, leading to increased 1,25(OH)<sub>2</sub>D, hypercalciuria and suppressed PTH, and in NaPi2, leading to the same metabolic profile via phosphaturia. IIH has not been previously described in CKD due to kidney hypodysplasia (KHD).

**Methods:** Retrospective study of children with bilateral KHD and simultaneously tested PTH and 1,25(OH)<sub>2</sub>D, followed in a tertiary care center between 2015-2021.

**Results:** Of 295 screened patients, 139 had KHD, 16 (11.5%) of them had IIH (study group), another 26 with normal PTH and any 1,25(OH)<sub>2</sub>D served as controls. There were no differences between groups' gender, obstructive uropathy rate and baseline eGFR. Study patients were younger [median (IQR) age: 5.2 (3.2-11.3) vs 61 (13.9 -158.3) months, p<0.001], had higher 1,25(OH)<sub>2</sub>D (259.1±91.7 vs 156.5±46.4 pmol/l, p<0.001), total Ca (11.1±0.4 vs 10.7±0.3 mg/dl, p<0.001), and lower phosphate standard deviation score (P-SDS) [median (IQR): -1.4 (-1.9,-0.4) vs -0.3 (-0.8,-0.1) in controls, p=0.03]. During 12 months of follow up, PTH increased among study group (8.8±2.8 to 22.7±12.4 pg/ml, p<0.001), serum calcium decreased (11±0.5 to 10.3±0.6 mg/dl, p=0.004), and 1,25(OH)<sub>2</sub>D decreased (259.5±91.7 to 188.2±42.6 pmol/l, p=0.1). P-SDS remained lower in study group vs controls at 12 months [-0.3 (-0.9, 0.4) vs 0.7 (0.6, 0.7), p<0.001]. eGFR did not deteriorate. Five of 9 study group patients with available urine calcium had hypercalciuria. Nephrocalcinosis/lithiasis was found in 5 patients.

**Conclusions:** Transient IIH was observed in infants with mild CKD due to KHD, in association with relative hypophosphatemia, resembling NaPi2 mutations metabolic profile.

## FR-PO422

**Selumetinib-Induced Hyperphosphatemia in a Pediatric Patient: A Rare Adverse Event**

Vimal Master sankar raj, Megan Narula. *UICOMP, University of Illinois Chicago College of Medicine at Peoria, Peoria, IL.*

**Introduction:** MEK, small molecule downstream inhibitors of Ras and Raf oncogenes are targets for oncological therapeutics in resistant malignancies. Selumetinib is one such MEK inhibitor used in Neurofibromatosis, type 1. We report the incidence of hyperphosphatemia, a rare adverse effect in a pediatric patient on treatment with the same.

**Case Description:** A 7-year-old girl was started on selumetinib for treatment of NF type I-related recurrent plexiform neurofibroma of the ankle. Prior to initiation, her serum phosphorus (P) was in the normal range for age at 5.4. Three weeks on therapy a rise in serum P was noted, reaching a peak of 6.7 approximately two months into treatment. Workup showed normal renal function with an estimated glomerular filtration rate (eGFR) >90 ml/min, parathyroid hormone normal at 37 pg/ml and alkaline phosphatase at 256 U/L. 25 hydroxy Vitamin D level was measured at 68 pg/ml and 1,25 dihydroxy Vitamin D at higher end of normal range at 80 pg/ml. Serum calcium level was 9.4 mg/dl with calcium phosphorus product ratio elevated at 63. Urine showed tubular reabsorption of phosphorus (TRP) of 90%, inappropriately elevated in the setting of hyperphosphatemia. Fibroblast growth factor 23 (FGF23) was measured and elevated at 55 pg/ml indicating resistance at the renal tubular level.

**Discussion:** The mitogen activated protein kinase (MAPK) cascade consisting of RAF/MEK/ERK molecular pathway regulates various aspects of cell survival, proliferation and differentiation via transducing signals from cell surface to nucleus. MEK is an attractive therapeutic target as it is the only known substrate in extracellular signal related kinase (ERK). MEK inhibition by altering cellular homeostasis has shown in toxicology studies of various adverse effects mimicking FGF23 or klotho knockout mice. The main phenotype is that of hyperphosphatemia, elevated 1,25 - dihydroxy vitamin D3 levels, and tissue mineralization indicative of renal resistance to FGF23. Pediatric literature on the adverse metabolic effect of selumetinib has not shown many issues with calcium or phosphorus homeostasis. The most common reported adverse effect is an increase in creatine phosphokinase. Here we report a case of isolated hyperphosphatemia noted after selumetinib initiation in a pediatric patient. This is likely due to FGF23 resistance as shown by elevated FGF23 levels and increased TRP with a normal GFR.

## FR-PO423

**Sclerostin and Wnt Signaling in Pediatric Renal Osteodystrophy**

Lauren V. Albrecht,<sup>1</sup> Marciana Laster,<sup>2</sup> <sup>1</sup>University of California Irvine School of Biological Sciences, Irvine, CA; <sup>2</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

**Background:** Renal osteodystrophy (ROD) is a complex disorder of bone and mineral metabolism that impacts pediatric CKD patients. Adverse clinical consequences of ROD include bone loss, increased fractures, and cardiovascular events, which often persist into adulthood. Current therapies and biomarkers of disease are limited by a lack of molecular insight into the mechanisms of disease at the cellular level. An emerging player in CKD progression is the osteocyte and its secreted factors. Sclerostin is secreted from osteocytes and leads to decreased bone formation through the inhibition of the Wnt signaling pathway. Whether sclerostin is misregulated in pediatric ROD and contributes to bone loss through the inhibition of the Wnt signaling pathway remains to be defined. Understanding the molecular underpinnings of ROD and the impact of relative signaling pathways could help to develop new targeted therapies or biomarkers.

**Methods:** Cross-sectional analysis of ROD pediatric CKD patients were used to evaluate bone sclerostin expression by immunofluorescence analyses. Bone biopsies were evaluated from patients before and after dialysis treatments. Sclerostin expression was evaluated with antibodies towards phosphorylated  $\beta$ -catenin and an unphosphorylated (active)  $\beta$ -catenin, marking Wnt inhibition or activity, respectively.

**Results:** We report that pediatric ROD patients demonstrated elevated levels of serum sclerostin was elevated in both early and late CKD. The increased levels of sclerostin in circulation were associated with histomorphometric parameters of bone turnover and mineralization. High resolution microscopy immunofluorescence revealed that the levels of sclerostin expression in bone corresponded to relative levels of circulating sclerostin. Further, sclerostin expression in bone was colocalized with a classic marker of Wnt inhibition with a phosphorylated  $\beta$ -catenin antibody. Patients with lower circulating sclerostin levels osteocytes had increased levels of an unphosphorylated  $\beta$ -catenin antibody, which indicates Wnt signaling activity.

**Conclusions:** We report that sclerostin expression in bone regulates the canonical Wnt pathway, which results in elevated serum sclerostin and regulation of Wnt signaling by sclerostin. These new insights into the pathogenesis of CKD-MBD raise the possibility that sclerostin should be investigated as a potential biomarker and/or therapeutic target in pediatric ROD.

## FR-PO424

**Metabolic Changes and Growth Impairment in a Rat Model of Juvenile CKD**

Alison J. Krieger, Chetan N. Patil, Emma T. Schwasinger. Medical College of Wisconsin, Milwaukee, WI.

**Background:** Many pediatric patients living with chronic kidney disease (CKD) experience growth impairment. Metabolic changes accompanying this are incompletely understood. Our laboratory has applied the surgical 5/6 nephrectomy (5/6Nx) model to study CKD in adult rats. The goal of this study was to determine if application of 5/6Nx in juvenile rats could be used to study CKD-related growth impairment. We hypothesized that 5/6Nx surgery in juvenile rats would lead to impaired somatic growth and metabolic dysregulation.

**Methods:** Young male Sprague Dawley rats (4-5 weeks of age; food and water ad libitum) underwent nuclear magnetic resonance imaging (NMR) in the to assess body composition and were randomized to naïve (N; n=6), Sham (S; n=9) or 5/6 nephrectomy (5/6Nx; n=11) groups. Two weeks later rats underwent a second NMR followed by 4 days of housing in a Promethion (Sable Systems International), a non-invasive metabolic phenotyping system.

**Results:** Rats from N and S groups more than doubled their body mass the initial two weeks of the study (2.27±0.22 and 2.43±0.19-fold, respectively), while 5/6Nx rats gained less mass (1.47±0.19-fold, p<0.05). NMR analysis revealed that the mean % fat mass at baseline averaged 4 to 4.5%. The % fat mass tend to increase in N and S rats (5.65±0.20% and 6.07±0.20 %, respectively) while dropping precipitously in 5/6Nx rats (2.08±0.52%; p <0.05 vs. control groups). The % lean mass showed an inverse relationship to that of % fat mass. Hydration (body water as % of body weight) increased in 5/6Nx rats (71.68±0.38%) when compared to N or S groups (69.06±0.15% and 68.75±0.30%, respectively). Promethion system data revealed that, when compared to N or S groups, 5/6Nx animals had significantly lower daily food intake and energy expenditure and were less active during their active phase. The respiratory exchange ratio was higher in 5/6Nx rats suggesting increased carbohydrate metabolism. The 5/6Nx animals exhibited greater water consumption during their inactive period than control groups.

**Conclusions:** Application of the 5/6Nx surgical model of CKD to juvenile rats impaired somatic growth, changed body composition, and altered metabolism, activity and drinking behavior. This indicates that this model recapitulates characteristics of CKD-related growth impairment in pediatric patients and may be a useful tool for developing new therapies to counteract these changes.

**Funding:** Private Foundation Support

## FR-PO425

**Impact of Lowering Dialysate Sodium Concentration on Interdialytic Weight Gain in a Pediatric Hemodialysis Center: A Quality Improvement Study**

Malek Al Barbandi,<sup>1,2</sup> Vaka K. Sigurjonsdottir,<sup>1,2</sup> Carolyn L. Abitbol,<sup>1,2</sup> Chryso P. Katsoufis,<sup>1,2</sup> Wacharee Seeherunvong,<sup>1,2</sup> Jayanthi Chandar,<sup>1,2</sup> Marissa J. Defreitas,<sup>1,2</sup> Jackson Memorial Hospital, Miami, FL; <sup>2</sup>University of Miami School of Medicine, Miami, FL.

**Background:** Chronic fluid overload in hemodialysis (HD) patients is associated with increased morbidity and mortality due to cardiovascular disease (CVD). We evaluated the safety and impact of decreasing dialysate sodium concentration on interdialytic weight gain (IDWG) in HD patients in a pediatric center.

**Methods:** This was a quality improvement study in which the aim was to decrease the average monthly IDWG in 50% of patients. We included 11 participants in a single HD pediatric center. The participants underwent two 8-week treatment phases. During phase 1 the dialysate sodium concentration was 140 mEq/L, during phase 2, the concentration was lowered to 137 mEq/L. The primary outcome was the average monthly IDWG, 2-months before and after the intervention.

**Results:** We included 11 patients, median age 19.7 years, 54.5% were male. Two did not tolerate the change due to hypotension during sessions and were excluded from the analysis and switched back to a sodium concentration of 140 mEq/L. The mean IDWG was 4.94 ± 1.04% compared to 4.27 ± 1.57% during phase 1 and phase 2, respectively. The IDWG decreased significantly by 0.67% in phase 2 compared with phase 1 (p = 0.04) (Figure, left). In addition, 89% of the patients had a decline in their average IDWG after the decrease in dialysate sodium, which was above our target of 50% (Figure, right).

**Conclusions:** While low sodium dialysate concentration in pediatric patients undergoing HD resulted in a clinical and statistically significant decrease in IDWG, it was not tolerated in some participants. Lower sodium gradient should be considered in children and young adults who are not prone to hypotension to decrease the thirst drive, limit excessive IDWG, and subsequent risk of CVD.

## FR-PO426

**Machine Learning Approach to Predict Post-Hemodialysis Blood Pressure in Children With ESKD**

Raed Bou Matar, Amy Bobrowski. Cleveland Clinic, Cleveland, OH.

**Background:** Hypertension in end-stage kidney disease (ESKD) is associated with increased cardiovascular morbidity. Blood pressure (BP) control on chronic hemodialysis (HD) is directly related to fluid removal targets and interdialytic fluid gains (IDWG). Clinicians rely on clinical judgement to set a prescribed dry weight (DW), taking into consideration complex trends in BP, IDWG and other clinical parameters.

**Methods:** A system to predict post-HD BP values was developed using machine learning (ML) models to assist clinicians in determining optimal DW. Our dataset included patient-specific trends in BP, IDWG, heart rate and weights collected from 2011 to 2021. To help improve the model's performance and scalability, input features were selected based on initial descriptive analysis. Input features included age, height, DW, post-HD weight, pre-HD weight, pre-HD heart rate, pre-HD BP and IDWG. Six models were fed the input features, trained and hyperparameters tuned using Sci-kit Learn and XGBoost python libraries. Model performance was assessed utilizing time series cross validation on a rolling basis (30-90 day training, 1 day testing). Tukey's HSD test was applied to compare mean absolute error (MAE) values between models after Box-Cox normalization.

**Results:** Children who underwent chronic HD for at least 3 months were included (49 patients, 14604 dialysis sessions). Support vector machines regression (SVR) with a linear kernel achieved better accuracy than K-nearest neighbor (p=0.013), extreme

gradient boosting (p<0.0001) and SVR with RBF kernel (p<0.0001). However, the differences in MAE between SVR (linear kernel), random forest and linear regression were not statistically significant (Table).

**Conclusions:** Utilizing vital signs trends and other readily available parameters, ML models may be useful in predicting post-HD BP in children with ESKD. Predictions are intended to guide DW adjustment, supplementing clinical judgment.

	R	MAE	RMSE
Support Vector Machines (Linear kernel)	0.75	8.21	10.5
Linear Regression	0.73	8.41	10.8
Random Forest	0.73	8.46	10.8
K-Nearest Neighbors	0.73	8.53	10.9
Support Vector Machines (RBF kernel)	0.71	8.71	11.1
Extreme Gradient Boosting (XGBoost)	0.68	9.42	12.1

R: Pearson's Correlation Coefficient; MAE: Mean Absolute Error; RMSE: Root Mean Square Error

FR-PO427

**High Prevalence of Sleep Pathology in Pediatric Hemodialysis Patients as Assessed by the ActiGraph® Accelerometer**  
Jonathan S. Chawla<sup>1,2</sup>, Molly R. Vega,<sup>2</sup> Shweta S. Shah,<sup>1,2</sup> Kevin Kaplan,<sup>1</sup> Jessica Geer,<sup>2</sup> Cortney T. Zimmerman,<sup>1,2</sup> Ayse Akcan Arikani,<sup>1,2</sup> Sarah J. Swartz,<sup>1,2</sup> Poyyapakkam Srivaths,<sup>1,2</sup> <sup>1</sup>*Baylor College of Medicine, Houston, TX*; <sup>2</sup>*Texas Children's Hospital, Houston, TX*.

**Background:** Adults with end-stage kidney disease (ESKD) have a higher prevalence of sleep disturbances, which is associated with higher rates of depression and worse quality of life. Poor sleep quality is underdiagnosed in pediatric (ped) ESKD. ActiGraph accelerometers (ACG) are validated assessors of ped sleep quality. We hypothesized ACG is more sensitive than sleep questionnaire in detecting poor sleep quality in ped HD pts.

**Methods:** In this prospective cohort study, pts 8-18 years on HD for >3 months wore an ACG on their non-dominant wrist for one week. They were asked to log sleep/wake times daily. Pts/parents completed the Sleep Disturbance Scale for Children (SDSC) and a restless leg syndrome (RLS) screening. Sleep time <7hrs, ACG sleep efficiency <85% and SDSC Total T-scores >55 considered significant sleep impairment as per previous published standards.

**Results:** 14 pts completed ACG: 64% male, mean age 15.6 ±2.5yr, mean HD vintage 1 ±0.9yr, mean BMI Z-score -0.42 ±1.5. All pts had three 240min treatments per week. ACG showed 50% pts had sleep duration <7hrs, and 85.7% had impaired sleep efficiency, while SDSC showed only 71.4% pts had poor sleep. There was a poor correlation between SDSC total score, RLS score, and ACG sleep efficiency (Pearson's R). ACG-detected total sleep time had positive correlation with sleep efficiency (R=0.64, p=0.01) and number of awakenings (R=-0.59, p=0.03), though those awakenings were shorter (R=-0.64, p=0.01). Age, vintage or CKD labs were not associated with sleep efficiencies. Pts with <7hrs of sleep tended to have lower sleep efficiency (mean 65.9% ±14.4%) compared with >7hrs (mean 77.4% ±5.6%; p=0.07).

**Conclusions:** In this study using ACG in ped HD pts, there was high prevalence of sleep disturbances with half getting <7hrs sleep and high prevalence of poor efficiency in all. ACG provided objective measures of sleep disturbance, superior to sleep questionnaire. Further studies are needed to assess the impact of poor sleep on quality of life and CV morbidity in ped HD pts.

Sleep Disturbance Scale for Children Scores

**Characteristics and Outcomes of Arteriovenous Fistula in Hemodialysis Pediatric Patients: Impact of the Monocyte-to-Lymphocyte Ratio in Access Dysfunction**  
Ana C. Brás<sup>1</sup>, Maria Faria,<sup>2</sup> Patrícia Sousa,<sup>3</sup> Ana Teixeira,<sup>2</sup> Teresa V. Costa,<sup>2</sup> Gabriela Teixeira,<sup>4</sup> Paulo J. Almeida,<sup>2</sup> Conceição Mota.<sup>2</sup> <sup>1</sup>*Hospital Professor Doutor Fernando Fonseca EPE, Amadora, Portugal*; <sup>2</sup>*Centro Hospitalar Universitario do Porto EPE, Porto, Portugal*; <sup>3</sup>*Hospital Senhora da Oliveira, Guimarães, Portugal*; <sup>4</sup>*Centro Hospitalar Tamega e Sousa EPE, Penafiel, Portugal*.

**Background:** Arteriovenous fistula (AVF) is considered the gold-standard access in adult and pediatric patients on hemodialysis (HD). Age and size combined with vessel immaturity can pose a challenge in creating AVF in children. We aimed to compare distal (dAVF) and proximal AVF (pAVF) regarding patency rates, complications and outcomes in a population of pediatric HD patients and evaluate the impact of monocyte-to-lymphocyte ratio (MLR) in access dysfunction.

**Methods:** All patients aged 0 to 18 years who underwent AVF creation for HD between January 2004 and May 2022 were included.

**Results:** We evaluated 33 patients with a median age of 13 years (IQR 5); 58% male. Median weight at time of AVF construction was 41kg (IQR 21.5); 30% weighted less than 30kg. The most frequent etiology of kidney disease was congenital anomalies of kidney and urinary tract (64%). Most patients (75%) underwent kidney replacement therapy previous to AVF construction. Of the AVF constructed, 46% were dAVF (radiocephalic) and 54% pAVF (brachiocephalic and brachioabasilic). Primary failure rate was 27%. Primary and secondary patency rate at one year were 62.5% and 93.8% respectively. AVF related complications were stenosis/thrombosis (54%), ischemic steal syndrome (6%) and high flow/aneurismatic AVF (6%). Regarding outcomes, 64% received a kidney transplant (KT) (median time of 11 months (mo) (IQR 21)); 6% died. Patients with pAVF were younger (p=0.03) and smaller (p=0.001). Median secondary patency was 29 mo (IQR 36.5) and 6.5 mo (IQR 10.8) in pAVF and dAVF respectively (p=0.01). There was no statistical significance regarding primary patency, AVF related complications or outcomes between the two groups. There was no association between MLR and access dysfunction.

**Conclusions:** Achieving a functional vascular access while sparing vascular territory for the future is of most importance in pediatrics. We showed that pediatric patients with pAVF as first access, although younger and smaller, had longer access patency and no more complications than those with dAVF. Although larger studies are needed, these results demonstrate the safety and efficacy of building such accesses in these patients. We found no association between MLR and access dysfunction.

FR-PO429

**Safety and Practical Use of 4% Tetrasodium EDTA for Pediatric Hemodialysis (HD) Line Locking**  
Cal Robinson<sup>1,2</sup>, Rosaleen M. Nemec,<sup>1</sup> Lor Tecson,<sup>1</sup> Elizabeth A. Harvey.<sup>1</sup> <sup>1</sup>*The Hospital for Sick Children, Toronto, ON, Canada*; <sup>2</sup>*University of Toronto Institute of Health Policy Management and Evaluation, Toronto, ON, Canada*.

**Background:** Central venous line (CVL)-associated bloodstream infections (CLABSI) are common in pediatric HD patients, and are associated with significant morbidity and healthcare costs. Unlike standard locking solutions (e.g., heparin and alteplase), 4% tetrasodium EDTA (KiteLock™) has antimicrobial and antibiofilm properties. We aim to study the safety and efficacy of 4% tetrasodium EDTA in pediatric HD patients.

**Methods:** Single-center, before-and-after quality improvement study. We included all chronic HD patients (6mo-18yr old), and excluded those with an active CLABSI, EDTA allergy, or <5kg. Our standard locking solution was heparin (1000 units/mL) pre-intervention and 4% tetrasodium EDTA post-intervention. For both, alteplase (1mg/mL) was used as required. We compared unit-level pre- and post-intervention data for laboratory results, alteplase use, HD treatment parameters, and CVL dysfunction.

**Results:** We present preliminary data for ten patients (median age 14yr, 50% female, median 14mo since CVL insertion). After introducing 4% tetrasodium EDTA, the prescribed blood flow rate was achieved in more HD sessions (115/117 (98.3%) post-vs. 100/108 (92.6%) pre-intervention, p=0.04). There was a trend towards decreased alteplase use (6.7% of sessions post- vs. 12% pre-intervention, p=0.11). There was no difference in CVL dysfunction (12% of sessions post- vs. 12% pre-intervention, p=0.99), after adjudicating for events unrelated to 4% tetrasodium EDTA use. Significant calcium, magnesium, and iron chelation were seen on labs drawn from the CVL after small discard volumes (<5mL), but not after a larger discard (≥6mL), or a small discard plus flushing protocol. We noted increased viscosity of the CVL discard using 4% tetrasodium EDTA. There were no differences in other HD treatment parameters (e.g., ultrafiltration, arterial/venous pressures). The mean locking solution cost decreased from \$20.71 to \$18.55 CAD per patient-session, which was due to lower alteplase use.

**Conclusions:** In pediatric HD patients, 4% tetrasodium EDTA locking increased the proportion of HD sessions achieving the prescribed blood flow, and slightly reduced alteplase use. However, significant chelation was seen on labs drawn from the CVL after small-volume discards, necessitating a change in sampling protocol. Further data is needed to evaluate if 4% tetrasodium EDTA can reduce CLABSI risk.

FR-PO430

**Use of Alteplase in Long-Term Catheters Causes Hyperphosphataemia in Children on Hemodialysis**  
Simone Vieira, Maria fernanda C. Carvalho, Cristina Henriques, Samanta L. Bergamo, Mariana G. Rockenbach, Belise K. de Sá, Camila P. Genzani, Ilka P. Gonçalves, Deborah Hirata, Vanessa Scaranti, Eliane Takabatake, Paulo C. Koch Nogueira. *Hospital Samaritano de Sao Paulo, Sao Paulo, Brazil*.

**Background:** Alteplase has phosphoric acid in its composition, and catheter use may distort patients' phosphatemia depending on where the sample is collected. To investigate whether the use of Alteplase in the permeabilization of connectorized catheters influences the levels of serum P in children on hemodialysis (HD). To analyze the influence of the site and time of collection.

**Methods:** We studied 40 children in HD at Hospital Américas Samaritano, using Alteplase to avoid obstruction of the long-stay catheter. We analyzed 6 blood samples obtained following: 1. peripheral vein before the HD session; 2 after aspiration of the catheter lumen volume preserving the connector; 3 after the connector is removed; 4. Pre-filter collection when starting HD; 5: after 3 minutes of HD start; 6. After 5 minutes of initiation of hemodialysis.

**Results:** The age of the children ranged from 7 m to 17 years, 82.5% of males. The mean difference of the peripheral P (Sample 1) was with the others by the Bland Altman Plot method and 95% confidence interval outside: Sample 2: -12.32 (-15.75 to -8.89); Sample 3: -2.93 (-4.12 to -1.73); Sample 4: 0.16 (cl -0.12 to 0.44); Sample 5: 1.04 (cl 0.61 to 1.48); Sample 6: 1.33 (cl 0.89 to 1.77). The results showed agreement between the P in the peripheral blood and the collected prefilter.

**Conclusions:** Altophase has phosphoric acid in its composition, and use in catheters may distort the phosphataemia of patients depending on the site of sample collection. Patients with a long-stay catheter in the use of altophase should analyze the serum P after the withdrawal of the connector, aspiration of the lumen volume and prefilter collection after the onset of hemodialysis, under risk of false diagnosis of hyperphosphatemia and introduction of unnecessary treatments.

## FR-PO431

### Beneficial Addition of Donor-Derived Cell-Free DNA Testing in Pediatric Kidney Transplantation

Jayanthi Chandar,<sup>1,2</sup> Marissa J. Defreitas,<sup>1,2</sup> Renata Ponsirenas,<sup>3</sup> George W. Burke,<sup>1,2</sup> University of Miami <sup>1</sup>University of Miami School of Medicine, Miami, FL; <sup>2</sup>Miami Transplant Institute, Miami, FL; <sup>3</sup>CareDx Inc, San Francisco, CA.

**Background:** Donor-derived cell-free DNA (dd-cfDNA) is a plasma biomarker to assess allograft injury in kidney transplant recipients (KTRs). Herein, we describe a single-center experience regarding indications for performing dd-cfDNA in pediatric KTRs and compare dd-cfDNA fractions in various clinical states.

**Methods:** Pediatric KTRs tested for dd-cfDNA for a clinical indication were reviewed in a cross-sectional, observational study. Median values were compared between each indicated category. Sensitivity and specificity of dd-cfDNA to predict biopsy-proven graft injury was determined by ROC curve analysis.

**Results:** dd-cfDNA was done in 77 children with a mean age of  $11.6 \pm 5.9$  years. Mean time from transplant to testing was  $3.5 \pm 3.2$  years. Indications for testing included presence of alloantibodies (N=12), clinical suspicion of rejection (N=7), BK nephropathy (N=1), reduced immunosuppression because of leukopenia, viral replication or recurrent bacterial infections (N=30), fluctuating serum creatinine (N=7), or increased serum creatinine with normal growth (N=6), increased post-transplant baseline creatinine for age (N=10) and suspected non-adherence with low tacrolimus levels (N=4). There was a significant difference in dd-cfDNA between children who had biopsy-proven acute rejection (BPAR), BK virus nephropathy (BKVN) and those who had alloantibodies (median 1.35 (95% CI 0.6,2.4) versus those who did not [median 0.3 (95%CI 0.25, 0.43);  $p=0.0012$ ]. Children who were on lower doses of immunosuppression because of leukopenia, viral or bacterial infections had low dd-cfDNA [median score: 0.32 (95%CI 0.25, 0.45); Figure 1]. ROC curve analysis revealed AUC of 98%, specificity 92.5% and sensitivity of 70% for dd-cfDNA to predict graft injury in the presence of alloantibodies.

**Conclusions:** dd-cfDNA is a clinically useful adjunct tool to determine allograft injury in pediatric KTRs which helps distinguish immune activation from immune quiescence. It has the potential to guide and serially monitor immunosuppression dosing.

Figure 1

## FR-PO432

### Incidence and Outcomes of Vesicoureteral Reflux After Pediatric Renal Transplant

Kelsi Alexander, Sharon M. Bartosh, Rachel M. Engen. University of Wisconsin-Madison, Madison, WI.

**Background:** Vesicoureteral reflux (VUR) is a common complication following pediatric renal transplant. There is little data on the incidence of VUR or its effect on histologic graft changes or graft survival.

**Methods:** All pediatric renal transplant recipients from 2007-2020 underwent voiding cystourethrogram at 6 months post-transplant and protocol biopsy at 3 months and 12 months post-transplant. Lich-Gregoir anastomosis was used for 95% of patients. Patients were categorized based on VUR grade: no/low-grade VUR (grades 0-2) and high-grade VUR (grades 3-5). Outcomes included time to graft failure, change in eGFR, and Banff score on protocol biopsy.

**Results:** Of 67 renal transplant recipients, 35% had no VUR, 2% had grade 1 VUR, 21% had grade 2 VUR, 30% had grade 3 VUR, 11% had grade 4 VUR, and 2% had grade 5 VUR. When controlling for age, patients with high-grade VUR had increased risk

of graft failure compared to patients with low-grade VUR (aHR 4.6 (95%CI 1.3-16.5)  $p=0.019$ ). Median decline in eGFR from 3 months to 5 years post-transplant was greater among those with high-grade VUR (-15.5 (IQR -19 to 16.7) ml/min/1.73m<sup>2</sup>) compared to those with no/low-grade VUR (0.55 (IQR -31.2 to -8.2) ml/min/1.73m<sup>2</sup>) ( $p=0.007$ ). There was a trend toward more acute inflammation on protocol biopsy among those with high-grade VUR, as demonstrated by change in Banff t and i score, but this did not reach statistical significance.

**Conclusions:** Pediatric patients with high-grade VUR at 6-months post-renal transplant appear to have worse long-term graft function and increased risk of graft failure compared to patients with no or low-grade VUR. Larger studies are needed further characterize the relationship between VUR and graft outcomes.

Protocol biopsy Banff Scores

## FR-PO433

### Association of Early Life Growth and Kidney Function With Blood Pressure in Ethiopian Children: Birth Cohort Study (IABC)

Daniel Yilma Bogale,<sup>1</sup> Beakal Z. Tefera,<sup>1</sup> Rahma A. Abagero,<sup>1</sup> Bikila Soboka Megersa,<sup>2</sup> Mubarek Abera,<sup>1</sup> Rasmus Wibæk,<sup>3</sup> Gregers S. Andersen,<sup>3</sup> Tsinuel Girma Nigatu,<sup>1</sup> Henrik Friis,<sup>2</sup> Jonathan C. Wells,<sup>4</sup> Dorothea Nitsch.<sup>5</sup> IABC-Kidney study Team <sup>1</sup>Jimma University, Jimma, Ethiopia; <sup>2</sup>Kobenhavns Universitet, Kobenhavn, Denmark; <sup>3</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>4</sup>University College London, London, United Kingdom; <sup>5</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom.

**Background:** The prevalence of hypertension is increasing in low and middle-income countries (LMIC). Studies in high-income countries have indicated the association of early life growth with hypertension later in life; but limited studies have examined this in LMIC. We examined the associations of low birth weight (LBW), linear growth in first five years of life, and kidney function with blood pressure (BP) at 7-11 years in Ethiopian children.

**Methods:** Children from birth cohort were followed up at age 7-11 years. Sociodemographic, anthropometric, and body composition data, and blood samples were collected. BP was measured three times five minutes apart and average was taken. Kidney function was assessed using estimated glomerular filtration rate (eGFR) using cystatin C. Term neonates with a birth weight <2.5 Kg were considered as LBW. Linear growth was assessed using height/length-for-age (HAZ) using WHO reference data and stunting was defined as HAZ <-2. Associations of LBW, HAZ and stunting (yes/no) at 2, 4, and 5 years and kidney function with BP were evaluated in separate linear regression models with adjustment for age, sex, fat mass and fat-free mass, height at current age.

**Results:** A total of 355 children participated in the current follow-up (mean age  $\pm$  SD:  $9 \pm 1$  year, boys: 51.3%). The median (IQR) systolic and diastolic BP was 93 (90, 100) mmHg and 60 (50, 60) mmHg respectively. Kidney function was assessed for 347 children and median (IQR) eGFR was 76 (70, 84) ml/min/1.73 m<sup>2</sup>. For every unit increase in HAZ at 2 year, there was 1% (95%CI: 0.4, 2) decrease in systolic BP at 7-11 years of age. Children who were stunted at 2 year had 3% (95%CI: 0.4, 5) higher in systolic BP compared to non-stunted children. We found no association between LBW, HAZ at 4 and 5 years and BP. We found 0.04% (95%CI: 0.01, 0.07) decrease in systolic BP per 1 ml/min/1.73 increase in eGFR.

**Conclusions:** Our findings from healthy Ethiopian children revealed that linear growth at two years of life and eGFR inversely associated with systolic BP at 7-11 years of age. Further follow up of this cohort during the adolescent and adulthood period will help to understand the association of early-life linear growth with hypertension in LMIC.

#### FR-PO434

### Schoolchildren From Disadvantaged Backgrounds Present a Significant Increase of Body Fat Mass and Blood Pressure During the COVID-19 Lockdown in Germany: Results From the MEDdirect Study

Rainer Büscher, Universitätsmedizin Essen, Essen, Germany.

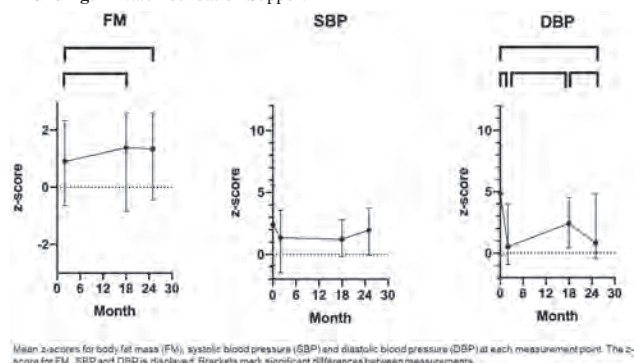

**Background:** The coronavirus (COVID-19) outbreak has become an unprecedented threat to global health which aggravated already existing health and emotional problems for children from underprivileged areas. MEDdirect is a medical students'-based project which encourages young medical students to teach schoolchildren in health care, sanitation, nutrition and physical activity. The study was designed to evaluate the regular commitment of first-year medical students as health advocates for underprivileged pupils and monitor changes in health, blood pressure and body composition during COVID-19 pandemic lockdown.

**Methods:** Twenty-five healthy schoolchildren from disadvantaged neighborhoods participated in this prospective prevention study and received regular courses about health care, sanitation, nutrition and exercise carried out by the medical students. Anthropometric and body composition monitoring (BCM) data were collected in parallel.

**Results:** Trainers and scholars finished four complete school days in 3-4-month intervals over a period of two years with different training courses. All participants gave an overwhelming positive response to the project. During the COVID-19 month-long school lockdown, body composition monitoring revealed a significant increase of body weight ( $28.7 \pm 9.2$  kg vs.  $38.0 \pm 11.8$  kg,  $p=0.023$ ) and BMI ( $18.8 \pm 2.0$  vs.  $23.3 \pm 0.4$ ). Particularly, body fat mass was increased ( $6.6 \pm 4.8$  vs.  $11.9 \pm 7.5$ ,  $p=0.031$ ) and muscle mass decreased. In addition, we observed a significant increase of the diastolic blood pressure (Figure 1).

**Conclusions:** The COVID-19 pandemic-related school lockdown lead to a significant weight gain and increase of body fat mass and blood pressure with unpredictable health consequences in the youngest. Therefore, stronger efforts to support this high-risk group are urgently needed and MEDdirect might be a feasible micro-intervention.

**Funding:** Private Foundation Support

#### FR-PO435

### Improving Blood Pressure Control in Young Patients at Elevated Cardiovascular Risk: A Pilot Study

Divya Seth,<sup>1,2</sup> Alexandra Bicki,<sup>2</sup> Sanobar Sadiq,<sup>2</sup> Elaine Ku.<sup>1,2</sup> <sup>1</sup>UCSF, University of California San Francisco, Division of Nephrology, San Francisco, CA; <sup>2</sup>UCSF, University of California San Francisco, Division of Pediatric Nephrology, San Francisco, CA.

**Background:** Promoting physical activity can reduce the risk of cardiovascular disease, potentially lower systolic blood pressure (SBP), and help patients maintain an appropriate weight. We sought to determine if children and young adults with hypertension, diabetes, and/or chronic kidney disease can improve BP control through randomized assignment to a pedometer vs. usual care in a parallel arm crossover design trial.

**Methods:** Subjects from a single-center were randomized in a 2:1 ratio using a Fitbit Flex2 coupled with bimonthly study team feedback on step count. After 6 months, control subjects were crossed over to intervention (Figure 1). Change in SBP (primary outcome), weight and average weekly step count (secondary outcomes) were tracked every 3 months for 1 year and compared using mixed models.

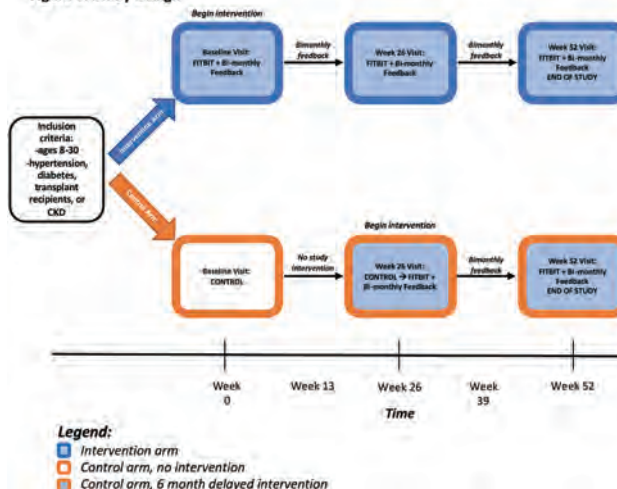

**Results:** 63 subjects enrolled (57% male, 48% Hispanic, 13% Black). Mean age was  $18 \pm 4$  years and mean BMI z-score was  $1.5 \pm 0.95$ . Coupling provider feedback with self-monitored pedometer use did not result in a significant change in step count when comparing intervention to control. There was no change in unadjusted SBP or weight over time. When adjusted for age, sex, baseline SBP, and weight, the intervention arm showed a decline in SBP at Week 39, as compared to the control arm, but this change was not sustained at Week 52 (Table 1).

**Conclusions:** Pilot results suggest that self-monitored pedometer use, even with provider feedback, may not result in sustained improvement in BP, daily step count, or weight. Augmented interventions or alternative strategies to mitigate risk are needed.

**Funding:** Other NIH Support - NHLBI

Follow-up	SBP in Intervention Median (IQR)	SBP in Control Median (IQR)	P-value for difference
Baseline			
Week 13	121.8 (118.7, 125.0)	120.1 (101.4, 138.7)	0.96
Week 26	122.9 (119.5, 126.4)	124.2 (119.4, 129.0)	0.66
Week 39	120.6 (116.4, 124.8)	128.5 (123.4, 133.6)	0.02

#### FR-PO436

### Association Between Anxiety and Hypertension in Adolescent Patients: A Single-Center Cross-Sectional Study

Yaritzy M. Astudillo,<sup>1,2</sup> Sankaran Krishnan,<sup>1,2</sup> Tanya E. Pereira,<sup>1,2</sup> Sonia Solomon,<sup>1,2</sup> Dmitry V. Samsonov.<sup>1,2</sup> <sup>1</sup>New York Medical College, Valhalla, NY; <sup>2</sup>Maria Fareri Children's Hospital, Valhalla, NY.

**Background:** Given its rising prevalence, identifying modifiable risk factors of primary pediatric hypertension remains an area of active research. Anxiety is a common childhood problem that may be associated with activation of the sympathetic system, plasma renin, and hypothalamic-pituitary-adrenal axis; thus, resulting in increased peripheral vascular resistance and hypertension (HTN). While anxiety is known to be associated with elevated blood pressure (BP) in adults, this has not been studied in children. The objective of this study was to assess the association between anxiety and HTN in adolescents.

**Methods:** Adolescents, aged 12 to 18 years old, referred to our Pediatric Nephrology clinic were eligible to participate. HTN was defined as either systolic (SBP) or diastolic (DBP) BP above the 95<sup>th</sup> percentile for age, height, and gender. Participants were evaluated for anxiety using the validated Screen for Child Anxiety Related Disorders questionnaire filled independently by child (SCARED-C) and a parent (SCARED-P) evaluating the child. A score of  $\geq 9$  was defined as a positive screen for anxiety. Proportions were compared using chi-square tests and difference in blood pressure between groups compared with the Mann-Whitney U test.

**Results:** 200 adolescents participated in this study with a subgroup of 130, not on any blood pressure medication. In this subgroup, the mean age was  $15.18 \pm 1.7$  years, 50% were male. 45% (58) had positive SCARED-C and 29% (37) positive SCARED-P scores. 43% (16) of SCARED-P positive had diastolic HTN compared to 19% (18) of SCARED-P negative,  $p = 0.005$ . DBP was significantly higher in SCARED-P positive ( $79.0 \pm 10.1$ ) and SCARED-C positive ( $77.1 \pm 10.4$ ) compared to SCARED-P negative ( $73.6 \pm 9.3$ ) and SCARED-C negative ( $73.8 \pm 8.9$ ) groups respectively (Table 1).

**Conclusions:** In this cohort of adolescents, those who were anxious by parental reporting were more likely to have diastolic HTN. For adolescents not treated with antihypertensive medications, DBP but not SBP was significantly higher in the anxious cohort both by self and parental reporting. The impact of anxiety on the pathogenesis of HTN in children warrants further study.

Table 1. Association between anxiety and diastolic hypertension in subgroup of adolescents not treated with antihypertensive medications.

	Self-Reporting		p	Parental Reporting		p
	Anxious SCARED-C $\geq 9$	Non-anxious SCARED-C $< 9$		Anxious SCARED-P $\geq 9$	Non-anxious SCARED-P $< 9$	
N=130	58 (45%)	72 (55%)		37 (29%)	93 (71%)

## FR-PO437

**Bordetella holmesii: A Rare Pathogen Causing Infective Endocarditis-Associated Glomerulonephritis**

Tara B. Gavcovich,<sup>1,2</sup> Malek Al Barbandi,<sup>1,2</sup> Wendy R. Glaberson,<sup>1,2</sup> Marissa J. Defreitas,<sup>1,2</sup> Chryso P. Katsofios,<sup>1,2</sup> Yiqin Zuo,<sup>1,2</sup> Carolyn L. Abitbol,<sup>1,2</sup> Wacharee Seeherunvong,<sup>1,2</sup> <sup>1</sup>Jackson Memorial Hospital, Miami, FL; <sup>2</sup>University of Miami School of Medicine, Miami, FL.

**Introduction:** Infective endocarditis (IE) can cause multiorgan failure and chronic kidney disease, in addition to cardiac sequelae. Presentation may be vague and can manifest as acute glomerulonephritis (GN). While the most common pathogens of IE are *Staphylococcus* and *Streptococcus* species, we report the rare pathogen *Bordetella holmesii* causing IE associated GN.

**Case Description:** A 20-year-old male born with pulmonary atresia and ventricular septal defect underwent corrective surgeries, and prosthetic pulmonary valve replacements at 3 and 9 years old. He was admitted to an outside hospital with fever and hematemesis, diagnosed with streptococcal pharyngitis. A month later, he presented to our institution with lower extremity edema and gross hematuria. On exam, he was afebrile, normotensive, had a 7-kg weight gain with anasarca, a loud systolic murmur, but no rash. Investigations revealed elevated serum creatinine, nephrotic proteinuria, hematuria, and hypocomplementemia, consistent with immune-mediated acute GN. Given his cardiac history, blood cultures were collected from 3 sites. Broad-spectrum antibiotics were initiated when he subsequently developed fever. Renal pathology showed IgM and C3-codominant diffuse proliferative GN (Figure). Transesophageal echocardiogram visualized a vegetation on the pulmonic valve. *Bordetella holmesii* was ultimately cultured from the prior and current hospitalization. A serum sample detecting microbial cell-free DNA sequencing confirmed *Bordetella holmesii* at very high levels. After completing 6 weeks of IV antibiotics with concurrent angiotensin receptor blockade, his kidney function recovered with improvement in hypocomplementemia and proteinuria (Table).

**Discussion:** This case report highlights the early recognition and comprehensive evaluation of a rare organism causing IE associated GN, which allowed for renal recovery and preserved cardiac function.

## Biochemistry Progression

	Normal	Presentation	Day 4	Week 1	Week 3	Week 6
Serum Creatinine (mg/dL)	0.6-1.2	3.4	3.3	2.3	1.7	1.0
Complement C3 (mg/dL)	90-180	52	49			87
Complement C4 (mg/dL)	10-40	5	3			15
Urine protein to creatinine ratio (mg/mg)	<0.2	1.9	1.7	2.6	6.5	2.2

## FR-PO438

**Renal Involvement and Novel Kidney Biopsy Findings in a Young Girl With Aicardi-Goutières Syndrome**

James B. Johnston, Geneviève Bernard, Sarah Campillo, Catherine Millar, Chantal Bernard, Audrey Lovett, Marie-Michele Gaudreault-Tremblay. *Montreal Children's Hospital, Montreal, QC, Canada.*

**Introduction:** Aicardi-Goutières Syndrome (AGS) is an inherited type I interferonopathy (IFN) characterized by a spectrum of disease manifestations, including neurologic (e.g. microcephaly, global developmental delay, spastic paresis, dystonia, cerebral calcifications) and systemic manifestations (e.g. hypothyroidism, skin lesions, recurrent fevers). Mutations in *TREX1*, *RNASEH2A*, *RNASEH2B*, *RNASEH2C*, *SAMHD1*, *ADAR1* or *IFIH1* have been associated with AGS. Clinical presentation is heterogeneous, with variable onset of disease. Renal involvement has only been rarely reported.

**Case Description:** A 3-year-old girl with a severe phenotype of AGS due to two pathogenic variants in *TREX1* had recurrent vomiting, irritability, and generalized panniculitis only partially responsive to prednisolone 1mg/kg/day. While undergoing screening assessment for JAK1/2 inhibitor therapy, she was found to have severe hypertension (136/94mmHg), hypoalbuminemia (20g/L) and nephrotic range proteinuria (urine protein:creatinine 12.5g/g). Renal function was normal. She was initially treated with enalapril, amlodipine, and prazosin. The renal biopsy revealed podocyte hypertrophy, abundant tubuloreticular inclusions and mild immune complex deposition. Despite initial concerns about EBV viremia and transaminitis, the patient was treated with baricitinib (initially 2mg BID, maximal dose reached 2mg TID). Improvement of vomiting, panniculitis, and irritability was observed over 3 months. Proteinuria also significantly improved (urine protein:creatinine 0.24g/g). Prednisolone was successfully weaned, and antihypertensive treatment reduced to enalapril alone. The patient has remained stable for 18 months, without any EBV disease.

**Discussion:** Renal involvement has not previously been described in association with *TREX1* mutations. Biopsy findings were novel, showing mixed features of podocytopathy, scattered immune deposition, and features of vascular lesions rather than one dominant histopathologic pattern. The effectiveness of JAK1/2 inhibitors in IFN with renal involvement has not been definitively established, but case reports have been encouraging. The correlation between JAK1/2 inhibition and clinical improvement in this case supports the use of baricitinib in other interferon-related disorders.

## FR-PO439

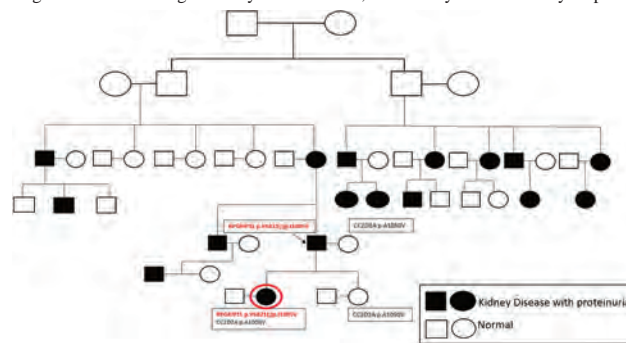

**Identification of Mutations in an Atypical Focal Segmental Glomerulosclerosis-Causing Gene**

Gaurav Rajashekar, Ying M. Chen. *Washington University in St Louis, St Louis, MO.*

**Introduction:** Focal segmental glomerulosclerosis (FSGS) is a histopathological diagnosis. More than 50 monogenic forms of FSGS have been identified. With broader utilization of genetic sequencing, mutations in genes, not commonly associated with glomerular disease, have been identified in FSGS.

**Case Description:** Here we present a 29-year old female with an extensive family history of proteinuria on her paternal side (Fig. 1) presenting with proteinuria (urine protein/creatinine ratio 1.7g/g) at the age of 18. Biopsy at that time showed FSGS. She underwent whole exome sequencing which showed variants in *RPGRIP1L*, p.V682I (heterozygous) and p.I1005V (heterozygous), as well as a variant in *CC2D2A*, p.A1050V (heterozygous). Although variants in *RPGRIP1L* or *CC2D2A* have not been associated with FSGS, due to her family history of proteinuria, we performed Sanger sequencing on her family members. Her father, who has proteinuria (without biopsy) carries the same two variants in *RPGRIP1L*, but not in *CC2D2A*. Her mother and sister (no proteinuria) harbor the same variant in *CC2D2A*, but not in *RPGRIP1L*. These sequencing results strongly suggest that the variants in *RPGRIP1L* could be pathogenic.

**Discussion:** *RPGRIP1L* encodes retinitis pigmentosa GTPase regulator-interacting protein-1 like, a ciliary and retinal protein important in ciliogenesis and tubular function. The mutation of *RPGRIP1L* is associated with Meckel and Joubert's syndrome but is not a known FSGS gene. The identified two variants in *RPGRIP1L* occur in relatively poorly conserved regions. The p.I1005V has been identified in the Genome Aggregation Database (gnomAD) with a minor allele frequency (MAF) 0.00004415 (very rare), while the other variant is not found in gnomAD. The in silico prediction about the effect of the missense mutations from the different algorithms is conflicting. Thus, we plan to use CRISPR/Cas9 to introduce these mutations to establish cell models first to determine their pathogenicity. Our case highlights those mutations in genes not typically thought of as glomerular disease genes may lead to FSGS, most likely as a secondary response.

## FR-PO440

**Trigenic COL4A3/COL4A4/COL4A5 Pathogenic Variants in Alport Syndrome: A Case Report**

Dipti Rao,<sup>1</sup> Rutger J. Maas,<sup>1</sup> Elisabeth A. Cornelissen,<sup>1</sup> Jack F. Wetzels,<sup>1</sup> Michel van Geel,<sup>2</sup> <sup>1</sup>Radboudumc, Nijmegen, Netherlands; <sup>2</sup>Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands.

**Introduction:** Alport syndrome (AS) is a hereditary autosomal recessive (semi-dominant) or X-linked disorder of type IV collagen caused by mutations in *COL4A3*, *COL4A4* and/or X-linked *COL4A5*. In recent years several cases of digenic AS, caused by two pathogenic variants in two *COL4A* genes, were reported. Patients with digenic AS may present with an atypical phenotype, depending on the percentage affected type IV trimeric collagen chain and inheritance advice may differ. We report a newly discovered case of trigenic AS.

**Case Description:** The female index patient, aged 51 years, was diagnosed with hematuria at age 24 yr, developed hypertension by the age of 30, and had pre-eclampsia and nephrotic syndrome during pregnancy at the age of 36. Post pregnancy proteinuria decreased to levels between 0.5 – 1.5 g/day with an ACE inhibitor. eGFR decreased initially, but has been stable in the past 5 years with eGFR 44ml/min/1.73m<sup>2</sup>. The patient wears hearing aids due to symmetric high tone sensorineural hearing loss. Her son was diagnosed with hypertension at 10 years old, attributed to the use of methylphenidate. He has minimal proteinuria and hematuria with normal eGFR. The 74-year-old mother is known with hypertension, hematuria and microalbuminuria. eGFR has been stable at 84ml/min/1.73m<sup>2</sup>. The father died at the age of 48 years, he was not known with a renal disorder or hearing loss. Because AS was suspected, genetic analysis in the index patient was performed. Two heterozygous pathogenic variants were detected: c.2691del in *COL4A3* and c.1663dup in *COL4A4*. Furthermore, a complete heterozygous deletion of *COL4A5* was detected, expanding beyond exon 1-4 of flanking *COL4A6*. Her son carried only the *COL4A3* mutation, and the mother the *COL4A4* mutation, confirming the familial autosomal mutations are present in *trans*. We presume the *COL4A5* deletion has occurred de novo since the father had no clinical symptoms.

**Discussion:** We describe the first patient with Alport syndrome caused by three pathogenic mutations in all three *COL4A* genes, thus trigenic AS. The moderate phenotype in the female patient could be the result of residual functional type IV trimeric collagen. This case report emphasizes the importance of examining all three *COL4A* genes for optimal follow-up and treatment of the patient and adequate genetic counseling of family members.

#### FR-PO441

##### Alport Syndrome Caused by a Novel Intronic Mutation Leading to Partial Aberrant mRNA Splicing: A Case Report

Dipti Rao,<sup>1</sup> Michel van Geel,<sup>2</sup> Bartholomeus T. van den Berge,<sup>1</sup> Jitske Jansen,<sup>1</sup> Bart Smeets,<sup>1</sup> Jack F. Wetzels,<sup>1</sup> Rutger J. Maas.<sup>1</sup> <sup>1</sup>Radboudumc, Nijmegen, Netherlands; <sup>2</sup>Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands.

**Introduction:** Alport syndrome (AS) is a hereditary disorder of type IV collagen. X-linked Alport syndrome (XLAS), caused by a mutation in the *COL4A5* gene, accounts for over 80% of all cases. Hematuria is the main initial symptom of AS. Most male patients develop end-stage-kidney-disease (ESKD) at young age, though there is variability in rate of progression. Genetic testing covering the coding regions of all three *COL4A3*, *COL4A4* and *COL4A5* genes is recommended in patients with suspected AS. However, in 10-20% of patients a mutation cannot be detected.

**Case Description:** We report a 63-year-old male who developed hematuria by one year of age. Over the years he developed proteinuria. The estimated glomerular filtration rate (eGFR) declined gradually; he reached ESKD at the age of 60. Kidney biopsy during childhood showed tubulointerstitial abnormalities and a thin GBM with segmental splitting. A skin biopsy showed absence of  $\alpha 5(IV)$  chains in the epidermal basement membrane, thus providing histological proof for diagnosis of XLAS. Glomerular hematuria was also detected in the patients' mother and both daughters; none of them developed proteinuria nor reduced eGFR. Initial genetic analysis by next-generation sequencing of the Alport gene panel (*COL4A3-COL4A4-COL4A5*) failed to detect the genetic cause. Reverse-transcriptase-PCR analysis on RNA extracted from urine-derived podocyte-lineage cells detected partial cryptic splicing, retaining an extra sequence between exon 21 and 22 derived from intron 21 (r.1423\_1424ins1423+1187\_1423+1230), putatively resulting in a frameshift and premature stop upon translation (p.(Asp476Profs\*96)). Subsequent Sanger sequencing revealed a hemizygous deep intronic variant c.1423+1175G>T in the *COL4A5* gene.

**Discussion:** We report a case of XLAS caused by a novel deep intronic mutation in *COL4A5*. Pathogenicity was experimentally confirmed by analysis of RNA isolated from urine-derived podocyte-lineage cells, which offers a non-invasive diagnostic method. The specific mutation strikingly results in partial aberrant mRNA splicing, putatively resulting in co-existence of a shorter, non-functional *COL4A5* protein and a normal functional protein. This finding could explain the relatively mild phenotype with development of ESKD at an older age as is common for XLAS.

#### FR-PO442

##### Late Diagnosis of Fabry Disease in a Kidney Transplant Patient

Tariku T. Guduru, Brian R. Stephany, Richard A. Fatica, Xiangling Wang. Cleveland Clinic, Cleveland, OH.

**Introduction:** Fabry disease (FD) is an X-linked lysosomal storage disorder due to deficiency of the lysosomal enzyme  $\alpha$ -galactosidase A ( $\alpha$ -Gal A). It causes deposition of glycolipids such as globotriaosylceramide (Gb3). Diagnosis can be challenging due to non-specific presentation varying from minor symptoms such as heat intolerance, limb pain and skin lesions to end organ damage such as kidney failure, cardiomyopathy and stroke. Here we present a case of delayed diagnosis of FD for a patient with kidney transplant.

**Case Description:** A 47-year-old man with hypertension, cardiomegaly, erythrocytosis, ESRD post kidney transplant in 2006 and recurrent stroke sent for evaluation. When he was 28, he presented to hospital with hypertensive crisis, pulmonary edema and proteinuric acute kidney injury (AKI) with creatinine of 21mg/dl necessitating dialysis. Echocardiogram at that time showed severe concentric left ventricular hypertrophy (LVH) and grade 3 diastolic failure. His kidney failure was presumed to be from thrombotic microangiopathy without kidney biopsy. Prior to recent admission for third stroke, his daughter was found to have FD at age of 14. Further evaluation of his family showed FD associated mutation for his mother, two aunts and his non donor brother. Recent work up during evaluation showed normal kidney allograft function. Erythropoietin and JAK2 mutation done for erythrocytosis was non-revealing. Suspected FD was confirmed by low Alpha Galactosidase S 0.001 U/L (0.0074 – 0.457), elevated total Globotriaosylceramide (GL-3) 7.74 ug/mL (1.37 – 4.04) and Lyso – GL-3 88 ng/ml (< 0.30), and genetic testing that showed pathogenic hemizygous variant in GLA, c.640.1G>A which is associated with X linked FD. He was started on recombinant human Alfa galactosidase.

**Discussion:** Delayed diagnosis of FD is not uncommon due its wide clinical presentation. Our patient presented with severe LVH and proteinuric AKI pre-transplant and recurrent strokes for over 5 years post-transplant. He was diagnosed only after his daughter was found to have disease. Kidney transplant from donor with FD is associated with premature graft loss for which his donor brother was offered testing but declined. While recurrence of disease is not common after kidney transplant, early diagnosis and enzyme replacement therapy will minimize systemic deposition of GL-3/Gb3 and improve patient and donor outcome.

#### FR-PO443

##### Recurrent Hemolysis in a Child With Shiga Toxin-Producing *Escherichia coli* and Two Heterozygous Variants Associated With Atypical Hemolytic Uremic Syndrome

Priyanka Chai, Davoud Mohtat, Patricia Seo-Mayer. Inova Fairfax Hospital, Falls Church, VA.

**Introduction:** The most common cause of hemolytic uremic syndrome in children is shiga toxin-producing *E. coli* (STEC-HUS). We report a patient with STEC-HUS who had an unusually persistent course, leading to discovery of two heterozygous gene variants associated with atypical HUS (aHUS).

**Case Description:** A 4 year old girl presented with vomiting and bloody stools. Stool PCR was positive for shiga toxin and labs showed hemolytic anemia, thrombocytopenia, hematuria, proteinuria, hypertension and AKI. The diagnosis was STEC-HUS. She received supportive care and required one red blood cell transfusion. Diarrhea and thrombocytopenia resolved and creatinine nadired at 0.6mg/L. One month post-discharge, she acquired a viral illness and developed worsened anemia, increased LDH and recurrence of thrombocytopenia, resulting in readmission. Due to persistence of HUS, additional workup was pursued, including C3 (81mg/dL, ref 82-163mg/dL) and genetic testing for aHUS. Due to suspicion for aHUS, eculizumab treatment was initiated. Ultimately two heterozygous mutations were identified: a known pathogenic variant in Complement Factor I (CFI): (c.123 A>T), and a mutation in Complement Factor H (CFH) (c.2918 G>A), a variant of unknown significance. One parent carries the CFI mutation; the other has the CFH mutation. Both are well without any history of HUS. After 9 months, eculizumab treatment was paused and the patient has not had recurrence of HUS (Figure 1).

**Discussion:** This case illustrates the role of genetic testing in selected cases of STEC-HUS and the efficacy of eculizumab in an unusual combination of CFI/CFH variants causing aHUS. This combination has never been previously reported. Eculizumab was effective in halting hemolysis in our patient, but she has done well without chronic treatment.

Figure 1: Laboratory trends in relation to discharge from 1st hospitalization, onset of viral illness prior to 2nd hospitalization, Eculizumab (Ecu) initiation and final dose of Ecu.

#### FR-PO444

##### Glycogen Storage Disease Type 1a Leading to Recurrent Nephrolithiasis

Nisarg Gandhi,<sup>1</sup> Noor Bazerbashi,<sup>1</sup> Hassan N. Ibrahim.<sup>2</sup> <sup>1</sup>Houston Methodist, Houston, TX; <sup>2</sup>Memorial Hermann Health System, Houston, TX.

**Introduction:** Nephrolithiasis is a common presenting problem, but recurrence especially at a young age should prompt further laboratory and genetic testing to determine the cause. Herein, we present a case of autosomal recessive glycogen storage disease type 1a with recurrent symptomatic kidney stones.

**Case Description:** A 19-year-old Caucasian man presents to clinic for evaluation of recurrent kidney stones at the ages of 10, 11, and 17. A previous CT scan from 2 years prior revealed multiple bilateral kidney stones and a previous stone analysis revealed its composition to be 50% calcium oxalate monohydrate and 50% calcium oxalate dihydrate. His laboratory testing revealed a parathyroid hormone level of 21 pg/mL, calcium of 10.0 mg/dL, creatinine of 0.92 mg/dL, and uric acid level of 5.1 mg/dL, all within normal limits. A Litholink 24-hour urine collection was conducted to evaluate for cause of kidney stones (Table 1). Given the hypocitraturic and hypercalciuric state at a young age with family history of kidney stones, a Natera genetic test was ordered. The results revealed autosomal recessive gene for glycogen storage disease type 1a. Subsequently, he was started on chlorthalidone and potassium citrate to lower urinary calcium and increase urinary citrate, respectively, to decrease his risk of developing additional kidney stones. At his most recent visit, the 24-hour urinary calcium had improved significantly, but the urinary citrate remained low (Table 1).

**Discussion:** Glycogen storage disease is a rare autosomal recessive disorder of fat and glycogen processing in the liver and kidneys, leading to a wide range of metabolic disturbances including hyperuricemia, hyperlipidemia, and fasting hypoglycemia. Kidney stones have been previously reported in approximately 6% of cases with hypercalciuria and hypocitraturia. Typically, uric acid levels are high in the serum and urine, but not necessary for diagnosis. Treatment involves decreasing urinary calcium, increasing

urinary citrate, and decreasing urinary uric acid. Long-term symptom management is necessary to prevent progression to CKD. This case illustrates the utility of genetic testing in patients with recurrent nephrolithiasis, especially at a young age.

Table 1: Litholink Results

24-Hour Urine Collection (Reference Range)	Volume (0.5-4.0 L)	Calcium (male < 250 mg)	Citrate (male >450 mg)	Uric Acid (male < 0.800 g)
Initial	4.17	326	222	0.535
6 Months Later	2.03	134	182	0.421

FR-PO445

**Renal Vein Thrombosis Leading to the Diagnosis of Nephrotic Syndrome**  
Kathryn Leonard, Ishmam Y. Alam, Bair Cadet, Jaswinder P. Singh. *Nassau University Medical Center, East Meadow, NY.*

**Introduction:** Primary MN is the most common cause of idiopathic nephrotic syndrome. We present the case of a 31-year-old Hispanic male with no prior past medical or family history, presenting with renal vein thrombosis and lab dysfunction, concerning for nephrotic syndrome. Further workup of kidney biopsy and serum antibody levels revealed the cause to be anti-PLA2R-mediated.

**Case Description:** 31-year-old Hispanic male with no past medical or family history presented with chest pain, dyspnea and swelling in his face and legs for one day. He reported recent pulmonary embolism and was discharged on anticoagulation therapy. He reported the chest pain and dyspnea felt similar to his prior hospitalization but the swelling was new. Physical exam revealed pitting edema to bilateral lower extremities and periorbital edema. Pan CT revealed subsegmental pulmonary emboli, renal vein thrombus and ascites. Laboratory workup revealed hypoalbuminemia less than 1.3 gm with total protein 3.4 g/dL. Lipid panel revealed elevated total cholesterol of 424 mg/dL and LDL of 339 mg/dL. Initial urinalysis showed proteinuria of >300 mg/dL, with spot urine protein creatinine ratio of 6.5, confirmed by 24-hour urine protein and creatinine ratio of 23.5. Serum PLA2R antibody panel was positive with a level of 47 RU/mL. Thrombophilic workup was unremarkable. Kidney biopsy with immunofluorescence staining for IgG, C3, kappa and lambda chains and PLA2R were positive, confirming primary MN

**Discussion:** While renal vein thrombosis is common, thromboembolic events preceding classic symptoms is unusual. MN is associated with lower extremity edema, periorbital edema, proteinuria and ascites. Uniquely, our patient presented with shortness of breath and chest pain. This case emphasizes the importance of imaging and highlights the role of anti-PLA2R antibody levels as a clinical predictor. Antibodies to PLA2R have been reported in 70% of patients with primary MN. Lower titer is associated with better remission rates. One study among patients with biopsy-proven MN revealed that high PLA2R antibody levels were linked with active disease and higher likelihood of declining renal function. These levels can dictate immunosuppressive therapies among patients. Additionally changes in circulating PLA2R antibodies occur more rapidly than changes in proteinuria, making it useful to monitor disease activity and treatment response.

FR-PO446

**Hypophosphatemia and Avascular Necrosis Requiring Hip Replacement in a 24-Year-Old due to SLC9A3R1 Mutation**  
Ayesha A. Khan, Nabeel Aslam, Michael A. Mao. *Mayo Clinic, Jacksonville, FL.*

**Introduction:** Phosphorus is involved in a variety of biological activities, and hypophosphatemia can result in a range of clinical multiorgan symptoms that can vary in severity. Hypophosphatemia can be due to decreased intestinal absorption, increased urinary excretion, or transcellular movement into cells.

**Case Description:** We report case of a 31-year-old female with history of bilateral distal femoral head avascular necrosis requiring right hip replacement at age 24, vitamin D deficiency, and nephrolithiasis who presented for evaluation of hypophosphatemia of 2.4. Laboratory studies showed creatinine 0.76, calcium 9.2, phosphorus 2.8, 25-hydroxy vitamin-D level 13, PTH 60, magnesium 2.2, and albumin 4.1. Urinalysis showed a bland sediment without proteinuria. Imaging included DEXA scan that was appropriate for age, x-ray of left knee demonstrated sclerotic areas in the distal femur and proximal tibia, and CT showing no nephrolithiasis in setting of patient reported passed stones. She was referred to clinical genomics. Genetic testing showed she was heterozygous for a variant in the SLC9A3R1 gene (mode of inheritance autosomal dominant).

**Discussion:** SLC9A3R1 (SLC9A3 Regulator 1) encodes a sodium/hydrogen exchange regulatory cofactor and is part of a group of rare hereditary renal phosphate wasting disorders. Heterozygous missense and splice site variants of the SLC9A3R1 gene have been reported in individuals with autosomal dominant hypophosphatemic nephrolithiasis/osteoporosis type 2, which is characterized by impaired renal phosphate reabsorption in the renal proximal tubules. This gene mutation can be associated with hypophosphatemia, nephrolithiasis, bone demineralization, and osteoporosis. This report illustrates a case of avascular necrosis of long bones associated with SLC9A3R1 gene mutation and highlights that early genetic testing may improve long-term outcomes and complications. Increased genetic testing will also allow further studies to investigate the penetrance and clinical relevance of SLC9A3R1 variants on clinical management and outcomes.

RESULT(S): UNCERTAIN CLINICAL SIGNIFICANCE						
Gene	Disease(s)	Mode of Inheritance	Variant	Zygosity	Inherited From	Classification
RUNX2	RUNX2-Related Disorder	Autosomal Dominant	c.1361 A>T p.Y455	Heterozygous	Unknown	Variant of Uncertain Significance
SLC9A3R1	Hypophosphatemic Nephrolithiasis/Osteoporosis Type 2	Autosomal Dominant	c.458 G>A p.R153Q	Heterozygous	Unknown	Variant of Uncertain Significance

**INTERPRETATION**

This individual is heterozygous for a variant of uncertain significance in the RUNX2 gene. This result does not establish a molecular diagnosis in this individual.

This individual is heterozygous for a variant of uncertain significance in the SLC9A3R1 gene. This result does not establish a molecular diagnosis in this individual.

FR-PO447

**Investigation of the Pathogenicity of Novel Missense Variants in the ARHGAP24 Gene by Quantitative Analysis of the Active Rac1: Two Cases of Proteinuria With Renal Dysfunction**  
Atsushi Kondo,<sup>1</sup> China Nagano,<sup>1</sup> Hideaki Kitakado,<sup>1</sup> Chika Masuda,<sup>1</sup> Shinya Ishiko,<sup>1</sup> Yuya Aoto,<sup>1</sup> Nana Sakakibara,<sup>1</sup> Tomoko Horinouchi,<sup>1</sup> Tomohiko Yamamura,<sup>1</sup> Kazumoto Iijima,<sup>2</sup> Kandai Nozu.<sup>1</sup> <sup>1</sup>*Kobe University Graduate School of Medicine, Kobe, Japan;* <sup>2</sup>*Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan.*

**Introduction:** Proteinuric kidney diseases including steroid-resistant nephrotic syndrome (SRNS) can lead to renal dysfunction, and one of its causative genes is *ARHGAP24* (NM\_001025616.2). It encodes a Rho-GTPase activating protein and acts as a negative regulator for Rac1. Excessive activation of Rac1 in podocytes has been reported to cause foot process effacement, and lead to persistent proteinuria and SRNS.

**Case Description:** **Case 1:** The patient is a 15-year-old female. She developed SRNS at the age of five. Although some immunosuppressive therapy had been administered, it was ineffective. At the age of ten, a renal biopsy was performed and the pathological diagnosis was focal segmental glomerulosclerosis. Subsequently, her renal function gradually declined to CKD Stage2. We performed a comprehensive genetic analysis of podocyte-related genes by targeted next-generation sequencing (NGS) using peripheral blood samples. A novel missense variant (c.1217G>T, p.(Ser406Ile)) in the *ARHGAP24* gene was detected, and it was a *de novo* variant. **Case 2:** The patient is a 26-year-old female. She has shown mild proteinuria from the age of ten. In adulthood, the proteinuria became more severe with renal dysfunction as CKD Stage2, so a detailed examination was performed. The pathological findings of the renal biopsy were minor glomerular abnormality. As in case 1, comprehensive genetic testing by targeted NGS was performed, and that revealed a novel missense variant (c.2234T>C, p.(Ile745Thr)) in the *ARHGAP24*. For these two variants, the quantitative analysis of active Rac1 in HEK293T cells transfected with the *ARHGAP24* plasmid vector carrying the variants was performed. As a result, both variants significantly increased active Rac1 compared to the wild type. Therefore, we concluded these novel missense variants are Pathogenic.

**Discussion:** It is definitely important to determine whether novel variants are pathogenic or not because almost immunosuppressive therapy for SRNS associated with genetic variants is often ineffective. In patients with *ARHGAP24* variants, quantitative analysis of active Rac1 protein is a simple and universal test for its pathogenicity, and is useful in determining pathogenicity.

FR-PO448

**An Unexpected Cause of Hypokalemia**  
Claire F. Schretlen,<sup>1</sup> Kanza Haq,<sup>1</sup> Carmen E. Cervantes,<sup>1</sup> Mohamad A. Hanounch.<sup>1,2</sup> <sup>1</sup>*Johns Hopkins University School of Medicine, Baltimore, MD;* <sup>2</sup>*Nephrology Center of Maryland, Baltimore, MD.*

**Introduction:** Gitelman syndrome is an autosomal recessive hypokalemic and salt wasting tubulopathy caused by loss-of-function mutations in the sodium chloride cotransporter encoded by *SLC12A3*, leading to disrupted entry of sodium and chloride at the apical membrane of distal convoluted tubule cells (fig 1).

**Case Description:** A 20-year-old man with bulimia nervosa and CKD stage IIIA was referred to clinic for refractory hypokalemia attributed to vomiting. Home medications included potassium chloride 60 mEq four times daily. His blood pressure was 100/60 mmHg. Basic laboratory values are shown in fig 2A. Further workup revealed elevated serum renin (62.6 ng/L) and normal serum aldosterone (10 ng/dL). Urine studies showed random urine chloride of 60 mEq/L with renal losses of sodium, potassium, and magnesium along with hypocalciuria (fig 2B). Genetic testing confirmed the diagnosis of Gitelman syndrome with 2 pathogenic variants in the *SLC12A3* gene [c.2221G>A (p.G741R) and c.247C>T (p.R83W)]. Aldosterone secretion is independently regulated by angiotensin II and plasma potassium concentrations. As such, aldosterone may not increase despite of high renin/angiotensin II levels in the context of severe hypokalemia. This can explain the normal level in our case. Further, the patient's CKD is likely due to longstanding severe hypokalemia causing tubulointerstitial disease. He was started on amiloride 10 mg daily with a normalization of potassium and magnesium levels without supplementation.

**Discussion:** Gitelman syndrome is associated with reduction of extracellular fluid volume, hyperreninemia and secondary hyperaldosteronism, metabolic alkalosis, renal wasting of potassium, sodium, and magnesium, and decreased urinary excretion of calcium. Its diagnosis is confirmed with genetic testing.

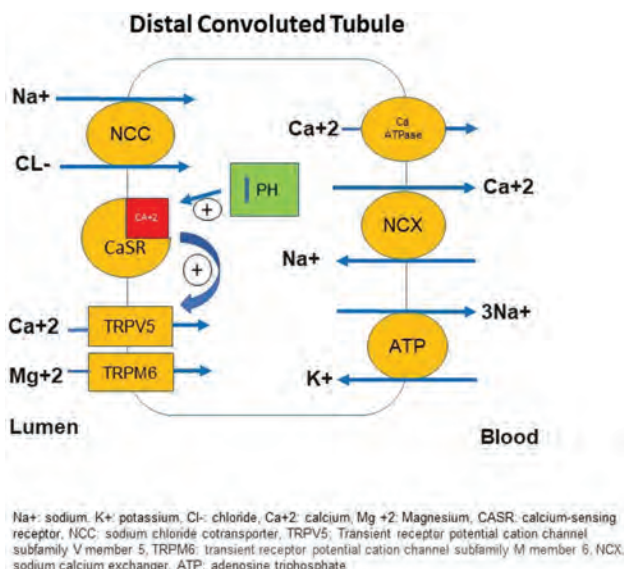

Figure 1

Figure 2-A

Tests	Results	Normal range
Sodium	130 mmol/L	132-148 mmol/L
Potassium	2.2 mmol/L	3.5-5 mmol/L
Chloride	97 mmol/L	98-111 mmol/L
Bicarbonate	30 mmol/L	23-32 mmol/L
Blood Urea Nitrogen	16 mg/dL	10-25 mg/dL
Creatinine	1.59 mg/dL	0.7-1.4 mg/dL
Calcium	9.6 mg/dL	8.4-10.5 mg/dL
Albumin	4.1 g/dL	3.5-5.0 g/dL
Glucose	90 mg/dL	65-100 mg/dL

Figure 2-B

Tests	Results
24-hour urine sodium	210 mmol
24-hour urine potassium	67.2 mmol
24-hour urine magnesium	156 mg
24-hour urine calcium	138 mg
Random urine potassium/creatinine	44.2 mmol/g

## FR-PO449

### Headache and Diplopia in Identical Twins With Nephropathic Cystinosis

Arsalan A. Alvi, Sarah L. Elfering. University of Minnesota Division of Renal Diseases and Hypertension, Minneapolis, MN.

**Introduction:** Cystinosis is an autosomal recessive lysosomal storage disease characterized by the accumulation of cystine in various organs due to a variant in the CTNS gene. Infantile nephropathic cystinosis presents in infancy with failure to thrive and results in kidney failure. There are many non-renal manifestations. We report identical twins with nephropathic cystinosis who both developed idiopathic intracranial hypertension (IIH).

**Case Description:** Case 1 is a female kidney transplant recipient with infantile nephropathic cystinosis who developed symptoms of headache, nausea and diplopia at age 33. Evaluation revealed bilateral optic disc swelling. Brain MRI/MRV was normal and opening pressure was elevated on lumbar puncture. IIH was diagnosed and managed with acetazolamide. Ultimately, a ventriculoperitoneal shunt was required. Case 2 is a female identical twin of case 1, also a kidney transplant recipient, with nephropathic cystinosis who developed headache and vomiting at age 35. Evaluation revealed papilledema, an elevated opening pressure (50 cm) on lumbar puncture and normal brain MRI. She was treated with acetazolamide. Her papilledema and symptoms resolved. After 2 years, acetazolamide was discontinued and symptoms have not recurred.

**Discussion:** We present a case of identical twins who developed IIH. It has been speculated that IIH is a late complication of cystinosis. Both IIH and cystinosis are rare but IIH has been reported to occur in patients with cystinosis at a higher rate compared to the general population. This case of identical twins with cystinosis and IIH contributes to the literature regarding the connection between these two diseases. Though genetic associations with IIH have been identified, none are on chromosome 17 (location of CTNS gene) so we suspect these twins did not have genetic variant causing IIH. It is theorized that cystine crystals deposit in meninges and arachnoid villi, leading to decreased absorption of CSF. Patients with cystinosis presenting with headaches and diplopia should be evaluated for IIH.

## FR-PO450

### Late Presentation of Bartter Syndrome Type 2

Amit Kaushal,<sup>1</sup> John C. Lieske,<sup>2</sup> Peter C. Harris,<sup>2</sup> Sarah L. Elfering.<sup>1</sup>  
<sup>1</sup>University of Minnesota Division of Renal Diseases and Hypertension, Minneapolis, MN; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN.

**Introduction:** Bartter syndrome (BS) is an autosomal recessive disorder characterized by salt wasting that results from variants in at least 5 genes that encode proteins important for ion transport in the thick ascending loop of Henle (TALH). Features include polyuria, metabolic alkalosis, hypokalemia, and secondary hyperaldosteronism (often with low blood pressure, BP). Variants in the ROMK1 potassium channel gene (KCNJ1) cause BS2 which often results in severe clinical manifestations in infancy. Cases of BS2 diagnosed in adulthood have only infrequently been reported. Here we report a BS2 patient that presented in adulthood with hypokalemia, metabolic alkalosis and nephrocalcinosis.

**Case Description:** A 33-year-old male with no prior medical history presented with flank pain. Imaging showed no stone but instead bilateral nephrocalcinosis and hydronephrosis. He reported polydipsia (5-6 L daily) since childhood. Family history was pertinent for a brother with kidney stones, polydipsia and polyuria. On evaluation, BP was 131/91, potassium 2.7 mmol/L, bicarbonate 30 mmol/L, and calcium 8.5 mg/dL, creatinine 0.94 mg/dL and eGFR > 90ml/min. A 24-hour urine revealed high calcium (410 mg), low citrate (74 mg), high pH (6.9), and high volume (5 L). Urine potassium was inappropriately high given the hypokalemia (55 mmol). Genetic testing on a 102 candidate gene panel revealed 2 missense variants in KCNJ1, with one variant (c.949A>G; p.Lys317Glu) that has been associated with low BP but not described in BS2 to date and a second novel variant predicted to be pathogenic (c.949A>G; p.Lys336Glu). Oral potassium chloride was initiated and on follow-up serum potassium was 3.1 mmol/L. His brother with a similar phenotype had the same biallelic KCNJ1 changes.

**Discussion:** BS2 is caused by variants KCNJ1 gene that cause loss of ROMK function. Reduced ROMK activity impairs effective TALH function resulting in hypokalemia, salt wasting and volume depletion with subsequent activation of renin-aldosterone axis, and metabolic alkalosis. Generation of an effective TALH transepithelial electrochemical gradient is also essential for paracellular reabsorption of Ca<sup>2+</sup> and Mg<sup>2+</sup>. Thus hypercalciuria, hypomagnesemia, and nephrocalcinosis are also frequently observed. Our case highlights that the diagnosis of BS should be considered beyond the neonatal period in patients who present with hypokalemia, hypercalciuria and nephrocalcinosis.

## FR-PO451

### Mesothelial and Endothelial Cell Barrier Characterization in Health, CKD, and Peritoneal Dialysis

Iva Marinovic,<sup>1</sup> Maria Bartosova,<sup>1</sup> Rebecca Herzog,<sup>2,3</sup> Juan M. Sacnun,<sup>2,3</sup> Conghui Zhang,<sup>1</sup> Robin Hoogenboom,<sup>2,3</sup> David Ridinger,<sup>4</sup> Eszter Levai,<sup>1,5</sup> Damir Kronic,<sup>6</sup> Felix Bestvater,<sup>6</sup> Michael Hausmann,<sup>4</sup> Sotirios G. Zarogiannis,<sup>1</sup> Klaus Kratochwill,<sup>2,3</sup> Claus Peter Schmitt.<sup>1</sup> <sup>1</sup>UniversitätsKlinikum Heidelberg, Heidelberg, Germany; <sup>2</sup>Medizinische Universität Wien, Wien, Austria; <sup>3</sup>zytoprotec GmbH, Wien, Austria; <sup>4</sup>Ruprecht Karls Universität Heidelberg Kirchhoff-Institut für Physik, Heidelberg, Germany; <sup>5</sup>Semmelweis Egyetem, Budapest, Hungary; <sup>6</sup>Deutsches Krebsforschungszentrum, Heidelberg, Germany.

**Background:** Solute transport across cellular barriers is defined by tight-junctions (TJ) and transmembrane transporters. Cell-specific expression and regulation by peritoneal dialysis (PD) is unknown.

**Methods:** Quantitative and functional cellular *in vitro* and peritoneal *ex vivo* barrier studies included RNAseq of polarized cell monolayers, Transwell experiments and tissue multi-omics followed by digital analysis.

**Results:** RNA sequencing of polarized human peritoneal mesothelial, immortalized pleural, umbilical vein and cardiac microvascular endothelial cells demonstrated distinct junction, transmembrane and transcytosis related transcripts across cell lines. Next to the tissue origin and transformation status, major differences in cell adhesion and migration, vasculature development and growth factor response were identified. Sealing TJ, claudin (CLDN)1 was expressed only in mesothelial cells, CLDN5 in endothelial cells. Findings were reconfirmed by western blot and immunofluorescence *in vitro* and in human parietal peritoneum *ex vivo*. Super resolution microscopy revealed less CLDN5 clustering in microvascular endothelial cells and transepithelial resistance was 50% lower compared to the three other cell lines; 4- and 10-kDa dextran permeability was higher. Multi-omics analyses from microdissected omental arterioles of children on high-GDP PD demonstrated downregulation of junctions and transcytosis as compared to non-CKD, ESRD and low-GDP PD treated children, transcellular transporter expression was comparable. The parietal peritoneal endothelial to mesothelial surface area available for exchange was age dependently 1.5 to 2-fold higher and increased with low-GDP PD. PD induced arteriolar TJ regulation was reconfirmed in the parietal peritoneum. Arteriolar and mesothelial pore-forming junctions CLDN2/4/15 correlated with transport function in peritoneal equilibration tests.

**Conclusions:** We provide the first comprehensive analysis of peritoneal solute transporters and their regulation by ESRD and PD. Mesothelial and endothelial sealing and transporter abundance differs substantially, associates with PD membrane function and indicates a functional role of both cellular barriers.

**Funding:** Government Support - Non-U.S.

## FR-PO452

**The Differential Roles of Leptin, Adiponectin, and Omentin on Phenotype Transition of Human Peritoneal Mesothelial Cells**

Hyun-Jung Kang, Dal-Ah Kim, Ye rim Her, Duk-Hee Kang, *Ewha Womans University, Seoul, Republic of Korea.*

**Background:** Functional and structural integrity of peritoneal membrane is essential for successful peritoneal dialysis (PD). Residential cells in peritoneal cavity are mesothelial cells (MCs), endothelial cells, fibroblasts, and adipocytes (ACs) located in submesothelial tissue. Previous studies focused on the role of peritoneal MCs in the development of peritoneal fibrosis, however the role of neighboring adipose tissue and adipokines released from ACs has not been investigated. Since there are now compelling evidences suggesting that ACs exert important metabolic and proinflammatory effects on peripheral tissue, we examined the effect of representative adipokines, leptin, adiponectin, and omentin on phenotype transition of MCs.

**Methods:** The effect of co- and pre-treatment of leptin (10–100 ng/mL) or adiponectin (1–2 µg/mL) or omentin (0.5–1 µg/mL) on epithelial-to-mesenchymal transition (EMT) of cultured human peritoneal MCs was investigated. The effect of leptin, adiponectin, and omentin gene silencing using siRNA technique on TGF-β-induced EMT was examined. EMT was assessed by the changes in morphology and markers of epithelial and mesenchymal cells both in mRNA and protein levels. Activation of Smad2/3, Erk1/2 MAPK, p38 MAPK phosphorylation was also assessed.

**Results:** Leptin, adiponectin or omentin per se did not alter the expression of the markers of EMT of MCs up to 72 hours. Leptin (100 ng/mL) aggravated TGF-β (1 ng/mL)-induced EMT whereas adiponectin (2 µg/mL) and omentin (1 µg/mL) ameliorated TGF-β-induced EMT of MCs at 48 hours of stimulation. Leptin gene silencing alleviated TGF-β-induced EMT and adiponectin or omentin siRNA treatment enhanced TGF-β-induced EMT. EMT induced by 24-hour exposure to TGF-β was reversible upon the removal of TGF-β, and this reversal of EMT was further accentuated with co-treatment of adiponectin for additional 48 hours. Reversibility of EMT after removal of TGF-β stimulation was blocked by leptin treatment. Leptin gene silencing ameliorated TGF-β-induced activation of Smad2/3 in MCs.

**Conclusions:** Our results suggest the differential role of leptin, adiponectin and omentin in phenotype transition of MCs and peritoneal fibrosis. Modulation of the expression/activity of adipokines can be a novel target for prevention and treatment of peritoneal fibrosis.

## FR-PO453

**Role of Cross-Talk Between Mesothelial Cells (MCs) and Adipocytes (ACs) in Phenotype Transition of MCs in Peritoneal Dialysis (PD)**

Hyun-Jung Kang, Ye rim Her, Dal-Ah Kim, Duk-Hee Kang, *Ewha Womans University, Seoul, Republic of Korea.*

**Background:** In peritoneal cavity, adipose tissue is buried under mesothelial monolayer and possibly interacts with neighboring MCs. Although a majority of previous work has focused on peritoneal MCs as a key player of peritoneal fibrosis, the role of neighboring ACs and their secreted adipokines in epithelial-to-mesenchymal transition (EMT) of MCs needs to be investigated.

**Methods:** Transwell co-culture system was used in which MCs were cultured with mature ACs differentiated from 3T3-L1 preadipocytes. EMT of MCs was evaluated by the changes in morphology and markers of epithelial and mesenchymal cells. Adipokines in supernatant and cell lysate were analyzed by adipokine array, real-time PCR, and Western blotting. Effect of stimulation or gene silencing of adipokines on EMT was examined.

**Results:** Co-culture of MCs and ACs induced EMT of MCs from 48 hours. Co-culture of MCs and ACs resulted in a decrease of adiponectin (0.4-fold) and plasminogen activator inhibitor-1 (PAI-1) (0.6-fold) and an increase in IL-6 (3.9-fold) and leptin (1.5-fold) in cell culture supernatant. Co-culture also led to an increased expression of monocyte chemoattractant protein-1 (MCP-1) (1.6-fold), vascular endothelial growth factor (VEGF) (2.4-fold), and PAI-1 (1.4-fold) whereas resulted in a decreased expression of adiponectin (0.9-fold) and resistin (0.8-fold) in cell lysates of ACs. Increased expression of adiponectin (83.5-fold) and PAI-1 (1.5-fold) was also observed in cell lysates of MCs. siLeptin or siPAI-1 treatment alleviated EMT of MCs whereas the treatment of IL-6 (50 ng/ml), MCP-1 (10 ng/ml), or VEGF (2 ng/ml) induced EMT of MCs.

**Conclusions:** ACs could induce phenotype transition of peritoneal MCs and trigger pro-fibrotic signal in peritoneal cavity. Precise mechanism for the pro-fibrotic cross-talk between MCs and ACs and the role of various adipokines which shows the different pattern of up- or down-regulation on co-culture system needs to be further investigated.

## FR-PO454

**Disentangling Peritoneal Protein Loss From Its Sources: A Novel Analytic Peritoneal Effluent Proteomics Approach**

Fabian Eibensteiner,<sup>1,2</sup> Rebecca Herzog,<sup>2,1</sup> Andreas Vychytil,<sup>3</sup> Christoph Aufricht,<sup>1</sup> Klaus Kratochwill,<sup>2,1</sup> <sup>1</sup>*Division of Pediatric Nephrology and Gastroenterology, Comprehensive Center for Pediatrics, Medical University of Vienna, Vienna, Austria;* <sup>2</sup>*Christian Doppler Laboratory for Molecular Stress Research in Peritoneal Dialysis, Medical University of Vienna, Vienna, Austria;* <sup>3</sup>*Division of Nephrology and Dialysis, Department of Medicine III, Medical University of Vienna, Vienna, Austria.*

**Background:** Worldwide, ca. 11% of patients requiring dialysis are being treated with peritoneal dialysis (PD). During each PD exchange high peritoneal protein losses (PPL) occur, reflecting toxin removal, serum loss and inflammation, and predicting

mortality and cardiovascular morbidity. Measured PPL is the result of transmembrane serum loss, lymphatic drainage, trans mesothelial reabsorption, local production, and cellular components. However, this concept is still poorly understood.

**Methods:** Peritoneal dialysis effluent (PDE) samples were obtained from peritoneal equilibrium tests during a prospective, multicenter, double-blinded, controlled, randomized, dual-period, 2-treatment, crossover, phase II, proof-of-concept study in Austria, before administration of the study treatment. PDE samples were submitted to proteomic analysis by Tandem Mass Tag Derivatization 2D-RP/RP Liquid Chromatography Mass Spectrometry. To disentangle transmembrane serum protein loss from local protein production we developed a novel and unique analytical approach. Briefly, partitioning around medoids and proximity in the Euclidean space for between visit single-protein kinetics was utilized to achieve this separation.

**Results:** We were able to identify 2,624 different proteins within the PDE of 12 patients across two time-points. At first a large cluster of proteins with stable abundances in collinearity with well-established clinical characteristics of PPL (e.g., total protein loss, dialysate-to-plasma-protein) was identified. After clustering and separation steps three groups of proteins were identified: transmembrane serum proteins, locally produced proteins, other (reflecting neither of these mechanisms). Locally produced proteins mainly reflect inflammatory activity whereas transmembrane serum proteins mainly describe transport functions.

**Conclusions:** PPL is an important but poorly understood undesired effect of PD associated with morbidity and mortality. Our novel and unique analytical approach enables us to disentangle the complexity of transmembrane serum protein loss and local protein production on single-protein level across the peritoneal proteome. This will aid conceptual pathophysiological understanding and identification of novel drug targets to improve PD patients' outcomes.

## FR-PO455

**L-Cysteine Attenuates Peritoneal Fibrosis by Inhibiting Pyruvate Kinase M2 in Mesothelial Cells**

Ma Xiaokun, Yin Li, Hui Peng. Department of Nephrology, The Third Affiliated Hospital of Sun Yat-sen University *Department of Nephrology, The Third Affiliated Hospital of Sun Yat-sen University, GuangZhou, China.*

**Background:** Peritoneal fibrosis is one of the main causes of peritoneal dialysis (PD) failure, our previous study has demonstrated that peritoneal dialysate-induced hyperglycolysis stimulates mesothelial-to-mesenchymal transition (MMT) in peritoneal mesothelium cells leading to peritoneal fibrosis but there is still a lack of effective and low-toxic drugs for preventing peritoneal hyperglycolysis and fibrosis in clinical practice.

**Methods:** The peritoneal dialysis effluents from patients with long-term or short-term peritoneal dialysis were collected for single cell transcriptome sequencing (scRNA-seq), and differential activation of glycolytic enzymes in the two groups was identified specifically in mesothelial cells. Human primary peritoneal mesothelial cell cultures and MET-5A cells were used to assess the relationship between specific glycolytic enzyme and MMT. Gene silencing, COIP, CHIP and other techniques were used to explore the mechanisms behind of this relationship. Finally, the therapeutic effect of glycolytic enzyme inhibitor was evaluated in mouse model of peritoneal fibrosis.

**Results:** scRNA-seq showed that long-term peritoneal dialysis reduced the number of peritoneal mesothelial cells, stimulated the expression of glycolysis enzymes, especially the pyruvate kinase isozymes M2 (PKM2), a key rate-limiting enzyme of glycolysis. In mesothelial cell cultures, TGF-β1 promoted MMT that was associated with the activation of PKM2, and addition of L-cysteine, a PKM2 inhibitor, significantly suppressed this response. Mechanically, PKM2 promoted the expression of transcription factor SNAIL2 through acetylation of H3K9, thus promoting the occurrence of MMT in mesothelial cells. In C57BL/6 mice, high glucose peritoneal dialysate induced peritoneal fibrosis with increased PKM2 expression in mesothelial cells. Administration of L-cysteine to these mice significantly reduced peritoneal fibrosis that was associated down-regulation of PKM2 activity and improved peritoneal ultrafiltration.

**Conclusions:** PKM2 activation is a critical step to induce mesothelial hyperglycolysis during peritoneal dialysis. Inhibition of PKM2 by L-cysteine suppresses mesothelial hyperglycolysis and hence peritoneal fibrosis, thus, providing a new therapeutic strategy for preventing peritoneal fibrosis in patients with peritoneal dialysis.

## FR-PO456

**Inhibition of H3K4 Trimethylation Ameliorates Peritoneal Fibrosis and Senescence**

Daisuke Hara, Kensuke Sasaki, Ayumu Nakashima, Takao Masaki. *Hiroshima University Hospital, Hiroshima, Japan.*

**Background:** Senescence is induced by aging as well as various stimuli, resulting in the development of organ inflammation and fibrosis. Recently, the accumulation of p16<sup>INK4a</sup>-positive cells is considered as a feature of organ senescence, and p16<sup>INK4a</sup> gene expression is regulated by Mixed-lineage leukemia 1 (MLL1)/WD-40 repeat protein 5 (WDR5)-mediated histone 3 lysine 4 trimethylation (H3K4me3). In this study, we investigated whether MLL1/WDR5 complex inhibition ameliorates peritoneal senescence together with peritoneal inflammation and fibrosis in methylglyoxal (MGO) induced peritoneal injury mice and cultured human peritoneal mesothelial cells (HPMCs).

**Methods:** Peritoneal fibrosis was induced by intraperitoneal injection of MGO in male C57/B6 mice for 3 weeks. MM-102, a MLL1/WDR5 complex inhibitor, was administered subcutaneously at the same time. After 3 weeks of treatment, peritoneal tissues were examined. In an *in vitro* study, TGF-β1 stimulated HPMCs were examined

with or without MM-102 preincubation. Chromatin immunoprecipitation (ChIP) assays were performed to clarify the status of p16<sup>INK4a</sup> gene promoter as an H3K4me3-enrichment region. Human nonadherent cells were isolated from the effluent of PD patients.

**Results:** MLL1 was upregulated in the peritoneum of MGO-injected mice, TGF- $\beta$ 1-stimulated HPMCs and human nonadherent cells. MM-102 significantly suppressed p16<sup>INK4a</sup> expression, as well as submesothelial zone thickness and cell density in MGO-injected mice. Immunohistochemical staining revealed that MM-102 decreased not only H3K4me3 and p16<sup>INK4a</sup> expression, but also peritoneal inflammation and collagen deposition. Moreover, p16<sup>INK4a</sup> expression was positively correlated with dialysate-to-plasma (D/P) ratio of creatinine in PD patients. In the *in vitro* study, MM-102 suppressed TGF- $\beta$ 1-induced upregulation of p16<sup>INK4a</sup>, H3K4me3 and fibrotic markers in HPMCs. Finally, ChIP assay revealed that MM-102 decreased the H3K4me3 levels at the promoter of p16<sup>INK4a</sup>.

**Conclusions:** The MLL1/WDR5 inhibitor MM-102 ameliorates peritoneal inflammation and fibrosis through suppression of senescence.

## FR-PO457

### Plasminogen Activator Inhibitor 1 (PAI-1) and Nuclear Factor of Activated T-Cells 5 (NFAT5) Mediates TGF $\beta$ -Induced Phenotype Transition of Human Peritoneal Mesothelial Cells (MCs)

Dal-Ah Kim, Hyun-Jung Kang, Ye rim Her, Duk-Hee Kang, *Ewha Womans University, Seoul, Republic of Korea.*

**Background:** The epithelial-to-mesenchymal transition (EMT) of MCs is an early mechanism of peritoneal dysfunction in peritoneal dialysis (PD). Plasminogen activator inhibitor-1 (PAI-1) is an inhibitor of fibrinolysis by hindering the proteolytic activity of tissue type plasminogen activator, and recently reported to regulate EMT of cancer cells. NFAT5 is known to regulate PAI-1 transcription, and also to promote EMT of cancer cells. The aim of this study is to investigate the role of PAI-1 and NFAT5 in TGF $\beta$ -induced EMT of MCs and its mechanism.

**Methods:** EMT was evaluated by the changes in morphology and markers of epithelial and mesenchymal cells. Effect of gene silencing of PAI-1 or PAI-1 inhibitor (Tiplaxtinin, 20  $\mu$ M) on TGF $\beta$ -induced EMT was examined. Activation of Smad2/3, Erk1/2 MAPK phosphorylation, snail expression, nuclear translocation of snail was assessed. MMP2 expression was evaluated by real time PCR and WB. The interaction between NFAT5 and  $\beta$ -catenin was analyzed by immunoprecipitation. RNA-seq was performed to analyze gene profiling in MCs isolated from omentum (HPMC, N=4) or MCs isolated from overnight dwell dialysates from PD patients (PDMC, N=9), respectively.

**Results:** Either PAI-1 gene silencing or Tiplaxtinin ameliorated TGF $\beta$ -induced changes in cell morphology and the expression of E-cadherin,  $\alpha$ -SMA, and fibronectin. TGF $\beta$ -induced decrease in E-cadherin promoter activity and nuclear translocation of snail were also alleviated by siPAI-1. PAI-1 gene silencing ameliorated TGF $\beta$ -induced activation of smad2/3 and Erk1/2 MAPK in HPMC. In addition, TGF $\beta$ -induced increase MMP2 expression was alleviated by siPAI-1. TGF $\beta$ -induced increase in PAI-1 was blocked by siNFAT5. siPAI-1 also ameliorated TGF $\beta$ -induced NFAT5/ $\beta$ -catenin interaction. RNA-seq analysis revealed an increased in PAI-1 expression in PDMC compared to HPMC, which was associated with altered expression of EMT-related genes.

**Conclusions:** PAI-1 plays a role in TGF $\beta$ -induced EMT of peritoneal MCs via an interaction with NFAT5, and modulation of PAI-1 expression/activity in MCs could be a novel strategy to prevent peritoneal fibrosis in PD patients.

## FR-PO458

### BMSC-Derived miR-34b-3p Inhibits Peritoneal Fibroblast-to-Myofibroblast Transdifferentiation by Downregulating Spi-C

Fang Yu, Kehong Chen, Yani He. *Army Medical Center of PLA, Chongqing, China.*

**Background:** Peritoneal fibrosis is the main reason for the failure of peritoneal dialysis (PD). However, there is no effective intervention. Here, we examined the role and mechanism of bone marrow mesenchymal stem cell-derived exosomes (BMSC-Exos) in regulating the differentiation of fibroblasts (FB) to myofibroblasts (MFB) in peritoneal fibrosis.

**Methods:** C57BL/6 mice were randomly divided into 3 groups: a control group (Saline), a peritoneal injury group (2.5% glucose peritoneal dialysate + LPS), and a peritoneal injury + BMSC-Exos group. The mice were sacrificed and the parietal peritoneum was collected after 6 weeks of modeling. The peritoneum of mice was examined by transcriptomics. The composition and function of BMSC-Exos were analyzed by miRNA sequencing.

**Results:** Our previous studies have confirmed that exosomes can inhibit peritoneal fibrosis. The expression level of MFB markers increased gradually with the prolongation of the peritoneal fibrosis model. BMSC-Exos treatment significantly decreased the expression of mouse peritoneal MFB markers, suggesting that exosomes can inhibit the differentiation of FB into MFB. Similarly, we further confirmed the effect of BMSC-Exos *in vitro*. Transcriptomic analysis results revealed that SPIC gene ranked first in the differential expression genes. The mRNA and protein levels of Spi-C were significantly increased in peritoneal injury group, while were significantly down-regulated in BMSC-Exos group. After overexpression of Spi-C *in vitro*, the differentiation of FB to MFB was significantly increased, and the fibrotic factor (TGF- $\beta$ 1) and TGF- $\beta$ /WNT pathway (Smad3,  $\beta$ -Catenin) related to FB differentiation was significantly increased, whereas BMSC-Exos intervention could inhibit FB differentiation. miRNA sequencing and bioinformatics analysis showed that miR-34b-3p is one of the main components of BMSC-Exos, and it is the only miRNA that can specifically bind to SPIC gene sequence.

*In vitro*, miR-34b-3p mimics could down-regulate the expression of Spi-C, and the expression of Spi-C was not affected after miR-34b-3p inhibitor intervention. The results suggested that BMSC-Exos-derived miR-34b-3p inhibited the differentiation of FB into MFB by targeting Spi-C.

**Conclusions:** BMSC-derived miR-34b-3p targeting Spi-C can alleviate peritoneal fibrosis by inhibiting the differentiation of subperitoneal mesothelial FB into MFB.

## FR-PO459

### Decorin Deficiency Accelerates Peritoneal Fibrosis in a Murine Model of Peritoneal Dialysis

Wing Long Cody Mok,<sup>1</sup> Rafter Y. Wu,<sup>1</sup> In Young Oh,<sup>1</sup> Renato V. Iozzo,<sup>2</sup> Tak Mao D. Chan,<sup>1</sup> Susan Yung.<sup>1</sup> <sup>1</sup>*Department of Medicine, School of Clinical Medicine, the University of Hong Kong, Hong Kong SAR, Hong Kong;* <sup>2</sup>*Department of Pathology, Anatomy, and Cell Biology, Thomas Jefferson University, Philadelphia, PA.*

**Background:** Preservation of structural and functional integrity of the peritoneal membrane is a major challenge limiting the feasibility of long-term peritoneal dialysis (PD). Decorin is a soluble dermatan sulphate proteoglycan, synthesized by peritoneal mesothelial cells, with anti-fibrotic properties. We investigated the role of decorin in a murine PD model.

**Methods:** Wild-type (WT) and decorin-knockout (DKO) mice were randomized to receive saline (Control) or glucose-based PD fluid containing 40 mM methylglyoxal (PDF Group) by intra-peritoneal injection, twice daily for up to 12 weeks, after which time the parietal peritoneum was excised to investigate the expression of  $\alpha$ -smooth muscle actin ( $\alpha$ -SMA), collagen and fibronectin (FN). Human peritoneal mesothelial cells (HPMC) were isolated from omentum and incubated with spent dialysate from stable PD patients, in the presence or absence of decorin (1  $\mu$ g/ml) for 24 h, and mediators of fibrosis assessed.

**Results:** After 12 weeks of treatment, PDF Group WT mice showed submesothelial thickening accompanied by decreased decorin expression and increased  $\alpha$ -SMA, FN and collagen expression, with infiltration by F4/80<sup>+</sup>CD206<sup>+</sup> macrophages and CD86<sup>+</sup>CD4<sup>+</sup> T cells. The submesothelium was inhabited with elongated fibroblast-like cells which were positive for  $\alpha$ -SMA and collagen I suggestive of myofibroblasts. These abnormalities were exacerbated in DKO mice ( $P < 0.05$  compared with WT), and was observed earlier, after 8 weeks of treatment. In cultured HPMC, PDF induced the expression of FN and its extra domain A/B isoforms (EDA-FN and EDB-FN) through increased ERK, p38 MAPK and PI3K phosphorylation, while addition of decorin decreased FN, EDA-FN and EDB-FN expression by 56.5%, 46.7% and 50.0% respectively.

**Conclusions:** Our data suggest that decorin ameliorates PDF-induced peritoneal fibrosis through its effects on FN and inflammatory cell infiltration.

**Funding:** Government Support - Non-U.S.

## FR-PO460

### Entangled: An Unusual Case of Encapsulating Peritoneal Sclerosis

Ricardo Uribe, John M. Duch, Chandan Takkar. *Audie L Murphy VA, San Antonio, TX.*

**Introduction:** Encapsulating Peritoneal Sclerosis (EPS) is one of the most serious complications of peritoneal dialysis (PD), characterized by progressive peritoneal membrane fibrosis and adhesions, and associated with high morbidity and mortality. Patients present with episodes of bowel obstruction, abdominal pain and distention, and weight loss. Risk factors include longer duration on PD, recurrent episodes of peritonitis and a high transporter status. We report a case of EPS on a patient presenting with new onset ascites and small bowel obstruction after transition from PD to Hemodialysis (HD).

**Case Description:** A 71 male with ESRD secondary to Diabetic Nephropathy, treated with HD for the past 6 months, presented with new onset ascites, abdominal pain and symptoms of small bowel obstruction (SBO). He had received PD for approximately 2.5 years, and was transitioned to HD due to 3 episodes of peritonitis. His transporter status prior to transition was high average. Ascitic fluid work up revealed serosanguinous fluid with a WBC count of 273/mm<sup>3</sup> with 67% lymphocytes, Protein concentration of 4g/dL, Albumin concentration 2g/dL and SAAG of >1.1, negative cultures and cytology. Evaluation for cardiac and hepatic causes of ascites was unremarkable. CT showed bowel loop dilatation affecting duodenum and proximal jejunum. Patient was discharged after paracentesis and bowel rest. This was followed by six additional hospitalizations with similar presentation, over the course of one year, managed with bowel rest regimen for partial SBO. Abdominal imaging one year after index hospitalization revealed loculated ascites, small bowel clustering with surrounding peritoneal thickening and scattered calcifications. A diagnosis of EPS was made, and he was started on Tamoxifen and Prednisone.

**Discussion:** This is an unusual case of EPS, presenting after a PD vintage of less than 3 years, albeit with the risk factors of recurrent peritonitis and high average transporter status. While the incidence of EPS in patients on PD < 3 years has been reported close to 0, there may be significant detection bias, related to the non-specific presenting symptoms and lack of characteristic imaging findings earlier on. Nephrologists should maintain a high index of suspicion in patients who have been on PD and present with non-specific GI symptoms, since intervention in the early, inflammatory phase, could perhaps lead to improved outcomes.

## FR-PO461

**Stimulator of Interferon Genes: A New Player in Peritoneal Damage**

Vanessa Marchant,<sup>1,2</sup> Jorge García-Giménez,<sup>2,3</sup> Guadalupe T. Gonzalez-Mateo,<sup>4</sup> Irene Rubio,<sup>1,2</sup> Valeria Kopytina,<sup>4</sup> Lucia Tejedor,<sup>1,2</sup> Laura Marquez-Exposito,<sup>1,2</sup> Pilar Sandoval,<sup>4</sup> José A. Jimenez,<sup>5</sup> Manuel Lopez-Cabrera,<sup>4</sup> Adrian M. Ramos,<sup>2,3</sup> Marta Ruiz-Ortega.<sup>1,2</sup> <sup>1</sup>Cellular and Molecular Biology in Renal and Vascular Pathology Laboratory, Fundación Instituto de Investigación Sanitaria-Fundación Jiménez Díaz-Universidad Autónoma Madrid, Madrid, Spain; <sup>2</sup>Red de Investigación Renal (REDINREN), Madrid, Spain; <sup>3</sup>Laboratory of Nephrology, IIS-Fundación Jiménez Díaz, School of Medicine, UAM, Madrid, Spain; <sup>4</sup>Molecular Biology Centre Severo Ochoa (CBM-SO), Spanish Council for Scientific Research (CSIC), Universidad Autónoma de Madrid, Madrid, Spain; <sup>5</sup>Servicio de Anatomía Patológica, Hospital de la Princesa, Madrid, Spain.

**Background:** Peritoneal dialysis (PD) is a current replacement therapy for ESRD patients. However, long-term exposure to PD fluids (PDF) may lead to a peritoneal membrane (PM) damage and solute transport failure through mechanisms that include activation of the inflammatory/immune response, mesothelial to mesenchymal transition (MMT), and fibrosis. Stimulator of Interferon Genes (STING) is a cytosolic DNA sensor involved in the innate immune response that induces the transcription of type I interferons, cytokines, chemokines, and interferon-stimulated genes (ISGs). This work aimed to study the role of STING in peritoneal damage development.

**Methods:** STING<sup>+</sup> cells were first studied in peritoneal biopsies from PD patients and mice exposed to PDF. Then, we performed 2 models of peritoneal damage in WT and STING-KO mice: a fibrosis model induced by daily ip. injections of 0.1% chlorhexidine gluconate (CHX) for 4 weeks and a 5-day model of post-surgical adhesions (ischaemic buttons). Animals were euthanized and peritoneal tissue and lavage fluids were collected. Peritoneal mRNA and protein levels of STING pathway, MMT, fibrosis, and inflammatory markers were measured by qPCR, western blot, or immunohistochemistry. Cell populations present in the peritoneal cavity were assayed by flow cytometry.

**Results:** STING<sup>+</sup> cells were found in the peritoneum of both PD patients and mice exposed to PDF. In CHX-treated WT mice, peritoneal levels of STING and their downstream effectors (TBK1, IRF3, and ISGs) were increased and STING<sup>+</sup> cells were found in PM thickness and cell infiltration areas. In STING-KO mice, the absence of STING improved CHX-induced peritoneal damage including decreased PM thickness and fibrosis, inflammatory cell tissue infiltration, and cell recruitment into the peritoneal cavity. At the molecular level, the absence of STING prevented NFκB pathway activation and reduced the peritoneal expression of MMT/fibrosis markers, cytokines, chemokines, and ISGs. Additionally, STING-KO showed less peritoneal adhesion formation and decreased expression of inflammatory markers and ISGs.

**Conclusions:** The absence of STING prevented peritoneal damage suggesting that it may become a new potential therapeutic target in PD-associated peritoneal damage.

## FR-PO462

**Comparison of Single-Cell Transcriptomic Profiles of Early and Late Peritoneal Dialysis**

Yi-Wen Chiu,<sup>1,2</sup> Siao Muk Cheng,<sup>3</sup> Daw-yang Hwang.<sup>3</sup> <sup>1</sup>Kaohsiung Medical University, Kaohsiung, Taiwan; <sup>2</sup>Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, Taiwan; <sup>3</sup>National Institute of Cancer Research, Tainan, Taiwan.

**Background:** The bio-incompatibility of peritoneal dialysate leads to peritoneal inflammation and fibrosis. However, the type of immune cells involving chronic inflammation and the interaction and coordination of each immune cell population during peritoneal dialysis (PD) treatment remains unclear.

**Methods:** PD samples from two early and two late PD patients were subjected to single-cell RNA sequencing analysis (scRNA-seq) and immune cell type identification. We further compared the hallmark pathways, cell trajectory, and cell-cell communications between early and late PD patients.

**Results:** A total of 16,986 qualified cells were analyzed, and eight subtypes of immune cells were identified. Monocytes (~55 %) dominated both early and late PD, followed by T cells (~25 %) and mesothelial cells (~12 %) in similar portions. Compared with those in early PD, there were more hematopoietic-like proliferating cells and conventional type 1 dendritic cells and fewer B cells, neutrophils, and plasmacytoid dendritic cells in late PD. Among the four subsets of monocytes, inflammatory responses were enriched in early PD. All five T cell subtypes were at effector status and like monocytes, had more enriched inflammatory pathways in early PD, with epithelial and fibroblastic characteristics found in all four subtypes of mesothelial cells. Again, inflammation was enriched in early PD, while mesothelial-to-mesenchymal transition (EMT), angiogenesis, and fibrosis in late PD. Further trajectory analysis of mesothelial cells revealed two different cell fates, that is, more inflammatory responses and enriched in early PD, with more cell stress and apoptosis and enriched in late PD. Cell-cell interaction analysis showed a close and complicated linkage between monocytes and mesothelial cells.

**Conclusions:** The dynamic changes in cellular composition during early and late PD identified by scRNA-seq might open new avenues for developing cell-based and anti-inflammatory therapies.

**Funding:** Government Support - Non-U.S.

## FR-PO463

**Inhibition of IL-18 Ameliorates Lipopolysaccharide-Induced Peritoneal Fibrosis in Mice**

Satoru Shichijo, Masayoshi Kukida, Itsuki Miyake, Ayu Makita, Jun Aono, Osamu Yamaguchi. *Ehime Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Toon, Japan.*

**Background:** Peritoneal dialysis (PD)-related bacterial peritonitis causes peritoneal fibrosis, leading to peritoneal deterioration and discontinuation of PD. Preventing peritoneal fibrosis is essential for the long-term PD, while there is no established treatment for peritoneal fibrosis. Interleukin (IL)-18 is a member of the IL-1 family of cytokines. We have previously demonstrated that IL-18 is involved in the pathophysiology of renal interstitial fibrosis. This study examined the role of IL-18 on the progression of peritonitis-induced peritoneal fibrosis.

**Methods:** We examined the effects of IL-18 deletion on peritoneal fibrosis using 8-week-old male C57BL/6J (WT) and IL-18-knockout (IL-18<sup>-/-</sup>) mice. Either vehicle or LPS (10mg/kg lipopolysaccharide, dissolved in 2ml saline) was injected to these mice once a week and sacrificed at days 15 after the first injection. Subsequently, mouse embryonic fibroblasts (MEF) from the E13.5 embryos of WT and IL-18<sup>-/-</sup> mice were extracted and incubated with 10ng/ml recombinant IL-18 to investigate the direct impacts of IL-18 on fibroblast *in vitro*. IL-18 binding protein (BP), a constitutively secreted protein, prevents IL-18 binding to its receptor. Since our results supported that IL-18 promoted fibroblast-mediated peritoneal fibrosis, we tested whether IL-18 BP is a therapeutic tool in LPS-induced peritoneal fibrosis. LPS-infused WT mice were also intraperitoneally administrated with either vehicle or 200µg/kg IL-18 BP.

**Results:** LPS induced significant peritoneal thickening with fibroblast proliferation compared with the vehicle injection in WT mice. The peritoneal fibrosis was attenuated in IL-18<sup>-/-</sup> mice. To examine these mechanisms, mice peritoneum were evaluated at days 2. LPS mainly induced macrophage infiltration in the peritoneum, which was attenuated by IL-18 deletion. Recombinant IL-18 increased the mRNA expression of TGF-β and CTGF in MEF from WT and IL-18<sup>-/-</sup> mice, equivalently. Both LPS- and IL-18 BP-injected mice showed less peritoneum thickening and fibroblast proliferation compared with only LPS-injected mice.

**Conclusions:** These data indicate IL-18 plays a pivotal role on LPS-induced peritoneal fibrosis. IL-18BP has a previously unrecognized therapeutic potential for peritonitis-induced fibrosis in PD patients.

## FR-PO464

**Fasting Blood Glucose Level and All-Cause Mortality in Peritoneal Dialysis Patients**

Sojin Lim, Hyeon Seok Hwang, Kyung hwan Jeong, Jin sug Kim, Soo-Young Yoon, Jongho Kim, Geon Woo Kim. Division of Nephrology, Department of Internal Medicine, Kyung Hee University Kyung Hee University, Seoul, Republic of Korea.

**Background:** Dialysis solutions that are used in Peritoneal dialysis (PD) patients contain high concentration of glucose, so the issue of glycemic control is especially important for PD patients. Fasting Blood Glucose (FBG) is the most widely used blood glucose index in the clinical field because it is a principal indicator of daily status of glycemic status and it can help determine the anti-diabetes management. While these strength of FBG monitoring is considered as critical component for ideal glycemic control, there is no consistent evidence to support the optimal level of FBG in PD patients.

**Methods:** We used data from the National Health Insurance database of Korea, screening 29,266 patients who received maintenance PD treatment between 2002 and 2018. A total of 943 patients were included, who diagnosed diabetes and received national health screening examination. The primary endpoint in this study was the association between time-updated FBG and all-cause mortality.

**Results:** During a median follow-up of 6.55 years, we analyzed 943 patients divided into 6 groups according to the FBG level. The mean age was 52.6 years and 63.6% was male. In addition, the mean FBG was 128.8 mg/dL. In the time-varying Cox models, 125 mg/dL ≤ FBG < 150 mg/dL group showed a significant increase in all-cause mortality (HR, 1.27; 95% confidence interval [CI], 1.02-1.58; p = 0.032) compared with 80 mg/dL ≤ FBG < 100 mg/dL group as the reference. Similar results were observed with 150 mg/dL ≤ FBG < 180 mg/dL and FBG ≥ 180 mg/dL groups (HR, 1.35; 95% CI, 1.02-1.58; p = 0.021/ HR, 1.61; 95% CI, 1.32-1.96; p < 0.001, respectively). Subgroup analysis revealed that patients who had age of <65 years, female gender, higher body mass index or less comorbidity score were significantly associated with higher mortality risk at FBG > 100 mg/dL, compared to those with 80 mg/dL ≤ FBG < 100 mg/dL.

**Conclusions:** Peritoneal dialysis Patients with 80 ≤ FBG < 100 mg/dL were significantly associated with lower risk of all-cause mortality than those with FBG < 80 mg/dL or ≥ 100 mg/dL. In addition, patient-specific conditions allowed even tighter FBG target for lower risk of mortality.

**Funding:** Government Support - Non-U.S.

## FR-PO465

## Association Between Calcium, Phosphate, Intact Parathyroid Hormone Levels, and Mortality Among Patients on Peritoneal Dialysis

Miho Murashima,<sup>1</sup> Takayuki Hamano,<sup>1</sup> Shunsuke Goto,<sup>2</sup> Takeshi Hasegawa,<sup>3</sup> Masafumi Fukagawa,<sup>4</sup> Masanori Abe,<sup>5</sup> Norio Hanafusa,<sup>6</sup> <sup>1</sup>Nagoya Shiritsu Daigaku, Nagoya, Japan; <sup>2</sup>Kobe Daigaku, Kobe, Japan; <sup>3</sup>Showa Daigaku, Shinagawa-ku, Japan; <sup>4</sup>Tokai Daigaku, Hiratsuka, Japan; <sup>5</sup>Nihon Daigaku, Chiyoda-ku, Japan; <sup>6</sup>Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.

**Background:** Association between calcium, phosphate, intact parathyroid hormone (PTH) levels and mortality has been extensively studied among patients on hemodialysis. However, studies limited to patients on peritoneal dialysis (PD) are lacking.

**Methods:** This is a prospective cohort study on Japan Renal Data Registry. Adults on PD at the end of 2009 were included. The observation period was up to 9 years and data were censored at the time of transplantation or transition to hemodialysis. Exposures were time-averaged albumin-corrected calcium (cCa), phosphate, and intact PTH levels. Outcomes were all-cause and cardiovascular (CV) mortality. Data were analyzed using Cox regression models and the results were shown as cubic spline curves.

**Results:** Among 2,017 patients with data for analyses, the mean age was 62 (14) years, 67 % were male, and the median PD vintage was 2.3 (1.0-4.3) years. During a median follow-up of 3.0 years, 590 death and 211 CV death (62 atherosclerotic and 149 non-atherosclerotic) were observed. Higher time-averaged cCa levels tended to be associated with higher mortality. Lower time-averaged phosphate levels were associated with lower all-cause mortality. No significant association between intact PTH levels and all-cause mortality was observed. The association between time-averaged cCa and CV mortality was U-shaped. Higher phosphate levels were associated with death due to atherosclerotic CV diseases but not with death due to non-atherosclerotic CV diseases. Sensitivity analyses by time-dependent model yielded similar results.

**Conclusions:** Among PD patients, higher cCa levels tended to be associated with higher all-cause mortality, and the relation between cCa levels and CV mortality was U-shaped. Lower phosphate levels were associated with lower all-cause mortality. Targeting cCa toward normal levels and phosphate levels toward the lower limit of normal range seems to be reasonable. Control of intact PTH might be of less importance among PD patients.

## FR-PO466

## Plasma Fibrinogen: A Driver of Left Ventricular Remodeling in Peritoneal Dialysis Patients and Its Related Risk Factors

Yun Chen, Chuanming Hao, Tongying Zhu. Huashan Hospital Fudan University, Shanghai, China.

**Background:** Plasma fibrinogen (FIB) has been recently proven to be significantly associated with an increased risk of cardiovascular events and all-cause mortality in patients undergoing peritoneal dialysis (PD). Left ventricular hypertrophy (LVH) is common among PD patients. However, the relationship between the plasma FIB and the LV remodeling in PD patients was rarely discussed. The study aimed to investigate the role of plasma FIB in LV remodeling and LV functions in patients on PD, and explore risks factors related to plasma FIB level.

**Methods:** Patients with echocardiography for three consecutive years were recruited between Dec. 2010 and May 2020. Echocardiographic measurements of LV geometry and LV function were collected and LVH-progression was evaluated. Correlation analysis was performed to explore the plasma FIB level and LV geometry and LV function. Pathogenic factors correlated to the LVH-progression were explored by logistic regression models and the role of FIB in it was verified by receiver operating characteristic (ROC) curve analysis. Linear regression models were conducted to identify factors associated with plasma FIB level.

**Results:** A total of 268 PD patients (96 males, 57.8%) were recruited with an average age of 55.9 ± 16.5 years. Patients were trisected according to plasma FIB level. Patients in the third tertile (with higher FIB level) had higher mean wall thickness (MWT), relative wall thickness (RWT) and left ventricular mass index (LVMI) and lower E/A ratio than those in the other tertiles. 112 patients were detected to have LVH progression. Multivariable logistic regression showed that plasma FIB level was an independent risk factor for LVH-progression (OR, 1.591; 95% CI, 1.243–2.037; p < 0.001). And the ROC analysis indicated that the area under the curve (AUC) of fibrinogen level for predicting

LVH-progression was 0.637 (p < 0.001). Multiple linear regression analysis identified history of diabetes, age, PD duration, CRP and ApoB were risk factors for a higher plasma FIB level in PD patients.

**Conclusions:** An elevated plasma FIB level was independently associated with LVH-progression and significantly related to declined LV function in patients undergoing PD. History of diabetes, age, PD duration, CRP and ApoB were risk factors for a high level of plasma FIB. Plasma FIB might be a valuable marker for LV-remodeling monitoring.

## FR-PO467

## Origin of Proteins and Metabolites in Peritoneal Dialysis Explained by a Multi-Omic Approach

Klaus Kratochwill, Rebecca Herzog, Andreas Vychytil, Christoph Aufricht. Medical University of Vienna, Vienna, Austria.

**Background:** Peritoneal dialysis effluent (PDE) is a rich but underexplored source for therapy monitoring and investigation of deregulated processes during PD. Modern high performance mass spectrometry (MS) and sequencing methods allow monitoring of hundreds of analytes in parallel. For understanding PD related processes on a systems biology level, a multi-level omics approach is particularly attractive. Here, we investigate the cellular transcriptome and cell-free proteome of PDE samples to investigate the origin of proteins found in PDE.

**Methods:** The effluent material from stable patients was separated into a cellular and cell-free component. Proteins in the cell-free compartment were processed using our equalizing and TMT-labelling workflow followed by LC-MS. The cellular material was subjected to RNA sequencing. A bioinformatic workflow conjoined information from the datasets to reveal novel insights into the “PD effluentome”, especially clarifying the source of proteins found in PDE.

**Results:** Metabolomics methods enabled detecting 207 unique metabolites in cell-free PDE. A mixed-effect ANOVA of all metabolites demonstrated dwell time-dependent concentration changes of 173. Post-hoc testing revealed most metabolites to be changed between 1h and 16h of fluid dwell, followed by 114 and 46 differently concentrated metabolites between 4h and 16h and 1h and 4 h of dwell respectively. We quantified 9,797 transcripts in PD-effluent cells and 2,729 proteins in PDE. 342 proteins were filtered from plasma, while 800 proteins were attributable to local production. A quantitative analysis of the interaction proteome and cellular transcripts of roughly 1700 protein-transcript pairs showed clusters of proteins explained by over-expression in peritoneal cells compared to plasma concentrations.

**Conclusions:** The exploitation of PD effluent information on multiple omics levels as identified by our bioinformatic approach will improve our understanding of the molecular processes in the peritoneal cavity and their role in development of complications for ultimately improving PD therapy. Our work suggests feasibility of multi-omics approaches to investigate cell derived biomarkers for their involvement in pathomechanisms relevant in PD.

## FR-PO468

## Can We Use the Modified Creatinine Index for Assessment of Muscle Mass in Peritoneal Dialysis Patients?

Cheuk-Chun Szeto, Gordon C. Chan, Winston W. Fung, Jack K. Ng. The Chinese University of Hong Kong, Hong Kong, Hong Kong.

**Background:** Sarcopenia is common in chronic dialysis patients and is associated with increased morbidity and mortality. The modified creatinine index (MCrI) is a simple that represents dietary protein intake and skeletal muscle mass, and has been found to be a reliable prognostic marker for chronic hemodialysis (HD) patients. Since single-pooled Kt/V (sp-Kt/V) for urea and pre-HD serum creatinine level for the calculation of MCrI, it remains unknown whether the index could be extrapolated to peritoneal dialysis (PD) patients.

**Methods:** We studied 138 patients (88 males) who were converted from PD to HD. We compared their MCrI measured within 6 months while on HD as computed by the standard formula and that computed by using the total weekly Kt/V and serum creatinine while the patient was on PD. The two parameters were compared by the Bland and Altman method.

**Results:** The mean age was 50.9 ± 12.7 years; 82 patients (59.4%) were converted to HD because of severe or recurrent peritonitis, and 56 (40.6%) due to mechanical problems. The average MCrI during HD and PD were 22.21 ± 2.90 and 22.97 ± 3.24 mg/kg/day, respectively. The bias of using total weekly Kt/V and serum creatinine in PD for the calculation of MCrI was 0.758 mg/kg/day (95% confidence interval [CI] -4.356 to +5.873 mg/kg/day), or 4% (95%CI -20% to +28%). The difference in MCrI calculated during HD and PD significantly correlated with serum albumin (r=0.342, p<0.0001), and inversely with residual glomerular filtration rate (GFR) (r=-0.359, p<0.0001). MCrI during PD significantly correlated with the Charlson's comorbidity index (r=-0.356, p<0.0001), serum albumin (r=0.315, p<0.0001), residual GFR (r=0.362, p<0.0001), percentage of fat-free edema-free body mass by creatinine kinetics (r=0.684, p<0.0001), lean tissue mass by multi-frequency bioimpedance spectroscopy (r=0.641, p<0.0001), but not normalized protein nitrogen appearance (r=0.034, p=0.7) or adipose tissue mass (r=-0.146, p=0.17).

**Conclusions:** MCrI, when calculated by total weekly Kt/V and serum creatinine in PD, results in a small bias, but it remains significantly correlated with other measures of skeletal muscle mass. Further studies are needed to determine the prognostic value MCrI in PD patients.

**Funding:** Clinical Revenue Support

## FR-PO469

## Pleuroperitoneal Leak in Peritoneal Dialysis: A Case Series

Gonçalo Ávila, Patrícia Matias, Rita Calça, Patrícia Q. Branco. *Centro Hospitalar de Lisboa Ocidental EPE Hospital de Santa Cruz, Carnaxide, Portugal.*

**Background:** Pleuroperitoneal leak (PPL) is a rare cause of pleural effusion in peritoneal dialysis (PD) patients due to congenital or acquired defects in the diaphragm muscle fibers or connective tissue. In the first case, it manifests on the first days after beginning PD. The latter situation may present months or years after and is associated with excessive intra-abdominal pressure. Peritoneal scintigraphy with Tc-99m macroaggregated albumin (MAA) injected into the abdominal dialysate port is a useful diagnostic test with good sensitivity. The aim of this study was to describe the characteristics and outcomes of a group of PD patients with diagnosed PPL.

**Methods:** We conducted a single center, retrospective study, that included patients on PD with confirmed PPL from 2011 to 2022. Demographic and clinical parameters were obtained. Patients were followed since the beginning of PD until technique dropout.

**Results:** Ten patients with PPL were included, with mean age of  $56.5 \pm 11.3$ , and 70% females. Mean body mass index was  $26.9 \pm 4.4$  kg/m<sup>2</sup>. Median DP vintage at the time of diagnosis was 92 days (IQR 29.5 - 412.5). All cases were right-sided leaks. In three patients it developed in the first month, in four patients within 3 months and in three patients after one year. Only one patient had one episode of peritonitis before diagnosis. The most common symptoms at the time of diagnosis were cough (50%) and pleuritic pain (40%). Diagnosis was made using peritoneal scintigraphy with MAA in 90% of patients. Seven patients underwent talc pleurodesis after a median time of 8 days after the diagnosis. In four patients, the pleural effusion recurred in the period of approximately one month after restarting PD. The median technique survival of patients in whom the procedure was effective was 12 months.

**Conclusions:** PPL are a rare cause of pleural effusion in PD patients that carry important morbidity, requiring immediate switching to another renal replacement therapy and requiring an invasive procedure for its treatment, which has a limited efficacy (42% in our cohort). There is currently no standardized method for its diagnosis. In this study, peritoneal scintigraphy with MAA demonstrated to be a safe, noninvasive, and cost-effective exam. Patients presenting with new onset right sided pleural effusion, particularly in the first weeks or months after beginning PD, should be investigated for PPL.

## FR-PO470

## Fast and Precise Pathogen Detection and Identification in Peritoneal Dialysis-Associated Peritonitis: Insight From Metagenomics Next-Generation Sequencing

Xiaoxiao Ma, Xiaowen Ha, Reziwanguli Abudula, Jiayinaxi Azati, Yaqin Wu, Yixiang Tan, Hong Jiang. *People's Hospital of Xinjiang Uygur Autonomous Region, Urumqi, China.*

**Background:** PD-associated peritonitis (PDAP) is one of the most common and detrimental complications for patients receiving PD. Metagenomics next-generation sequencing technique (mNGS) potentially provides a fast and precise option for the detection and identification of pathogens in the PDAP by sequencing the nucleic acid of microorganisms in the samples.

**Methods:** We investigated 12 PDAP patients by identifying the potential pathogens of the peritoneal dialysate samples using the traditional microorganism culture (TMC) and mNGS respectively. The pathogens detection rate, species coverage of pathogens, sensitivity, and specificity between these two assays were analyzed.

**Results:** Total concordance between TMC and mNGS was noted. The pathogenic bacteria detection rate using mNGS was significantly higher than that of TMC (75% vs 58.3%,  $P < 0.05$ ). The rates for greater than 2 pathogens using mNGS dramatically increased than that of TMC (91.7% vs 58.3, 41.4% vs 0%,  $P < 0.05$ ). The sensitivity and specificity of mNGS for the detection of pathogens in the PDAP are higher than that of TMC. Of note, the TMC results from three PDAP patients showed negative due to previous antibiotics treatment before enrolling in this study, whereas positive pathogens were still detected by using mNGS. The adjustment of treatment according to the result of mNGS controlled the infection, 2 patients and peritoneal dialysis was achieved independently after 1 week. The time of results was 5-7 days for TMC and 1-1.5 days for mNGS. The sensitivity of mNGS is 70% and the specificity of it is 100%.

**Conclusions:** These findings suggest that mNGS in diagnosis and guidance of treatment for PDAP is possibly superior to TMC its higher sensitivity and specificity.

**Funding:** Government Support - Non-U.S.

## FR-PO471

## QuickCheck: A Point-of-Care Leukocyte Counter for PD Management

Curtis B. Dobson,<sup>1,2</sup> Rachel Cant,<sup>1</sup> Michael G. Barker,<sup>2</sup> Darren Kell,<sup>2</sup> Stephnie M. Kennedy,<sup>2</sup> Adam S. Milner,<sup>2</sup> Ida M. Jackson,<sup>2</sup> Thomas C. Willett,<sup>2</sup> Ryan Griffiths,<sup>2</sup> John P. Foster,<sup>2</sup> Chris Knight,<sup>3</sup> David M. Lewis,<sup>4</sup> Anand Vardhan,<sup>5</sup> Martin E. Wilkie,<sup>6</sup> Nishal Govindji-Bhatt.<sup>2</sup> <sup>1</sup>The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; <sup>2</sup>Microbiosensor Ltd., Manchester, United Kingdom; <sup>3</sup>School of Natural Sciences, The University of Manchester, Manchester, United Kingdom; <sup>4</sup>Salford Royal NHS Foundation Trust, Salford, United Kingdom; <sup>5</sup>Manchester University NHS Foundation Trust, Manchester, United Kingdom; <sup>6</sup>Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom.

**Background:** Peritonitis is a major cause of peritoneal dialysis (PD) technique failure, and causes significant morbidity, mortality and anxiety. Cloudy effluent caused by increased leukocytes (typically neutrophils) is an early indicator, but visual assessment is unreliable. We have developed QuickCheck, a simple point-of-care device to provide an instant leukocyte count. Here we confirm which leukocytes are present in PD patients without peritonitis, and which should be detectable by the instrument. We also compare the relative performance of QuickCheck and a UK 'gold standard' hospital laboratory flow cytometer (Sysmex UF5000).

**Methods:** Leukocytes present in PD effluent were determined for 9 PD patients without peritonitis. Isolated leukocytes were stained (with CD45, CD3, CD4, CD8, CD19, CD33, CD14, CD16, CD56, CD66b, HLA-DR, CD11b, CD303 and EpCam) followed by mass cytometry to identify the leukocyte type. QuickCheck performance was compared with Sysmex using leukocytes from effluent from 6 PD patients (IRAS 294250) resuspended in filtered (cell-free) effluent to yield test concentrations (10-1000 cells/ $\mu$ l). The percentage error, linearity of response and bias were compared. Accuracy and precision were also calculated.

**Results:** Leukocytes from PD patients without peritonitis comprised many sub-types, including macrophages (47%), monocytes (11%), T-Cells (CD4+) (7%), T-Cells (CD8+) (12%), B-Cells (6%), neutrophils (12%), NK cells (0.4%). Percentage error between the QuickCheck and Sysmex was 10% across the range 10-1000 cells/ $\mu$ l, linearity ( $R^2$ ) was 0.99 and Bland-Altman analysis showed no bias (0.000). Accuracy of the Sysmex was 95.9% and QuickCheck was 90.5%. Precision for Sysmex was 5.6% and QuickCheck was 3.0%.

**Conclusions:** Leukocytes present in PD patients without peritonitis are diverse, and so detecting all types is important for use with initially 'well' patients, as infection begins to develop. QuickCheck and Sysmex both showed good correlation with each other by linearity, and neither showed appreciable bias. Independent analysis showed QuickCheck was more precise though slightly less accurate than Sysmex, but has the advantage of speed, simplicity, portability and suitability for use at point-of-care.

**Funding:** Commercial Support - Microbiosensor Ltd., Government Support - Non-U.S.

## FR-PO472

## Regular Monitoring for Nasal Carriage of Staphylococcus aureus May Reduce Risk of Peritoneal Dialysis Associated Infections

Hari Dukka, Ugonna Onwuchekwa. *University of Derby and Burton, Derby, United Kingdom.*

**Background:** Staphylococcus Aureus (SA) causes a significant proportion of Peritoneal dialysis (PD) associated infections. Patients with nasal carriage of SA are four times more likely to develop PD catheter exit site infections, which can lead to peritonitis. Mupirocin has been used to treat SA nasal carriage.

**Methods:** We did a retrospective study to see if patients receiving PD in our department were being monitored for SA carriage with nasal swabs, every 3 months as per department policy and the impact it had on PD associated infections (PDAI). The study period was 2.5 years and electronic data base was used to capture information. Timing of nasal swabs and any PDAI were captured.

**Results:** 60 patients were analysed during the study period. The mean age  $72 \pm 4$  years. 23 patients received 3 monthly nasal swabs to identify SA carriage (group 1). The rest had swabs done at median time of 4 months (4-17 months) (group 2). 29 patients during this study period developed PDAI. There were 26 peritonitis episodes and 23 exit site infections. The relative risk of developing PDAI with a positive nasal swab was 1.5 (odds ratio of 2.34). Patients in group 1 who had 3 monthly monitoring and appropriate treatment with mupirocin (n = 8) developed PDAI and in group 2 the incidence was (n = 21). Three monthly monitoring for nasal carriage of SA reduced risk of PDAI by 22%.

**Conclusions:** Patients on PD should have regular and timely monitoring for nasal SA carriage. This may reduce the incidence of PDAI.

## FR-PO473

# Icodextrin Is Associated With Lower Risks of Peritonitis, Technique Failure, and Mortality: A Cohort Study From Taiwan

I-kuan Wang,<sup>1,2</sup> Chan Ip Chan,<sup>3,4</sup> Hsing-Fen A. Lin,<sup>5</sup> Ping chin Lai.<sup>1</sup> <sup>1</sup>*Divisions of Nephrology, China Medical University Hospital, Taichung, Taiwan;* <sup>2</sup>*Department of Medicine, College of Medicine, China Medical University, Taichung, Taiwan;* <sup>3</sup>*Baxter Healthcare Ltd., Taipei, Taiwan;* <sup>4</sup>*Graduate Institute of Management, National Taiwan University of Science and Technology, Taipei, Taiwan;* <sup>5</sup>*Raising Statistics Consultant Inc, Taipei, Taiwan.*

**Background:** It studied the effects of icodextrin (ICO) on the risks of peritonitis, switching to HD, death and technique failure in a large group of PD patients using extended data from a medical center in Taiwan.

**Methods:** The study included incident PD patients receiving PD for at least 90 days from Jan. 1, 2007 to Dec. 31, 2018 at China Medical University Hospital, Taiwan. ICO users were defined as use of ICO for >50% of their PD duration. ICO was considered a time-varying exposure in Cox proportional hazard model. The outcomes of interest were the first episode of peritonitis, switching to HD (defined as transfer to HD for at least 30 days), death, and technique failure (defined as transfer to HD for at least 30 days or death on PD). If patients died within 90 days after switching to HD, the death was attributed to PD and counted as a death event.

**Results:** A total of 725 PD patients including 190 ICO users and 535 ICO non-users were recruited. Compared to ICO non-users, ICO users had significant lower risks of the first peritonitis episode (adjusted HR=0.22, 95% CI=0.14-0.34), switching to HD (adjusted HR=0.55, 95% CI=0.37-0.80), mortality (adjusted HR=0.58, 95% CI=0.39-0.88) and technique failure (adjusted HR=0.60, 95% CI=0.45-0.80). Age, diabetes (DM), nPA and 24-hour net ultrafiltration were the risk factors for peritonitis. The subgroup analyses showed ICO delivered additional benefits for lowering the risk of peritonitis in PD patients with DM (adjusted HR=0.07 in DM vs. 0.56 in non-DM; *P* for interaction<0.001) and with cardiovascular diseases (CVD) (adjusted HR=0.04 in CVD vs. 0.31 in non-CVD; *P* for interaction=0.02). The protective effect of ICO on mortality was more prominent in high transporter PD patients (adjusted HR=0.16 in high transporter vs. 0.70 in non-high transporters; *P* for interaction=0.063).

**Conclusions:** ICO can lower the risks of peritonitis, switching to HD, mortality and technique failure in a large group of Asian PD population. Its protective effects on mortality were more prominent in high transporter and patients with DM or CVD.

Table 1. The association between the use of ICD and the risk of outcomes without and with covariate adjustment

Outcome	Number of patients	Hedgehog <sup>a</sup>		Unadjusted analysis		Adjusted for age, comorbidity <sup>b</sup>

# Effect of Protein Supplement in Patients With Peritoneal Dialysis-Associated Peritonitis on Clinical Outcomes: A Multicenter, Randomized-Controlled Trial

**Surasak Faisaitatham,<sup>1,2</sup> Piyatida Chuengsaman,<sup>3</sup> Chaiwat Pisutpaisan,<sup>4</sup> Rhonachai Lawsuanakul,<sup>5</sup> Chanchana Boonyakrai,<sup>6</sup> Sarassawan Kananuraks,<sup>2</sup> Rutchanee Chieochanthanajit,<sup>7</sup> Kamol Khositrangisuk,<sup>8</sup> Jeerath Phannajit,<sup>1</sup> Somkanya Tungsanga,<sup>1</sup> Somchai Eiam-Ong,<sup>1</sup> Talerngsak Kanjanabuch.<sup>1</sup>**  
<sup>1</sup>*Chulalongkorn University Faculty of Medicine, Bangkok, Thailand;* <sup>2</sup>*Khon Kaen Hospital, Khon Kaen, Thailand;* <sup>3</sup>*Banphaeo-Chaorenkrung Peritoneal Dialysis Center, Bangkok, Thailand;* <sup>4</sup>*Samut Prakan Hospital, Samut Prakan, Thailand;* <sup>5</sup>*Chonburi Hospital, Chonburi, Thailand;* <sup>6</sup>*Taksin Hospital, Bangkok, Thailand;* <sup>7</sup>*Sawanpracharak Hospital, Pak Nam Pho, Thailand;* <sup>8</sup>*Maharaj Nakhon Si Thammarat Hospital, Nakhon Si Thammarat, Thailand.*

**Background:** Malnutrition is associated with increased mortality in peritoneal dialysis (PD) patients with peritonitis. Data on protein supplementation during peritonitis episodes are limited.

**Methods:** A multicenter, open-label, randomized trial across 9 PD centers in Thailand was conducted. Adult PD patients above 18 years, diagnosed with peritonitis with serum albumin below 3.5 g/dL were randomly assigned to receive protein supplementation (intervention group) or none (control group). Participants with tuberculous/fungal/secondary peritonitis or septic shock were excluded. Whey protein of 30 g/day was given to the intervention group for 30 days. Participants in both groups received nutritional counseling according to SPENT guideline (dietary energy intake of 30 kcal/kg/day and dietary protein intake of 1.5 g/kg/day). The primary outcome was a composite outcome of peritonitis-related death or relapsing/repeat peritonitis. The secondary outcome was serum albumin levels across study period between groups. Outcomes were monitored for 120 days.

**Results:** From June 2021 to February 2022, 74 participants were randomized to the intervention group (N=37) and control group (N=37). Both groups had comparable demographics and baseline serum albumin. Dietary protein intake on the 30<sup>th</sup> day was 1.4±0.4 g/kg/day in the intervention group and 1.0±0.2 g/kg/day in the control group ( $p=0.07$ ). Primary outcome events were reported in 15 (41%) and 19 (51%) participants in the intervention and control groups, respectively (hazard ratio 0.84; 95% confidence interval [CI] 0.43-1.67). Serum albumin concentrations were significantly higher in the intervention group across study period (linear mixed-effects model,  $p<0.001$ ), with a mean difference on the 120<sup>th</sup> day of 0.35 g/dL (95% CI 0.06-0.64) ( $p=0.02$ ).

**Conclusions:** Serum albumin concentrations in patients with PD-associated peritonitis were higher with protein supplementation compared with nutritional counseling alone, although death or relapsing/repeat peritonitis were not affected. Further studies with a longer follow-up period and a larger number of participants are warranted.

**Funding:** Private Foundation Support

## FR-PO475

### Influence of Peritoneal Dialysis Solution Type and Strength on Bacterial Growth

Annie V. Hong,<sup>1,2</sup> Arunima Mishra,<sup>3</sup> Soo min Jang,<sup>4,2</sup> Sergio Infante,<sup>2</sup> Enrica Fung,<sup>1,2</sup> Jeffrey Perl,<sup>5</sup> Roy O. Mathew,<sup>2,1</sup> Hansel M. Fletcher.<sup>3</sup> <sup>1</sup>*Loma Linda VA Medical Center, Loma Linda, CA;* <sup>2</sup>*Loma Linda University School of Medicine, Loma Linda, CA;* <sup>3</sup>*Loma Linda University Health, Loma Linda, CA;* <sup>4</sup>*Loma Linda School of Pharmacy, Loma Linda, CA;* <sup>5</sup>*St. Michael's Hospital, Toronto, ON, Canada.*

**Background:** The role of solution type and strength on peritonitis risk is unclear in patients receiving peritoneal dialysis (PD). We evaluated the *in vitro* growth characteristics (inhibition or promotion) of common peritonitis bacterial species in various PD solution types.

**Methods:** Common bacterial pathogens including: *Staphylococcus aureus* (SA), *Staphylococcus epidermidis* (SE), *Pseudomonas aeruginosa* (PA), and *Enterococcus faecalis* (EF) were cultured in a compatible growth medium overnight (Brain heart infusion, Luria-Bertani broth, or Todd Hewitt broth). An aliquot from the cultures was grown in a 1:1 combination of growth media (control- CON) + PD solution (Baxter: 1.5%, 2.5%, 4.25% dextrose (DEX), and 7.5% icodextrin (ICO)). All cultures were incubated in glass tubes aerobically for 16 h and 20 h at 37 °C; growth at 16h is reported due to minimal increase after that. Bacterial concentrations were measured by optical density of each sample at 600 nm (OD600) and a mean of three independent experiments were taken. The error bars represent the standard deviations.

**Results:** Compared to control, PA growth was most robust in combined growth media and PD fluid (Figure: growth in PD fluid to growth medium 1:1 mixture at 16h). In particular, PA underwent stronger growth in DEX ( $p < 0.001$  DEX vs CON) and grew less in ICO versus all DEX ( $p = 0.002$ ). In contrast, SA had greater growth in ICO versus all DEX ( $p < 0.001$ ). EF demonstrated the weakest growth in growth medium + PD fluid.

**Conclusions:** Common PD-associated bacteria appear to grow similarly in routine PD fluids with the most favorable growth environment for SE. When PD fluids are combined with growth media to better simulate physiologic conditions, ICO limits PA and DEX limits SA growth. Further research is warranted in clinical settings.

Bacterial growth in lab media combined with PD fluids (1:1)

## FR-PO476

# Nationwide Standardized Peritonitis Reporting: Updated Results From the Optimizing the Prevention of Peritoneal Dialysis Associated Peritonitis in the United States (OPPUS) Study

Muthana Al sahlawi,<sup>1</sup> Brian Bieber,<sup>2</sup> Shweta Bansal,<sup>3</sup> Geoffrey A. Block,<sup>4</sup> Tahsin Masud,<sup>5</sup> Beth M. Piraino,<sup>6</sup> Martin J. Schreiber,<sup>7</sup> Vesh Srivatan,<sup>8,9</sup> Isaac Teitelbaum,<sup>10</sup> Suzanne Watnick,<sup>11,12</sup> Leslie Garcia,<sup>2</sup> Ronald L. Pisoni,<sup>2</sup> Jeffrey Perl.<sup>13</sup> <sup>1</sup>King Faisal University, Al-Hasa, Saudi Arabia; <sup>2</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>3</sup>The University of Texas Health Science Center at San Antonio, San Antonio, TX; <sup>4</sup>US Renal Care, Inc, Plano, TX; <sup>5</sup>Emory University, Atlanta, GA; <sup>6</sup>University of Pittsburgh School of Medicine, Pittsburgh, PA; <sup>7</sup>DaVita Inc, Denver, CO; <sup>8</sup>Rogovin Institute, New York, NY; <sup>9</sup>Weill Cornell Medicine, New York, NY; <sup>10</sup>University of Colorado Denver School of Medicine, Aurora, CO; <sup>11</sup>Northwest Kidney Centers, Seattle, WA; <sup>12</sup>University of Washington, Seattle, WA; <sup>13</sup>Saint Michael's Hospital, Toronto, ON, Canada.

**Background:** Peritoneal Dialysis (PD) associated peritonitis is a common complication of PD and is the leading cause of transfer to hemodialysis in the US. No formal mechanism or surveillance system exists for nationwide peritonitis reporting. Our primary aim was to develop a uniform widescale peritonitis reporting mechanism and evaluate its implementation in the Optimizing Prevention of PD-associated Peritonitis in US (OPPUS) study.

**Methods:** Following literature review, stakeholder consultation, and ISPD guidelines review, a web-based peritonitis tracker tool (OPPUS-Link) was developed. Pilot sites for one-year data collection were selected based on geography and reported peritonitis rates, including 3 medium-large dialysis organizations. We provided formal training, central data review, and adjudication of all peritonitis episodes and outcomes. Data collection began in October 2020 and is ongoing.

**Results:** Initial data for 53 participating facilities with a median follow-up time of 31 patient-years includes 350 peritonitis episodes (rate of 0.24 episodes/year). Permanent transfer to HD, PD catheter removal, and hospitalization occurred in 14%, 15%, and 41% of episodes respectively, with 6% of episodes resulting in death. Only 1.5% of peritonitis episodes occurred following PD catheter insertion but prior to PD at home. Ongoing challenges include high prevalence of culture-negative peritonitis (22% of episodes) and high percentage of peritonitis acquired in hospital (15%).

**Conclusions:** Standardized, uniform peritonitis reporting is feasible, a first step in national PD-peritonitis surveillance, allowing for benchmarking, outbreak identification, and quality improvement initiative implementation. Further data validation is necessary and integrating routine peritonitis reporting in electronic health records with an overall goal of peritonitis reduction and improved outcomes for PD patients.

## FR-PO477

# Variation in the Approach to Antibiotic Administration for the Treatment of Peritoneal Dialysis-Associated Peritonitis: Results From a Survey of US Medical Directors Participating in the OPPUS Study

Muthana Al sahlawi,<sup>1</sup> Brian Bieber,<sup>2</sup> Sana F. Khan,<sup>7</sup> Osama El Shamy,<sup>8</sup> Beth M. Piraino,<sup>3</sup> Martin J. Schreiber,<sup>4</sup> Isaac Teitelbaum,<sup>5</sup> Leslie Garcia,<sup>2</sup> Ronald L. Pisoni,<sup>2</sup> Jeffrey Perl.<sup>6</sup> <sup>1</sup>King Faisal University, Al-Hasa, Saudi Arabia; <sup>2</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>3</sup>University of Pittsburgh School of Medicine, Pittsburgh, PA; <sup>4</sup>DaVita Inc, Denver, CO; <sup>5</sup>University of Colorado Denver School of Medicine, Aurora, CO; <sup>6</sup>St. Michael's Hospital, Toronto, ON, Canada; <sup>7</sup>University of Virginia, Charlottesville, VA; <sup>8</sup>Vanderbilt University Medical Center, Nashville, TN.

**Background:** Peritoneal dialysis (PD)-associated peritonitis carries significant morbidity and is the leading cause of technique failure and transition to hemodialysis. This study aimed to explore the variation in antibiotic dosing and administration for the treatment of PD-associated peritonitis among a diverse group of PD facilities participating in the Optimizing Prevention of PD-associated Peritonitis in US (OPPUS) study.

**Methods:** As part of the OPPUS study, an online peritonitis-focused survey was administered in quarter 1 of 2022 to medical directors at 40 PD study sites, representing independent, small, medium, and large sized dialysis organizations. Surveys to date were completed by 38 of these study sites.

**Results:** Most centers (78%) provide patients with antibiotics for self-administration at home whenever peritonitis is suspected but to be taken during clinic off-hours. Clinics differ considerably regarding the types and numbers of intraperitoneal vs oral antibiotics prescribed for such self-administration. Antibiotics are routinely administered in one exchange/day in 95% of facilities; only 47% of facilities adjust dose for residual kidney function. Moreover, most centers (82%) indicated having no access to effluent cell count before initiation of antibiotics, with typically >12-hour turnaround time before effluent cell count results are available at 74% of PD units. Large inter-facility variability was seen as to when repeat PD effluent cell count(s) and culture(s) should be taken. In addition, only 62% of facilities routinely check vancomycin trough levels when intra-peritoneal vancomycin is prescribed.

**Conclusions:** Prompt administration of antibiotics has been consistently shown to be associated with better outcomes of peritonitis treatment. Significant variations exist in antibiotic dosing and administration for PD-associated peritonitis across PD facilities in the US. It is notable that less than 20% of PD units routinely have access to PD effluent

cell count results before treatment is initiated. Identifying optimal antibiotic dosing and administration practices that maximize the likelihood of cure is an important step to improve peritonitis outcomes and decrease related adverse events.

**Funding:** Other NIH Support - AHRQ

## FR-PO478

# Home Pets and Peritonitis: Friend or Foe?

Zahir Ali Shaikh, Imara Dissanayake, Akilandanayaki Angamuthu, Astha Gupta. *Albert Einstein Medical Center, Philadelphia, PA.*

**Introduction:** Peritonitis is a major complication in peritoneal dialysis and remains the main cause of patients switching to hemodialysis. The usual organisms in peritonitis are pathogenic skin bacteria including staphylococcus epidermidis and staphylococcus aureus. There are rare causes which include gram negative and fungal peritonitis. Here we are presenting a case of pastorella multocida which is transferred by pets, especially cats.

**Case Description:** A 41 year old male with medical history of type 1 diabetes mellitus, hypertension, hyperlipidemia, coronary artery disease status post coronary artery bypass graft, end stage renal disease on continuous cyclic peritoneal dialysis came with nausea, vomiting and watery diarrhea of one week. On admission, the exit site was clean with some redness at the peritoneal dialysis catheter insertion site. The initial PD cell count was 8 with 36% neutrophils, however, the PD fluid culture was reported as gram negative rods the following day. The repeat cell count was 2287 with 69% polymorphs. The patient was started on intraperitoneal Cefepime for gram negative peritonitis while awaiting culture and sensitivity. Subsequently the PD fluid culture was positive for pastorella multocida and patient was switched to intraperitoneal ceftriaxone. On further questioning regarding pets at home, the patient attested that his cat plays around the machine tubings while he connects himself for peritoneal dialysis. The patient recovered, however he developed relapsing peritonitis, which was treated successfully, and patient remains on peritoneal dialysis with no complications eight months later.

**Discussion:** Pastorella multocida is an aerobic, small gram negative coccobacillus found in pets (cats & dogs) as part of their normal oral flora. It can cause a variety of infections in humans through scratching, licking or biting, leading to infections ranging from mild cellulitis to severe pneumonia, sepsis or meningitis. Treatment includes penicillin, third generation cephalosporins and carbapenems. The pastorella multocida peritonitis in a peritoneal dialysis is rare, however needs to be considered in patients having pets. The patient's home environment & understanding of sanitization measures should be discussed in detail with patients before starting on peritoneal dialysis and nurse should visit patient's home to ensure the safety and sanitization measures.

## FR-PO479

# Antibiomania With Intraperitoneal Ceftazidime: The First Case Report

Abdul Hannan A. Rasheed,<sup>1,2</sup> Sujith K. Palleti,<sup>1,2</sup> Anuradha Wadhwa,<sup>1,2</sup> <sup>1</sup>Edward Hines Junior VA Hospital, Hines, IL; <sup>2</sup>Loyola University Health System, Maywood, IL.

**Introduction:** Antibiomania or antibiotic induced mania, is rare (47 published cases with 12 different antimicrobials). Macrolides and quinolones are most implicated followed by beta lactams. We present the first case of mania precipitated by ceftazidime, administered intraperitoneally (IP) for treatment of peritonitis in peritoneal dialysis (PD) patient.

**Case Description:** 55-year-old male with end stage kidney disease (ESKD) due to diabetes and hypertension on PD, history of depression (stable off-medications for a year) presented with abdominal pain. PD effluent was cloudy, WBC's 2694 with 78% neutrophils. He was started on IP ceftazidime for gram negative rods (culture showed capnocytophaga) with gradual improvement in cell counts. On day 12 of treatment, changes in his behavior were noted (agitation, anxiety and tearful). Psychiatry recommended starting sertraline for depression. Patient was discharged home to complete 3 weeks of ceftazidime. He was readmitted 4 weeks later due to disruptive behavior (delusions, irritability, agitation). Psychiatry diagnosed him with mania due to ceftazidime and started him on divalproex sodium. PD fluid showed recurrence of peritonitis with 7251 WBCs, 95% neutrophils and Enterobacter cloacae on culture. He was treated with cefepime but due to abdominal pain and increasing WBC, PD catheter was removed. He was transitioned to hemodialysis and completed 2 weeks of cefepime. His mental status was monitored on divalproex sodium. After a year of therapy with antipsychotics, his mood remained stable, and he has switched back to PD.

**Discussion:** This first reported case of antibiomania with IP ceftazidime highlights the importance of recognizing psychiatric side effects of antibiotics which, if left untreated can have devastating effects on patient care and quality of life. There is strong temporal relationship between start of antibiotic and onset of mania symptoms in this case. Underlying psychiatric history may or may not be present. The pathophysiology of antibiomania remains elusive with several postulated hypothesis including disruption of gut microbes and increased excitability of postsynaptic neurons. Remission of mania symptoms with discontinuation of causative agent has only been reported in 1/3<sup>rd</sup> cases hence treatment with antipsychotics may be required.

## FR-PO480

**The Green Menace: Biliary Peritonitis due to Acute Cholecystitis in Peritoneal Dialysis**

Anuroop Yekula,<sup>1</sup> Aakriti Soni,<sup>1</sup> Suzanne G. Martin.<sup>1,2</sup> Pees in a pod. <sup>1</sup>*Saint Vincent Hospital, Worcester, MA;* <sup>2</sup>*Reliant Medical Group Inc, Worcester, MA.*

**Introduction:** The incidence of acute cholecystitis is significantly higher in dialysis patients compared with the general population (5.8 vs 0.92 per 1000 patient-years). Gallbladder (GB) perforation is a life-threatening complication of acute cholecystitis with an incidence of 2-11%. The dialysate effluent in peritoneal dialysis (PD) is a window into the peritoneal cavity and can help identify this intra-abdominal pathology.

**Case Description:** 57M with ESRD on PD for over 10 years presented with diffuse abdominal pain. Peritoneal fluid analysis revealed straw-colored, hazy fluid with a WBC count of >6000 cells/mL with 70% PMNs. CT abdomen showed a mildly distended gallbladder containing gallstones but no evidence of cholecystitis. There was a mild dilation of the common bile duct (8mm). PD fluid cultures grew *Staphylococcus epidermidis*, and the patient was treated with intraperitoneal (IP) vancomycin for 2 weeks with symptom improvement. Five days after discharge, he developed worsening right upper quadrant pain and green dialysate. Peritoneal fluid analysis showed greenish-amber fluid with a WBC count of 1500 cells/mL with 86% PMNs. PD fluid culture was negative. Repeat CT abdomen showed a markedly distended and thickened GB with cholelithiasis. Ultrasound was concerning for acute cholecystitis, which was confirmed by a HIDA scan, and he was started on IV piperacillin-tazobactam and IP vancomycin. As the patient was at high risk for surgery, a cholecystostomy tube was placed to decompress the gallbladder. PD was held initially and successfully resumed as his symptoms improved. The dialysate fluid cleared within 24 hours.

**Discussion:** Green dialysate is a sign of biliary leak into the peritoneal cavity and reflects an abdominal catastrophe. Appropriate and timely surgical intervention should be employed to ensure definitive therapy and prevent morbidity and mortality. Most reported cases were treated with cholecystectomy with PD catheter removal and transition to hemodialysis. This transition is usually temporary, and patients can resume PD after healing from surgery. In our case, the patient was able to continue PD successfully, as he did not undergo cholecystectomy.

## FR-PO481

**A Rare Case of Peritonitis Associated With Sevelamer-Induced Colitis in a Peritoneal Dialysis Patient**

Takayuki Yamada, Arjun L. Kalaria, Shula Schechter, Filitsa H. Bender. *UPMC, Pittsburgh, PA.*

**Introduction:** Sevelamer is a phosphate binder frequently used for end-stage renal disease (ESRD) patients. Several cases have reported sevelamer crystal-induced colitis. Here, we present a rare case of peritonitis associated with sevelamer-induced colitis in a peritoneal dialysis patient.

**Case Description:** A 24-year-old woman with a history of ESRD on peritoneal dialysis (PD), hypertension, and coronary artery disease presented for abdominal pain and dark stool for two days. Symptoms were associated with a decrease in drain and cloudiness of PD fluid. Laboratory tests were notable for severe anemia. She was admitted for further management. PD catheter was not functioning. We initiated empiric vancomycin and cefepime intravenously. On day 3, she had a colonoscopy which showed ulcerations in the cecum. Biopsy revealed crystalline material consistent with sevelamer. PD culture was positive for *Enterococcus faecalis* and was treated with intraperitoneal vancomycin. Peritonitis is likely due to bacterial translocation in the setting of sevelamer colitis. Sevelamer was discontinued and switched to ferric citrate. She was discharged on day 8 with intraperitoneal vancomycin.

**Discussion:** Hyperphosphatemia is a common complication in ESRD and is associated with vascular calcification. Sevelamer is an anion exchanger free of calcium. Sevelamer can crystallize, leading to gastrointestinal mucosal injury. The adverse events are mild in most cases. However, sevelamer rarely causes gastrointestinal (GI) bleeding or severe colitis. As far as we know, this is the first case of sevelamer-induced colitis, which is complicated by PD peritonitis, likely secondary to bacterial translocation. Sevelamer-induced colitis may be underdiagnosed; it can be confirmed by colonoscopy with biopsy. Thus, it is unclear the risk factors of sevelamer-induced colitis. Clinicians need to be aware of these severe adverse events with sevelamer.

## FR-PO482

**Streptococcus canis: A Rare Cause of Peritonitis in a Peritoneal Dialysis Patient**

Christina E. Thoonkuzhy, Nidhi Sukul. *University of Michigan, Ann Arbor, MI.*

**Introduction:** Peritoneal dialysis (PD) is an effective form of renal replacement therapy, but peritonitis can be a serious complication. The most common peritonitis-causing organisms are gram-positive bacteria, specifically *Staphylococcus aureus* and coagulase-negative *Staphylococcus* species. Bacteria of zoonotic origin are a rare, but well-described cause of peritonitis. While the typical zoonotic culprit pathogen is *Pasteurella multocida*, we present a case of peritonitis secondary to isolated *Streptococcus canis*, a group G streptococcus that colonizes the skin and genital and gastrointestinal tracts of dogs and cats.

**Case Description:** A 66-year-old female with end-stage renal disease on PD presented with a one-day history of abdominal pain, nausea, and purulent drainage from her PD catheter site. She was hemodynamically stable, but her exam demonstrated diffuse abdominal tenderness and erythema surrounding her PD catheter site. Her serum white blood cell count (WBC) was 12,800/uL and peritoneal fluid WBC was 9,300/uL with 84% neutrophils. She was empirically started on intraperitoneal (IP) vancomycin and ceftazidime and admitted for further management. Her final cultures speciated to *S. canis*, and she was initiated on IP ceftriaxone. Repeat peritoneal fluid studies obtained on day 3 of treatment showed a WBC of 91/uL with no bacterial growth. She was discharged with a 2-week course of IP ceftriaxone.

**Discussion:** To the best of our knowledge, this is the first case of isolated *S. canis* peritonitis in a PD patient. *S. canis* is transferred primarily from companion animals such as dogs and cats, though has been isolated from a myriad of other animals as well, and has been implicated in a wide variety of human infections, typically susceptible to penicillin or 3<sup>rd</sup> generation cephalosporins. Our patient later endorsed having 11 dogs at home, which were not kept out of her bedroom when performing her PD treatments, with conflicting reports of the presence of a bedroom door. This case reinforces the importance of thorough screening of the home environment of PD patients and education that pets need to be kept away during PD treatments and away from dialysis supplies. Fortunately, she experienced rapid clinical improvement with ceftriaxone, and catheter removal was deemed unnecessary. The patient continues to tolerate PD well with no further episodes of peritonitis.

## FR-PO483

**An Uncommon Cause of Peritonitis in a Peritoneal Dialysis Patient**

Karla G. Carias Martinez, Dipal Patel. *Johns Hopkins Medicine, Baltimore, MD.*

**Introduction:** Peritonitis is a common complication of peritoneal dialysis (PD), associated with significant morbidity and mortality, catheter loss and transfer to hemodialysis. It is caused mostly by gram-positive organisms. *Neisseria* species have been rarely reported as a causative agent.

**Case Description:** 28-year-old female with ESKD secondary to FSGS on automated PD presented with abdominal pain and cloudy dialysis effluent after sustaining a motor vehicle accident 2 days prior. She was hemodynamically stable with marked midline abdominal pain. Her PD catheter exit site and tunnel were clean and without evidence of inflammation or trauma, but she was noted to have milky white fluid in her catheter tubing. Labs were significant for leukocytosis of 27.5K/mm<sup>3</sup>, hemoglobin 10.4 g/dL, and lipase 15 U/L. Abdominal imaging was negative for pancreatitis, drainable fluid collections, or free air and her PD catheter was appropriately positioned. PD effluent analysis (**Table 1**) revealed leukocytosis with neutrophil predominance and a negative gram stain, with effluent amylase 8 U/L. Given ongoing suspicion for peritonitis, she was started on empiric antibiotics with IV cefepime, vancomycin, and metronidazole. After 3 days of therapy, effluent studies were repeated with improvement in cell counts (**Table 1**). Her effluent culture later grew *Neisseria gonorrhea*, after which antibiotics were narrowed to ceftriaxone to complete 14 days of treatment. Several months post-treatment, she has not had a recurrence of peritonitis and continues to perform PD successfully without significant change in her transport characteristics. Though she denied breaks in sterile technique, she did mention a preceding episode of unprotected intercourse.

**Discussion:** *Neisseria gonorrhea* is a gram-negative pathogenic microorganism that has rarely been isolated as a cause of peritonitis in patients in PD. Prior to our report, there has been only one other case report in which the patient also effectively responded to IP antibiotic therapy. *Neisseria gonorrhea* should be considered as a possible causative agent of peritonitis in young sexually active patients performing PD.

**Table 1. Peritoneal Fluid Diagnostic Studies**

PD Fluid Cell Count	Pre-Treatment	Post-Treatment
Appearance /Color	Cloudy, Yellow	Hazy, No Color
WBC Count	39,415	782
RBC Count	1,000	8
<b>PD Fluid Differential</b>		
Cells Counted	100	100
Neutrophils %	89	79
Lymphocytes %	3	6
Eosinophils %	0	0

## FR-PO484

### A Rare Case of Bacterial Peritonitis Caused by *Ralstonia mannitolilytica* in an Adult Peritoneal Dialysis Patient

Litty Thomas, Ramesh Saxena. *The University of Texas Southwestern Medical Center Department of Internal Medicine, Dallas, TX.*

**Introduction:** Peritonitis is associated with a high risk of morbidity and technique failure, mostly caused by gram-positive or gram-negative commensals. Rarely, PD patients can develop peritonitis from an unusual bacteria. We describe a case of peritonitis caused by *Ralstonia mannitolilytica*. To our knowledge, this is the first reported case of *Ralstonia* peritonitis in an adult PD patient.

**Case Description:** A 67-year-old woman with a history of end-stage kidney disease due to obstructive uropathy from renal tuberculosis, status post-Left nephrectomy, and right PCN has been on PD for 12 years, chronic Hepatitis B, atrial fibrillation, type II diabetes, and hypertension, presented to the ED a day after her routine colonoscopy with severe abdominal pain, and cloudy urinary output from the PCN. She was started on empiric antibiotic therapy. Peritoneal fluid studies were done and were consistent with peritonitis. Peritoneal fluid culture grew *E.coli*. Urine culture from the right PCN also grew *E.coli*. She was treated with a 3-week course of intraperitoneal (IP) cefazolin and ceftazidime with the resolution of peritonitis. The patient presented to the PD clinic with recurrent symptoms 2 weeks after the resolution of 1st peritonitis. PD fluid analysis was consistent with gram-negative rods. Final culture and sensitivity results showed *Ralstonia* species, which is pan-sensitive. She was treated for 3 weeks with cefepime and gentamycin IP with complete resolution of peritonitis. She presented to the ED again due to persistent abdominal pain, N/V. The PD fluid analysis confirmed the third episode of peritonitis. During the 3rd episode of peritonitis, the *Ralstonia* species was resistant to most antibiotics which were sensitive during the prior episodes. Based on the sensitivities she was treated with oral Bactrim. Recurrent infection with the same organism even after treating with appropriate antibiotics and duration raised the concern of PD catheter seeding of the organism. Hence, the PD catheter was removed, and the patient was started on hemodialysis.

**Discussion:** *Ralstonia* is Gram-negative bacteria that have the ability to pass through the filters used to sterilize the solutions, resistant to hospital disinfectants, and moreover, a tendency to form a biofilm that enhances the organism's survival and likely plays a role in their frequent antibiotic resistance.

## FR-PO485

### A Rare Case of Bilateral Pleuroperitoneal Leaks in a Patient on Peritoneal Dialysis

Bhamini Gutty, Amar M. Mahdi. *University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

**Introduction:** We present a case of bilateral pleuroperitoneal leaks in a young patient on peritoneal dialysis (PD). Pleuroperitoneal leak is a rare but important complication of PD, occurring in 1%-2% of patients. It is thought to develop due to increased intra-abdominal pressure on a background of congenital or acquired diaphragmatic defects. Patients typically present with dyspnoea but may have a reduction in ultrafiltration. Pleural effusion due to pleuroperitoneal leak is usually unilateral, most commonly on the right. Left sided pleuroperitoneal leaks are uncommon. It is thought that diaphragmatic defects are protected on the left side by the heart.

**Case Description:** This 28-year-old female, on automated PD for 9 months, presented with dyspnoea and a reduction in ultrafiltration. Chest radiograph revealed moderate bilateral pleural effusions, in a euvoelaemic patient with no prior history of heart disease. She underwent diagnostic bilateral thoracentesis which revealed transudative pleural effusions. Left and right pleural aspirates showed a glucose concentration of 16.3 mmol/L and 18.1 mmol/L respectively. Both showed negligible lactate dehydrogenase (<30 U/L) and protein levels (<8 g/L). A paired serum glucose was 3.6 mmol/L (normal range 3.9 - 5.8 mmol/L) and protein was 60 g/L (normal range 60 - 80 g/L). The presence of high pleural fluid glucose relative to serum glucose confirmed the diagnosis of bilateral pleuroperitoneal leaks. She was managed conservatively with peritoneal rest and transitioned to intermittent haemodialysis. PD was discontinued permanently with subsequent removal of her peritoneal catheter. A chest radiograph two weeks later showed complete resolution of the bilateral pleural effusions.

**Discussion:** By having a high index of suspicion in this patient with bilateral pleural effusions, an early diagnosis of bilateral pleuroperitoneal leaks was made. Although pleuroperitoneal leaks are typically right sided, it is important to recognise that clinical presentation may vary and patients can present with bilateral pleuroperitoneal leaks.

## FR-PO486

### Peritoneal Dialysis Peritonitis With *Acinetobacter pittii*

Tushar Bajaj,<sup>1</sup> Nader Ismail,<sup>1</sup> Anuja Trivedi,<sup>2</sup> Menaka Sarav.<sup>1</sup> <sup>1</sup>*University of Chicago Pritzker School of Medicine, Chicago, IL;* <sup>2</sup>*Jackson Park Hospital Foundation, Chicago, IL.*

**Introduction:** *Acinetobacter baumannii* has been reported as an uncommon cause of PD-peritonitis; however, we report the first case of PD-peritonitis caused by *A. pittii*.

**Case Description:** A 49 YO AA Male with ESRD on PD, HTN, and morbid obesity presented with a 4 day history of nausea, emesis, and diffuse abdominal pain. PD fluid was collected as outpatient and patient was started on intraperitoneal (IP) cefazolin and IP ceftazidime. Patient was PD dependent for two years, never had a prior similar episode, and was oliguric. The patient was not using the sterile aseptic technique as per usual, rather using dish towels to wipe his hand before and after accessing the transfer set. Physical exam pertinent for a distended abdomen, tenderness to light palpation, positive fluid wave, and dullness to percussion. Labs significant for leukocytosis, hypokalemia, and elevated anion gap. Records from initial sample identified organism as *Acinetobacter pittii*. Table 1 demonstrates the fluid characteristics by day. Empirically IP ceftazidime and IP gentamicin was started; however, sensitivity to ceftazidime returned at 4mcg/mL. Patient was started on IP Ceftazidime as last fill for 3 weeks initially; however, increased to 4 weeks due to persistent cloudy effluent. Unfortunately, readmitted to the hospital with abdominal pain, tachycardia, and tachypnea. Due to concerns for sepsis, increased peritoneal fluid count with the same organism, the PD catheter was subsequently removed, patient was placed on IV antibiotics and discharged with intermittent hemodialysis.

**Discussion:** *Acinetobacter pittii* is a strictly aerobic, gram-negative, non-motile, non-lactose fermenting, oxidase negative, catalase positive coccobacilli. Infections outside hospital settings are rare with such organisms, hand hygiene and infection control practices are crucial to reduce incidence. Common presentations of *acinetobacter* peritonitis include abdominal pain, cloudy dialysate fluid, and fever. Our case is important to demonstrate a rare cause of PD peritonitis, the importance of hand hygiene with sterile technique, and elucidate treatment failure.

#### Fluid Characteristics by Day

	Day 1	Day 4	Day 8	Day 28
Fluid Color	Yellow	Colorless	Colorless	Yellow
Appearance	Cloudy	Clear	Clear	Cloudy
Fluid TNC	93557	998	213	43245
Neutrophil %	80	54	57	80

## FR-PO487

### Flaccid Paralysis in Peritoneal Dialysis Patient After Using Acetazolamide

Ahmed S. Shai, Adrian J. Baudy, Farah Harasis. *Tulane University School of Medicine, New Orleans, LA.*

**Introduction:** Neurotoxicity is a serious life threatening and rare side effect of Acetazolamide (ACTZ). There are only several studies found in literature about ACTZ toxicity and pharmacokinetics in dialysis patients. Here, we describe an unusual case of a patient with end stage renal disease (ESRD) on peritoneal dialysis (PD) with normal cognitive function that presented with progressive confusion, lethargy and paralysis. We diagnosed him with ACTZ toxicity and he had a complete recovery after treatment.

**Case Description:** A 58-year-old male with ESRD due to diabetes (DM) on PD was admitted for 3 days of confusion and progressive weakness that presented with flaccid paralysis. Complete workup for cognitive impairment including blood test and images were done without identify a cause. Detailed history was taken and we determined that his symptoms started after treated with high dose of ACTZ 250 mg thrice a day as prescribed by his ophthalmologist after cataract surgery. Symptoms started after 500mg taken over 16 hours and he became paralyzed and confused after 2250 mg over 3 days. ACTZ was stopped on the day of admission, and we did daily PD. He started to improve after 3 days and completely recovered after 8 days of last dose and daily PD with total 93 hours.

**Discussion:** ACTZ is a carbonic anhydrase inhibitor commonly used to reduce intraocular pressure. Since it is entirely excreted in the urine, accumulation and severe side effects may occur with renal impairment. Toxicity is more common in advance age, diabetes, concurrent salicylates use and in renal impairment or ESRD as it depends on renal clearance. Symptoms included lethargy, drowsiness, confusion, and coma which are potentially reversible with early diagnosis and treatment. Early diagnosis is important to avoid life threatening conditions and should be considered in any patient with CKD or ESRD receiving high dose of ACTZ came with neurological symptoms or metabolic acidosis, as it blocks absorption of bicarbonate. Levels should be measured to help in the diagnosis. The drug should be stopped as soon as the diagnosis is made and started on dialysis immediately. The time of recovery vary according to patient condition and risk factors and half-life of ACTZ in PD patient according to one study is prolong to 28.5 hours with continuous PD compared to patient with normal renal function, in which the half-life is 5-10 hours.

## Developing a Predictive Model for Adverse Outcomes for Patients on Peritoneal Dialysis (PD)

Alex Blair, Yang Dai, Hwei Hsun Wen, Eric Wu, Girish N. Nadkarni, Shuchita Sharma, Jaime Uribarri, Lili Chan. *Icahn School of Medicine at Mount Sinai, New York, NY.*

**Background:** Peritonitis, cardiac events, and inadequate dialysis are leading causes of morbidity, mortality, and technique failure in PD. New automated cyclers provide remote data that may improve prediction of events

**Methods:** This is a retrospective single-center study of PD patients at the Mount Sinai Kidney Center between 2019 and 2021. We included patients >18 years of age using cyclers with data available on Shoresource. The outcome of interest was a composite of time to first peritonitis, death, or technique failure. Models were developed using Cox regression with covariates selected via univariate testing (p-value  $\leq 0.1$ ) or clinical input. Correlated covariates were removed. Model 1 included demographic variables (age, gender, race/ethnicity) and Elixhauser Comorbidity Index (ECI). Model 2 included model 1 + mean and standard deviation (SD) of 30-day Shoresource Data (blood pressure (BP), pulse, total ultrafiltration (UF), and night fill volume). Model 3 was similar to model 2 but included Shoresource data as time-varying covariates. To evaluate each model, the cohort was split into 70/30 testing and training sets and iterated 100 times. Model performance was assessed using area under the receiver operator characteristic curves (AUC) over time

**Results:** We identified 95 patients with complete remote data, 59 with composite endpoint and 36 controls. Patients with the composite outcome were older (59 vs. 53), more often male (59% vs. 39), and had higher ECI (7.9 vs 5.8). With univariate testing, ECI, BP SD, and total UF SD were significantly associated with events. Model 3 which included the Shoresource data as time-varying covariates had the best performance with an average AUC of 0.724 (Figure 1). In all models, performance was best during the first 6 months of follow-up

**Conclusions:** Addition of Shoresource data as a time-varying covariate improved model performance for prediction of a composite clinical outcome. This model could be used to identify new start PD patients who are at high risk of adverse outcomes

Figure 1: 12-month time-varying ROC curves of models 1 (AUC 0.56), 2 (AUC 0.69), and 3 (AUC 0.72)

## FR-PO489

## A Dominican Republic National Health System Retrospective Multi-center Peritonitis Study in Peritoneal Dialysis Patients According to the 2022 ISPD Guidelines

Erwin I. Campos,<sup>1,2</sup> Elianny S. Polanco,<sup>1</sup> Sergio O. Hernandez-Ordóñez,<sup>1</sup> Mercedes Aquey,<sup>1</sup> Janny Guzman Chavez,<sup>1</sup> Miguel A. Cuevas Budhart,<sup>3</sup> Jose C. Divino-Filho,<sup>4</sup> Alfonso Ramos,<sup>1</sup> Macrotech *Macrotech, Santo Domingo, Dominican Republic;* <sup>2</sup>Hospital Salvador Bienvenido Gautier, Santo Domingo, Dominican Republic; <sup>3</sup>Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico; <sup>4</sup>Division of Renal Medicine, CLINTEC, Stockholm, Sweden.

**Background:** Among the peritoneal dialysis (PD) complications, those microbial related or infectious peritonitis figures as the most frequent. Peritonitis (P) is recognized as one of the main causes of technique failure and HD transfer. It is associated with faster loss of residual renal function, greater peritoneal membrane damage (sclerosis) and consequently PD adequacy issues. Also, those with P have a lower quality of life and impose a higher healthcare expenditure<sup>(1)</sup>. Early on this year, the ISPD recommended a new target for the overall peritonitis rate and the percentage of patients free of P per unit time<sup>(2)</sup>. Our aim is to apply these new ISPD targets to our 7-year PD cohort.

**Methods:** A retrospective, multicentric, and descriptive cohort study in patients with PD, belonging to the National Health System of the Dominican Republic. Conducted between January 1, 2016, and December 31, 2021. Sociodemographic data and disease characteristics were included. Quantitative variables are expressed as mean  $\pm$  standard deviation, while qualitative variables were presented with absolute and relative frequencies. In addition, the incidence of peritonitis rate, HD transfer, deaths, and cure was analyzed. The Peritonitis was diagnosed according to the ISPD guidelines.

**Results:** A total of 4,575 PD patients were included, 57% men; the mean age was 49  $\pm$  19 years, 53% had Diabetes Mellitus (DM) diagnosis, and 65% had a basic educational level. Patients censored were 151 (11%). 575 peritonitis episodes were recorded, the median time to the 1st peritonitis event was 476 days, 81% episodes cured, 10% were transfer to HD 7.3% death, and 63 patients present more than 1 peritonitis episode. The overall peritonitis rate was 0.13/year, having 53% of positive cultures.

**Conclusions:** Our PD program showed a superior peritonitis rate than that recommended by the new ISPD 2022 guidelines. We found no difference between our HD transfer rate and that reported by other programs. We still need to improve our culture-negative peritonitis rates which are high (47%). As a result of our continuous quality improvement (CQI) program, home visit, and follow-up protocol explains the median time to the 1st peritonitis event, far beyond the year.

## FR-PO490

## The Prevalence of Frailty in Patients on Peritoneal Dialysis

Yi-Ting Chen, Shuei-Liong Lin, Yung-Ming Chen. *National Taiwan University Hospital, Taipei, Taiwan.*

**Background:** Frailty is an age-related disorder and it is associated with fall, hospitalization and mortality. Recent studies displayed high prevalence of frailty in chronic kidney disease and hemodialysis population but the study of patients under peritoneal dialysis (PD) was rare. The aim of this study was to evaluate the prevalence of frailty in patients on PD.

**Methods:** We prospectively enrolled patients under PD. The Asian Working Group for Sarcopenia criteria, the Fried Frailty phenotype and the Frailty Index 80 (FI<sub>80</sub>) were used to diagnose sarcopenia and frailty and second times survey were measured after 6 months.

**Results:** Totally 337 patients under PD had been enrolled since Jan. 01 to Dec. 31, 2020. 258 of whom were prevalent PD patients and others were incident PD patients. The prevalence of frailty in all patients were 73 (21.7%). Incident PD patients had initially higher frailty rate and improved after starting dialysis. Although elderly patients (age>75 years) had initially improved frailty but aggravated when dialysis more than 5 years.

**Conclusions:** Dialysis improved frailty in incident PD patients and frailty transitions were common in prevalent PD patients. However, frailty in elderly patients with PD more than 5 years was worse.

## FR-PO491

## Increased Access, Widened Inequities: Trends in Disparities in Peritoneal Dialysis Access, 2010-2020

Christopher D. Knapp,<sup>1</sup> Jiannong Liu,<sup>2</sup> Haifeng Guo,<sup>2</sup> Eric D. Weinhandl,<sup>3,2</sup> James B. Wetmore,<sup>2,4</sup> Kirsten L. Johansen.<sup>2,4</sup> *<sup>1</sup>Hennepin Healthcare, Minneapolis, MN; <sup>2</sup>Hennepin Healthcare Research Institute, Minneapolis, MN; <sup>3</sup>Satellite Healthcare, San Jose, CA; <sup>4</sup>University of Minnesota Twin Cities, Minneapolis, MN.*

**Background:** The percentage of incident dialysis patients electing PD as their initial dialysis modality increased over the last decade. Prior to 2010, PD rates were lower among patients of lower socioeconomic status, older age, urban residence, and Black and Hispanic race/ethnicity. We examined how the increased uptake of PD has changed these disparities.

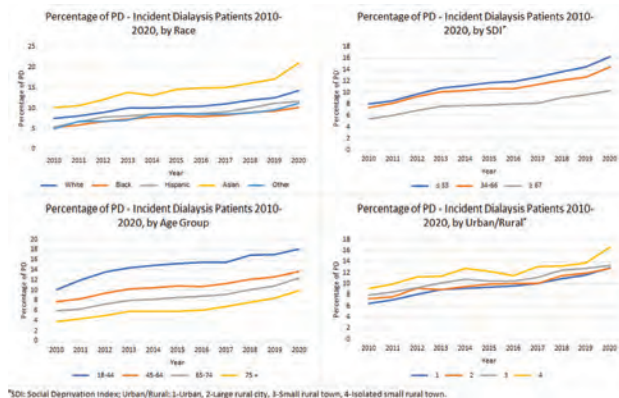

**Methods:** We used USRDS data to generate PD usage rate among demographic groups of interest (race/ethnicity, neighborhood characteristics using the Social Deprivation Index (SDI), sex, age, rural/urban residence) for incident ESKD patients on dialysis in the US each year between 2010-2020. We analyzed the change and difference of change of PD rate among these groups using generalized linear regression.

**Results:** The proportion of incident dialysis patients selecting PD approximately doubled over the period. Rates of PD usage among incident patients increased more among Asian patients relative to White patients (0.88% annual increase vs 0.58%) and more among White than among Black patients (0.43% per year). The proportion initiating dialysis using PD also increased faster in more advantaged neighborhoods relative to less advantaged ones (0.74% for SDI  $\leq 33$  vs. 0.43% for SDI  $\geq 67$ ). Younger patients experienced higher annual increases in PD usage (0.68% for 18-44 vs. 0.50% for age 75+), but older patients had the highest growth in PD use compared to their 2010 baseline (255% increase from 2010 to 2020 for 75+ vs. 178% for 18-44).

**Conclusions:** The increase in PD use resulted in worsened disparities among race groups and SDI groups, in an absolute sense. However, PD access for older patients grew substantially, perhaps as a result of improved payment incentives or increased provider comfort with PD in this population. Further studies of racial and economic disparities in PD access are indicated.

**Funding:** NIDDK Support

Trend of PD access (% of all incident dialysis patients among age, race, SDI, and rural/urban groups)

## FR-PO492

### Peritoneal Transport of Small and Large Solutes During Long Dwells With Icodextrin

Bengt Lindholm,<sup>1</sup> Joanna Stachowska-Pietka,<sup>2</sup> Jacek Waniewski,<sup>2</sup> Anna Olszowska,<sup>3</sup> Elvia Garcia-lopez,<sup>1</sup> Zofia Wankowicz,<sup>2</sup> <sup>1</sup>Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Instytut Biocybernetyki i Inżynierii Biomedycznej im Macieja Nalecia Akademii Nauk, Warszawa, Poland; <sup>3</sup>Wojskowy Instytut Medyczny, Warszawa, Poland.

**Background:** Whereas icodextrin maintains effective ultrafiltration during long exchanges, data on solute removal and kinetics in long dwells with icodextrin are more scarce. We investigated impact of dwell duration up to 16h on the removal of small and large solutes.

**Methods:** Twenty patients underwent 16-h dwell with icodextrin. I-albumin was used as volume marker and frequent dialysate plasma samples were taken during the dwell. Clearances were evaluated at 4, 8, and 16-h of dwell for glucose, urea, creatinine, sodium, potassium, b2-microglobulin, total proteins, albumin, and IgG as the mass removed divided by the solute average plasma concentration and dwell duration.

**Results:** Ultrafiltration was increasing during the whole dwell to  $0.7 \pm 0.3$  L after 16h. Lower small solutes clearances were found after 4h for glucose (on average from  $5.7 \pm 1.2$  at 4h to  $3.0 \pm 0.7$  at 16h), urea ( $5.2 \pm 0.9$  to  $3.0 \pm 0.5$ ), creatinine ( $4.8 \pm 1.0$  to  $2.9 \pm 0.5$ ), and potassium ( $4.6 \pm 0.9$  to  $2.5 \pm 0.5$ ) mL/min and decreased only between 4 and 8h for sodium ( $1.2 \pm 0.8$  to  $0.8 \pm 0.4$ ) mL/min with  $p < 0.001$ . Moreover, although small solute concentrations in dialysate increases, they were not fully equilibrated with plasma (D/P being lower than 1 after 16h in case of urea, creatinine, potassium and sodium,  $p < 0.001$ ). Increase of urea and creatinine plasma concentration (by 6 and 4%, respectively) at 16 vs. 4h was found ( $p < 0.001$ ). In case of larger molecules, a decrease from 4 to 8h was found for b2-microglobulin ( $1.5 \pm 0.5$  to  $1.2 \pm 0.4$ ) mL/min, total proteins ( $85.9 \pm 29.9$  to  $70.1 \pm 25.0$ ), albumin ( $90.4 \pm 34.6$  to  $75.8 \pm 29.1$ ), and IgG ( $74.1 \pm 28.0$  to  $60.5 \pm 23.5$ )  $\mu$ L/min with  $p < 0.001$ , whereas after 8h it was significant only in case of IgG and total proteins with  $p < 0.05$ , reaching at 16h  $56.0 \pm 19.6$  and  $61.4 \pm 18.4$   $\mu$ L/min, respectively.

**Conclusions:** The rate coefficient (clearance) of small and large solute removal slows down with dwell time but is still maintained at 16-h dwell with icodextrin, especially for small solutes that are not fully equilibrated at the end of the dwell.

**Funding:** Government Support - Non-U.S.

## FR-PO493

### Peritoneal Small Solute Transfer Rate (PSTR) vs. Clinical Outcome in Peritoneal Dialysis Patients: Assessment by Restricted Mean Survival Times (RMST)

Rafael A. Gomez,<sup>1</sup> Bengt Lindholm,<sup>2</sup> Abdul Rashid T. Qureshi,<sup>2</sup> <sup>1</sup>Servicio de Terapia Renal Cali SAS, Cali, Colombia; <sup>2</sup>Karolinska Institutet, Stockholm, Sweden.

**Background:** Fast PSTR is in most studies linked to worse outcomes. To explore the impact of PSTR on clinical outcomes in patients undergoing chronic peritoneal dialysis (PD) in Colombia, we analyzed RMST, a robust and clinically interpretable measure that quantifies the entire observed survival curve.

**Methods:** In a cross-sectional study using peritoneal equilibration test (PET), 8170 prevalent PD patients, 2705 on APD and 5465 on CAPD, were classified by PSTR according to Twardowski method into slow (16.0%), slow average (35.4%), fast average (32.9%) and fast (15.7%) PSTR categories. Demographic and clinical variables were recorded. During follow-up for a median of 1.99 years, 2633 patients died, and 661 patients underwent renal transplantation. All-cause mortality, cardiovascular disease (CVD) mortality, and technique survival were analyzed with RMST and restricted mean time lost (RMTL), adjusting for age, sex, body mass index, albumin, Hb, phosphate, residual renal function, presence of diabetes and hypertension.

**Results:** RMST analysis showed that fast PSTR as compared to slow PSTR associated with shorter patient survival due to all-cause mortality (by -0.28 years;  $p = 0.003$ ) or due

to CVD related mortality (by -0.18 years;  $p = 0.05$  as well as shorter technique survival (by -0.22 years;  $p = 0.03$ ) whereas associations of fast-average PSTR with clinical outcomes were not statistically significant.

**Conclusions:** Analysis using RMST confirms that fast PSTR as compared to slow PSTR is associated with impaired patient and technique survival. However, the magnitude of the survival disadvantage (about 0.2 years) may not be clinically significant.

**Funding:** Commercial Support - Baxter Healthcare Corporation, Government Support - Non-U.S.

## FR-PO494

### Consistency in Membrane Transport in Early and Later Peritoneal Equilibration Testing

Paul E. Smith,<sup>1</sup> Michelle Carver,<sup>2</sup> Christopher R. Rutzen,<sup>1</sup> Sarah Ledoux,<sup>1</sup> Samantha Draughon,<sup>1</sup> Angela L. Davis,<sup>1</sup> Bridget R. Robideaux,<sup>1</sup> Selma Johnson,<sup>1</sup> Joanna Willetts,<sup>2</sup> Sheetal Chaudhuri,<sup>2</sup> John W. Larkin,<sup>2</sup> Dinesh K. Chatoth,<sup>1</sup> The Early PET Group <sup>1</sup>Fresenius Kidney Care, Waltham, MA; <sup>2</sup>Fresenius Medical Care, Global Medical Office, Waltham, MA.

**Background:** The peritoneal equilibration test (PET) has been recommended to be done 6-12 weeks after starting peritoneal dialysis (PD) (Morelle, Perit Dial Int 2021). The PET requires a special overnight pre-exchange process and 4-hour dwell in the clinic, which can be challenging for patients to complete. This can be seen by estimates suggesting >30% PD patients do not have a PET (Mehrotra, CJASN 2015). There is a lack of evidence defining optimal timing for the PET and it might be easier for patients to complete during PD training. We conducted a quality improvement pilot to evaluate if repeated PET results differ during training versus 6-12 weeks after PD start.

**Methods:** From Jan 2020 to Aug 2021, incident PD patients treated at a network of clinics could have a PET ordered during in-center training (typically the first 14 days of PD) and 6-12 weeks after PD start. The D/D0 glucose (ratio of dialysate glucose at 4 vs 0 hours) and D/P creatinine (ratio of dialysate vs plasma creatinine at 4 hours) was assessed between each patient's two PET tests using correlation statistics and ANOVA.

**Results:** Forty-four PD patients from 32 clinics (mean age  $55 \pm 13$  years, 43% female, 50% Black race, 11% Hispanic ethnicity, and 61% with diabetes) had a PET during training and another repeated later (mean=52 days & median=47 days between PETs). There were strong correlations in D/D0 glucose (correlation coefficient=0.45,  $p < 0.001$ , Figure 1A) and D/P creatinine (correlation coefficient=0.43,  $p < 0.001$ , Figure 1B) between the PET during training versus 6-12 weeks after PD start.

**Conclusions:** We found the profiles of peritoneal membrane solute transport identified in the PET during training were significantly correlated to and representative of the membrane transport kinetics performed 6-12 weeks after initiation of PD. It appears the membrane transport characteristics are reasonably consistent throughout the first months of PD.

## FR-PO495

### Successful Measurement of Intraperitoneal Pressure (IPP) in Peritoneal Dialysis Patients With a Pressure Transducer Demonstrates Significant Interindividual Variation and a Complex Relationship With IP Volume

Jaime Uribe,<sup>1</sup> Nabeel Aslam,<sup>2</sup> Shuchita Sharma,<sup>1</sup> Marzuq M. Billah,<sup>1</sup> Alyssa Wilmington,<sup>3</sup> Brad Keller,<sup>3</sup> Matthew R. Muller,<sup>3</sup> Peter Rutherford,<sup>3</sup> <sup>1</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>2</sup>Mayo Clinic Florida, Jacksonville, FL; <sup>3</sup>Baxter International Inc, Deerfield, IL.

**Background:** High IPP has been linked to abdominal fullness, mechanical complications and reduced ultrafiltration. Studying IPP is limited by the cumbersome manual fluid manometry method. A device making IPP measurement easier to conduct regularly may assist clinicians to adjust prescribed fill volumes (V). This study determined whether pressure-transducer IPP measurement is related to manual IPP measurement and fill volume.

**Methods:** IPP measured by a commercially-available transducer was compared to IPP measured simultaneously by fluid manometry in a PD disposable set in 10 APD patients over 3 replicate fill cycles. IPP was measured after the drain, after 750ml fill volume and after 5 additional equidistant increments [(prescribed fill volume - 750ml)/5] up to the individual's prescribed fill volume.

**Results:** There was moderate overall agreement between transducer and manual IPP measurements ( $\pm 3$  cm H<sub>2</sub>O, Figure 1), with no systematic biases observed across the range of measured IPP. Large inter-patient variability in IPP was observed; at 750 ml of fill volume, IPP varied from 4-20 cm H<sub>2</sub>O. There was a lack of correlation between the transducer derived IPP and fill volume among the patients (Spearman correlation coefficient 0.2). All 10 patients showed a significant relationship between IPP and IPV

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

at an individual level, but with significant inter-patient variation in slope and intercept of the best fit line. A potential joint relationship between IPP, IPV and patient weight was observed

**Conclusions:** IPP can be measured with a pressure transducer, results are similar to the manual method but is easier to perform. IPP is highly variable across individuals and has complex relationships with fill volume in individual patients meriting further study to determine the clinical utility of IPP measurement

**Funding:** Commercial Support - Baxter

**Figure 1 Scatterplot of Transducer-derived IPP vs Manual IPP**

## FR-PO496

### Assessment of Fluid Transport Between Extra- and Intraperitoneal Spaces During Peritoneal Dialysis Using Segmental Bioimpedance

Fansan Zhu,<sup>1</sup> Laura Rosales,<sup>1</sup> Lela Tisdale,<sup>1</sup> Maricar Villarama,<sup>3</sup> Peter Kotanko.<sup>1,2</sup> <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>3</sup>Mount Sinai Hospital Mount Sinai Heart, New York, NY.

**Background:** In peritoneal dialysis (PD), ultrafiltration (UF) failure is generally attributed to excessive absorption of dialysate from the peritoneal cavity. Currently, we are lacking methods to measure the peritoneal fluid absorption rate. Our goal was to evaluate whether fluid absorption and UF can be assessed by monitoring intraperitoneal fluid volume using segmental bioimpedance analysis (SBIA).

**Methods:** Twenty PD patients were studied during either a peritoneal equilibration test (PET; n=7) or automated PD (APD; n=13). Eight electrodes were placed on the lower abdomen (Fig.1) and connected to a bioimpedance device (Hydra 4200). The abdominal extracellular volume ( $V_{ABD}$ ) was measured comprising the tissues surrounding the peritoneal cavity ( $V_{EPF}$ ) plus the intraperitoneal ( $V_{IPF}$ ) fluid (Fig.2). Baseline was defined as the  $V_{ABD}$  at the state prior to dialysate fill ( $V_{IPF} = 0$ ).  $\Delta V_{EPF}$  was calculated after dialysate drainage ( $V_{IPF} = 0$ ) minus the baseline.  $\Delta V_{Dwell}$  was defined as  $V_{ABD}$  at the end, minus  $V_{ABD}$  at the start of the dialysate dwell. The change in  $\Delta V_{Dwell}$  was due to UF or fluid absorption. The clinically measured UF volume ( $UFV_{Clin}$ ) was calculated as the weight of the drained dialysate fluid minus the dialysate fill (2 L; approximated as 2 kg).

**Results:**  $UFV_{Clin}$  and  $UFV_{SBIA}$  were highly correlated (PET:  $R^2=0.98$ ,  $p<0.0001$ ; APD:  $R^2=0.94$ ,  $p<0.0001$ ) (Fig.3).  $\Delta V_{Dwell}$  decreased in eight patients (2 PET; 6 APD) (Fig.4) which indicated absorption of  $V_{ABD}$ ; it was stable in nine patients (4 PET; 5 APD) (Fig.5) and increased in three (1 PET; 2 APD). Stable  $\Delta V_{EPF}$  ( $\Delta V_{EPF}=0$ ) was observed in three PET patients, allowing us to explore its association with membrane transport status; notably, stable  $\Delta V_{EPF}$  was associated with high glucose transport.

**Conclusions:** This pilot study demonstrated a new bioimpedance approach to monitor fluid changes between extra- and intraperitoneal compartments. If confirmed in a larger population, the method may provide a direct measurement of fluid transport across the peritoneal membrane.

### Genetic Determinants of Ultrafiltration With Peritoneal Dialysis

Ian B. Stanaway,<sup>1,12</sup> Olivier Devuyst,<sup>2,5</sup> Jeffrey Perl,<sup>3</sup> Mark Lambie,<sup>4</sup> Johann Morelle,<sup>5</sup> Gail P. Jarvik,<sup>1</sup> Arsh Jain,<sup>9</sup> Jonathan Himmelfarb,<sup>1,12</sup> Olof Heimbürger,<sup>8</sup> David W. Johnson,<sup>10,11</sup> James L. Pirkle,<sup>6</sup> Bruce M. Robinson,<sup>7</sup> Peter Stenvinkel,<sup>8</sup> Simon J. Davies,<sup>4</sup> Rajnish Mehrotra.<sup>1,12</sup> Bio-PD Consortium <sup>1</sup>University of Washington School of Medicine, Seattle, WA; <sup>2</sup>University of Zurich, Zurich, Switzerland; <sup>3</sup>University of Toronto, Toronto, ON, Canada; <sup>4</sup>Keele University, Keele, United Kingdom; <sup>5</sup>Cliniques Universitaires Saint-Luc, Brussels, Belgium; <sup>6</sup>Wake Forest University, Winston-Salem, NC; <sup>7</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>8</sup>Karolinska Universitetssjukhuset, Stockholm, Sweden; <sup>9</sup>London Health Sciences Center, London, ON, Canada; <sup>10</sup>Princess Alexandra Hospital, Woolloongabba, QLD, Australia; <sup>11</sup>The University of Queensland, Saint Lucia, QLD, Australia; <sup>12</sup>Kidney Research Institute, Seattle, WA.

**Background:** The inter-individual variability in the peritoneal dialysis (PD) ultrafiltration (UF) capacity is largely unexplained by demographic and clinical variables. We tested the hypothesis that common genetic variants are associated with variability in UF.

**Methods:** The Bio-PD study enrolled participants from 69 centers in 6 countries. The phenotype of UF volume at 4 hours was obtained from the 1<sup>st</sup> peritoneal equilibration test (PET) when starting PD. Genotyping was done with the Illumina InfiniumOmni2-5 array and imputed using the Michigan Imputation Server. Heritability was estimated using genomic-restricted maximum likelihood analysis, genome-wide association was performed for single nucleotide variants (SNVs) with minor allele frequency >2%, and gene-wise analyses were done with the Generalized Berk-Jones test. Analyses were adjusted for sex, age, body mass index, country, diabetes, dialysate dextrose concentration, interval between PD start and PET, and principal components of ancestry. Additional analyses included 4-h Dialysate/Plasma (D/P) creatinine ratio as covariate.

**Results:** Analysis included 2413 participants (64% men, 32% diabetes, 82% White). The PETs were done at a median of 63 days (IQR 36-121) from PD start, 78% were completed with 2.5% dextrose, with a mean 4-h D/P creatinine of 0.70 and a median UF of 250mL (IQR 0-494). The heritability of UF was estimated at 58% and 42% in models without and with 4-h D/P creatinine, respectively ( $p=6 \times 10^{-4}$  and 0.01). No SNV reached genome-wide significance using 7,052,235 SNVs. Analyses testing association with 18,330 genes showed significant association of 3 genes at a false discovery rate (FDR) <10% (*PTGES* FDR=0.02, *GPHN* FDR=0.04, *SLC24A3* FDR=0.05). Further adjustment for 4-h D/P creatinine showed association with 2 genes remained significant (*PTGES* and *SLC24A3*).

**Conclusions:** Common genetic variants account for a substantial proportion of the variability in UF and these analyses suggest a potential association with variation in *PTGES* and *SLC24A3* genes.

## FR-PO498

### Phloretin Improves Ultrafiltration and Reduces Glucose Absorption During Peritoneal Dialysis in Rats

Karin Bergling, Giedre Martus, Carl M. Öberg. Lunds Universitet, Lund, Sweden.

**Background:** Harmful glucose exposure and absorption remain major limitations of peritoneal dialysis. We previously showed that inhibition of sodium glucose co-transporter 2 did not affect glucose transport during peritoneal dialysis in rats. However, more recently we found that phloretin, a dual blocker of sodium glucose co-transporter 1 and 2, was effective in reducing glucose diffusion in peritoneal dialysis, implicating either that sodium glucose co-transporter 1 inhibition or blockade of facilitative glucose channels by phloretin metabolite phloretin would be effective in reducing glucose transport in peritoneal dialysis.

**Methods:** Here we tested a selective blocker of sodium glucose co-transporter 1, mizagliflozin, as well as phloretin, a non-selective blocker of facilitative glucose channels in an experimental model of peritoneal dialysis in anesthetized Sprague-Dawley rats.

**Results:** Intra-peritoneal phloretin treatment reduced glucose absorption by more than 30% and resulted in a more than 50% higher ultrafiltration rate compared to control animals. Sodium removal and sodium clearances were similarly improved, whereas there was no difference in the amount of ultrafiltration per mmol sodium removed. Mizagliflozin did not influence glucose transport or osmotic water transport.

**Conclusions:** Taken together, our present and previous results indicate that blockers of facilitative glucose channels may be a promising target for reducing glucose absorption and improving ultrafiltration efficiency.

**Funding:** Government Support - Non-U.S.

**Association of Bioimpedance Guided Fluid Management in Patients Receiving Peritoneal Dialysis and Cardiovascular Outcomes: A Systematic Review and Meta-Analysis**  
Sara S. Almutair, Conor S. Judge, Abdulmajeed A. Alsadhan, K. S. Brimble, Peter Margetts. *McMaster University, Hamilton, ON, Canada.*

**Background:** Fluid management in patients receiving peritoneal dialysis is a major challenge for nephrologists. This systematic review and meta-analysis evaluates the association with bioimpedance guided fluid management in patients receiving peritoneal dialysis and cardiovascular outcomes.

**Methods:** PubMed, Embase and CENTRAL were searched from database inception to 09-Jan-2022 for randomized clinical trials comparing bioimpedance and clinical examination guided fluid management in patients receiving peritoneal dialysis. A random-effects meta-analysis was used to estimate the pooled treatment-effect. The primary outcome measure was a composite cardiovascular outcome. Secondary outcome measures included all-cause mortality, cardiovascular mortality, hospitalizations, technique failure, change in systolic blood pressure (mmHg), weight (kg) and urine output (ml/day).

**Results:** Seven trials were eligible for inclusion (n=1238) (mean follow-up: 19 months). The association of bioimpedance guided fluid management compared to clinical examination guided fluid management and cardiovascular outcomes was not-significant (Odds Ratio (OR) 0.81, 95% Confidence Interval (CI), 0.49-1.33; Absolute Risk Reduction (ARR) 2.2%, -3to7.1). Bioimpedance guided fluid management compared to clinical examination guided fluid management was associated with a significant reduction in cardiovascular mortality (OR 0.50, 95%CI, 0.26-0.98, ARR 4.5%, 0.3-8.7), systolic blood pressure (mean reduction -0.2 mmHg [-0.36 to -0.04]) but not all-cause mortality, weight (kg) or residual urine output (ml/day).

**Conclusions:** Bioimpedance guided fluid management in patients receiving peritoneal dialysis compared to control was not associated with a lower incidence of cardiovascular outcomes. However, bioimpedance guided fluid management, compared to control, was associated with statistically significant lower cardiovascular mortality and lower systolic blood pressure without a reduction in residual urine output.

FR-PO500

**Peritoneal Dialysis Modality Survival**  
Antonia Harford,<sup>1</sup> S. Paine,<sup>1</sup> Nien Chen Li,<sup>1</sup> Karen M. Majchrzak,<sup>1</sup> Christos Argyropoulos,<sup>2</sup> Maria-Eleni Roumelioti,<sup>2</sup> V. Shane Pankratz,<sup>2</sup> Dana Miskulin,<sup>3</sup> Daniel E. Weiner,<sup>3</sup> Caroline M. Hsu,<sup>3</sup> Harold J. Manley,<sup>1</sup> Page Salenger,<sup>1</sup> Doug Johnson,<sup>1</sup> Eduardo K. Lacson.<sup>1,3</sup> <sup>1</sup>Dialysis Clinic Inc, Nashville, TN; <sup>2</sup>University of New Mexico Health Sciences Center, Albuquerque, NM; <sup>3</sup>Tufts Medical Center, Boston, MA.

**Background:** Given limited modality longevity, we evaluated incident peritoneal dialysis (PD) patients at different time points after ESRD start date to identify modifiable factors to improve modality survival.

**Methods:** Incident dialysis patients treated by a national not-for-profit dialysis provider from Jan 2010-Dec 2019 were included in multivariable time-dependent survival analyses. A priori, patients were stratified into 3 groups: PD as initial modality; early conversion from HD to PD (<90 days); or late conversion to PD (≥90 days). Other model variables included patient and facility characteristics. The outcome of interest was sustained transfer to HD for >90 days. Transplant, death or dialysis withdrawal while remaining on PD were considered as competing events. Patients were censored at 5 years follow-up, loss to follow-up or study end.

**Results:** Among 5173 PD patients, 3132 patients initiated dialysis with PD, 937 transitioned early and 1104 transitioned late; 1459/5173 (28%) of the entire cohort subsequently switched from PD to HD. Patients who initiated dialysis with PD were at lowest risk of modality switch, while those with ≥2 peritonitis episodes had the highest risk of modality switch. Prior HD exposure was associated with lower PD modality survival, while higher renal (K<sub>rt</sub>/V) and peritoneal (K<sub>pt</sub>/V) clearances and higher serum albumin were associated with lower modality switch risk (Table). Patient age, sex, race, ESRD cause, number of training days, PD program size and year of training were not significant.

**Conclusions:** Initiating dialysis with PD is associated with increased modality survival while other potentially modifiable factors including peritonitis are associated with decreased PD longevity, highlighting potential strategies including preserving residual renal function and peritoneal membrane function which may increase PD modality survival.

Table: Significant factors associated with patient modality switch from PD to HD		
Variable	Hazard Ratio	95% Confidence Interval
Peritonitis episodes, ≥2 vs none	5.41	4.61, 6.36
Peritonitis episode, 1 vs none	3.22	2.82, 3.69
Late vs Immediate PD start	1.43	1.26, 1.63
Early vs Immediate PD start	1.21	1.05, 1.39
BMI, per 5 kg/m <sup>2</sup> increase	1.07	1.04, 1.11
K <sub>rt</sub> /V, per 0.1 unit increase	0.93	0.92, 0.95
K <sub>pt</sub> /V, per 0.1 unit increase	0.98	0.96, 0.99
Albumin, per 0.1 g/dL increase	0.93	0.92, 0.94

FR-PO501

**Rheologic and Fill/Drain Pressure Differences Between a Novel Gravity-Based Automated Peritoneal Dialysis Cyclers (APD) and Conventional Pump-Based Cyclers**  
Steve J. Lindo,<sup>1</sup> Rick Pendergraft,<sup>1</sup> Jacob D. Henderson,<sup>1</sup> James A. Sloand.<sup>1,2</sup> <sup>1</sup>Simergent, LLC, Oklahoma City, OK; <sup>2</sup>Division of Kidney Diseases and Hypertension, Washington, DC.

**Background:** APD offers patients selecting Peritoneal Dialysis (PD) greater convenience, autonomy, & lifestyle flexibility than Continuous Ambulatory PD. APD is the predominant mode of PD in the US and other countries. PD fluid inflow and outflow in most contemporary APD cyclers is pump, rather than gravity-based, technology integrated into cyclers for travel portability. However, a previous study showed PD patients and RNs prefer the features of a quiet, gravity-based cycler with reduced setup time and portability within the home over current pump-driven cyclers. Data have also shown increased delivery/suction pressures generated by pump-driven PD flow can be associated with patient complaints of drain pain and tidal PD used to help address it. Tidal PD is the leading contributor to development of increased intraperitoneal volume (IIPV), a complication potentially leading to patient morbidity and mortality. This evaluation assessed pressures & fill/drain flow rates generated by a novel gravity-based APD cycler and current commercially-available pump-based APD cyclers.

**Methods:** Manufacturer-specified\* rheologic and fill/drain pressure differences for pump-based cyclers were compared to gravity-based Archimedes cycler test results†. These fill/drain flow rate tests were conducted *in vitro* using 71 cm bed height, 305 cm patient line, 15 cm transfer set, and a 60 cm curled catheter placed inside a container. A 140 cm heater bag height and 30 cm drain container height were used.

**Results:** Comparative filling and draining pressures & flow characteristics of three cyclers are shown below.

**Conclusions:** The novel Archimedes gravity-based APD cycler with features previously demonstrated to be preferred by patients and PD RNs achieves comparable rheologic benchmarks using inflow (fill) and outflow (drain) pressures that are much lower than current pump-based cyclers by leveraging continuous flow vs. pulsatile flow. The former has the potential to significantly improve patient experience and reduce drain pain complaints.

FR-PO502

**The Impact of Urgent Start Peritoneal Dialysis on Patient Outcomes**  
Rachel A. Lasky,<sup>1</sup> Sheetal Chaudhuri,<sup>1</sup> Derek M. Blankenship,<sup>1</sup> Michael A. Kraus,<sup>1</sup> Murat Sor,<sup>2</sup> Dinesh K. Chatoth.<sup>1</sup> <sup>1</sup>Fresenius Medical Care, Waltham, MA; <sup>2</sup>Azura Vascular Care, Malvern, PA.

**Background:** In the last decade, there has been significant interest in urgent start PD (USPD), defined as use of PD catheter within 14 days of insertion, as a viable option for patients initiating dialysis. This strategy helps increase PD use in a population that typically would have started on HD. Studies have reported higher rate of pericatheter leaks, exit site infections and peritonitis in patients who started USPD compared to conventional starts at FKC clinics.

**Methods:** All FKC PD patients that had a peritoneal catheter placed at an outpatient surgical center or hospital between August 1, 2019 and August 31, 2021 were included. Unadjusted logistic regression was used to compare patients based on the number of days between catheter placement and the first PD treatment: urgent start ( $\leq 14$  days) or conventional start ( $>14$  days). Catheter leaks, peritonitis events, and exit site infections within the first 90 days following catheter placement were identified using electronic medical records. Patient dialysis treatment data were used to identify breaks in training treatments (three days or more between treatments) and back-up treatments.

**Results:** 5,429 urgent start and 17,435 conventional start patients were included. Urgent start patients had 1.3 time the odds of peritonitis when compared to conventional start patients (2.5% vs 1.9%;  $p=0.01$ ). Urgent start patients also had 2.5 times the odds to experience leaks (1.1% vs 0.4%;  $p<0.0001$ ) and 1.5 times the odds to have a break in training treatment ( $p<0.0001$ ). However, urgent start patients had 0.5 times the odds to have a back-up in-center treatment during training ( $p<0.0001$ ). There was no significant difference between groups in exit site infections.

**Conclusions:** In this large incident PD cohort, while USPD patients were more likely to have peritonitis, pericatheter leaks and break in training treatments, rates of both complications in both groups are quite low. Interestingly, the leaks or mechanical complications associated with PD catheters in USPD patients did not result in significant HD backup treatments but were successfully managed with break in PD training treatments.

**Funding:** Commercial Support - Fresenius Medical Care

CATEGORY		N PATIENTS			
Urgent Start ( $\leq 14$ days)		5,429

FR-PO503

**Analysis of an On-Call Peritoneal Dialysis Support in an Outpatient Reference Care Center**  
Christian Albert,<sup>1,2</sup> Philipp Kalk,<sup>1</sup> Rainer P. Woitas,<sup>1</sup> Annemarie Albert.<sup>1</sup> <sup>1</sup>Diaverum Deutschland GmbH, Potsdam, Germany; <sup>2</sup>University Clinic for Cardiology, Magdeburg, Germany.

**Background:** To analyze the nature of medical or technical emergency issues of ambulatory peritoneal dialysis (PD) patients calling an after-hours emergency support of a PD reference center that is provided all year.

**Methods:** We retrospectively analyzed patient issues directed to an on-call PD support service comprising complete years from 2015-2021. Calls were systematically categorized being technical/procedural-, medical-, material-related or type of correspondence and analyzed for necessity and urgency. Patients' chief complaint, resolution and association to current PD treatment and modality were documented in protocols. Call outcomes were classified according to whether patients were able to initiate/resume/finalize their treatments or whether additional interventions were required.

**Results:** In total 753 calls were categorized and evaluated. Of those, 51% (N=384) were related to technical issues, 12.35% (N=93) to medical, 10.62% (N=80) to material related issues and 19.21% (N=144) were other correspondences. 6.24% (N=47) were associated with (intermittent)-PD performed in a teaching hospital. Calls peaked at 6:49 a.m. and 6:28 p.m. (each  $\pm 2:36$  hours). We identified 504 calls (66.9% of total calls) with an "immediate consequence". Of those 69.4% (N=350 calls) were technical/procedural issues, 11.3% (N=57) medical, and 5.6% (N=28) material related and 4.6% (N=23) were categorized as other correspondence. Calls regarding I-PD performed in a teaching hospital (N=47) were labeled as urgent, usually performed perioperatively, or being associated with treating peritonitis on the ICU and normal ward. Issues disrupting the course of PD were identified in 481 cases. In 79.83% (N=384) patients were able to initiate, resume or finalize their treatment after phone consultation. Last-bag exchange was used in 5.2% enabling continued therapy in 85.03% of such cases. In 35 cases, the patient was supposed to visit the center at the earliest possible time while acute hospitalization was required in eight cases (4.65%/1.06% of total calls, respectively).

**Conclusions:** In the majority of calls, the on-call PD service provides patients sufficient and adequate support for acute and imminent issues enabling patients to successfully continue, resume or finalize their prescribed treatment. Medical support amends risk of or averting adverse events considerably.

FR-PO504

**Adverse Events and Hospitalizations With Remote Monitoring of Patients on Automated Peritoneal Dialysis (APD)**  
Ramón Paniagua,<sup>1</sup> Abdul Rashid T. Qureshi,<sup>2</sup> Marcela Avila,<sup>1</sup> Alfonso Ramos,<sup>3</sup> Bengt Lindholm.<sup>2</sup> <sup>1</sup>Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico; <sup>2</sup>Karolinska Institutet, Stockholm, Sweden; <sup>3</sup>Macrotech Pharmaceutical, Ciudad de Mexico, Mexico.

**Background:** Remote monitoring (RM) of patients (pts) on APD provides new opportunities to prevent cardiovascular (CV) and metabolic complications derived from low ultrafiltration or insufficient dialysis. We analyzed the impact of RM-APD on adverse events (AdEv) and hospitalizations.

**Methods:** In a cluster-randomized, open-label, controlled trial, 21 hospitals were randomly assigned to treat their APD patients with RM-APD (10 hospitals; 403 pts) or conventional APD (11 hospitals; 398 pts). Rates of AdEv and hospitalizations during follow up of one year were analyzed using Poisson regression, adjusting for pts' identity and centers. Incidence-rate ratio (IRR) was calculated with zero-inflated Poisson model.

**Results:** Rates of AdEv including mechanical, hydro balance, CV-related, and metabolic AdEv, as well as all-cause mortality and CV mortality were significantly lower in RM-APD compared to conventional APD, see table chart. Hospitalizations due to mechanical AdEv (IRR 0.41 (95%CI)(0.22-0.66)  $p=0.001$ ) and AdEv linked to fluid overload or insufficient dialysis efficiency (IRR 3.24 (95%CI)(1.24-7.53)  $p=0.03$ ) were less frequent in RM-APD compared to conventional APD. Rates of AdEv and hospitalizations due to PD infection events were similar.

**Conclusions:** This randomized controlled trial shows that remote monitoring adds important advantages to APD by reducing the rate of adverse events and hospitalizations, which may have economic benefits.

**Funding:** Commercial Support - Baxter, Private Foundation Support

Poisson regression for Group APD versus reference RM APD adjusting for patients' identification and centers

	Crude APD /RM-APD	IRR (95% CI)	P> z
PD infection events	100/86 (p=0.12)	1.28(0.69-2.37)	0.42
Mechanical events	62/33(p=0.001)	0.42(0.18-0.98)	0.04
Intra-abdominal pressure events	6/13(p=0.07)	0.48(0.16-1.40)	0.18
Hydric balance events	123/35(p=0.001)	3.44(1.95-6.07)	0.001
Cardiovascular events	79/44(0.02)	1.81(1.03-3.09)	0.03
Metabolic events	108/44(p=0.001)	2.78(1.51-5.38)	0.005
Other events	53/77(p=0.005)	1.01(0.45-2.29)	0.97
All-cause mortality	55/33(p=0.01)	1.82(1.18-2.81)	0.006
Cardio-vascular mortality	24/13(p=0.05)	2.03(1.03-3.97)	0.04

Result of crude analysis is calculated with Chi-square test. IRR incidence-rate ratio is calculated with Poisson regression. IRR incidence-rate ratio adjusting for patients' identification and centers. PD infection events sum of exit site infection + tunnel infection + Peritonitis. Mechanical events sum of kinking + disconnection + catheter removal + device extrusion (staining, undraining). Intra-abdominal pressure events sum of abdominal discomfort + peritoneal/abdominal fluid + intra-abdominal pressure + leakage + transudate/ascites + hernia. Hydric balance events sum of glomerular filtration + dehydration + overhydration. Cardiovascular events sum of unstable angina + hypertensive crisis + stroke + heart failure + hypertension + acute myocardial infarct + congestive heart failure + chronic heart failure + coronary + stroke + sudden death. Metabolic events sum of malnutrition + hyperglycemia + hypoglycemia + hyperkalemia + hypokalemia + hyponatremia + acid-base disorder + uremia. Other events sum of gastrointestinal disorders + urinary tract infection + respiratory tract infection.

FR-PO505

**Cluster Randomized Controlled Trial (CRCT) of Remote Monitoring (RM) of Patients on Automated Peritoneal Dialysis (APD): Impact on Restricted Mean Survival Time (RMST)**  
Ramón Paniagua,<sup>1</sup> Abdul Rashid T. Qureshi,<sup>2</sup> Marcela Avila,<sup>1</sup> Alfonso Ramos,<sup>3</sup> Bengt Lindholm.<sup>2</sup> <sup>1</sup>Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico; <sup>2</sup>Karolinska Institutet, Stockholm, Sweden; <sup>3</sup>Macrotech Pharmaceutical, Ciudad de Mexico, Mexico.

**Background:** RM of patients (pts) on APD provides new opportunities to prevent complications and improve treatment quality. We analyzed the effects of RM-APD with RMST, a robust and clinically interpretable measure which quantifies the survival curve without assumptions of distribution of events.

**Methods:** In a CRCT, 21 hospitals were randomly assigned to use either RM-APD (n=10) or conventional APD (n=11) for the treatment of pts with recent onset of peritoneal dialysis. 403 pts in RM-APD and 398 in APD were followed up for at least one year. Primary outcomes were time to first event of Composite Index 1 (all-cause mortality or adverse event (AdEv) or hospitalization), and Composite Index 2 (cardiovascular mortality, or first AdEv or hospitalization related to cardiovascular disease, fluid overload and insufficient dialysis efficiency). We used and compared RMST and Cox proportional regression analysis for statistical analysis.

**Results:** Overall RM-APD associated with longer RMST resulting in shorter restricted mean time lost. Over 16 months, RM-APD as compared to APD can delay the first occurrence of outcomes by on average: for Composite Index 1 by 0.78 months ( $p=0.09$ ), and its components mortality index 1 by 1.13 months ( $p=0.001$ ), AdEv index 1 by 0.82 months ( $p=0.08$ ) and hospitalization index 1 by 0.68 months ( $p=0.09$ ), and for Composite Index 2 by 1.12 months ( $p=0.01$ ), and its components mortality index 2 by 1.09 months ( $p=0.001$ ), AdEv index 2 by 1.16 months ( $p=0.007$ ) and hospitalization index 2 by 0.94 months ( $p=0.005$ ). Cox regression analysis showed broadly similar results. All-cause and cardiovascular deaths, shifts to hemodialysis and unscheduled visits were more frequent among APD group.

**Conclusions:** Whereas both RMST and Cox analysis show that RM-APD may delay first occurrence of deaths, AdEv and hospitalizations, RMST is more robust as it is free from assumptions of proportional hazards demanded by Cox models.

**Funding:** Commercial Support - Baxter

## FR-PO506

### Efficacy of Empirical Voriconazole vs. Amphotericin B Plus Flucytosine in Peritoneal Dialysis Patients With Fungal Peritonitis (VAF Study): Early Results From a Randomized Controlled Trial

Pongpratch Puapatanakul, Somkanya Tungsanga, Talerngsak Kanjanabuch. VAF study steering committee Chulalongkorn University, Bangkok, Thailand.

**Background:** Fungal peritonitis is a rare but life-threatening complication in patients undergoing peritoneal dialysis (PD). We studied the efficacy of two different empirical antifungal regimens for the treatment of PD-related fungal peritonitis.

**Methods:** In a multicenter open-label randomized controlled trial (TCTR20210316001), PD patients aged  $\geq 18$  presenting with fungal peritonitis from 18 centers in Thailand were randomized to receive an empirical antifungal regimen of either oral voriconazole (Vz) 6 mg/kg twice daily on day 1 followed by 4 mg/kg twice daily or intravenous amphotericin B (AmB) 1 mg/kg/day plus oral flucytosine (Fluc) 500 mg twice daily, stratified by fungal types (yeast or mold). The PD catheter was removed as soon as possible, and antifungal drugs were continued for at least 14 days after catheter removal and stopped if clinical response was evident. Change in the antifungal drug was allowed upon knowledge of pathogen species but not earlier than 7 days. The primary outcome was mortality at 90 days.

**Results:** 82 PD patients with fungal peritonitis were enrolled (32 [40%] yeast and 48 [60%] mold) of which 39 and 41 patients received empirical treatment with Vz or AmB plus Fluc, respectively. Empirical drugs resulted in clinical response at 14 days after PD catheter removal, and treatments could be stopped in 87% in Vz group and 83% in AmB plus Fluc group ( $p=0.59$ ). There was a trend toward a higher mortality rate at 90 days in AmB plus Fluc group compared with Vz group but did not reach statistical significance (Vz 5% vs. AmB plus Fluc 20%,  $p=0.052$ ). The proportion of patients in whom physicians attempted to resume PD (Vz 28% vs. AmB plus Fluc 29%,  $p=0.92$ ) and success rate of resuming PD (Vz 82% vs. AmB plus Fluc 83%,  $p=0.92$ ) were not significantly different between treatment groups. Reversible elevation of serum alkaline phosphatase was documented in 5% of patients in Vz group.

**Conclusions:** Both empirical antifungal treatment regimens are feasible and well tolerated by PD patients. A trend of superior 90-day survival for treatment with Vz could be attributable to a high incidence of mold peritonitis in this study.

**Funding:** Commercial Support - Siam Pharmaceutical Co., Ltd. provided study drugs (voriconazole, flucytosine), Government Support - Non-U.S.

### Home Dialysis Caregivers in the Veterans Health Administration: Qualitative Study of Motivation, Roles, Experiences, and Needs

Lindsey A. Jones,<sup>1</sup> Elisa J. Gordon,<sup>2</sup> Timothy P. Hogan,<sup>3,4</sup> Cindi Fiandaca,<sup>5</sup> Bridget M. Smith,<sup>5</sup> Kevin Stroupe,<sup>5</sup> Michael J. Fischer.<sup>6,7</sup> <sup>1</sup>VA Information Resource Center, Hines, IL; <sup>2</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>3</sup>VA Center for Healthcare Organization and Implementation Research, Bedford, MA; <sup>4</sup>Department of Population and Data Sciences, Dallas, TX; <sup>5</sup>Center of Innovation for Complex Chronic Healthcare, Hines, IL; <sup>6</sup>Jesse Brown VA Chicago Healthcare System, Chicago, IL; <sup>7</sup>University of Illinois Chicago Chicago UI Health, Chicago, IL.

**Background:** Although home dialysis often confers greater survival and quality of life than in-center dialysis for end-stage kidney disease patients, it is substantially underutilized. Informal caregivers play a key role in patients' eligibility, availability, and use of home dialysis. Nonetheless, little is known about the burdens confronting caregivers or their unmet needs, which must be addressed to inform support strategies. We assessed motivation, roles, experiences, and needs of caregivers assisting Veterans receiving home dialysis in the Veteran's Health Administration (VHA).

**Methods:** Semi-structured phone interviews were conducted with informal (unpaid) caregivers of Veterans receiving home dialysis at five geographically dispersed VHA facility-based programs during 2017-2018. Transcribed interviews were analyzed using content analysis to identify themes emergent in the data.

**Results:** Participants included 20 caregivers - 16 cared for home peritoneal dialysis patients and 4 for home hemodialysis patients. Caregivers had a mean age of 63 years. Most were female (95%), non-Hispanic (96%), White (79%), married or partnered (95%), had some college education (63%), and were retired (58%). Twenty-five percent of caregivers spent more than 5 hours per day on caregiving tasks, and 50% assisted with at least one-half of dialysis treatments. Themes for motivation included: concern for patient well-being, altruism, conversations with others, prior experience, and convenience. Themes for roles described: treatment supporting tasks, treatment related tasks, and treatment unrelated tasks. Themes for experiences included: impacts on caregiver

wellbeing, freedom, and finances. Themes describing needs included: additional staff and peer support, improved education and resources, incorporation of mental health support, resources to mitigate geographical barriers, assistance with caregiving tasks, respites, and financial support.

**Conclusions:** Our findings underscored the substantial burdens and wide-ranging needs confronting home dialysis caregivers, as well as their motivations for continuing to serve in this role. These insights can inform the development of targeted strategies intended to support caregivers and by extension, enhance use of home dialysis by Veterans.

**Funding:** Veterans Affairs Support

### Excess Incidence of Home Dialysis Attrition During the COVID-19 Pandemic

Eric D. Weinhandl,<sup>1,2</sup> Graham E. Abra,<sup>1</sup> Brigitte Schiller.<sup>1</sup> <sup>1</sup>Satellite Healthcare, San Jose, CA; <sup>2</sup>University of Minnesota Twin Cities, Minneapolis, MN.

**Background:** Home dialysis utilization in the United States was rapidly increasing before the COVID-19 pandemic. Although patients dialyzing at home during the pandemic had lower risks of COVID-19 hospitalization, relative to patients undergoing in-center hemodialysis (IHD), it is unknown whether attrition—that is, transfer from home dialysis to IHD—was more likely during the pandemic, possibly due to the stress of isolation, as well as the uncertain impact of telehealth in place of in-person visits. We estimated the excess incidence of home dialysis attrition in a small dialysis organization during the pandemic.

**Methods:** We analyzed home dialysis attrition between March 13, 2020, and March 12, 2022, among patients at Satellite Healthcare. During each month of this interval, we calculated observed and expected numbers of patients who transferred from home dialysis to IHD. The expected number of transfers was derived from a logistic regression model of transfers among all home dialysis patient-days between March 13, 2018, and March 12, 2020, a pre-pandemic interval ending at the declaration of a national emergency. The regression model included time since home dialysis initiation, modality, and age.

**Results:** The excess incidence of transfer from home hemodialysis (HHD) to IHD was  $>1.00$  between June 2020 and August 2021, but  $<1.00$  thereafter, whereas the excess incidence of transfer from peritoneal dialysis (PD) to IHD was typically between 0.9 and 1.1. Overall, there were 94 transfers from HHD to IHD, compared to 91.5 expected transfers, resulting in excess incidence of 1.03 (95% confidence interval, 0.83-1.24). Meanwhile, there were 518 transfers from PD to IHD, compared to 499.2 expected transfers, resulting in excess incidence of 1.04 (0.95-1.13).

**Conclusions:** Despite some variability in the excess incidence of home dialysis attrition during first 2 years of the pandemic, attrition from both HHD and PD was in line with pre-pandemic levels.

## FR-PO509

### Simulating Strategies to Launch a Home Therapies Program in a Conventional Hemodialysis Facility

Eric D. Weinhandl,<sup>1,2</sup> Stephan C. Dunning,<sup>3</sup> Tonya Saffer,<sup>3</sup> Michael A. Aragon.<sup>3</sup> <sup>1</sup>Satellite Healthcare, San Jose, CA; <sup>2</sup>University of Minnesota Twin Cities, Minneapolis, MN; <sup>3</sup>Outset Medical, San Jose, CA.

**Background:** Over half of dialysis facilities in the United States either do not offer home dialysis or have no active patients (pts) on home dialysis. Launching a home therapies program from this base leads to questions about patient selection, modality mix, device utilization, and financial impact. We designed a Markov chain Monte Carlo simulation to explore 5-year clinical and economic outcomes in a conventional hemodialysis (CHD) facility that pursues various strategies for growing home dialysis.

**Methods:** We simulated modality mix and total revenue in a 100-patient CHD facility in December 2022 and an average of two new patients per month during 2023-2027. We modulated three parameters: (1) prevalent patient conversion from CHD to home

hemodialysis (HHD); (2) incident patient adoption of peritoneal dialysis (PD) and HHD; and (3) HHD device utilization, using an innovative HHD device that reduces HHD training attrition and the rate of conversion from HHD to CHD by 40%.

**Results:** Under current conditions, the launch of a home therapies program results in home penetration of 12.1% by 2027. Focusing only on increasing home dialysis adoption among incident patients increases penetration to 23.1%, while maintaining that focus and increasing conversion from CHD to HHD increases penetration to 36.8%. Reducing HHD attrition with an innovative device increases HHD utilization by 1.5 to 3.5 percentage points in most scenarios, and increases cumulative revenue per HHD start by 10% to 16%.

**Conclusions:** In a CHD facility, growth of home dialysis requires sustained focus on both incident and prevalent dialysis patients. Utilization of innovative devices, like the Tablo® Hemodialysis System, that improve HHD retention can accelerate home dialysis growth and positively impact facility revenue.

CHD-to-HHD conversion	Incident modality mix	PD (%) in 2027	HHD (%) in 2027	Mean annual revenue (\$ millions) during 2023-2027
Current State	14.5% PD, 0.5% HHD	7.5 (7.5)	5.3 (4.6)	4.97 (4.95)
	20% PD, 5% HHD	10.2 (10.2)	7.5 (6.7)	4.98 (4.99)
	20% PD, 20% HHD	10.5 (10.2)	15.1 (12.9)	5.10 (5.10)
3x Higher Rate	14.5% PD, 0.5% HHD	7.3 (7.4)	14.5 (12.8)	5.07 (5.05)
	20% PD, 5% HHD	10.3 (10.2)	16.4 (14.2)	5.12 (5.07)
	20% PD, 20% HHD	10.1 (10.0)	23.3 (20.5)	5.22 (5.18)
5x Higher Rate	14.5% PD, 0.5% HHD	7.5 (7.3)	22.5 (20.0)	5.20 (5.17)
	20% PD, 5% HHD	10.1 (10.2)	23.9 (20.9)	5.22 (5.22)
	20% PD, 20% HHD	10.3 (10.1)	30.2 (26.7)	5.34 (5.27)

Each cell displays the statistic with (without) use of an innovative HHD device.

FR-PO510

Initial Experience With Home Hemodialysis Using the Tablo Hemodialysis System

Eric D. Weinhandl,<sup>1,2</sup> Josh Schumacher,<sup>3</sup> Michael A. Aragon,<sup>3</sup> Graham E. Abra.<sup>1</sup>  
<sup>1</sup>Satellite Healthcare, San Jose, CA; <sup>2</sup>University of Minnesota Twin Cities, Minneapolis, MN; <sup>3</sup>Outset Medical, San Jose, CA.

**Background:** Home hemodialysis (HHD) utilization in the United States is approximately 2%. The modality offers customizability of therapy, but places stress on patients and their care partners. Devices that greatly improve the user experience are needed. One such device, the Tablo Hemodialysis System, was cleared for use in the home setting in early 2020. We analyzed the evolving clinical experience of HHD with Tablo at Satellite Healthcare (SHC), a dialysis provider with >3% utilization of HHD.

**Methods:** We identified patients who initiated use of Tablo for HHD in SHC facilities between 1 January 2021 and 30 April 2022. We summarized patient characteristics, including modality prior to initiation of HHD with Tablo and vascular access. We tallied the number of training sessions and estimated distributions of prescribed treatment frequency and hours per week. Using digital flowsheets, we assessed treatment adherence between 1 October 2021 and 15 May 2022. We estimated the cumulative incidence of attrition due to death, conversion to in-center hemodialysis (IHD), or conversion to HHD with an alternative device.

**Results:** The cohort included 34 patients. Patient proportions were 27% aged 18-44 years, 32% aged 45-64 years, 41% aged ≥65 years, 71% male, and 47% with diabetes. Regarding modality history, 29% were incident end stage kidney disease (ESKD) patients, 41% on IHD, 21% on HHD with an alternative machine, and 9% on peritoneal dialysis (PD). Regarding vascular access, 26% had a catheter. Mean numbers of training sessions were 11, 11, and 9 for incident ESKD, IHD, and existing HHD patients, respectively. Prescribed treatment frequency was 4 sessions/week in 82% of patients; prescribed hours/week were 12.0-14.9 in 70% of patients, with equal shares below and above this range. Adherence to prescribed hours was 90% with ≤3.5 sessions/week and 86% with ≥4.0 sessions/week. At 12 months, the cumulative incidence of death, conversion to IHD, and conversion to HHD with alternative device was 11%, 13%, and 3%, respectively.

**Conclusions:** Patients performing HHD with Tablo have been diverse in age, modality history, and vascular access. On average, HHD training has been completed in 11 or fewer sessions, regardless of prior modality, and treatment adherence at home has exceeded 85%. HHD attrition has been low, thus portending continued growth of the modality with the use of Tablo.

FR-PO511

Low Dialysis Patient Volume in Many Skilled Nursing Facilities: An Obstacle to Improved Outcomes

Eric D. Weinhandl,<sup>1,2</sup> Alice Hellebrand,<sup>4</sup> Eran Y. Bellin,<sup>3</sup> Allen Kaufman.<sup>4</sup>  
<sup>1</sup>Chronic Disease Research Group, Minneapolis, MN; <sup>2</sup>University of Minnesota Twin Cities, Minneapolis, MN; <sup>3</sup>Albert Einstein College of Medicine, Bronx, NY; <sup>4</sup>Dialyze Direct, Neptune City, NJ.

**Background:** Approximately 15% of dialysis patients are admitted to a skilled nursing facility (SNF) each year. These high-acuity patients represent a challenge to SNFs, as most facilities lack on-site clinical expertise in this domain. In other medical and surgical domains, maintenance of quality requires adequate volume, thus offering ongoing experience to providers. Nothing is known about the volume of dialysis patients in individual SNFs. We analyzed Medicare fee-for-service claims to quantify the experience of SNFs who have admitted at least one dialysis patient during one recent quarter of the pandemic era.

**Methods:** We analyzed 100% of Medicare Parts A and B claims during the first quarter of 2021. We identified patients who received outpatient dialysis during the quarter, and subsequently ascertained all Part A claims for SNF care during the quarter. We estimated the distribution of dialysis patient placements per SNF with ≥1 placement. We also grouped SNFs into core-based statistical areas (CBSAs), according to ZIP code, and calculated distributions of SNFs per CBSA.

**Results:** We identified 289,858 dialysis patients in the first quarter of 2021, among whom 21,053 (7.3%) received Medicare-covered care in a SNF. These patients were placed in 7858 SNFs. The median number of dialysis patient placements per SNF was 2, with a 25th percentile of 1 patient, a 75th percentile of 3 patients, a 90th percentile of 6 patients, and a 95th percentile of 8 patients. The 7858 SNFs were distributed among 821 CBSAs: 177 (21.6%) CBSAs had only 1 SNF in which dialysis patients were placed, 186 (22.7%) had 2; 170 (20.7%) had 3-4; and 288 (35.1%) had ≥5. CBSAs with ≥5 SNFs represented 89.9% of all dialysis patient placements. The 5 largest CBSAs—New York, Los Angeles, Chicago, Dallas, and Houston—had ≥100 SNFs with dialysis patient placements.

**Conclusions:** Over 75% of SNFs in which Medicare-covered dialysis patients are placed after hospitalization receive ≤3 patients per quarter. This volume is not sufficiently high to sustain expertise, although the large number of SNFs in urban markets offers an opportunity for centralization. On-site dialysis providers with specialized staff and innovative care models, financed by the dialysis process itself and informed by a central organization with amortized resources for quality improvement, can provide local expertise to SNFs.

FR-PO512

Patient Characteristics Associated With Attrition to In-Center From Home Hemodialysis Treatment

Derek M. Blankenship, Dinesh K. Chatoth, Michael A. Kraus, Len A. Usvyat, Franklin W. Maddux. *Fresenius Medical Care, Global Medical Office, Waltham, MA.*

**Background:** Numerous clinical and practical benefits exist for patients receiving hemodialysis at home (HHD) compared to incenter (ICHD). As important as patients initiating HHD is patients remaining on HHD as benefits persist. The purpose of this study was to assess factors associated with HHD patients who attrition to ICHD.

**Methods:** This retrospective cohort study identified Fresenius Kidney Care (FKC) patients initiating HHD between Jan. 1<sup>st</sup>, 2016 and Dec. 31<sup>st</sup>, 2020. Patients were followed 2 years for time to ICHD transition. A multivariate Cox regression model with baseline characteristics and time updating clinical factors at 3-month intervals assessed ICHD attrition.

**Results:** 3,434 HHD patients were studied of which 361 transitioned to ICHD. Males (Hazard Ratio=1.6, reference=female), single/unknown relationship status (HR=1.5, ref=partnered), uncollected Patient Health Questionnaire-2 (HR=1.3, ref=PHQ-2<3), and Phosphorous >5.5 mg/dL (HR=1.3, ref=5.5 mg/dL or less) were associated with greater likelihood of attrition. Conversely, albumin >4 g/dL (HR=0.7, ref=<3.5 mg/dL) and residual renal urea clearance (KRU) >2 (HR=0.58, ref=0) had a protective association. Race, ethnicity, BMI, dual Medicare/Medicaid, training year, vascular access, diabetes, heart failure, employment, education, dialysis frequency or change, dialysate volume, stan. Kt/V, training sessions, hospitalizations, and blood stream infections were not statically significant. When adjusting for number of home treatments, an increase in the number of support calls had a protective association as well (HRs=0.67, 0.53, and 0.38 for 1, 2-5, and >5 with ref=0 calls per quarter).

**Conclusions:** Study identified several clinical and demographic factors associated with HHD patients' attrition to ICHD. These factors can be used by social workers and clinical staff to identify patients at risk for HHD attrition. Further research should include the creation of a predictive model to optimize the identification of at risk HHD patients. The unsuspected protective association observed for support calls may be an indirect indication of patients' treatment engagement and should be further investigated as well.

FR-PO513

Changes in Health-Related Quality of Life and Home Dialysis Modality Selection in Predialysis

Maude Pichette,<sup>1</sup> Catherine Morin,<sup>1</sup> Naoual Elftouh,<sup>1</sup> Benoit Imbeault,<sup>1</sup> Louis-Philippe Laurin,<sup>2</sup> Remi Goupil,<sup>3</sup> Annie-Claire Nadeau-Fredette.<sup>2</sup> <sup>1</sup>Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; <sup>2</sup>Hopital Maisonneuve-Rosemont Centre de Recherche, Montreal, QC, Canada; <sup>3</sup>Hopital du Sacre-Coeur de Montreal Centre de Recherche, Montreal, QC, Canada.

**Background:** Patients with advanced chronic kidney disease (CKD) have lower health-related quality of life (HRQOL) than the general population. There are still few data on patterns and predictors of HRQOL changes before dialysis initiation. We aimed to characterize HRQOL trajectory and assess its association with selected dialysis modality in advanced CKD.

**Methods:** In this prospective study, adult with an eGFR ≤15ml/min/1.73m<sup>2</sup> completed Kidney Disease Quality of Life-Short Form at baseline and every 6-month until dialysis initiation. Planned dialysis modality, our main exposure, was based on patient's choice, with home dialysis defined as selection of peritoneal dialysis or home hemodialysis. Predictors of changes in KDQOL components, including Physical Component scores

(PCS), Mental Component scores (MCS) and Symptoms/Problems of kidney disease (SPKD) were modelled using mixed effect multivariable linear regressions to account for within-patient changes over time.

**Results:** One hundred nine patients were included. Patients selecting home dialysis ( $n=41$ ) were younger ( $61\pm 15$  vs.  $76\pm 11$  yrs) and had less cardiovascular disease (34% vs 60%). At baseline, crude PCS ( $45\pm 10$  vs.  $39\pm 8$ ) was significantly higher in patients choosing home dialysis, while MCS and SPKD were similar in both groups. (Figure) After adjustment for demographics, comorbidities and psychosocial characteristics, patients choosing home dialysis had an 8-point higher MSC for each year of follow-up ( $B$  8.1 per year,  $p=0.002$ ) compared to those selecting in-center HD or undecided. Similarly, the decrease in SPKD score through time was attenuate (i.e. lower burden) for patients selecting home dialysis compared to others ( $B$  12.4 per year,  $p<0.001$ ). These differences were clinically significant considering the minimal important difference of 3-point for this instrument.

**Conclusions:** Patients choosing home dialysis had improved HRQOL scores in predialysis compared to those not selecting home dialysis. More work is needed to determine if differences in process of care (e.g. enhanced multidisciplinary team support) or unmeasured patient characteristics modulate this association.

## FR-PO514

### Sex and Racial/Ethnic Differences in Home Hemodialysis Mortality

Silvi Shah,<sup>1</sup> Nupur Gupta,<sup>2</sup> Annette L. Christianson,<sup>1</sup> Karthikeyan Meganathan,<sup>1</sup> Anthony C. Leonard,<sup>1</sup> Charuhas V. Thakar.<sup>1</sup> <sup>1</sup>University of Cincinnati, Cincinnati, OH; <sup>2</sup>Indiana University, Bloomington, IN.

**Background:** Women and minorities constitute substantial portions of the prevalent population of kidney failure patients. Little is known about sex and racial/ethnic differences in mortality among patients with kidney failure on home hemodialysis in the United States.

**Methods:** Using the United States Renal Data System, we retrospectively evaluated a cohort of 42,849 patients who started home hemodialysis between January 1, 2005, and December 31, 2015. We examined the association of sex and race/ethnicity with the outcome of all-cause mortality using adjusted Cox proportional hazard models and logistic regression models.

**Results:** In the study cohort, 40.4% were women, and 57.4% were White. Women on home hemodialysis had higher unadjusted death rates (26.9 vs. 22.4 per 100 person-years) as compared to men. There was no difference in adjusted all-cause mortality between men and women, but women had an 8% higher adjusted risk of all-cause mortality at one-year after initiating home hemodialysis (OR 1.08, 1.01-1.15). With regards to race/ethnicity, Hispanic, White, and Blacks had higher unadjusted death rates as compared to Asians and Native Americans (25.1 vs. 24.8 vs. 23.2 vs. 17.4 vs. 16.6 per 100 person-years). There was no difference in adjusted all-cause mortality in Black, Hispanic, and Native Americans as compared to Whites, while Asians had a lower risk of all-cause mortality than did Whites (HR, 0.81; CI, 0.72-0.92). There was no difference in adjusted one-year mortality for Asian, Black, Hispanic, and Native American patients, as compared to White patients.

**Conclusions:** Among patients undergoing home hemodialysis, women have higher one-year mortality than men, and women and men have comparable survival on long-term follow-up after adjusting for other covariates. Compared to Whites, there was no difference in adjusted survival on long-term follow-up for Blacks, Hispanics, or Native Americans, while Asians had better survival. Our results suggest the need for population-wide strategies to overcome differences in home hemodialysis care.

**Funding:** Other NIH Support - NHLBI K23 career development award, under Award Number 1K23HL151816-01A1

## FR-PO515

### HOME-R: A Home Dialysis Conceptual Model for Implementation Research

Yuvaram N. Reddy,<sup>1,2</sup> Ann M. O'Hare,<sup>3</sup> Peter P. Reese,<sup>2</sup> Shimrit Keddem,<sup>1,2</sup> Meghan B. Lane-Fall,<sup>2</sup> Robert Burke.<sup>1,2</sup> <sup>1</sup>VA Center for Health Equity Research and Promotion, Philadelphia, PA; <sup>2</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>3</sup>VA Puget Sound Health Care System Seattle Division, Seattle, WA.

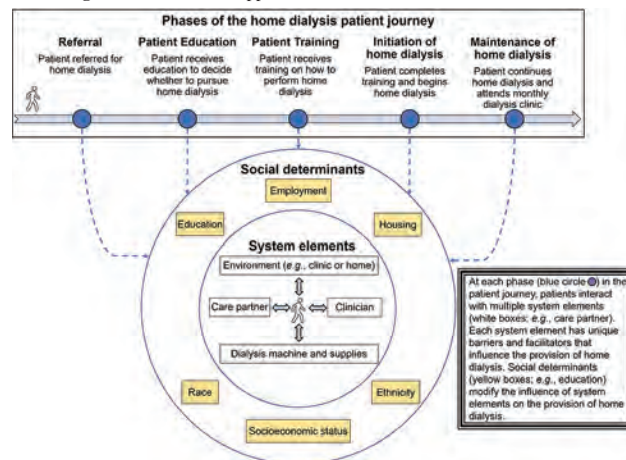

**Background:** The Advancing American Kidney Health initiative aims to grow home dialysis towards 80% by 2025. With <14% of patients currently receiving home dialysis, there is an urgent need to develop strategies to expand home dialysis. To maximize success, a conceptual model of barriers and facilitators is needed to help identify and evaluate strategies to expand home dialysis.

**Methods:** We reviewed published implementation science models to identify constructs that: 1) aligned with clinical knowledge of home dialysis barriers and facilitators; 2) could be consistently defined, measured, and evaluated in the context of home dialysis; and/or 3) incorporated health equity. We refined the model through an iterative process involving 4 rounds of stakeholder feedback from 4 nephrologists, 3 patients, 3 implementation scientists, 2 nephrology nurses, and 1 care partner.

**Results:** We developed the HOME dialysis conceptual model for implementation Research (HOME-R, Figure 1) using constructs from two frameworks: 1) the Systems Engineering Initiative for Patient Safety (SEIPS) and 2) the Equity-based framework for Implementation Research (EquIR). HOME-R uses SEIPS to define 5 phases of the home dialysis patient journey and 4 system elements. The 5 phases include referral, patient education, patient training, initiation, and maintenance of home dialysis. At each phase, patients interact with 4 system elements: providers, care partners, the dialysis machine and supplies, and the environment (e.g., home, home dialysis clinic, primary care) – all of which can serve as barriers or facilitators to home dialysis use. HOME-R also uses EquIR to identify and evaluate how social determinants of health modify the influence of system elements on home dialysis.

**Conclusions:** HOME-R—a conceptual model that incorporates SEIPS, EquIR, and stakeholder input—can be used to identify and evaluate strategies that are designed to improve home dialysis use, quality, and equity.

**Funding:** Veterans Affairs Support

## FR-PO516

### Identifying Major Barriers to Home Dialysis (The IM-HOME Study): Findings From a National Survey of Patients and Providers

Yuvaram N. Reddy,<sup>1,2</sup> Matthew D. Kearney,<sup>1</sup> Michaela Ward,<sup>1</sup> Robert Burke,<sup>1,2</sup> Peter P. Reese,<sup>1</sup> Meghan B. Lane-Fall.<sup>1</sup> <sup>1</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>2</sup>VA Center for Health Equity Research and Promotion, Philadelphia, PA.

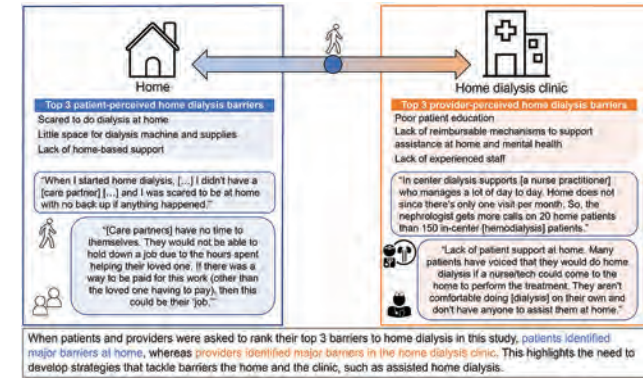

**Background:** Increasing home dialysis use from 13% towards 80% of patients with kidney failure by 2025—a goal of the Advancing American Kidney Health initiative—requires a comprehensive understanding of home dialysis barriers. In this national survey, we sought to identify major home dialysis barriers from the perspective of patients and providers to inform strategies to improve home dialysis use.

**Methods:** We identified major home dialysis barriers using the modified Delphi method—a technique that iteratively leverages stakeholder feedback in multiple stages to reach consensus. First, each of the 7 members of our advisory board of patients and providers listed major barriers to home dialysis. The advisory board then met as a group to discuss these barriers and compile a final list of 12 patient-perceived and 9 provider-perceived barriers. This final list of barriers was distributed as a survey to patients and providers across the US. The survey was informed by the Systems Engineering Initiative for Patient Safety 3.0 conceptual model. Participants ranked their top 3 home dialysis barriers from the list included in the survey. We aggregated participants' scores to identify the top 3 patient-perceived and top 3 provider-perceived barriers to home dialysis.

**Results:** There were 522 complete responses: 223 providers and 289 patients (response rates, 11.2% and 1.9%). Patients perceived their top 3 barriers as fear of dialysis, lack of space, and the need for home-based support – all of which occur at home. Providers perceived their top 3 barriers as poor patient education, lack of reimbursable mechanisms to provide additional support, and the need for experienced staff – all of which occur in the clinic.

**Conclusions:** While patients perceived major barriers at home, providers perceived major barriers in the clinic. These findings highlight the need for novel strategies, such as assisted dialysis, that can simultaneously overcome barriers at home and in the clinic.

FR-PO517

Evaluating Home Dialysis Training Requirements: A Survey of Nephrology Program Directors and Division Chiefs

Yuvaram N. Reddy,<sup>1,2</sup> Jeffrey S. Berns,<sup>1</sup> Shweta Bansal,<sup>6</sup> James F. Simon,<sup>5</sup> Ryan Murray,<sup>7</sup> Molly Jacob,<sup>7</sup> Jeffrey Perl,<sup>3</sup> Edward Gould,<sup>4</sup> ASN Home Dialysis Task Force <sup>1</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>2</sup>VA Center for Health Equity Research and Promotion, Philadelphia, PA; <sup>3</sup>St. Michael's Hospital, Toronto, ON, Canada; <sup>4</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>5</sup>Cleveland Clinic, Cleveland, OH; <sup>6</sup>The University of Texas Health Science Center at San Antonio, San Antonio, TX; <sup>7</sup>American Society of Nephrology, Washington, DC.

**Background:** The American Society of Nephrology (ASN) convened a Home Dialysis Task Force in 2021 to improve awareness and outcomes of home dialysis. An identified need was to ensure universal and adequate training, education, and exposure to home dialysis during nephrology fellowship. As a first step, The Task Force surveyed program directors and division chiefs to explore perspectives on 1) what constitutes adequate home dialysis training, and 2) what home dialysis training resources are needed.

**Methods:** Using REDCap, we anonymously surveyed program directors and division chiefs of US adult nephrology fellowship programs from 03/04/22-04/05/22. **Program directors were asked to** 1) select the minimum training fellows should receive before they could provide home dialysis without supervision (defined by number of clinics attended or patients seen) and 2) select home dialysis training resources that ASN could support. **Division chiefs were asked to** select the minimum training fellows should receive before they could be hired as faculty to manage home dialysis patients.

**Results:** Among 158 program directors and 170 division chiefs in ASN's database, 43 and 31 responded (response rate, 27% and 18%, respectively). When asked about the minimum training fellows should receive before they could provide peritoneal dialysis without supervision, the most common answers were 10-12 clinics (53% of program directors and 35% of division chiefs), and 11-15 patients (33% of program directors and 29% of division chiefs). For home hemodialysis training, please see Table 1. When program directors were asked which resources they would like ASN to facilitate, 74% requested a virtual case-based home dialysis mentorship program.

**Conclusions:** Most program directors and division chiefs felt that fellows could provide home dialysis independently if they attended a minimum of 10-12 home dialysis clinics. Most program directors wanted ASN to help create a virtual case-based home dialysis mentorship program.

**Funding:** Other NIH Support - Agency for Healthcare Research and Quality

Survey question	Program Directors (n=43)	Division Chiefs (n=31)
In your opinion, upon graduation, how many of your fellows can provide home dialysis without supervision?	—	—
Peritoneal dialysis	—	—
All fellows	3 (7%)	22 (71%)
Most fellows	8 (19%)	6 (19%)
Some fellows	4 (9%)	3 (10%)
Home hemodialysis	—	—
All fellows	13 (30%)	14 (45%)
Most fellows	14 (33%)	6 (19%)
Some fellows	12 (28%)	5 (16%)
None of our fellows	3 (7%)	6 (19%)
No response	1 (2%)	—
In your opinion, how many home dialysis clinics should a fellow attend before they can provide home dialysis without supervision?	—	—
Peritoneal dialysis	—	—
< 4 clinics	2 (5%)	1 (3%)
4-6 clinics	3 (7%)	6 (19%)
7-9 clinics	4 (9%)	3 (10%)
10-12 clinics	23 (53%)	11 (35%)
13-18 clinics	3 (7%)	5 (16%)
19-24 clinics	6 (14%)	2 (6%)
> 24 clinics	2 (5%)	3 (10%)
Home hemodialysis	—	—
< 4 clinics	3 (7%)	8 (26%)

Predicting Transfer From Peritoneal Dialysis to Hemodialysis Using the Peritoneal Dialysis Surprise Question

Ayesha Anwaar,<sup>1,2</sup> Sai Liu,<sup>1</sup> Hatsumi Nielsen,<sup>2</sup> Maria E. Montez-Rath,<sup>1</sup> Graham E. Abra,<sup>2,1</sup> Sumi J. Sun,<sup>2</sup> Brigitte Schiller,<sup>2,1</sup> Wael F. Hussein.<sup>2,1</sup> <sup>1</sup>Stanford University, Stanford, CA; <sup>2</sup>Satellite Healthcare, San Jose, CA.

**Background:** People on peritoneal dialysis (PD) at risk of transfer to hemodialysis (HD) need support to remain on PD or ensure a safe transition to HD. In this study, we evaluated the clinicians' ability to identify high-risk patients.

**Methods:** In this prospective observational study, we included 1275 patients undergoing PD in 35 home programs of a non-profit dialysis organization. We modified the palliative care 'Surprise Question' to evaluate the risk of transfer to HD by asking the registered nurse (RN) and nephrologist (MD): "Would you be surprised if this patient transferred to HD in the next 6 months?" We called this the PD Surprise Question. A "yes"/"no" answer indicated low/high risk respectively. We followed patients for 6 months. Using Cox proportional hazards regression we estimated the hazard ratio (HR) of transfer to HD.

**Results:** Patients' mean age was 59 ± 16 years and 41% were female. The median PD vintage was 20 months (IQR: 9-40), and 92% were on automated PD. Responses were received from RNs for 1123 patients, indicating 169 (15%) as high risk and 954 (85%) as low risk. Over the next 6 months, transfer to HD occurred in 18 (11%) versus 29 (3%) of the high and low-risk groups respectively (HR: 3.92, 95% confidence interval (CI): 2.17 – 7.05). MD responses were obtained for 692 patients, indicating 118 (17%) and 574 (83%) as high and low risk respectively. Transfer to HD was observed in 14 (12%) of the high-risk group and 14 (2%) of the low-risk group (HR: 5.56, 95% CI: 2.65 – 11.67).

**Conclusions:** The PD Surprise Question can help identify patients at high risk of transfer to HD. This tool can be used to modify care to support patients to remain on PD or to prepare for safe and timely transfer to HD.

## FR-PO519

**A Report on Home Hemodialysis Training Time in Patients With Kidney Failure Using the Quanta SC+ Hemodialysis Device**

Ryan J. Bamforth,<sup>1</sup> Reid Whitlock,<sup>1</sup> Paul Komenda,<sup>1,7</sup> Kelley L. Gorbe,<sup>7</sup> Angela Pietrafesa,<sup>2</sup> Charlotte Bebb,<sup>3</sup> Suzanne Forbes,<sup>4</sup> Saeed Ahmed,<sup>5</sup> David T. Collister,<sup>6</sup> <sup>1</sup>Seven Oaks General Hospital, Winnipeg, MB, Canada; <sup>2</sup>Churchill Hospital, Oxford, United Kingdom; <sup>3</sup>Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom; <sup>4</sup>Barts Health NHS Trust, London, United Kingdom; <sup>5</sup>South Tyneside and Sunderland NHS Foundation Trust, South Shields, United Kingdom; <sup>6</sup>University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; <sup>7</sup>Quanta Dialysis Technologies Ltd, Alcester, United Kingdom.

**Background:** Frequent self-care hemodialysis (HD) in the home setting has several advantages to patients and providers including improved health outcomes, health-related quality of life, patient satisfaction, and lower health care costs. The Quanta SC+ is a contemporary, portable HD device intended to be operated by a broad range of lay users. It was developed in collaboration with experienced home HD patients and human factors engineers with intuitive linear workflows, on-screen step-by-step instructions, and troubleshooting help screens that are easy to navigate. This study is a descriptive report on the home HD training time of first-time users of the Quanta SC+ HD device in the United Kingdom.

**Methods:** From August 2020 until March 2022, patients on dialysis across 5 sites in the United Kingdom were trained on the Quanta SC+ HD device as part of standard of care for self-care home HD as treatment for their kidney failure. We collected data on the number of total training weeks and sessions to be signed off as safe by a nephrologist and the frequency of training loss. Training time included organizational delays plus needing training time.

**Results:** As of March 2022, a total of 34 patients completed training on the Quanta SC+ HD device. The mean age of the patients was 52.3 ± 15.1 years, 14 (41.2%) were female. Patients had an average dialysis vintage of 2.6 ± 2.2 years. A total of 9 (26.5%) patients were already on home HD and converted to Quanta SC+ from another device. Training time for these individuals before being signed off as safe by a nephrologist ranged from 2 to 3 weeks (6 to 9 sessions). A total of 25 (73.5%) patients converted to Quanta SC+ from another dialysis modality. The average training time for these individuals before being signed off as safe by a nephrologist was 6 weeks (18 sessions).

**Conclusions:** A descriptive report of 34 patients with kidney failure who trained for frequent self-care home HD with the Quanta SC+ HD device reported an average training time within expectations set from national kidney organizations with minimal training. These results indicate that the device is user-friendly and intuitive to learn.

## FR-PO520

**Patient Perspectives on the Training and Early Initiation Phase of Peritoneal Dialysis**

Christopher D. Knapp,<sup>1,2</sup> Scott Reule,<sup>2,3</sup> Kirsten L. Johansen,<sup>1,3</sup> Allyson Hart,<sup>1,3</sup> <sup>1</sup>Hennepin Healthcare, Minneapolis, MN; <sup>2</sup>VISN 23 VA Midwest Health Care Network, Minneapolis, MN; <sup>3</sup>University of Minnesota Twin Cities, Minneapolis, MN.

**Background:** Patients initiating peritoneal dialysis are at higher risk for PD catheter dysfunction, peritonitis, and transfer to hemodialysis during the first 90 days of treatment, making it an important window to target interventions to reduce PD failure rates. However, qualitative data on patient perspectives and barriers during this time is lacking.

**Methods:** 25 semi-structured interviews of incident PD patients were conducted from six dialysis centers in the Minneapolis area. Participants were interviewed during the last week of their PD training and re-interviewed approximately 90 days after initiation. A grounded theory approach was used to develop an interview codebook and identify themes.

**Results:** The first theme that emerged is “mismatched concerns between patients and family”. Patients’ concerns were oriented towards maximizing independence whereas family members were concerned about medical safety. The second theme is “Comfort with process of PD training.” Patients reported comfort with the technical aspects of PD during their training period or confidence asking for help. The third theme is “Surprising negative experiences”. Unexpected negative experiences that were not discussed prior to starting PD caused patients stress. The fourth theme is “Coping strategies to overcome barriers”. Patients reported that focusing on expected long term benefits of PD and talking to peer mentors helped them. The fifth theme is “Expected benefits of starting peritoneal dialysis”. Patients reported that PD would allow them to maintain their roles within their family and community and improve their sense of ownership about their health.

**Conclusions:** Better preparing patients for potential negative medical experiences with starting PD and improving communication between patients and their families could be targets to improve the patient experience during PD training. A focus on coping strategies and expected benefits of PD could be useful strategies for peer mentorship and provider to patient communication in this period.

**Funding:** Private Foundation Support, Clinical Revenue Support

Theme	Representative Quote
Surprising Negative Experiences after starting PD	"The leaking fluid was a big deal for me but it wasn't nothing that was harming me... But I didn't know that...I think it would have been better if they talk to you"
Coping strategies to overcome barriers to starting or continuing PD	"You know, one thing about the dialysis, this dialysis...is that they don't have no groups...they found this lady that's here and she talked to me. Talking to her is what kept me going through all the other stuff"
Mismatched concerns between patient and family	"My mom would lay her head on me and pray. I need somebody who can talk to me and tell me it's going to be okay and tell me what to do"
Comfort with Process of PD training	"And they're really good about giving me instructions you know, so she gave me a written instruction so if I follow that every time I feel like, that will lessen the chance of getting an infection"
Expected Benefits of PD	"Schedule-wise it's easier too because during the day, it kind of frees me up to do other things, chores around the house, frees me up to help my fiancé with his business"

## FR-PO521

**Human Factors Validation of the Tablo Hemodialysis System in Home Patients**

Brittany Lim, Josh Schumacher, Elise Edson, Cynthia J. D'Alessandri-Silva, Michael A. Aragon. *Outset Medical, San Jose, CA.*

**Background:** Home hemodialysis (HHD) is a complex, lifesaving therapy for patients with end-stage kidney disease (ESKD). As such, the high level patient interaction needed to use devices safely and effectively while educating patients and care partners to administer dialysis at home requires significant training and can be facilitated by using more intuitive, patient-centered technology. The Tablo® Hemodialysis System (“Tablo”) is an all-in-one, easy-to-learn system indicated for clinic, hospital, and home settings. Features include a simplified user interface touchscreen GUI, coupled with images to assist with system operation. Prior validation testing of Tablo, showed a user error rate of 1.2%. Here we report simulated use human factors validation testing of a recent software version of Tablo in the home setting.

**Methods:** Patients and their care partners (one pair considered a “participant”) were recruited to test the Tablo user interface in a simulated use home environment. Participants underwent two days of hands-on training to learn device setup, takedown, monitoring of treatments, maintenance, and alarm resolution. After a decay of at least 24 hours, participants performed all tasks without assistance from the trainer. Task performance (including use errors, close calls, and difficulties) were recorded, along with subjective interview and knowledge task assessments.

**Results:** Fifteen (15) participants were recruited and consisted of 6 who held prior HHD experience and 9 with no prior HHD or self-care experience. A total of 5400 tasks were assessed across all participants, with 98.4% completed without difficulty and 0.7% completed with minor difficulty noted. The remaining 0.9% were classified as use errors, with none of these posing an unacceptable level of residual risk. Following completion of testing, 100% of participants reported confidence they could use Tablo safely and effectively.

**Conclusions:** This human factors study demonstrates that Tablo is safe and easy to use in a simulated home environment regardless of prior experience with self-care. More recent software further reduces Tablo’s already lower user error rate. This data endorses prior reports of Tablo being easy to learn and use for patients and care partners and may contribute to the high adoption and retention rates observed with the Tablo Hemodialysis System for home use.

## FR-PO522

**Exploring Preconceptions in Peritoneal Dialysis Eligibility: The PD Myths Survey**

Nikhil A. Shah,<sup>1</sup> Paul N. Bennett,<sup>2</sup> Graham E. Abra,<sup>3</sup> Talerngsak Kanjanabuch,<sup>5</sup> Yeoung Jee Cho,<sup>6</sup> Saskia Leibowitz,<sup>6</sup> Jyoti B. Baharani.<sup>4</sup> <sup>1</sup>PDMyths <sup>1</sup>University of Alberta, Edmonton, AB, Canada; <sup>2</sup>University of South Australia, Adelaide, SA, Australia; <sup>3</sup>Stanford University, Stanford, CA; <sup>4</sup>University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; <sup>5</sup>Chulalongkorn University, Bangkok, Thailand; <sup>6</sup>Princess Alexandra Hospital, Woolloongabba, QLD, Australia.

**Background:** Peritoneal dialysis (PD) is underutilized globally. A contributory factor may be myths around its use, some of which are mistaken as evidence after being shared routinely, gaining credence with repetition.

**Methods:** An online global survey (in English and Thai) was administered for completion by nephrologists and trainees, to ascertain decisions on choosing PD as a treatment modality in various clinical settings. Ethical approval was granted by the University of Alberta, Canada. Informed consent was obtained prior to survey completion from each participant. The obtained outcomes were further evaluated according to status (nephrologist vs. trainee), experience, region and income group of the country.

**Results:** In total, 645 participants (522 nephrologists; 123 trainees; 56% male) from 54 countries completed the survey. Participants were mostly 36-45 years old (36%) with 0-5 years experience in nephrology (39%) and from high-income countries (HIC; 66%). In general, PD was recommended for most scenarios, including repeated exposures to heavy lifting, swimming (especially in a private pool and ocean), among patients with

cirrhosis or cognitive impairment with available support, and those living with a pet if a physical separation can be achieved during PD. Divergent responses were observed in other scenarios, including patients with BMI>40 whereby PD was discouraged by clinicians from low-income countries (75%) but not from HIC (21%). Certain abdominal surgeries were more acceptable to proceed with PD (hysterectomy 90%) compared to others (hemicolecotomy 45%). Similar variation was noted for different types of stomas (nephrostomies 74%; suprapubic catheters 53%; ileostomies 27%). The probability of recommending PD in various scenarios was greater among clinicians from HIC, larger units and consultants with longer years of clinical experience.

**Conclusions:** There is a huge disparity in approach to recommending PD across various clinical scenarios driven by experience, unit-level characteristics and region of practice. Globally, evidence-informed education is warranted to rectify misconceptions to enable greater PD uptake.

FR-PO523

**The Tablo Hemodialysis System at Home: Comparing Real World to the IDE Trial**  
Josh Schumacher, Michael A. Aragon, Cynthia J. D'Alessandri-Silva. *Outset Medical, Inc., San Jose, CA.*

**Background:** The Tablo® Hemodialysis System (“Tablo”) obtained FDA clearance for home hemodialysis (HHD) in March 2020. Approval was based on a prospective, crossover trial, where 30 patients were followed for 8 weeks during each study phase (in-center and home). Tablo met all safety and effectiveness endpoints, reported high rates of treatment adherence, patient retention, and included a diverse patient population (NCT02460263). The HOME Registry (NCT04526301) is an ongoing study of real-world patients utilizing Tablo for HHD.

**Methods:** Using the same eligibility criteria as the Tablo IDE, incident and prevalent patients were initiated on Tablo at participating study sites. Treatment data were obtained wirelessly via the Tablo data platform. All other data were reported by site staff into the study database. Data collected from the first 30 patients on the HOME Registry over the first 8 weeks was compared to the 30 patients who participated in the IDE.

**Results:** Mean patient age was 55.2 years, with the majority being male (66.7%), white (73.3%) and with an AV fistula (60.0%). Mean prescribed treatment time was 3.3 hours, with a mean prescribed frequency of 3.8 treatments per week. Treatment adherence was 95%, with 92% of treatments completing at least 90% of prescribed time. The mean number of clinically significant alarms per treatment was 1.3 (±2.9), with an average time to resolution of 10.8 (±23.1) seconds. The mean weekly standard Kt/V at the 4-week visit was 2.3±0.5. Patient retention was 100%, with no patients opting out of HHD with Tablo. One serious adverse event (SAE) was reported, a seizure and subsequent hospitalization. The event was deemed not related to Tablo or to the HD treatment by the site investigator.

**Conclusions:** Initial real-world experience from the Home Registry mirrors the IDE with reports of high treatment adherence and patient retention, with low rates of treatment alarms and SAEs. This data supports that Tablo achieves standard adequacy goals in more flexible dialysis schedules than current HHD options for a diverse patient population.

**Funding:** Commercial Support - Outset Medical, Inc.

Abstract Withdrawn

FR-PO525

**Hemodialysis Program in a Subacute Care Facility for ESRD Patients With Tracheostomy**  
Guoping Xu,<sup>1</sup> Gary V. Halick,<sup>2</sup> Leonid Pravoverov,<sup>1</sup> Ritchie M. Nabong-Salem,<sup>1</sup> Sijie Zheng.<sup>1</sup> <sup>1</sup>The Permanente Medical Groups, Oakland, CA; <sup>2</sup>Kaiser Permanente, Oakland, CA.

**Background:** ESRD patients with tracheostomy require long-term mechanical ventilation in addition to need for maintenance dialysis. Due to regulations in California, majority of such patients have prolonged acute hospital stays due to lack of availability of a lower level of care facility, capable of providing ventilation care and hemodialysis. Need for these services increased during the COVID 19 pandemic. Kaiser Permanente Northern California (KPNC) is an integrated health care system providing health care for 4.6 million members. Partnering with a large dialysis organization (LDO) and a

local Subacute Care facility (SAC), a program has been developed to provide home hemodialysis for patients requiring long-term mechanical ventilation using Low Dialysate Volume Approach (LDVA) machines.

**Methods:** The program was initiated in Q4 2017. A set of clinical criteria for admission was developed between the LDO, SAC and KPNC. Weekly meetings with physicians, dialysis nurses, and SAC staffs were conducted to review the potential candidates currently hospitalized in one of twenty-one KPNC hospitals. Dialysis has been performed by a HD nurse four times a week (M-T-Th-F) for 3-3.5 hours for each dialysis treatment. Each treatment was conducted using a LDVA machine with standard LDVA prescriptions using a Watson calculator to achieve a weekly Kt/V above 2.1.

**Results:** Since the inception of the program, 45 patients have been admitted to the program, 24 female and 21 male patients. The mean age is 65 (±13) on the date of admission. The average length of stay per patient at an acute hospital prior to admission was 125 days, and after the admission, the total days in the SAC is 7,498 days, an average of 167 days per person. Total acute hospital re-admission days after admission to the program is 1,071 days, an average of 25 days per patient (range: 0 to 115 days). Nine patients are currently residing in the SAC.

**Conclusions:** It is feasible to provide hemodialysis care for patients requiring long term mechanical ventilation at the appropriate level of care. This approach reduces the patient length of stay (LOS) in acute hospitals and burden to critically stretched healthcare system. Further discussion with local regulatory agencies is needed to develop additional models of care to effectively deliver dialysis to patients requiring facility-based long-term care.

FR-PO526

**A Case of Successful Palliative Care With Peritoneal Dialysis for Severe Cyanotic Congenital Heart Disease**  
Nozomi Kadota, Yugo Ito, Kotaro Shimoyama, Kasumi Konishi, Takuya Fujimaru, Fumika Taki, Masahiko Nagahama, Masaaki Nakayama. *St. Luke's International Hospital, Tokyo, Japan.*

**Introduction:** Peritoneal dialysis (PD) is an optimal renal replacement therapy (RRT) for kidney dysfunction by cardio-renal syndrome and unstable hemodynamics. However, there is little evidence that PD is also effective for terminal care in heart failure patients to improve quality of life (QOL). To our knowledge, this is the first case report that PD enabled a cyanotic congenital heart disease patient to pursue his palliative care at home, maintaining better QOL without aggravation of heart failure.

**Case Description:** A 50-year-old man who was diagnosed with tricuspid atresia and underwent Blalock-Taussig shunt in his infancy was consulted to our clinic with his eGFR of 20 ml/min/1.73 m<sup>2</sup>. His chronic kidney disease was exacerbated gradually. Two years later, as his volume overload was uncontrollable without continuous intravenous inotropic agent and diuretics, he was hospitalized as often as twice a month. As a result of patient-centered team discussion, PD was selected for his RRT, considering for reduction his cardiac burden. On admission, he was classified as New York Heart Association (NYHA) class IV. His blood pressure was 88/52 mmHg, and oxygen saturation was 78% on room air. After the initiation of PD, fluid overload and dyspnea improved to NYHA class II. It allowed him to spend rest of his life at home with better QOL without hospitalization for heart failure for three years. At last, atrial fibrillation, untreatable with anti-arrhythmia drugs nor defibrillation, caused low output syndrome. Although he had no symptoms of uremia nor difficulty breathing, he died of heart failure at the age of 56.

**Discussion:** In general, patients with congenital heart disease with Eisenmenger syndrome and NYHA classification IV are expected to have shorter life spans than those of healthy population for more than 40 years. Among those patients, the main cause of death is heart failure. Declined kidney function is a risk of hospitalization. For this case, hemodialysis might have worsened his hemodynamics or susceptibility to blood stream infection. For the patients of cardio-renal syndrome due to cyanotic heart disease, PD could be the best choice to pursue better palliative care, maintaining QOL.

FR-PO527

**Point of Care Peritoneal Dialysis: Initial Usability Assessments**  
Ben Talbot,<sup>1,2</sup> Sue R. Lynch,<sup>3</sup> Jenny A. Burman,<sup>2</sup> Vincent J. Garvey,<sup>1,2</sup> Navneet Kaur,<sup>2</sup> John Knight.<sup>1,2</sup> <sup>1</sup>The George Institute for Global Health, University of New South Wales, Sydney, NSW, Australia; <sup>2</sup>Ellen Medical Devices, Sydney, NSW, Australia; <sup>3</sup>MedTech Pathways, Sydney, NSW, Australia.

**Background:** The Ellen Medical Devices Point-Of-Care (EM-POC) system can be used by patients and care-givers to produce PD fluid from potable water at the point-of-care. Early identification of potential use errors is important within the medical device design process. IEC 62366-1 is a medical device human factors engineering process standard used to establish the safety of medical devices with respect to usability. Formative evaluations are completed iteratively, early and often throughout an optimal design process, with feedback used to improve device design. We present results from early formative evaluations which have informed the ongoing design and development of the EM-POC system.

**Methods:** Formative human factors evaluations compliant to IEC 62366-1 were completed with an experienced PD patient, PD nurses and internal company personnel: 1. Participants assessed usability of a prototype device when used to to complete PD bag fills with sterile water produced by the EM-POC system at home. (n=4) 2. Participants completed tasks and provided opinions regarding aspects of design and usability through online evaluations using images of the prototype and software simulation of the user interface. (n=3)

**Results:** The most common potential harm identified was concern over contamination risk leading to peritonitis. Resulting design adjustments have included: 1. Tactile and auditory feedback during connection of the PD bag 2. Improved geometry and visibility of the connection port 3. A single step connection process 4. Prohibited distilling if the connection is incomplete or incorrect

**Conclusions:** Early formative evaluations have successfully identified potential use errors enabling design refinement and improvement prior to further clinical evaluation.

**Funding:** Commercial Support - Ellen Medical Devices

## FR-PO528

### Long-Term Survival Rates in Peritoneal Dialysis Initiated Immediately After Catheter Insertion: Comparative Study With Hemodialysis

Yoonsun Joo, Young-Il Jo, Jung Hwan Park. Konkuk University Medical Center, Gwangjin-gu, Seoul, Republic of Korea.

**Background:** The aim of this study was to compare long-term survival rates of patients on peritoneal dialysis (PD) who started immediately after catheter insertion without a break-in procedure and those on hemodialysis (HD).

**Methods:** We conducted a retrospective study including all ESRD patients who started HD or PD between Jan 2005 and Dec 2021. PD catheters were inserted using percutaneous catheter insertion and initiated immediately. All patients were followed up until death, renal transplantation, or the end of the study. Patient survival rates were calculated using Kaplan-Meier analyses.

**Results:** A total of 379 HD patients and 150 PD patients were included. During followup, death occurred in 34.0% (n=129) of HD and 21.3% (n=32) of PD cases. The survival rates of HD patients were 92.5%, 81.1% and 44.8% at 1, 3 and 10 years. In PD patients, the survival rates were 95.5%, 86.4% and 55.7% at 1, 3 and 8 years. There was no difference in long-term survival between two groups (Fig1A). However, in the first year of dialysis, PD was associated with a greater survival than HD ( $p=0.007$ ) (Fig1B). Advanced age (defined as  $\geq 60$  years) and diabetes were associated with an increase in mortality regardless of dialysis modality (Fig1C). Particularly, the survival rate of non-diabetic PD was higher than that of non-diabetic HD as well as HD and PD patients with diabetes (Fig1D).

**Conclusions:** There is no difference in long-term survival rate between HD and immediate-start PD, but in the first year of dialysis, PD patients have better survival rate than HD. In particular, in non-diabetic patients, PD seems to have a superior survival rate than HD.

Long-term survival rates in HD and PD patients who started immediately after catheter insertion (A) Overall survival (B) 1-Year survival (C) Age-specific survival (D) DM-related survival

## FR-PO529

### A Retrograde Implantation Approach for Peritoneal Dialysis Catheter Placement in Mice

Isaac E. Sellinger,<sup>1,2</sup> Saran Lotfollahzadeh,<sup>1,2</sup> Lauren D. Stern,<sup>1,2</sup> Jean M. Francis,<sup>2,1</sup> Vipul C. Chitalia,<sup>2,4</sup> Mostafa Belghasem,<sup>3</sup> <sup>1</sup>Boston University School of Medicine, Boston, MA; <sup>2</sup>Boston University Renal Section, Boston, MA; <sup>3</sup>Kaiser Permanente Bernard J Tyson School of Medicine, Pasadena, CA; <sup>4</sup>Veterans Affairs Boston Healthcare System, Boston, MA.

**Background:** Chronic kidney disease (CKD) has reached pandemic proportions. Almost one in seven and two in 1,000 Americans have CKD, and End-Stage Kidney Disease (ESKD), respectively. While hemodialysis is the mainstay of renal replacement therapy, peritoneal dialysis (PD) provides distinct advantages. Murine models are employed to investigate details of peritoneal membrane failure. Current murine models suffer from technical challenges like catheter migration and kinking that often warrant early catheter removal and compromise the models' performance. We set out to improve a PD murine model and overcome these key limitations.

**Methods:** Ten C57BL/6J mice, 8–12 weeks in age, were used. Peritoneal catheters were placed with a novel retrograde technique. This method was validated using an LPS-induced inflammation assay. LPS was injected with 2 mg/kg bodyweight for 7 days. The peritoneal membrane was probed for fibrosis, neovascularization, and sub-peritoneal space using integrated density measurements normalized to the area.

**Results:** A retrograde method of PD catheter was adopted. Accordingly, the catheter was customized with a side hole and retrograde tube passing through a prefabricated tract. All the implanted catheters were functional till the end of the study. No incidences of catheter dislodgement, leaking of PD fluid, skin damage, or catheter kinking were noted. Compared to PBS, LPS exposure resulted in a significant increase in the extracellular matrix in the sub-peritoneal space ( $P=0.008$ ), a 3-fold increase in sub-peritoneal fibrosis ( $P=0.015$ ), and an 8–9-fold increase in the vascularity ( $P=0.0168$ ).

**Conclusions:** Out of 3 conventional murine models of PD, we now describe a modified method that significantly improved the PD catheter functions and avoided all the complications noted with the previous method. The current modifications will now pave the way to generate a durable murine model to investigate the long-term consequences of peritoneal membrane failure in human ESKD patients.

### Medical, Radiological, and Surgical Peritoneal Dialysis Catheter Insertion Outcomes at a Single UK Centre

Gemma D. Banham, Matthew Tabinor, Amar M. Mahdi, Jyoti B. Baharani. University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.

**Background:** We sought to determine success rates of peritoneal dialysis (PD) catheters inserted at our centre.

**Methods:** Audit of PD catheter outcomes from 2019 to 2021 at Birmingham Heartlands Hospital (BHH), University Hospitals Birmingham NHS Foundation Trust (UHB). Surgery was performed at BHH and Queen Elizabeth Hospital Birmingham, UHB.

**Results:** In 182 patients referred for PD catheter placement, 220 procedures were performed (83 (37.7%) medical, 80 (36.4%) radiological, 57 (25.9%) surgical). The initial insertion attempt was successful in 128/182 (70.3%) cases - 56/83 (67.5%) medical, 44/60 (73.3%) radiological and 28/39 (71.8%) surgical. Catheters were successfully sited in 28/35 (80.0%) patients on further attempts. After failed medical placement, catheters were sited medically in 1/23 (4.3%), radiologically in 10/23 (43.5%) and surgically in 7/23 (30.4%), with 5/23 (21.7%) commencing haemodialysis (HD) after another failed attempt. After failed radiological placement, catheters were successfully sited in 1/8 (12.5%) radiologically and 6/8 (75.0%) surgically, with 1/8 (12.5%) commencing HD following unsuccessful placement. Surgical placement was successful with a second procedure in 2/4 (50%) of those failing surgical placement. 19 patients opted against a second attempt. There were no differences in one year catheter survival between catheters inserted medically, radiologically and surgically (log rank test  $p=0.68$ ). Catheter insertion modality, age, sex, ethnicity, cause of renal disease and index of multiple deprivation were not predictors of catheter failure in cox regression analysis.

**Conclusions:** Catheters placed medically were comparable to those placed radiologically and surgically and offer an option for PD catheter insertion in day case and acute settings in suitable patients. Without predictors of poor outcome, clinical judgement remains critical in determining patient suitability.

##### Surgical and Image-Guided Percutaneous Peritoneal Dialysis Catheter Placement Associated With Similar Outcomes: A Single-Center Retrospective Study in Canada

Kahina Ait Zaid,<sup>1</sup> Yaniss Heniche,<sup>2</sup> Isabelle Ethier.<sup>3,4</sup> <sup>1</sup>Universite de Montreal, Montreal, QC, Canada; <sup>2</sup>Universite de Sherbrooke, Sherbrooke, QC, Canada; <sup>3</sup>Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; <sup>4</sup>Centre Hospitalier de l'Universite de Montreal Centre de Recherche, Montreal, QC, Canada.

**Background:** The current ISPD guidelines do not recommend any specific peritoneal dialysis (PD) catheter placement technique due to lack of demonstrated superiority of one technique over the others. We aimed to evaluate outcomes following catheter placement in our center, comparing surgical placement and image-guided percutaneous insertion.

**Methods:** In this retrospective cohort study, all patients (prevalent and incident) enrolled in our PD program from June 2017 until December 2021 were included. Incidence of immediate complications and early (<30 days) exit-site infections and peritonitis were evaluated. Time-to-first peritonitis and first exit-site infection were also analyzed using the Kaplan-Meier product-limit method and log-rank test.

**Results:** Of the 73 patients enrolled in our PD program during the study period, 39 and 34 underwent surgical and percutaneous catheter placement, respectively. Baseline characteristics were similar in both groups, except for history of cancer, year of PD start and left/right localization of the peri-umbilical catheter exit-site. There were 1 and 3 immediate complications; 2 and 1 early exit-site infections; 0 and 1 (associated to an immediate complication) early peritonitis in the surgical and percutaneous groups, respectively. Two patients in each group required repositioning or new catheter placement within 90 days of the first intervention. Percutaneous catheter placement showed similar time-to-first peritonitis (p=0.35) and time-to-first exit-site infection (p=0.30) compared to surgical placement.

**Conclusions:** Surgical and percutaneous PD catheter placement showed similar outcomes in our center. Future studies could also evaluate other aspects of catheter placement techniques, such as cost and patient experience.

Table 1. Baseline characteristics at time of PD catheter placement

	Surgical placement N=39	Percutaneous placement N=34	p-value
Age (years; mean $\pm$ SD)	58.4 $\pm$ 14.2	57.1 $\pm$ 12.0	0.663

##### Complications in Peritoneal Dialysis Catheters Placed Percutaneously vs. Surgically in a Second Level Hospital in Merida, Mexico

Naomi A. Alvarez Zapata, Leticia M. Tapia Silva. Hospital General Agustin O'Horan, Merida, Mexico.

**Background:** The state of Yucatan has the highest prevalence of obesity, diabetes and nephrolithiasis in Mexico. The Hospital Dr. Agustin O'Horan is located in Merida and receives uninsured patients of indigenous Mayan descent. Due to the limited access to healthcare in these regions and the high prevalence of comorbidities, most patients progress to renal failure and end up in the emergency department with uremic syndrome. The objective of our study is to describe the frequency of mechanical and infectious complications within 30 days of peritoneal dialysis (PD) catheter insertion between the percutaneous and surgical technique.

**Methods:** This is a descriptive study conducted at our hospital from January 1st to April 24th, 2022. Data was collected from patients who were candidates to start renal replacement therapy with PD. Percutaneous catheter insertion was performed with a bedside blind technique or with an open mini-laparotomy. Patient preparation in the percutaneous approach included fasting, insertion of a urinary catheter and colonic enema. Informed consent and preoperative blood tests were obtained. Analgesia and antibiotic prophylaxis were administered and double cuff Tenckhoff catheters were used.

**Results:** 48 dialysis catheter insertions took place in 44 patients while 4 of them underwent catheter removal and replacement. The mean age of the participants was 49.9 years, 61.3% were women and 70.4% were diabetic. Of the total of PD catheter insertions, 18 were percutaneous and 30 surgical. There was no difference between groups in terms of mechanical and infectious complications, while transfer to hemodialysis was more common in the surgical group.

**Conclusions:** One of the greatest challenges that Mexico faces is the accelerated growth of chronic kidney disease in a vulnerable population with limited access to healthcare. Achieving safer, and more convenient PD catheter placement with the use of minimal human and material resources is key to our institution in order to reduce the cost and the impact of kidney failure.

Variable	Percutaneous (n=18)	Surgical (n=30)	p
Mechanical dysfunction (%)	2(11)	8(26)	0.16
Exit-site infection (%)	1(5.5)	1(3.3)	0.76
Peritonitis (%)	2(11)	2(6.6)	0.68
Uncomplicated catheter within 30 days (%)	13(72)	15(50)	0.13
Transfer to hemodialysis (%)	9(0)	9(30)	0.007

## FR-PO533

# Percutaneous vs. Surgical Catheter Placement in Subjects With ESKD Referred Late to Start of Peritoneal Dialysis

Hugo E. Chavez. Instituto Mexicano del Seguro Social, Jalisco, Mexico.

**Background:** In developing countries, end-stage kidney disease (ESKD) patients are often referred late for renal replacement treatment. In this context requiring immediate treatment, it is unknown whether percutaneous peritoneal dialysis (PD) catheter placement is feasible and safe compared to surgical insertion. Aims: To compare clinical outcomes of percutaneous vs surgical catheter placement in a cohort of ESKD patients with need to initiate as soon as possible dialysis and referred for PD initiation.

**Methods:** Prospective cohort study performed at the General Regional Hospital IMSS 180, a tertiary reference center for PD care in Jalisco, Mexico (2018-2020). Subjects were selected for percutaneous catheter placement unless there was a contraindication in which case surgical insertion was performed. The goal was a short break-in period to achieve PD initiation as soon as possible.

**Results:** A total of 261 subjects underwent percutaneous (n=102, 39%) or surgical (n=159, 61%) catheter placement. Patients who underwent percutaneous insertion were younger (39 [IQR 28-58] vs 54 [IQR 35-64] years), had more males (75% vs 50%), had a higher burden of uremic symptoms (54% vs 27%), lower eGFR (4.5 [IQR 3-6] vs 6 [IQR 4-7.5] mL/min/1.73m<sup>2</sup>), and higher frequency of serum K<sup>+</sup>>6 mmol/L (22% vs 6%), all with a P<0.001. Subjects in percutaneous group had less waiting time between admission and catheter placement (6 [IQR 3-9] vs 11 [IQR 9-15] days), less time of break-in waiting period (1 [1-1] vs 2 [2-3] days) and shorter length of stay (13 [10-19] vs 18 [14-23], days, Fig 1). Nevertheless, percutaneous procedure was associated with a higher number of complications (48% vs 20%, P<0.001), including catheter dysfunction requiring surgery repair and/or exchange (29% vs 11%, P<0.001). Mortality during 3 year of follow-up was similar between percutaneous (23%) and surgical (24%) groups (log-rank=0.76, 95% CI: 0.46-1.26).

**Conclusions:** Compared to SX catheter insertion, percutaneous catheter placement in patients with need to initiate as soon as possible dialysis, significantly decreases waiting time between admission and catheter placement, break-in period, and the length of stay. Although the need for catheter exchange was more frequent with percutaneous technique, percutaneous placement allowed PD start in the majority of late-referred patients with advanced uremia.

# Antibiotic Prophylaxis for Tenckhoff Catheter Insertion: A Prospective Randomized Controlled Trial

Tatiana Tanasychuk, Daniel Kushnir, Oleg Sura, Ilona Mendelovich, Victor Frajzewicki. Carmel Medical Center, Haifa, Israel.

**Background:** The incidence of early (postoperative) peritonitis after catheter insertion was described as high as 17%. Current guidelines recommend intravenous (IV) preoperative antibiotic prophylaxis. For the last 20 years, our protocol includes a single dose of Cefazoline administered intraperitoneally (IP) through the Tenckhoff catheter immediately after its insertion. Our previous retrospective study (2016) showed the effectiveness of this protocol. Over the past years, we conducted a prospective randomized trial using the same protocol of Cefazoline prophylaxis. The aim of the trial is to compare the effectiveness of both methods of prophylaxis

**Methods:** The trial includes all adult patients at our Institution who were candidates for peritoneal catheter insertion, able to give informed consent, without history of antibiotic use in the two weeks prior to the procedure and without history of allergy to cephalosporins. The study has two arms: intravenous preoperative or intraperitoneal postoperative, while in both arms we used the same dose (1 gr) of Cefazoline. Follow-up period was 2 weeks after the catheter insertion procedure

**Results:** From March 8, 2017 - December 15, 2021 sixty two patients were included in the trial, the IP group included 30 individuals and the IV arm 32 persons. Mean age was 64.7 years (31-87), 64.5% were male and 56.5% were diabetics. A percutaneous insertion was done in 95% of the procedures, only 5% surgical. Patient's characteristics were similar in both groups. Twenty four percent of patients were Staphylococcus aureus nose carriers (37% in IP arm and 13% in IV arm) and received antibacterial topical prophylaxis. Two cases of peritonitis (3%) were recorded, without difference between the groups (one in each group).

**Conclusions:** Taking in count the relatively small size sample of one single center, early results of our study support the hypothesis of non-inferiority effectiveness of IP postoperative Cefazolin administration in comparison to IV preoperative for early peritonitis prophylaxis after percutaneous peritoneal catheter insertion.

# Change in Payment Method and the Use of Etelcalcetide and PTH Values Among Dialysis Patients in Two Dialysis Organizations

Carol Moore,<sup>1</sup> Najma Saleem,<sup>1</sup> Junjie Ma,<sup>1</sup> Gina C. Mak,<sup>5</sup> Kevin J. Martin,<sup>4</sup> Stuart M. Sprague.<sup>2,3</sup> <sup>1</sup>Amgen, Thousand Oaks, CA; <sup>2</sup>NorthShore University HealthSystem, Evanston, IL; <sup>3</sup>University of Chicago Pritzker School of Medicine, Chicago, IL; <sup>4</sup>Saint Louis University, Saint Louis, MO; <sup>5</sup>IQVIA Inc, Durham, NC.

**Background:** The CMS has provided reimbursement for the treatment of end-stage renal disease (ESRD) under a Medicare bundled prospective payment system (PPS) since 2011. A new payment adjustment system, Transitional Drug Add-On Payment Adjustment

(TDAPA), was established in 2016 to account for new therapies. Calcimimetics became eligible for TDAPA in 2018. On January 1<sup>st</sup> 2021 calcimimetics were no longer reimbursed using TDAPA. Instead, the bundle base rate was increased for all patients to support utilization of etelcalcetide based on a national average usage of 6.3% of dialysis treatments. This study described the use of etelcalcetide and the parathyroid hormone (PTH) values before and after January 1<sup>st</sup> 2021.

**Methods:** This was a repeated cross-sectional study. Data were collected from electronic medical records of two dialysis organizations between January 2019 and December 2021. All etelcalcetide users who visited dialysis facilities operated by the dialysis organizations were included. The number and percent of etelcalcetide continuers and the average PTH values of all patients by month were reported. Additionally, we identified those whose last dose of etelcalcetide was between December 1<sup>st</sup> 2020 and January 31<sup>st</sup> 2021 and reported PTH values among those in the 9 months prior and after the month of last dose.

**Results:** The mean of monthly average number of patients was 34,924 during the study period. The mean of monthly average number of etelcalcetide continuers was 5,105 (14.2%) between January 2019 and December 2020 and dropped to 217 (0.7%) in 2021 after the ESRD PPS policy change. The mean of monthly average PTH values between January 2019 and December 2020 was 483 pg/ml (range, 436 pg/ml to 533 pg/ml), while it increased to 544 pg/ml (range, 485 pg/ml to 601 pg/ml) in 2021. We identified 3,560 etelcalcetide discontinuers whose last dose was between December 1<sup>st</sup> 2020 and January 31<sup>st</sup> 2021. The mean of monthly average PTH values in the 9 months prior to the last dose was 579 pg/ml, while it was 745 pg/ml in the 9 months after the last dose.

**Conclusions:** A major decrease in etelcalcetide use and an increase in average PTH values were observed after the implementation of changes in the ESRD PPS. Future studies are warranted to investigate the impact of the policy change on patient outcomes.

# The Bioimpedance Spectroscopy to Preserve Renal Output (BISTRO) Multicentre Randomised Controlled Trial: Quality of Life and Blood Pressure Outcomes

Simon J. Davies,<sup>1</sup> Mandana Zanganeh,<sup>2</sup> Ivonne Solis-Trapala,<sup>1</sup> David F. Keane,<sup>3</sup> Andrew Davenport,<sup>4</sup> Martin E. Wilkie,<sup>10</sup> Paula Ormandy,<sup>7</sup> Jamie H. Macdonald,<sup>6</sup> Indranil Dasgupta,<sup>9</sup> Ken Farrington,<sup>8</sup> Fergus Caskey.<sup>5</sup> on behalf of the BISTRO Investigators <sup>1</sup>Keele University, Keele, United Kingdom; <sup>2</sup>University of Warwick University House, Coventry, United Kingdom; <sup>3</sup>Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; <sup>4</sup>Royal Free London NHS Foundation Trust, London, United Kingdom; <sup>5</sup>University of Bristol, Bristol, United Kingdom; <sup>6</sup>Bangor University, Bangor, United Kingdom; <sup>7</sup>University of Salford, Salford, United Kingdom; <sup>8</sup>Hertfordshire Partnership University NHS Foundation Trust, Hatfield, United Kingdom; <sup>9</sup>NHS Birmingham and Solihull Clinical Commissioning Group, Birmingham, United Kingdom; <sup>10</sup>Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom.

**Background:** BISTRO examined if using bioimpedance (BIS) to avoid setting the post-dialysis target weight (PD-TW) below the normally hydrated weight (NHW) could preserve residual kidney function (RKF) when compared to a standardized fluid management protocol. This pre-specified secondary analysis reports the effect of BIS on health-related quality of life, symptoms, and blood pressure.

**Methods:** BISTRO is an open-label, clinician-blinded, randomized controlled trial in incident HD patients with >500ml urine volume/day or residual GFR >3 ml/min/m<sup>2</sup>. Randomization was by centralized concealed allocation, 1:1, stratified by centre. BIS measurements were taken by independent observers and concealed in the control arm. Secondary outcomes included BP, self-rated health (EQ visual analogue scale), dialysis symptoms, health-related quality of life (EuroQol and Short Form 12), collected at baseline and 3-monthly until month 24. ISCTN Number: 11342007; Funding: UK NIHR Health Technology Assessment Programme

**Results:** Questionnaire completeness was 52%–89%, similar by group. Median EQ-VAS rose from 60 to 65 in both groups at 3 months, then back to baseline, remaining stable. Despite a progressive fall in RKF, dialysis symptoms were remarkably stable over 24 months (see Table) with only modest worsening of recovery time, no between-group differences. There was no longitudinal change or between-group difference in BP, just a tendency for a lower post-dialytic BP and more hypotensive symptoms in the control group between 18 and 24 months. Mean difference in PD-TW and NHW was not different between study arm assessments: BIS, n=1335 observations, -0.038Kg (SD 2.7); Control, n=1166 -0.25Kg (2.6)

**Conclusions:** Using a standardised fluid assessment protocol secondary outcomes were stable in those remaining in the trial and not benefited by the addition of BIS, possibly because clinician fluid assessments were close to the NHW.

**Funding:** Government Support - Non-U.S.

Discordance Between Cause of Death Reported to USRDS and National Death Index for Hemodialysis Patients

Yoshitsugu Obi,<sup>1</sup> Anna Xu,<sup>2</sup> Jonathan A. Wilson,<sup>2</sup> Patti Ephraim,<sup>6</sup> Daniel E. Weiner,<sup>3</sup> Julia J. Scialla,<sup>4</sup> Bernard G. Jaar,<sup>5</sup> Benjamin A. Goldstein,<sup>2</sup> Tariq Shafi.<sup>1</sup> <sup>1</sup>The University of Mississippi Medical Center, Jackson, MS; <sup>2</sup>Duke University Medical Center, Durham, NC; <sup>3</sup>Tufts Medical Center, Boston, MA; <sup>4</sup>University of Virginia School of Medicine, Charlottesville, VA; <sup>5</sup>Johns Hopkins University, Baltimore, MD; <sup>6</sup>Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY.

**Background:** The USRDS reports that over 40% of deaths in patients with kidney failure on hemodialysis (HD) are due to cardiovascular disease (CVD), most of which are attributed to sudden cardiac death (CVD-SCD). These data are based on the Death Notification Form completed by dialysis clinics. The validity of USRDS reported cause of death has not been rigorously evaluated against the National Death Index (NDI) death certificate data, which provide epidemiological assessment of cause-specific mortality in the US.

**Methods:** Among 32,640 US adult incident HD patients, we identified 8,029 patients who died between 2003 and 2009 with cause of death not classified as hospice or dialysis withdrawal. We linked the NDI data to the dialysis cohort and compared USRDS vs. NDI cause of death using concordance and kappa ( $\kappa$ ) statistics.

**Results:** At the time of death, the patients' median age was 71 years and 44% were female. CVD accounted for 50% of deaths in the USRDS but only 37% in the NDI (Table). 32% of all deaths were classified as CVD-SCD by the USRDS compared to 17% by the NDI. Overall concordance of the USRDS with the NDI was low at 29%. The agreement between the USRDS and the NDI was poor (overall  $\kappa$ , 0.13), irrespective of the location of death (i.e., in-hospital vs. out-of-hospital) or the time since the last outpatient HD (i.e., <72 hours vs. >72 hours post HD). The poorest agreement ( $\kappa$ , 0.09) was observed among out-of-hospital deaths that occurred >72 hours after the last HD.

**Conclusions:** Significant discordance exists between cause of death reported by USRDS versus NDI. These findings may have major implications for the presumed CVD burden and risk factors associations with cause-specific mortality in the US HD population.

**Funding:** NIDDK Support

	National Death Index						Total [NDI %]
	CVD-SCD	CVD-non-SCD	Cancer	Infection	Other	Unknown/ Missing

FR-PO538

Cost-Effectiveness Analysis of Paricalcitol and Calcitriol in Beijing Patients With Secondary Hyperparathyroidism

Jiannan Zhou. Beijing Aerospace General Hospital, Beijing, China.

**Background:** To compare the cost efficacy analysis and the effect on calcium and phosphorus variability of paricalcitol and calcitriol in the treatment of hemodialysis CKD-MBD patients in Beijing from the payer's perspective.

**Methods:** Patients were divided into the paricalcitol group and the calcitriol group, and both groups could be treated with a combination of cinacalcet. The treatment duration was 6 months, and the attainment endpoint was mean iPTH  $\leq$  300 pg/ml in the 4th-6th month of treatment. Efficacy was the attainment rate of patients in both groups. The cost is the sum of medications and laboratory tests over a 6-month period. We evaluated incremental cost-efficacy analysis (ICER) and plotted to scatter plots of incremental cost-effects using nonparametric Bootstrap repeated sampling 1000 times. A one-way sensitivity analysis of factors affecting ICER was also performed, and probabilistic sensitivity analysis of parametric random sampling was performed using Monte Carlo simulation.

**Results:** The effective rates in the two groups were 88.7% (paricalcitol group) and 56.5% (calcitriol group), respectively. The cost-effect basis analysis showed that the ICER of paricalcitol and calcitriol was CNY 41554.702. Single-factor sensitivity analysis showed that the price of paricalcitol is the most sensitive factor, and the probabilistic sensitivity analysis showed that paricalcitol was a more economical solution when the willingness to pay (WTP) was above CNY 32500. There is no differences of the calcium and phosphorus smoothing index between tow groups.

**Conclusions:** Paricalcitol has an economic advantage when the six-month willingness to pay is CNY 32,500 or more per effective patient treated.

FR-PO539

Nurse Caseload and Patient Survival in Hemodialysis Units: A Korean Nationwide Cohort Study

Do Hyoung Kim, Seyeon Park, Yoseop Cha, Hayne C. Park. Kangnam Sacred Heart Hospital, Yeongdeungpo-gu, Seoul, Republic of Korea.

**Background:** The patient-to-nurse ratio is highly variable among dialysis facilities. However, there is little known about the association between nurse caseload and hemodialysis (HD) patient outcomes. We evaluated the association between patient-to-nurse ratio and mortality in the Korean patients undergoing HD.

**Methods:** We used HD quality assessment data and National Health Insurance Service claim data from the year of 2013 for collecting demographic and clinical data. Altogether, 21,817 patients who participated in the HD quality assessment in 2013 were included in the study. Nurse caseload was defined as the number of HD sessions performed by a nurse per working day. The patients were divided into two groups according to the nurse caseload as follows: low nurse caseload group ( $\leq$ 6.0) and high nurse caseload group ( $>$ 6.0). We analyzed mortality risk based on nurse caseload using the Cox proportional hazard model.

**Results:** The mean age was 59.1 years, and males accounted for 58.5%. The mean hemoglobin was 10.6 g/dL and albumin was 3.99 g/dL. At the mean follow-up duration of 51.7 (20.6) months, the ratio between low and high groups was 69.6% (15,184 patients) versus 30.4% (6,633 patients). The patients in the high nurse caseload group were older and showed lower levels of hemoglobin, albumin, calcium, and iron saturation and higher levels of phosphorus than those in the low nurse caseload group. A high nurse caseload was associated with a lower survival rate. In the adjusted Cox analysis, a high nurse caseload was an independent risk factor for all-cause mortality (hazard ratio 1.08; 95% confidence interval, 1.02–1.14;  $p = 0.01$ ).

**Conclusions:** High nurse caseload was associated with an increased mortality risk among the patients undergoing HD. Further prospective studies are needed to determine whether a caseload of nursing staff can improve the prognosis of HD patients.

FR-PO540

Professional Fulfillment and Burnout Among US Dialysis Technicians: A National Association of Nephrology Technicians/Technologists (NANT) Survey

Megan A. Urbanski,<sup>1</sup> Fran W. Rickenbach,<sup>2</sup> Alexis A. Bender,<sup>1</sup> Courtney E. Hoge,<sup>1</sup> Clarica Douglas- Ajayi,<sup>2</sup> Jennifer C. Morgan,<sup>3</sup> Bernard G. Jaar,<sup>4</sup> Laura Plantinga.<sup>1</sup> <sup>1</sup>Emory University, Atlanta, GA; <sup>2</sup>National Institute of Nephrology Technicians/Technologists, Dayton, OH; <sup>3</sup>Georgia State University, Atlanta, GA; <sup>4</sup>Johns Hopkins University, Baltimore, MD.

**Background:** High levels of professional fulfillment and low levels of burnout are necessary for a stable, satisfied dialysis workforce. We examined professional fulfillment and burnout among critical frontline hemodialysis staff — dialysis technicians.

**Methods:** A one-time, anonymous, online survey was administered to NANT members, recruited via postcards distributed at professional conferences, newsletter and social media announcements, and direct emails. Surveys included Likert-scale items (range, 0-4; see Figure) related to professional fulfillment and two domains of burnout (work exhaustion and interpersonal disengagement).

**Results:** A total of 222 working U.S. dialysis technicians [42.6% aged 35-49; 83.9% female; 20.8% Black; 15.7% Hispanic] completed the survey. Overall domain scores for professional fulfillment, work exhaustion, and interpersonal disengagement [median (interquartile range)] were 2.6 (2.0-3.2), 2.3 (1.3-3.0), and 1.0 (0.3-1.8), respectively; scores for individual items are shown in the Figure. More than half of respondents stated that salary (66.5%), supervisor support (64.0%), respect from other dialysis staff (57.8%), sense of purpose about work (54.5%), hours worked per week (52.9%), respect from patients (52.0%), and autonomy (50.4%) "contributed a lot" to fulfillment and burnout.

**Conclusions:** NANT members report moderate professional fulfillment and low interpersonal disengagement scores, but high work exhaustion scores, which may lead to burnout and compromise patient safety. We identified several modifiable factors, including competitive salaries, reduced workloads and/or work hours, and improved collegial relationships, that could be addressed to improve professional fulfillment and reduce burnout among dialysis technicians.

## FR-PO541

### Work Experiences and Turnover Intention Among US Dialysis Technicians: A National Association of Nephrology Technicians/Technologists (NANT) Survey

Laura Plantinga,<sup>1</sup> Fran W. Rickenbach,<sup>2</sup> Megan A. Urbanski,<sup>1</sup> Jennifer C. Morgan,<sup>3</sup> Clarica Douglas-Ajayi,<sup>2</sup> Courtney E. Hoge,<sup>1</sup> Alexis A. Bender,<sup>1</sup> Bernard G. Jaar.<sup>4</sup> <sup>1</sup>Emory University, Atlanta, GA; <sup>2</sup>National Association of Nephrology Technicians/Technologists, Dayton, OH; <sup>3</sup>Georgia State University, Atlanta, GA; <sup>4</sup>Johns Hopkins University, Baltimore, MD.

**Background:** Turnover among dialysis staff is high, leading to understaffing, increased training costs, and decreased quality of care, but little is known about dialysis technicians specifically. We examined dialysis technicians' work experiences and turnover intention.

**Methods:** We administered a one-time, anonymous, online survey to NANT members, who were recruited via postcards distributed at professional conferences, newsletter and social media announcements, and direct emails. Surveys included items related to participant and work characteristics and turnover intention.

**Results:** A total of 222 actively working dialysis technicians completed the survey (3/22/22-5/5/22). Representing 39 U.S. states/territories, respondents were primarily middle-aged (42.6% aged 35-49), female (83.9%), white (67.8%), and non-Hispanic (85.3%). Most (80.4%) had at least some college. The majority (75.0%) worked in a freestanding outpatient hemodialysis facility. Half (50.0%) treated >9 patients per day, and 72.8% worked ≥40 hours per week; 23.7% worked at multiple facilities. While most respondents reported being certified (most commonly, Certified Clinical Hemodialysis Technician (73.7%) or Certified Hemodialysis Technician (22.4%)), fewer than half (45.5%) reported receiving formal (*i.e.*, not including on-the-job) training. Free responses reinforced perceived excessive work burden and lack of training. Only 52.6% reported that they plan to be working as a dialysis technician in 3 years (Figure).

**Conclusions:** Our results suggest that NANT members experience heavy workloads and have limited access to high-quality training. Even among this relatively engaged group of technicians, turnover intention is high, and with nearly half intending to soon seek new careers. Because of the critical, frontline role of dialysis technicians in hemodialysis care, strategies to improve training and working conditions and reduce turnover are imperative.

## FR-PO542

### Cost-Utility of Real-Time Potassium Monitoring in Hemodialysis Patients

Ryan J. Bamforth, Thomas W. Ferguson, Paul Komenda. *Chronic Disease Innovation Centre, Winnipeg, MB, Canada.*

**Background:** Patients with kidney failure requiring dialysis are at high risk for hyperkalemia, a result of elevated levels of potassium, which is associated with increased morbidity and mortality. Interventions aimed at early detection of hyperkalemic events may be useful to prevent these outcomes and their associated costs. As such, we performed a cost-utility analysis comparing an intervention where a real-time potassium monitoring device is administered in hemodialysis patients in comparison to usual care.

**Methods:** We performed a cost-utility analysis by developing a decision analytic microsimulation model from the perspective of the United States health care payer. Outcomes included the monthly break-even cost per patient of the proposed intervention and the incremental cost-effectiveness ratio (ICER) comparing use of the real-time potassium monitoring device to usual care. Costs associated with hyperkalemic events (emergency department and hospitalization specific) and dialysis were included. Utility estimates from a systematic review and meta-analysis were used to derive utilities for patients on hemodialysis. A reduction in hyperkalemic events of 25% was applied in the intervention scenario as a baseline effectiveness estimate, with a range between 10-50% considered in sensitivity analyses.

**Results:** Threshold analysis yielded a monthly break-even cost of \$689.56 US dollars per patient in the base case scenario. In addition, the microsimulation model found the intervention provided 0.04 additional quality-adjusted life-years (QALYs), and as such at any price point below or equal to the break-even cost the intervention was dominant in comparison to usual care. When altering effectiveness estimates between a reduction of hyperkalemic events between 10% to 50%, the monthly break-even cost ranged from \$265.36 to \$1387.90 USD respectively.

**Conclusions:** Implementing a real-time potassium monitoring device in hemodialysis patients to prevent hyperkalemic events has the potential for cost savings and increased quality of life from the perspective of the United States health care payer.

## FR-PO543

### Development and Validation of Deep Learning Algorithm for Detecting Hyperkalemia Based on Electrocardiogram

Dong Hee Lee, Jung Nam An, Sungmin Kim, Jwa-kyung Kim, Sung Gyun Kim. *Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.*

**Background:** Hyperkalemia is a common electrolyte abnormality, which in severe cases can cause fatal arrhythmia and cardiac arrest. However, it is often asymptomatic, and diagnosis is difficult without blood tests. The purpose of this study is to detect hyperkalemia quickly and easily through a deep learning-based model that has learned an electrocardiogram (ECG) that is non-invasive and can be quickly measured.

**Methods:** Among patients who underwent an ECG at least once from 2006 to 2020, patients with blood test results within 24 hours were included, and dialysis patients were excluded. All ECGs were acquired using a GE ECG machine and the raw data (XML datatype) were stored using the MUSE data management system. For model training and evaluation, the ECG-serum K pair was separated into train, validation, and test set. Hyperkalemia and severe hyperkalemia were defined as 5.5 mEq/L ≤ K+ and as 6.5 mEq/L ≤ K+. We trained a 4-class classification model using a Convolutional Neural Network. The model input was a standard 10-second, 12-lead ECG and the output being the likelihood of the ECG being from a patient with classes of serum potassium concentration.

**Results:** A total of 362,896 cases of ECG-serum K were analyzed in a total of 299,431 patients, of which 330,137 cases were in the train set, 15,250 cases in the validation set, and 28,783 cases in the test set. In the validation set, AUROC for hyperkalemia was 0.97 and AUPRC was 0.79, and AUROC for severe hyperkalemia was 0.99 and AUPRC was 0.86. In the test set, for hyperkalemia, the sensitivity and specificity of deep learning model were 81.1% and 80.9%.

**Conclusions:** The deep learning model using the 12-lead ECG waveform detected hyperkalemia with high accuracy, and in severe hyperkalemia, the diagnostic predictive power was further increased. These results suggest the clinical applicability of AI software for diagnosing hyperkalemia using ECG.

## FR-PO544

# Impact of Hyperkalemia on Mortality in Patients With Advanced Kidney Disease With and Without Hemodialysis: Implications for Deferring Hemodialysis Initiation Under Value-Based Models

Elani Streja,<sup>1,2</sup> Jui-Ting Hsiung,<sup>1,2</sup> Abiy Agiro,<sup>3</sup> Souhiela Fawaz,<sup>3</sup> Laura Westfall,<sup>3</sup> Yemisi Oluwatosin,<sup>3</sup> Kamyar Kalantar-Zadeh.<sup>1,2</sup> <sup>1</sup>University of California Irvine, Irvine, CA; <sup>2</sup>U.S. Department of Veterans Affairs, Long Beach, CA; <sup>3</sup>AstraZeneca Pharmaceuticals LP, Wilmington, DE.

**Background:** The relationship between hyperkalemia (HK) and mortality in patients with stage 5 chronic kidney disease (CKD) or end-stage kidney disease (ESKD) with or without hemodialysis (HD) is not well established. This study examines the relationship between HK and all-cause mortality and whether it is dependent on HD initiation.

**Methods:** This retrospective cohort study of the United States (US) Veterans Affairs database identified 14,681 individuals initiating HD (HD cohort, N=5063) or with estimated glomerular filtration rate (eGFR) <10 mL/min/1.73m<sup>2</sup> but not on HD (non-HD cohort, N=9618) who had at least one potassium (K+) measurement within 30 days of HD or eGFR index date and complete data for covariates. The association between HK (K+ >5.0 mEq/L) and all-cause mortality was analyzed by Cox regression analysis.

**Results:** In the total cohort, 8548 (58.2%) individuals had HK within 1 year prior to index (baseline HK). A greater proportion of the HD cohort than the non-HD cohort had baseline HK (69.6% and 52.3%, respectively). All-cause mortality rates within 1 year post-index in the HD and non-HD cohorts were 11.3% and 20.5%, respectively. After adjustment for baseline HK, demographic characteristics, comorbidities, medication use, and baseline eGFR, HD was associated with a 60% decrease in 1-year all-cause mortality compared with no HD (adjusted hazard ratio [aHR] 0.40; 95% CI 0.37–0.44; P<0.0001). In the total cohort, 1-year all-cause mortality rates for those with and without baseline HK were 21.9% and 11.0%, respectively. Baseline HK was associated with a 50% increase in 1-year all-cause mortality compared with no baseline HK (aHR 1.50; 95% CI 1.37–1.64; P<0.0001).

**Conclusions:** HK was a strong independent risk factor for all-cause mortality among patients with stage 5 CKD/ESKD with and without HD. Patients with stage 5 CKD/ESKD managed conservatively without HD likely have less control of HK than those receiving HD. These data may have important implications for the goal of deferring HD initiation under value-based models.

## FR-PO545

# Hyperkalaemia in Patients Receiving Renin-Angiotensin-Aldosterone System Blockade: Clinical Epidemiology and Outcomes

Desmond Yap, Yu Fai Benjamin So, Chi Ho Paul Lee, Siu Han Jojo Hai, Tak Mao D. Chan. *The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong.*

**Background:** Hyperkalaemia is a common side effect of patients receiving renin-angiotensin-aldosterone system (RAAS) blockade, but its prevalence and clinical impact can vary between different localities due to differences in diets and patient characteristics. Data regarding the epidemiology and outcomes of hyperkalaemia in Asian patients is relatively limited.

**Methods:** We analyzed all patients receiving RAAS blockade at Queen Mary Hospital, Hong Kong during 2018–2021 and identified patients with hyperkalaemia. The prevalence and clinical outcomes of patients with or without hyperkalaemia were compared.

**Results:** A total of 14,206 patients were analysed, including 6085 (42.8%), 5849 (41.2%) and 379 (2.7%) patients on angiotensin converting enzyme inhibitors (ACEI), angiotensin receptor blockers (ARB) and mineralocorticoid receptor antagonists (MRA) respectively. 1893 patients (13.3%) received dual or triple RAAS blockade. Hyperkalaemia occurred in 3959 (27.9%) patients. 1647 patients (11.6%) died during follow up, and 3-year mortality rate was significantly higher in patients with hyperkalaemia compared with those without (25.5% vs. 6.2%, p<0.001). 616 patients (4.3%) had major cardiovascular events (MACE), and patients with hyperkalaemia showed increased rates of MACE compared to those without hyperkalaemia (7.8% vs. 3.0%, p<0.001). Patients with hyperkalaemia also showed more rapid deterioration of eGFR compared with those without hyperkalaemia (2.8±6.0 mL/min/year vs. 1.3±4.3 mL/min/year, p<0.001). 314 patients (2.2%) developed end-stage kidney disease (ESKD) during a follow up of 3 years, and the incidence of ESKD was significantly higher in patients with hyperkalaemia (6.2% vs. 0.7%, p<0.001).

**Conclusions:** Hyperkalaemia is highly prevalent among Asian patients receiving RAAS blockade and is associated with unfavourable clinical outcomes.

## FR-PO546

# Persistent Reduction in RAASI Therapy Following an Episode of Hyperkalemia

Anjay Rastogi,<sup>1</sup> Eiichiro Kanda,<sup>2</sup> Toyoaki Murohara,<sup>3</sup> Eva Lesén,<sup>4</sup> Abiy Agiro,<sup>5</sup> Mina Khezrian,<sup>6</sup> Gengshi Chen,<sup>6</sup> Naru Morita,<sup>7</sup> Krister Järbrink,<sup>4</sup> Charles V. Pollack,<sup>8</sup> <sup>1</sup>David Geffen School of Medicine at the University of California Los Angeles, Los Angeles, CA; <sup>2</sup>Kawasaki Medical School, Okayama, Japan; <sup>3</sup>Nagoya University Graduate School of Medicine, Nagoya, Japan; <sup>4</sup>AstraZeneca, Gothenburg, Sweden; <sup>5</sup>AstraZeneca, Wilmington, DE; <sup>6</sup>AstraZeneca, Cambridge, United Kingdom; <sup>7</sup>AstraZeneca, Osaka, Japan; <sup>8</sup>University of Mississippi School of Medicine, Jackson, MS.

**Background:** RAASI therapy reduces the risk of cardiorenal events in patients with CKD or HF, but fear of hyperkalemia (HK) is a barrier towards achieving guideline-directed target dosing. The objective of this analysis was to describe longitudinal RAASI treatment patterns in patients after a HK episode.

**Methods:** This observational study used hospital records and claims data from the US (Optum MarketClarity) and Japan (Medical Data Vision). Patients with a HK episode (ICD-10 E87.5) from Jul 2019–Sep 2021 (US) or May 2020–Sep 2021 (Japan) and CKD or HF were included. RAASI classes encompassed ACE inhibitors, ARB, MRA and ARNi. Average dose across RAASI classes was described as a percentage of local guideline-directed target dose prior to the HK episode and at 3, 6 and 12 months after.

**Results:** Of 46,820 patients from the US, 89% had CKD and 52% had HF. In Japan (N=26,979), 52% had CKD and 74% had HF. 18,652 US patients and 8,467 patients in Japan filled ≥1 RAASI prescription in the 3 months prior to the HK episode. The most common RAASI classes were ACE (used by 56.4%), ARB (31.9%) and MRA (21.8%) in the US, and ARB (74.1%), MRA (26.5%) and ACE (17.2%) in Japan. In the US, 60% attained >50% of target dose across RAASI classes prior to the HK episode (Figure), dropping to 41–45% in the subsequent 3–12 months. At 3 months, 28% had discontinued, and 23% had no RAASI treatment at 12 months. While attainment of guideline-target dose prior to the HK episode was lower in Japan, the patterns over time were similar to those in the US.

**Conclusions:** Despite guideline recommendations to maintain RAASI therapy with antihyperkalemia treatment, RAASI therapy is commonly discontinued following a HK episode and the RAASI reduction persists over time.

**Funding:** Commercial Support - AstraZeneca

Target RAASI dose attainment

## FR-PO547

# Recurrent Hyperkalemia and Renin-Angiotensin-Aldosterone System Inhibitor (RAASI) Down-Titration in a US Integrated Healthcare System

Hui Zhou,<sup>1,2</sup> Liang Ni,<sup>1</sup> John J. Sim,<sup>3,2</sup> Teresa N. Harrison,<sup>1</sup> Oluwaseye Ogun,<sup>1</sup> Rong Wei,<sup>1</sup> Abiy Agiro,<sup>4</sup> Yasmin G. Brahmabhatt,<sup>4</sup> Yemisi Oluwatosin,<sup>4</sup> Craig G. Schilling,<sup>4</sup> Jaejin An.<sup>1,2</sup> <sup>1</sup>Kaiser Permanente Southern California, Pasadena, CA; <sup>2</sup>Kaiser Permanente Bernard J Tyson School of Medicine, Pasadena, CA; <sup>3</sup>Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; <sup>4</sup>AstraZeneca Pharmaceuticals LP, Wilmington, DE.

**Background:** While RAASI down-titration (discontinuation and dose reduction) is common after new-onset hyperkalemia, how RAASI down-titration is related to recurrent hyperkalemia is not well understood. We evaluated recurrent hyperkalemia and factors associated with RAASI down-titration among patients with chronic kidney disease (CKD) and/or heart failure (HF).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Methods:** A retrospective cohort study was conducted among adults with CKD and/or HF who experienced new-onset hyperkalemia (potassium  $\geq 5.0$  mEq/L, index) at Kaiser Permanente Southern California. We required patients to have  $\geq 2$  fills of RAASi within 1 year prior to the index and followed them for up to 1 year. We evaluated recurrent hyperkalemia every 3 months from Month 1 to 9 and RAASi down-titration [discontinuation ( $\geq 90$ -day gap in refills of  $\geq 1$  RAASi) or  $\geq 25\%$  dose reduction compared with the dose prior to the index] in the following 3 months from Month 4 to 12. Secondary analysis was conducted using discontinuation as an outcome. Generalized estimating equation models were performed to identify factors associated with RAASi down-titration.

**Results:** Of 7,875 patients, the percentages of RAASi dose reduction were stable at 17% in all 3-month periods and discontinuation decreased from 12% to 7% in the last 3 months. The percentages of recurrent hyperkalemia were 10% and 8% in the first and the last 3 months, respectively. Recurrent hyperkalemia was associated with a higher likelihood of RAASi down-titration [rate ratio (RR) 1.36, 95%CI 1.16-1.60] and discontinuation [RR 1.75, 95%CI 1.48-2.08] (Figure). Inpatient recurrent hyperkalemia and worse kidney function were associated with a higher likelihood of RAASi down-titration.

**Conclusions:** After new-onset hyperkalemia, those who developed recurrent hyperkalemia were more likely to discontinue or reduce the dose of RAASi.

**Funding:** Commercial Support - AstraZeneca

Figure. Rate Ratios of RAASi down-titration (A) or RAASi discontinuation (B) with recurrent hyperkalemia and other selected factors

FR-PO548

Cardiorenal and Mortality Outcomes Associated With Renin-Angiotensin-Aldosterone System Inhibitor (RAASi) Discontinuation After New-Onset Hyperkalemia

Jaejin An,<sup>1,2</sup> Hui Zhou,<sup>1,2</sup> Liang Ni,<sup>1</sup> John J. Sim,<sup>3,2</sup> Teresa N. Harrison,<sup>1</sup> Oluwaseye Ogun,<sup>1</sup> Rong Wei,<sup>1</sup> Abiy Agiro,<sup>4</sup> Yasmin G. Brahmbhatt,<sup>4</sup> Yemisi Oluwatosin,<sup>4</sup> Craig G. Schilling,<sup>4</sup> <sup>1</sup>Kaiser Permanente Southern California, Pasadena, CA; <sup>2</sup>Kaiser Permanente Bernard J Tyson School of Medicine, Pasadena, CA; <sup>3</sup>Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; <sup>4</sup>AstraZeneca Pharmaceuticals LP, Wilmington, DE.

**Background:** Discontinuation of RAASi is common after hyperkalemia. We evaluated the risk of cardiorenal outcomes and recurrence of hyperkalemia associated with RAASi discontinuation among patients with chronic kidney disease (CKD) and/or heart failure (HF).

**Methods:** We identified adults with hyperkalemia (potassium  $\geq 5.0$  mEq/L, index) and CKD and/or HF between 2016-2017 from Kaiser Permanente Southern California and followed them through 2019. We required patients to have no history of hyperkalemia and  $\geq 2$  fills of RAASi within 1 year prior to the index. We defined RAASi discontinuation as having  $\geq 90$ -day gap in refills of  $\geq 1$  RAASi within 3 months after index. We used multivariable Cox proportional hazards models to evaluate the association between RAASi discontinuation and cardiovascular (CV) events (myocardial infarction, stroke, HF hospitalization) or all-cause mortality, and recurrence of hyperkalemia. Renal events (40% reduction in eGFR, dialysis, kidney transplant) or all-cause mortality were evaluated among patients with CKD.

**Results:** Of 7,875 patients (mean age 75 years, 91% CKD), 15% discontinued RAASi within 3 months after index. During the median 2 years of follow-up, 32% had a composite of CV/mortality (16% CV, 16% death) and 36% experienced hyperkalemia recurrence. Among those with CKD, 33% had a composite of renal/mortality. Patients who discontinued RAASi had a higher incidence of cardiorenal outcomes compared with those who continued RAASi (Table). RAASi discontinuation was associated with a higher risk of cardiorenal outcomes [adjusted hazard ratio (aHR) 1.20, 95%CI 1.09-1.33 for CV/mortality, aHR 1.20, 95%CI 1.07-1.34 for renal/mortality] and a lower risk of hyperkalemia recurrence [aHR 0.86, 95%CI 0.76-0.97].

**Conclusions:** RAASi discontinuation after hyperkalemia was associated with worsened cardiorenal and/or mortality outcomes, which underscores the benefits of continuing RAASi in CKD and/or HF.

**Funding:** Commercial Support - AstraZeneca

Table. Incidence and Hazard Ratios of Outcomes for Patients who Continued vs. Discontinued RAASi

Outcome	RAASi Continuation	RAASi Discontinuation	Crude Hazard Ratio (95% CI)	Adjusted Hazard Ratio* (95% CI)
<b>Cardiovascular events or all-cause mortality (N=7,875)</b>				
Number of event/total person-years	2041/13170	486/2119		
Event per 1000 person-years (95% CI)	155.0 (148.4, 161.6)	229.4 (209.9, 250.7)	1.46 (1.32, 1.61)	1.20 (1.09, 1.33)
<b>Renal events or all-cause mortality<sup>‡</sup> (N=6,803)</b>				
Number of event/total person-years	1829/11596	372/1673		
Event per 1000 person-years (95% CI)	157.7 (150.7, 165.1)	222.3 (200.8, 248.1)	1.41 (1.26, 1.58)	1.20 (1.07, 1.34)
<b>Hyperkalemia recurrence<sup>§</sup> (N=6,983)</b>				
Number of event/total person-years	2103/9311	316/1470		
Event per 1000 person-years (95% CI)	225.9 (216.4, 235.7)	215.0 (192.5, 240.0)	0.94 (0.83, 1.06)	0.86 (0.76, 0.97)

Abbreviations: RAASi = Renin-Angiotensin-Aldosterone System Inhibitor. Covariates included age, sex, race/ethnicity, serum potassium levels, body mass index, a history of myocardial infarction, stroke, heart failure, diabetes, unstable angina, atrial fibrillation/flutter, estimated glomerular filtration rate categories, Elixhauser comorbidity index. <sup>†</sup>The analysis excluded patients with missing eGFR or eGFR  $\leq 50$  (no chronic kidney disease) or  $<15$  mL/min/1.73m<sup>2</sup> or having renal events within 3 month after index. <sup>‡</sup>The analysis excluded patients with recurrent hyperkalemia within 3 month after index and censored at the first hyperkalemia recurrence, or cardiovascular/all-cause mortality.

FR-PO549

Impact of Chronic Potassium Binder Treatment on Clinical Outcome in Patients With Hyperkalemia: A Nationwide Hospital-Based Cohort Study

Eiichiro Kanda,<sup>1</sup> Takashi Kikuchi,<sup>2</sup> Naru Morita,<sup>2</sup> Toshitaka Yajima.<sup>2</sup> <sup>1</sup>Kawasaki Medical School, Kurashiki, Japan; <sup>2</sup>AstraZeneca K.K., Osaka, Japan.

**Background:** While hyperkalemia (HK) is often a chronic condition, short-term and intermittent treatment of potassium binders (PB) has been largely applied to control the serum potassium (S-K) level. In this study we investigated the impact of the long-term and chronic PB treatment on the clinical outcomes.

**Methods:** A retrospective observational study using a Japanese hospital-based claim database (April 2008–September 2018) was conducted. HK was defined as at least two S-K  $\geq 5.1$  mmol/L within a 12-months (M) interval. The index date was defined as initial PB prescription date and S-K values were examined at 3M, 6M and 12M after the index. Medication possession ratio (MPR), which is usually used for adherence measures, was used to evaluate the proportion of a time period where PB were prescribed since no prescription refill is allowed in Japan. Clinical outcomes were analyzed by comparing HK patients with MPR  $\geq 80\%$  to those  $< 80\%$  using Cox proportional hazards regression analysis.

**Results:** Out of 1,353,826 patients, 4,321 patients who were on initial PB treatments with HK (mean age 74.6  $\pm$  12.83 years, mean eGFR 28.5  $\pm$  20.8, mean S-K value 5.71  $\pm$  0.64 mmol/L). In MPR  $< 80\%$  (n=993) and MPR  $\geq 80\%$  (n=3,328) groups, mean prescription days were 114.7  $\pm$  9.1 and 1151.2  $\pm$  22.5, and S-K value at 12M were 4.67 mmol/L and 4.64 mmol/L (p<0.307), respectively. Compared to MPR  $\geq 80\%$  group, the patients with MPR  $< 80\%$  group had significantly higher risks for introduction of hospitalization (HR 1.41, p<0.001), recurrence of HK (HR 1.67, p<0.001), eGFR decline (HR 1.41, p<0.001) and renal replacement therapy (HR 1.25, p=0.003) (Figure 1).

**Conclusions:** Although S-K levels were similarly controlled in the two groups, PBs treatment with MPR  $< 80\%$  increased the risk of adverse clinical outcomes compared to that with MPR  $\geq 80\%$ . The results suggest that chronic and continuous treatment with PBs might be beneficial for better clinical outcomes, including renoprotective effects in patients with HK.

**Effects of Sodium Zirconium Cyclosilicate (SZC) on CKD Progression: Rationale and Design of the Phase 3 STABILIZE-CKD Trial**  
George L. Bakris,<sup>1</sup> Kai-Uwe Eckardt,<sup>2</sup> Tom Greene,<sup>3</sup> Carol A. Pollock,<sup>4</sup> Robert D. Toto,<sup>5</sup> Matthew R. Weir,<sup>6</sup> Ayman Al-shurbaji,<sup>7</sup> Nicolas J. Guzman,<sup>8</sup> Vera Lisovskaja,<sup>7</sup> Peter Wessman,<sup>7</sup> Yanli Zhao,<sup>8</sup> Glenn Chertow.<sup>9</sup> <sup>1</sup>University of Chicago, Chicago, IL; <sup>2</sup>University of Erlangen-Nürnberg, Erlangen-Nuremberg, Germany; <sup>3</sup>University of Utah Health Sciences, Salt Lake City, UT; <sup>4</sup>University of Sydney, Sydney, NSW, Australia; <sup>5</sup>University of Texas Southwestern Medical Center, Dallas, TX; <sup>6</sup>University of Maryland, Baltimore, MD; <sup>7</sup>AstraZeneca, Gothenburg, Sweden; <sup>8</sup>AstraZeneca, Gaithersburg, MD; <sup>9</sup>Stanford University, Stanford, CA.

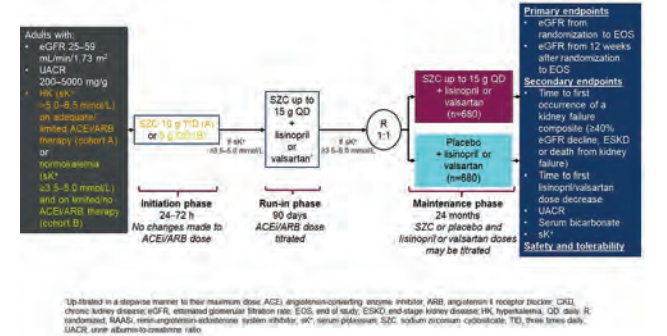

**Background:** Patients with CKD who may benefit from angiotensin-converting enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB) therapy frequently discontinue or do not receive ACEi/ARB therapy at recommended doses due to hyperkalemia (HK) or HK risk, and thus do not experience maximal renoprotection. We hypothesize that SZC, an oral anti-hyperkalemic, will enable ACEi/ARB optimization and slow CKD progression in patients with HK or high HK risk.

**Methods:** This Phase 3, international, randomized withdrawal, parallel-group trial is enrolling adult patients with CKD and HK on ACEi/ARB therapy, or CKD and normokalemia on limited/no ACEi/ARB therapy due to HK or high HK risk (NCT05056727; Figure). After establishing normokalemia with SZC (without ACEi/ARB dose change; initiation phase), lisinopril or valsartan therapy will be up-titrated to guideline-recommended doses while continuing SZC (run-in phase), then patients will be administered SZC or placebo (in a double-blind randomized fashion) and lisinopril or valsartan for up to 24 months (maintenance phase), with repeated estimated glomerular filtration rate (eGFR) measurements.

**Results:** The primary endpoints are eGFR measures from randomization to end of study (EOS) and from 12 weeks after randomization to EOS. Secondary endpoints include time to a kidney composite endpoint and time to first lisinopril or valsartan dose decrease. Safety and tolerability will be assessed by an independent data monitoring committee.

**Conclusions:** The STABILIZE-CKD study will assess if SZC attenuates CKD progression in patients treated with ACEi or ARB with HK or high HK risk.

**Evaluation of Patiromer Monotherapy for Acute Hyperkalemia in an Institutional Setting Based on Presence of Renal Impairment**  
Pavel Goriacko,<sup>1,2</sup> Katherine E. Di Palo,<sup>1,2</sup> Mark Sinnott,<sup>1</sup> Ladan Golestaneh.<sup>1,2</sup> <sup>1</sup>Montefiore Health System, Bronx, NY; <sup>2</sup>Albert Einstein College of Medicine, Bronx, NY.

**Background:** Patiromer has been widely studied in patients with renal impairment and chronic hyperkalemia. However, its effectiveness for acute, non-life-threatening hyperkalemia is not well described. We aimed to evaluate patiromer monotherapy in a representative cohort of patients with and without renal impairment at an urban medical center.

**Methods:** Using EHR data, we identified adults treated with a one-time dose of patiromer. Patients with pending HD orders or concomitant hyperkalemia therapy within 3 hours of patiromer administration were excluded. The primary endpoint was mean reduction in serum potassium (sK+) from baseline at 3 distinct time intervals (0 to 6 hours, >6 to 12 hours, >12 to 24 hours) and secondary endpoint was incidence of hypokalemia at 24 hours. Outcomes were compared by presence of renal impairment (defined as eGFR of <60 mL/min).

**Results:** There were 2048 one-time patiromer doses. Demographics are presented in Table 1. The mean reduction in potassium was 0.4 mEq/L at interval 1, 0.4 mEq/L at interval 2, and 0.4 mEq/L at interval 3 (P < .001 for all compared to baseline). The incidence of hypokalemia was 0.2%. Significant reduction in sK from baseline were noted in both groups at all time intervals. Reduction in sK+ was greater in patients without renal impairment at time intervals 1 and 2 (Figure 1).

**Conclusions:** A single dose of patiromer was associated with a significant decrease in sK+ and low incidence of hypokalemia. These findings suggest clinical utility of patiromer for episodic hyperkalemia in hospitalized patients with and without renal impairment.

**Funding:** Commercial Support - Vifor

**APPETIZE: Palatability of and Preference for Potassium Binders in Patients With CKD and Hyperkalemia**  
David C. Wheeler,<sup>1</sup> Cathy W. Gwynn,<sup>2</sup> Jonatan Hedberg,<sup>3</sup> Alaster Allum,<sup>4</sup> Eric T. Wittbrodt,<sup>5</sup> Jennifer Kim,<sup>5</sup> Jon D. Morris.<sup>2,6</sup> <sup>1</sup>University College London, London, United Kingdom; <sup>2</sup>AdSAM, Gainesville, FL; <sup>3</sup>AstraZeneca PLC, Mölndal, Sweden; <sup>4</sup>AstraZeneca, Cambridge, United Kingdom; <sup>5</sup>AstraZeneca, Gaithersburg, MD; <sup>6</sup>University of Florida, Gainesville, FL.

**Background:** Traditional K+ binders (PB) such as sodium and calcium polystyrene sulphonate (C/SPS), while not indicated for the chronic management of hyperkalemia (HK) are often believed to be unpalatable, poorly tolerated by patients, and associated with gastrointestinal side effects. Novel PB such as sodium zirconium cyclosilicate (SZC) and patiromer sorbitex calcium (CPaS) may be better tolerated; no published data exist for palatability, an important patient-centric endpoint. The primary study aim was to compare the patient-reported overall palatability of 3 currently available PB.

**Methods:** APPETIZE (NCT04566653) was a cross-sectional, randomized crossover study evaluating the palatability of and patient preference for C/SPS, SZC, and CPaS. Participants with chronic kidney disease (CKD), documented HK, and no recent use of PB were randomized to one of six taste sequences, with a 'sip and spit' taste test approach. Each PB was scored with respect to patient-centric attributes (taste, texture, smell, and mouthfeel) on a 0–10 scale, combined into an overall palatability composite score (0–40), and analyzed using linear mixed models. Patients were also asked to rank by palatability their first choice among the 3 PB. Further analyses of relevant factors are planned for the palatability of and emotional response to HK treatment options.

**Results:** A total of 144 patients participated from the US (N=58), EU (France, Italy, and Spain, N=62), and Canada (N=24) including 77 (53%) dialysis-dependent and 67 (47%) non dialysis-dependent CKD patients; 12% had history of heart failure. Mean age was 66 y, 70% were male.

**Conclusions:** In all regions palatability of SZC was superior to C/SPS and similar to CPaS, and patients ranked preference for SZC numerically higher than for the other products. These findings suggest that patients prefer newer PB, and this may improve compliance to long-term HK treatment.

**Funding:** Commercial Support - AstraZeneca

Product	Palatability Composite Score (mean +/- SD)				Overall Preference Ranking (t% who ranked first choice)*
	US	EU	CAN	All countries/regions	All countries/regions
SZC	24.9 (8.1) <sup>1</sup>	23.2 (9.4) <sup>1</sup>	27.3 (9.3) <sup>1</sup>	24.6 (9.0)	36.8%
CPaS	24.8 (9.2)	22.6 (9.2)	24.2 (11.9)	23.8 (9.7)	24.3%
C/SPS	18.9 (9.0)	18.6 (12.1)	16.0 (9.6)	18.3 (10.5)	11.8%

\*p < .001 for SZC vs C/SPS, †p < .025 for SZC vs C/SPS, ‡missing values in 27.3%

FR-PO553

**Real-World Evaluation of Empagliflozin on Serum Potassium Levels at a Veterans Affairs Medical Center**  
Mackenzie Lloyd,<sup>1</sup> Danielle N. Cooney,<sup>1</sup> Alessandra Lyman,<sup>1</sup> Shivali D. Singh,<sup>1</sup> Christopher J. Burant,<sup>1</sup> Niraj Desai.<sup>1,2</sup> <sup>1</sup>VA Northeast Ohio Healthcare System, Cleveland, OH; <sup>2</sup>Case Western Reserve University, Cleveland, OH.

**Background:** Recent major clinical trial results show conflicting data regarding the impact of sodium glucose co-transporter 2 (SGLT2i) inhibitors on serum potassium (K+) levels. This study aimed to identify the effect of SGLT2i use on serum K+ levels in a real-world setting.

**Methods:** We performed a retrospective cohort study of patients prescribed empagliflozin at a Veterans Affairs hospital between 12/1/16 and 11/30/21. The primary outcome was change in serum K<sup>+</sup> value from the date of first empagliflozin prescription to the following timepoints: 2-4 weeks, 3 months, and 6 months. Secondary outcomes included changes in serum K<sup>+</sup> when stratified by eGFR, effect of SGLT2i dose on serum K<sup>+</sup> level, and changes to concomitant medications because of dyskalemia (K<sup>+</sup> < 3.4 meq/L or K<sup>+</sup> > 5.1 meq/L).

**Results:** 100 patients with baseline potassium levels and 47, 61, and 72 patients were included in the analysis at 2-4 weeks, 3 months, and 6 months, respectively. All patients had type 2 diabetes mellitus, 86% were white, 26% had baseline eGFR of 60 ml/min or lower, and 64% of patients prescribed a renin-angiotensin-aldosterone system inhibitor at baseline. Mean change in serum K<sup>+</sup> level from baseline was insignificant at all timepoints: -0.51 mmol/L (95% CI -0.48 to 0.15) at 2-4 weeks, -0.03 mmol/L (95% CI -0.13 to 0.07) at 3 months, and 0.03 mmol/L (95% CI -0.06 to 0.12) at 6 months. Twelve participants had either hypo- or hyperkalemia at any pre-specified timepoint. Hyperkalemia was more common in patients with eGFR < 60 ml/min (70%). There was no dose dependent relationship between SGLT2i and change in serum K<sup>+</sup> value. Hypokalemia more often prompted changes to concomitant medications that may impact serum K<sup>+</sup> values.

**Conclusions:** There was no statistically significant change in serum K<sup>+</sup> values after empagliflozin initiation in subjects with DM2. Monitoring of serum K after initiation of empagliflozin may be considered in patients with CKD or in patients at risk of hypokalemia.

## FR-PO554

### Familial Hyperkalaemic Hypertension Is Associated With Immunodeficiency

**Keith Siew**, Rhys D. Evans, Stephen B. Walsh. *University College London, London, United Kingdom.*

**Background:** Familial hyperkalaemic hypertension (FHHT) is also known as Gordon syndrome or pseudohypoaldosteronism type II. It is an autosomal dominant condition that leads to salt retention through over activation of the sodium chloride co-transporter (NCC) in the distal convoluted tubule causing salt-sensitive hypertension. Pathogenic mutations in WNK1, WNK4, CUL3 and KLHL3 cause FHHT. Our recent study on patients with salt-losing tubulopathies (SLTs e.g. Gitelman syndrome) found significantly altered immunity, predisposing patients to a variety of infections. We studied whether FHHT (a salt retaining tubulopathy) also led to an altered immune phenotype.

**Methods:** 12 patients with FHHT were studied. Information such as past medical history, medications, autoimmunity, atopy, allergy status, childhood infections, recurrent and fungal infections were collected amongst other data. This was compared to 24 healthy controls and 47 patients with salt losing tubulopathy.

**Results:** Patients with FHHT were found to have significantly more viral (p=0.0094) and fungal infections (p=0.04) compared to healthy controls. They also experienced more recurrent upper respiratory tract infections (p=0.04) and urinary tract infections (p=0.04). Compared to patients with salt losing nephropathy, FHHT patients suffered significantly more recurrent viral infections (p=0.0021) but less allergic disease (p=0.03).

**Conclusions:** Our data suggests altered immunity in patients with FHHT. Their phenotype and range of infections were different to both healthy controls and patients with salt losing nephropathy. Further work is required to replicate these differences in larger cohorts and to investigate underlying mechanisms that may explain changes in immunity and whether this can be corrected with treatment. **References:** 1. Evans RDR *et al. Nat Commun* 2020; **11**: 4368

## FR-PO555

### Abnormal Electrocardiogram Incidence and Risk Factors in Hypokalemic Salt-Losing Tubulopathy

**Seong Ryeong Kang**,<sup>1</sup> Naye Choi,<sup>1,2</sup> Jeesu Min,<sup>1,2</sup> Yo Han Ahn,<sup>1,2</sup> Hee Gyung Kang,<sup>1,2</sup> Seon Hee Lim.<sup>3</sup> <sup>1</sup>*Seoul National University Children's Hospital, Seoul, Republic of Korea;* <sup>2</sup>*Seoul National University College of Medicine, Seoul, Republic of Korea;* <sup>3</sup>*Korean Society of Nephrology, Seocho-gu, Seoul, Republic of Korea.*

**Background:** Hypokalemic salt-losing tubulopathy including Batter's/Gitelman's syndrome (BS/GS) is characterized by hypokalemia, hyponatremia, and hypomagnesemia, which may prolong the corrected QT (QTc) interval and lead to cardiac arrhythmias. So far, 6 cases of arrhythmia or cardiac death in BS/GS have been reported. Despite its fatality, limited information is known about the frequency or risk factors of arrhythmia in patients with hypokalemic salt-losing tubulopathy.

**Methods:** A total of 83 patients under the age of 18 at diagnosis with hypokalemic salt-losing tubulopathy at our center were reviewed. Thirty-four of 83 patients had a 12-lead electrocardiogram during follow-up. Among them, the abnormalities of the rhythms and the QTc were investigated. Sex, age, body mass index (BMI), serum electrolytes level, and genetic background were compared between those with abnormal ECG and cases with normal ECG.

**Results:** Eight of 34 (23.5%) patients showed abnormal heart rhythms, 21 (61.8%) prolonged QTc beyond borderline, and 7 showed both abnormal heart rhythms and prolonged QTc. These 22 (64.7%) patients were classified as abnormal ECG group. There was no difference in sex, age, BMI, and serum levels of sodium, potassium, magnesium, and calcium at the time of ECG when compared with the normal ECG group (p>0.05). Two of 22 (9.09%) patients had the procedure for arrhythmia. One was performed catheter ablation and the other was inserted a pacemaker. There was no cardiac arrest during follow-up. Only 1 of 9 patients with follow-up ECG was normalized. Among the normal ECG group, 2 cases (16.7%) showed QTc prolongation in adults. Of 13 patients who performed echocardiography, 3 had dilated cardiomyopathy findings, and the rest are normal findings. Currently, 18 of 34 patients (52.9%) are under follow-up at our center, of which 6 have progressed to chronic kidney disease, and one is on hemodialysis.

**Conclusions:** Among hypokalemic salt-losing tubulopathy patients at our center, ECG abnormality was relatively high (64.7%). There were no significant differences in sex, age, BMI, and serum electrolyte levels. As arrhythmia can be fatal when it occurs, prevention is important. Therefore frequent follow-up is required to monitor laboratory findings, ECG, and patient compliance. Cardiac evaluation should also be performed regularly.

## FR-PO556

### Familial Autosomal Dominant Hyponatremia With Reset Osmostat

**Emanuel Zitt**,<sup>1</sup> Kate E. Lines,<sup>2</sup> Fadil Hannan,<sup>3</sup> Alistair T. Pagnamenta,<sup>4</sup> Edoardo Giacomuzzi,<sup>4,5</sup> Jenny C. Taylor,<sup>4</sup> Karl Lhotta,<sup>1</sup> Rajesh V. Thakker.<sup>2</sup> <sup>1</sup>*Academic Teaching Hospital Feldkirch, Department of Internal Medicine 3 (Nephrology and Dialysis), Feldkirch, Austria;* <sup>2</sup>*University of Oxford Radcliffe Department of Medicine, Oxford, United Kingdom;* <sup>3</sup>*University of Oxford Nuffield Department of Women's & Reproductive Health, Oxford, United Kingdom;* <sup>4</sup>*University of Oxford Wellcome Centre for Human Genetics, Oxford, United Kingdom;* <sup>5</sup>*Fondazione Human Technopole, Milan, Italy.*

**Background:** Hyponatremia is frequent and we report a four-generation family with autosomal dominant hyponatremia due to reset osmostat, characterised by: reduced Na<sup>+</sup> set-point for arginine vasopressin (AVP) secretion; linear relationship between serum Na<sup>+</sup> and urine osmolality; and normal water load excretion.

**Methods:** Sixteen of 19 living family members (9 males and 7 females, mean±SD age 46±18 years) consented for clinical and genetic studies.

**Results:** The index patient (male aged 59 years) presented with severe resistant hypertension and longstanding hyponatremia (<135 mmol/l). His hypertension eventually responded to amiloride (-20 to -30 mmHg). Similar findings in his 56-year-old brother suggested a hereditary condition. Investigation of family members revealed 10 (62.5%) to have hyponatremia, consistent with autosomal dominant inheritance. Overall, mean±SD serum Na<sup>+</sup> differed significantly between affected (133±5.1 mmol/l) and unaffected individuals (141±1.5 mmol/l; p<0.001), with affected individuals having inappropriately normal plasma copeptin concentrations, when compared to unaffected relatives (4.9±3.1 vs 2.5±2.0 pmol/l, p=0.08). All individuals had normal kidney function, and serum Na<sup>+</sup> and urine osmolality showed a significant positive correlation, but with a set-point shift towards lower Na<sup>+</sup> values in affected individuals. Water loading led to brisk excretion of diluted urine in the index patient and his affected brother, consistent with reset osmostat. Renal response to tolvaptan was normal, which excluded nephrogenic syndrome of inappropriate antidiuresis. Plasma renin concentrations were lower in affected individuals compared to unaffected relatives (3.3±2.2 ng/l vs 12.8±6.7 ng/l, p<0.05). DNA sequence analysis did not reveal abnormalities of candidate genes such as *AVP*, *AVPR2*, *ENAC* subunits (*SCNNIA*, *SCNNIB*, *SCNNIG*, and *SCNNID*), and *TRPV4*.

**Conclusions:** We describe a family with autosomal dominant hyponatremia due to reset osmostat, which is likely caused by a novel gene mutation.

## FR-PO557

**Beer Potomania Is Associated With Normal Uric Acid Homeostasis and Alcohol Tubulopathy**

Gregory L. Braden, Marat Abdullin, Daniel L. Landry, Spencer Hodgins, Jeffrey Mulhern. Kidney Care and Transplant Service of N.E. *UMass Chan Medical School-Baystate, Springfield, MA.*

**Background:** Uric acid homeostasis has never been studied in beer potomania (BP) & whether alcohol related tubulopathies occur in BP is unknown.

**Methods:** We reviewed all patients (pts) over 6 years referred to our service for severe hyponatremia caused by BP. 8 pts were found, 5 male / 3 female drinking 12-16 cans of beer daily. We looked for signs of volume depletion & compared blood pressure and pulse at admission to 24 hrs later after normal or 3% saline infusion. We also measured uric acid dynamics on admission & 24 & 48 hours during Na correction. All the data shown are mean $\pm$  SEM along with the range of levels found.

**Results:** The mean blood pressure initially was 113 $\pm$ 64 vs 131 /75 24 hours after saline, p<.01. Heart rate decreased from 107 $\pm$ 3 b/min to 81 $\pm$ 5 b/min after 24 hrs, p<.02, suggesting ECF volume depletion. 6 pts developed tremulousness, 1 delirium tremens & 1 hallucinations. Serum Na was initially 108 $\pm$ 3 (95-117) mEq/L, POSM 239  $\pm$ 14 (216-270) mOsm/kg, urine NA 13  $\pm$ 2 (8-19) mEq/L, Fractional Excretion (FE) of Na was 0.6 $\pm$ .04 (4-.9)% & UOSM 231 $\pm$ 14 (127-270) mOsm/kg. All pts had hypokalemia, 3.2  $\pm$ .2 (2.9- 3.6) mEq/L & low serum albumin 3.4 $\pm$ .2 (3-3.6) gm/dl. Serum uric acid (UA) was normal in all 8 pts 4.0  $\pm$ .04 (3.4-5) mg/dl & the FE UA was normal in all 8 pts, 8.4 $\pm$ 1 (2-11)%. The serum UA and FE UA remained normal during 24 & 48 hrs of Na correction. Serum Mg was low in 4/8 pts (1.3-1.5) mg/dl with the FE Mg increased at >2% in all 4. Serum PO4 was low in 4/8 pts (2.6-3.0) mg/dl with a FE PO4 of 19-24%. IV Mg and PO4 were used in the 4 pts. 3 pts were treated with hypertonic saline clamp and q 6 hr DDVP. 5 pts needed IV D5 & W to prevent overcorrection. No CPM occurred.

**Conclusions:** BP often presents with signs of ECF volume depletion which can be subtle & is associated with normal serum UA levels and normal ranges of FE of UA despite serum Na levels <100 mEq/L. The urine OSM in these pts is >100 mOsm/kg suggesting serum ADH stimulation possibly from ECF volume depletion. All of our pts developed clinical alcohol withdrawal and half had renal Mg and PO4 wasting associated with alcohol tubulopathy. Normal UA and FE UA differentiates BP from SIADH in alcoholics.

## FR-PO558

**Hyponatremia in the Outpatient: Does Low GFR Contribute to Hyponatremia?**

Masahiko Nagahama, Takehiko Kawaguchi, Takuya Fujimaru, Yugo Ito, Fumika Taki, Masaaki Nakayama. *St. Luke's International Hospital, Tokyo, Japan.*

**Background:** The essential mechanism of developing hyponatremia is decreased urinary dilution in response to vasopressin (AVP). Because urinary dilution is affected as kidney function deteriorates, it is plausible that the risk of developing hyponatremia is related to decreased GFR. However, the results of previous studies on the prevalence of hyponatremia in CKD populations are contradictory. On the other hand, AVP secretion by various comorbid conditions, such as CHF and malignancy was identified. We hypothesized that comorbidity induced AVP secretion rather than decreased GFR contribute to hyponatremia.

**Methods:** We performed an observational cross-sectional investigation in a single hospital (35 specialties in outpatient clinic) in Tokyo, Japan. Among 351,662 patients who visited the outpatient clinic from January 2010 to December 2020, we analyzed clinical and biochemical parameters of 131,184 patients. Using the Diagnosis Procedure Combination database, we collected 10 most common comorbidities in clinic: diabetes, malignancy, hypertension, COPD, CVA, dementia, depression, arthritis, anxiety and CHF. Comorbidity in our study is defined by presence of either 1 of those 10 diseases. Dialysis and transplant patients were excluded. Risk factors for hyponatremia were sought using multivariate logistic regression.

**Results:** Prevalence of hyponatremia (serum Na<135mEq/L) was 2.9% in all patients. Multivariate logistic regression analysis identified higher eGFR (OR:1.01 95% CI 1.01-1.01) and positive dipstick proteinuria (OR:2.09 95% CI 1.87-2.33), but not comorbidity (OR:1.0 95% CI 0.79-1.27) as independent risk factors for hyponatremia. However, stratifying the analyses by eGFR of 60ml/min, the association of eGFR, comorbidity and proteinuria with hyponatremia was pronounced in eGFR>60 patients (OR:1.01 95% CI 1.00-1.01 for eGFR, OR:1.42 95% CI 1.02-1.9 for comorbidity, OR:2.46 95% CI 2.09-2.89 for proteinuria), but diminished in eGFR $\leq$ 60 patients (OR:1.00 95% CI 0.98-1.02 for eGFR, OR:0.49 95% CI 0.09-2.54 for comorbidity, OR:0.67 95% CI 0.36-1.25 for proteinuria).

**Conclusions:** The present study shows that development of hyponatremia is correlated with not a lower but a higher GFR. Comorbidity becomes more prominent risk factor as GFR increases. These results suggest that the concomitant comorbidities combined with a higher GFR affect hyponatremia.

## FR-PO559

**The Association of Hyponatremia With Cognitive Function and All-Cause Mortality: A Post Hoc Analysis of the Systolic Blood Pressure Intervention Trial**

Amara Sarwal, Robert E. Boucher, Nikita Abraham, Ravinder Singh, Xiangyang Ye, Farahnaz A. Moghaddam, Sydney E. Hartsell, Guo Wei, Srinivasan Beddhu. *University of Utah Health, Salt Lake City, UT.*

**Background:** Severe hyponatremia (hypoNa) needing treatment with hypertonic saline was associated with probable dementia (PD) in a retrospective study. It is unknown whether mild hyponatremia is a risk factor for mild cognitive impairment (MCI)/PD.

**Methods:** The Systolic Blood Pressure Intervention Trial (SPRINT) MIND study (N= 8561) evaluated the effects of intensive systolic BP control (goal <120mmHg) vs. standard SBP control (goal <140 mmHg) on risk of adjudicated MCI/PD. In this post-hoc secondary analysis, we included 8541 SPRINT-MIND participants with baseline serum Na > 130 meq/L and non-missing baseline and 6-months (6m) serum Na. We defined incident hypoNa as a serum Na < 130 mmol/L at 6m and related incident hypoNa with time to MCI alone, PD alone, a composite of MCI/PD and all-cause mortality (ACM) in separate Cox regression models adjusted for the SBP intervention, age, gender, race, CVD, CHF, smoking, BMI and eGFR.

**Results:** The mean baseline serum Na was 140  $\pm$  2 meq/L. 129 (1.5%) participants developed incident hyponatremia at 6m with a mean serum sodium of 127 $\pm$ 3 meq/L. Compared to those without incident hyponatremia, those with incident hyponatremia were in general, older, had lower BMI and more likely to be women, African-American, treated with thiazide diuretics and assigned to intensive SBP arm. The mean follow-up duration was 4.8  $\pm$  1.4 yrs. There were 1254 MCI, 324 PD, 1485 MCI/PD and 324 ACM events. As shown in table incident hypoNa was not associated with MCI or MCI/PD composite but with higher risk of PD and ACM.

**Conclusions:** In this post hoc analysis of SPRINT, while hypoNa was not associated with subsequent MCI or MCI/PD, it was associated with PD and ACM.

	MCI	PD	MCI/PD	ACM
Unadjusted	0.84 (0.50, 1.43)	2.46 (1.31, 4.61)	1.17 (0.78, 1.77)	1.64 (0.77, 3.46)

**Thiazide-Related Hyponatremia: A Nationwide Population-Based Cohort Study**

Heejin Cho, Hyo jin Boo, Jin Ho Hwang. *CAUH-NEP Chung Ang University Hospital, Seoul, Republic of Korea.*

**Background:** After thiazides were recommended as the first-line drug for adult hypertension in the JNC 7 guideline, hospitalization for thiazide-related hyponatremia (TRH) has often been experienced in clinical settings, but the exact incidence and risk of TRH have not been documented in Korea.

**Methods:** For risk evaluation of thiazide and other drug-associated hyponatremia, we used the big data provided by the National Health Insurance Sharing Service. A total of 1,943,345 adult patients who were confirmed to have been treated for hypertension from January 2014 to December 2016 were included for analysis set. The patients were divided into two groups depending on the use of thiazides.

**Results:** Hospitalization for hyponatremia was significantly higher in the thiazide group than control group (2.19 vs. 1.45%), and the risks further increased when two or more thiazides were concurrently prescribed (2.8 times), or combination therapy with other diuretics or desmopressin (4 times), and thiazide+spironolactone+desmopressin were used at the same time (6.9 times). When thiazide and desmopressin were used together, the risk of multiple hospitalization was 11 times higher. In multivariate analysis, the occurrence of hyponatremia increased with age (HR 1.069, CI 1.068-1.070, per 1-year increase), DM (HR 1.453, CI 1.415-1.492), depression (HR 1.53, CI 1.496-1.565), and the use of thiazides (HR 1.436, CI 1.404-1.469, all P<0.001). The thiazide group showed a better 6-year overall survival than the control group (P<0.001), but had more fractures, and hyponatremia (all P<0.001). Among all patients, patients with hyponatremia showed significantly higher mortality rates, hospitalizations for fractures, and pneumonia compared to those without hyponatremia (all P<0.001).

**Conclusions:** There is an increased risk of hyponatremia and related complications in those who were prescribed thiazides. However, the survival rate decreased in those who received thiazides, suggesting that thiazide itself is not harmful, but that it will be more helpful in reducing complications and improving the prognosis if properly used with caution in high-risk groups.

## FR-PO561

**Comparison of i-STAT Point of Care vs. Indirect Ion Selective Electrode Measurements of Sodium in Severe Hyponatremia**

Daniel G. Gomez, Spencer Hodgins, Vijayakumar Paramasivam, Daniel L. Landry, Jeffrey Mulhern, Brian H. Nathanson, Gregory L. Braden. *University of Massachusetts Chan Medical School - Baystate Regional Campus, Springfield, MA.*

**Background:** We sought to determine whether point-of-care (POC) sodium (Na) levels by I-STAT were accurate enough compared to Main Lab sodium measured by ion-specific electrode technique (the "Gold Standard") to allow for its use in monitoring the administration of 3% hypertonic saline to correct severe hyponatremia.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Methods:** We extracted all consecutive data from Baystate Medical Center inpatients with  $\text{Na} \leq 135$  mmol/L from January 2015 to December 2019 who had a POC and Main Lab Na level within 30 minutes of each other. This was a venous-to-venous comparison using direct ion-selective electrode by I-STAT vs indirect ion-selective electrode by Main Lab. We compared values with a Bland-Altman plot and repeated the analysis with Main Lab sodium  $\leq 125$  mmol/L.

**Results:** We obtained 406 Na paired samples from 355 patients. The bias (i.e., mean difference) of POC - Main Lab was significantly greater than 0; 1.2 mmol/L; 95% CI (0.8-1.5);  $p < 0.001$ . Severe hyponatremia samples  $\leq 125$  mmol/L ( $n = 44$ ) demonstrated a larger bias with a disagreement by as much as 10 mmol/L: bias = 1.7 mmol/L, 95% CI (0.3-3.1);  $p = 0.003$ .

**Conclusions:** I-STAT POC significantly overestimates Na levels when compared to Main Lab indirect ion-selective electrode analysis when Na is either  $\leq 135$  mmol/L or  $\leq 125$  mmol/L. The use of POC for monitoring Na levels during 3% hypertonic saline administration in severe hyponatremia is not recommended.

FR-PO562

**Treatment of Severe Hyponatremia in the Usual Clinical Scenarios: Time to Include Urinary Output in Algorithms?**  
Grecia J. Gonzalez Rivera, Karina C. Felix Bauer, Alfonso Gindl-Bracho, Ricardo Correa-Rotter, Juan Carlos Ramirez-Sandoval. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

**Background:** Rapid correction of severe hyponatremia ( $\text{Na} < 125$  mEq/L) can lead to adverse outcomes, including osmotic demyelination syndrome. Although non-modifiable risk factors for rapid correction are widely described, most clinical algorithms do not include bedside biomarker during treatment.

**Methods:** Retrospective cohort of 249 hospitalized patients with severe hypotonic hyponatremia. We assessed the association between rapid correction (sNa increase of  $> 8$  mEq/L/24 h) and clinical variables during first hours of treatment, including renal free water loss ( $(U_{\text{Na}} + U_{\text{K}})/S_{\text{Na}} \cdot U_{\text{Na}} \cdot U_{\text{osm}}$ ), and water balance.

**Results:** Median age was 62 (IQR 22-91) years, 54% were women, 47% had AKI, 71% cirrhosis, 45% CKD 3-4, 7% heart failure, and 14% received 3% IV hypertonic saline due symptomatic hyponatremia. In 36% previous use of diuretics was documented. Etiology of hyponatremia was not possible in the first 24h of assessment in 181(73%) subjects; in these cases, the main cause of hyponatremia was evident only retrospectively. Rapid correction during the first 24 h occurred in 17%. Diuresis during the first 12 h was higher in the rapid correction group (1.3 [IQR 0.5-2.6] mL/Kg/h Vs. 0.8 [IQR 0.4-1.2] mL/kg/h,  $P < 0.001$ ). In multivariate analysis, each mL/kg/h was associated with an OR of 1.57 (95% CI 1.12-2.20,  $P < 0.009$ ) for rapid correction. Assessment of  $U_{\text{Na}} \cdot U_{\text{osm}}$ , and free water loss were not associated with the risk of rapid correction.

**Conclusions:** The only bedside prognostic marker to predict overcorrection was diuresis in the first 6-12 hours after treatment initiation, urinary indices had no association with rapid correction. The high prevalence of comorbidities in real clinical scenarios greatly limits the diagnostic value of current algorithms, as cases of hyponatremia are rarely “pure”. Preventive measures for rapid correction should include hourly diuresis evaluation.

FR-PO563

**The Use of DDAVP During Overcorrection of Severe Hyponatremia**  
Florence Lamarche, Helene Ammann, Gabriel Dallaire, Louis Deslauriers, Stephan Troyanov. *Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada.*

**Background:** The correction of severe hyponatremia can be challenging. A too slow or rapid pace increases the risk of neurological complications. Current guidelines recommend a serum sodium (sNa) correction rate of  $\sim 6$  mmol/L per day. Overcorrection can justify lowering the sNa. Desmopressin (DDAVP) is used to decrease free water excretion and thus stabilize or decrease the sNa but to date, the evidence supporting its use is scarce. We studied sNa trends after subcutaneous (SC) DDAVP administration in cases of severe hyponatremia.

**Methods:** We performed a single-center retrospective cohort study looking at all episodes of hyposmolar hyponatremia. Every sNa value  $< 120$  mmol/L from 2012 to 2022 was identified and all subsequent serum and urinary sodium and osmolalities were extracted. Spurious cases were excluded. Correction rates between all measurements separated by  $\geq 8$  hours were calculated and categorized from most to least clinically significant (Table). We also reviewed SC DDAVP administration and sNa trends following it.

**Results:** There were 388 episodes of severe hyponatremia in 356 patients. The correction rates and DDAVP received are listed in the table: 45% of patients had an overcorrection  $> 9$  over  $> 24$ h. Ninety episodes received DDAVP, 70 of which were followed by a drop in sNa. The average drop in sNa 12 h after receiving doses of 1 mcg (35 doses) and 2 mcg (31 doses) were  $-0.6 \pm 3.5$  mmol/L and  $-2.2 \pm 3.1$  mmol/L, respectively ( $p = 0.035$ ). Thirteen episodes treated with DDAVP experienced a  $> 6$  mmol/L maximal drop in sNa.

**Conclusions:** This cohort highlights frequent sNa overcorrections and the usefulness of SC DDAVP to slow or decrease sNa correction rates. One mcg SC DDAVP stabilized sNa for 12 hours whereas 2 mcg SC resulted in a mean 2 mmol/L decrease. The amount of water ingested must be carefully assessed when using DDAVP, as some experience worrisome drops in sNa.

**Funding:** Private Foundation Support

Category (mmol/L)	Cohort (%)	DDAVP doses given (%)
>9/day over >48h	18 (5%)	5 (28%)
>9/day over 24-48h	155 (40%)	68 (44%)
7-9/day over >48h	44 (11%)	7 (16%)
7-9/day over 24-48h	95 (24%)	8 (8%)
>9/day over <24h	24 (6%)	2 (8%)
7-9/day over <24h	33 (9%)	0
Always <6/day	19 (5%)	0

FR-PO564

**Mathematical Model of Intradialytic Acid-Base Dynamics in Patients Subjected to Extracorporeal CO<sub>2</sub> Removal**  
Paulo Panque Galuzio,<sup>1</sup> Alhaji Cherif,<sup>1</sup> Lisa-Marie Kunz,<sup>2</sup> Juergen Klewinghaus,<sup>2</sup> Hans Peter Leinenbach,<sup>2</sup> David Thompson,<sup>4</sup> Peter Kotanko.<sup>1,3</sup>  
<sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany; <sup>3</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>4</sup>Fresenius Medical Care North America, Waltham, MA.

**Background:** The use of low flow extracorporeal CO<sub>2</sub> removal (ECCO<sub>2</sub>R) devices in ICU has been introduced to assist in decarboxylation and augmenting protective ventilation strategies for patients with acute respiratory distress syndrome (ARDS). AKI

may develop in 25-60% of patients with ARDS. These patients often develop mixed acid-base disorders and need renal replacement therapy (RRT). To manage complex metabolic derangements, it is possible to attach an oxygenator, post-filter, in the continuous kidney replacement therapy (CKRT) circuit as a combined low flow extracorporeal strategy.

**Methods:** Using a previous acid-base model (Cherif, 2020, *Math Biosci Eng*), we incorporated models of dialyzer and ECCO<sub>2</sub>R oxygenator. The model describes the regulation of H<sup>+</sup>, CO<sub>2</sub> and HCO<sub>3</sub><sup>-</sup>. Each component of the system has been separately validated with literature data. The model was structured to capture CVVHD with a gas exchanger integrated into the continuous kidney replacement system post-filter.

**Results:** The model was parametrized to average data from 10 ventilated critically ill patients with ARDS and AKI undergoing renal and respiratory replacement therapy (Forster *et al. Critical Care* 2013). We fixed blood flow 355±79 ml/min, dialysate flow 2.3±0.7 L/h, ultrafiltration rate 58ml/h (ranging from 0 to 200 ml/h), gas flow 5.2±1.0 L/min, and treatment duration 95±68 h. The model accurately predicts serum pH and pCO<sub>2</sub> for the first 24 h of treatment, with R<sup>2</sup> values of 0.98 for pH and 0.94 for pCO<sub>2</sub> (Fig. 1). We observe that pH and pCO<sub>2</sub> equilibrate within the first 4 hrs.

**Conclusions:** Our model captured the appropriate dynamical behavior of serum pH, pCO<sub>2</sub> and HCO<sub>3</sub><sup>-</sup>. The model could be used as a tool to prescribe CKRT parameters to control acid-base status and to help understand the effectiveness of different arrangements.

**Figure 1:** Model prediction for a patient with renal failure and low ventilation. The solid line is the model prediction, the dots are patient data. R<sup>2</sup> values of 0.98 for pH and 0.94 for pCO<sub>2</sub>.

FR-PO565

**Variability Between Measured Organic Acids and Net Acid Excretion and Estimated Organic Acids and Net Acid Production**  
Tanushree Banerjee, Lynda Frassetto. *University of California San Francisco, San Francisco, CA.*

**Background:** Formulas for diet acid load use estimates of organic acids (OA) production. Lemann et al. and Remer et al. have developed differing but widely used methods to estimate OA and hence net acid excretion (NAE) from diet composition. How well estimated dietary OA (DOA) correlates with measured urinary OA excretion (UOAE) is unclear, as is how much this variability contributes to variability in estimates of net endogenous acid production (NEAP) compared to measures of NAE.

**Methods:** 24-hour urine from metabolic balance studies in 13 healthy males on a fixed diet/kg body weight were collected for 6 days sequentially at baseline and intervention phase. Measures for each time period were pooled. We compared repeated measures of UOAE to dietary OA estimates, and NAE to NEAP. DOA was estimated from diet unmeasured anions by Lemann; Remer used individual body surface area (BSA). Lemann used urinary measurements of SO<sub>4</sub> and OA to calculate NEAP, while Remer used BSA (using DuBois and Mosteller formulas) and dietary calculations of SO<sub>4</sub>. UOAE was measured by titration. We determined the concordance correlation coefficient (CCC) for the repeated measures data with the King et al. U-statistics approach (Stats Med 2007).

**Results:** 13 males with a median age of 27 years were studied. The estimates of CCC and the confidence intervals are displayed below (Figure). CCC estimates indicate a very poor degree of agreement between UOAE and DOA using either Lemann's or Remer's methodology. We find a modest degree of agreement between NAE and NEAP with Lemann, and better concordance with Remer.

**Conclusions:** Dietary equations estimating OA production do not correlate well with the measured OA. This contributes to the variability for the dietary equations estimating NEAP. Using urinary citrate or targeted metabolomics in a clinical setting may be more accurate to quantify OA.

Table: Concordance Correlation Coefficient (95% CI)	
Between UOAE and DOA	
UOAE and DOA <sub>Lemann</sub>	0.24 (0.08-0.41)
UOAE and DOA <sub>Remer-DuBois</sub>	0.07 (-0.19, 0.27)
UOAE and DOA <sub>Remer-Mosteller</sub>	0.06 (-0.19, 0.28)
Between NAE and NEAP	
NAE and NEAP <sub>Lemann</sub>	0.66 (0.35-0.98)
NAE and NEAP <sub>Remer-DuBois</sub>	0.83 (0.71-0.96)
NAE and NEAP <sub>Remer-Mosteller</sub>	0.82 (0.71-0.97)

FR-PO566

**Unmeasured Organic Anions as Predictors of Clinical Outcomes in Lactic Acidosis due to Sepsis**  
Richard M. Treger, Kirillos E. Zaki, Mark Asef. *Kaiser Foundation Hospitals, Pasadena, CA.*

**Background:** In lactic acidosis, lactate can only explain 25% of the variance in the anion gap (AG). Our recent work has shown that the elevated AG not explained by lactate is due to unmeasured organic anions (UOA). Small studies suggested that UOA may better predict clinical outcomes than lactate. The aim of this study was to determine whether UOA predict clinical outcomes better than lactate levels.

**Methods:** This was a retrospective cohort study of adult ICU patients with sepsis. A baseline period beginning 1 year prior was used to obtain baseline AG and albumin measurements. An albumin-corrected delta AG was calculated. UOA were estimated using the formula: Delta AG – serum lactate. A logistic regression model was constructed to explore the relationship between in-hospital mortality, UOA and lactate.

**Results:** 526 patients were included (Table). In the adjusted model examining lactate and UOA, the OR [95% CI] for predicting in-hospital mortality was 1.18 [1.03-1.34] and 0.97 [0.89-1.04], respectively.

**Conclusions:** Lactate was associated with higher in-hospital mortality. However, UOA were not associated with increased risk of in-hospital mortality. This disproved our hypothesis that UOA would predict in-hospital mortality better than lactate suggested by previous small studies. However, these studies used strong ion gap to estimate UOA while our study used a more precise quantitative estimate of UOA, including use of baseline albumin-corrected AG. Prior studies attempting to identify UOA have identified Krebs cycle intermediates including citrate and isocitrate, suggesting that in our study UOA were not associated with increased in-hospital mortality because they are a marker of disrupted aerobic metabolism rather than a complete switch to anaerobic metabolism

**Funding:** Commercial Support - The research is supported by a grant from the Regional Research Committee of Kaiser Permanente. Grant No. KP-RRC-20210504.

Patient characteristics

N		526
Age (years; mean + SD)		71.1 ± 13.14

**Immobilization-Associated Hypercalcemia in the Hospital Setting: A Cohort Study**

Jacob Park,<sup>1</sup> Walter Lam,<sup>2</sup> Dustin Chalmers,<sup>2,1</sup> Juan Carlos Q. Velez,<sup>2</sup> Ochsner Nephrology <sup>1</sup>The University of Queensland Ochsner Clinical School, Herston, QLD, Australia; <sup>2</sup>Department of Nephrology, Ochsner Health, New Orleans, LA.

**Background:** Immobility is an established cause of hypercalcemia. Supporting evidence is primarily derived from experimental studies and clinical case reports. Cohort studies are lacking. We examined the relative contribution of immobilization-associated hypercalcemia (Immob-HCa) to all causes of in-hospital hypercalcemia.

**Methods:** A retrospective review of medical records was conducted searching for cases of hypercalcemia at Ochsner Medical Center over a 1-year period. Hypercalcemia was defined as serum calcium > 11.0 mg/dL. *Definite* Immob-HCa was defined as presence of immobility by history combined with absence of disqualifying laboratory data (PTH > 60 ng/dL, 1,25 vitamin D > 70 pg/mL, 25 vitamin D > 80 ng/mL, PTH-related peptide > 2.5 pmol/L or monoclonal gammopathy), lytic lesion by imaging, or alternative etiology (malignancy, sarcoidosis, exposure to thiazide, end-stage kidney disease (ESKD) or calcium or vitamin D supplementation). *Probable* Immob-HCa was defined as documented immobility and absence of alternative etiology, but incomplete laboratory data.

**Results:** From a total of 364 patients with in-hospital hypercalcemia, 114 had elevated PTH, 83 had malignancy, 63 were on calcium or vitamin D supplements, 25 had ESKD, 22 were on a thiazide and 14 had sarcoidosis or elevated 1,25 vitamin D, adding to 321 cases excluded. The remaining 43 charts were manually reviewed. Among them, 5 cases were categorized as *Definite* Immob-HCa and 26 were categorized as *Probable* Immob-HCa. Twelve cases were undetermined. Thus, Immob-HCa accounted for up to 8.5% (31/364) of in-hospital hypercalcemia. Among the 31 Immob-HCa cases, median age was 72 (22-92), 35% women, 48% white, 29% self-identified black; median peak serum calcium was 12.2 (11.2-17.8) mg/dL. Corrected serum calcium was available in 20/31 (65%) of the cases, with a median of 12.8 (11.7-15.4) mg/dL. High ionized calcium was verified in 9 (29%) cases. Concomitant acute kidney injury (AKI) was present in 11 (35%) of the cases of Immob-HCa.

**Conclusions:** Immob-HCa accounts for approximately 1 in 12 of cases of in-hospital hypercalcemia and it is accompanied by AKI in one third of the cases. Incomplete diagnostic work up for hypercalcemia may underestimate its incidence. Raising awareness of this entity could lead to prevention and more prompt diagnosis and treatment.

FR-PO568

BMI and Calcium Kidney Stone Formation

Tammy Yu,<sup>1,2</sup> Himesh Sheth,<sup>1,2</sup> Jie Tang,<sup>1,2</sup> <sup>1</sup>Lifespan Health System, Providence, RI; <sup>2</sup>Brown University, Providence, RI.

**Background:** Population studies show a clear association between obesity and kidney stone incidence. Here, we examined the relationship between body mass index (BMI) and laboratory markers of stone risk in calcium stone formers (CSF).

**Methods:** Patients were recruited from a kidney stone clinic for this retrospective study. All had either confirmed prior calcium (Ca) stones or a 24-hour urine stone risk index predictive of Ca stones. Participants had a 24-hour urine stone risk profile and a renal ultrasound to evaluate stone burden. Medical history and BMI were obtained within 3 months of laboratory testing.

**Results:** A total of 187 CSF were included in this study. Mean age was 53, 44% were male, 80% were Caucasian, 19% had diabetes, 42% had hypertension, and 32% had dyslipidemia. BMI was positively correlated with calculated 24-hour urine creatinine clearance (CrCl), both before (p=0.00003) and after (p=0.00002) adjustment for demographics (age, race, and gender). However, in subgroup analysis this association became nonsignificant in women (p=0.09), perhaps due to lower muscle mass. Higher BMI was correlated with increased stone burden both before and after demographic adjustment (p=0.02, 0.02, respectively). BMI was inversely associated with serum Ca (p=0.04) and 25-hydroxy vitamin D (p=0.01) levels. No significant association was observed with other serum markers of bone-mineral metabolism, including phosphorus (P), 1,25-dihydroxy-vitamin D, and PTH. Table 1 shows the association between BMI and several urinary markers of increased Ca stone risk. No association was observed with other urinary risk factors (not shown).

**Conclusions:** Higher BMI was associated with higher CrCl, lower serum Ca and vitamin D, and higher stone burden in our cohort of CSF. As in prior studies of uric acid (UA) stone formers, obesity likely contributes to an increased Ca stone risk by lowering urine pH and increasing urine UA and P. Hyperuricosuria promotes the crystallization of Ca oxalate, while hyperphosphaturia may play a role in the formation of Randall plaque.

Table 1

Urine Marker	Without Adjustment for Demographics	Adjusted for Demographics
pH	-0.02 (p=0.004)	-0.02 (p=0.002)
Ammonia	0.5 (p=0.00003)	0.5 (p=0.0008)
Uric Acid	10.6 (p=0.00002)	10.2 (p=0.0003)
Uric Acid Supersaturation	0.04 (p=0.002)	0.03 (p=0.004)
Phosphorus	14.9 (p=0.00003)	13.6 (p=0.00007)

FR-PO569

Artificial Intelligence-Enabled Electrocardiography Helps Identify Severe Dyscalcemia and Provide Additional Prognostic Value

Shih-Hua P. Lin, Chih-Chien Sung. Tri-Service General Hospital Department of Internal Medicine, Taipei, Taiwan.

**Background:** The detection of hypocalcemia and hypercalcemia (collectively dyscalcemia) relies on blood laboratory tests requiring turnaround time while abnormal serum calcium concentrations may affect the heart and alter the electrocardiogram (ECG). The study aimed to develop a bloodless artificial intelligence (AI)-assisted (ECG) to rapidly detect dyscalcemia and analyze its contribution to prognostic predictions.

**Methods:** This study collected 86,731 development, 15,611 tuning, 11,105 internal validation, and 8,401 external validation ECGs from electronic medical records with at least 1 ECG labeled by an albumin-adjusted calcium (aCa) value within 4 hours. The main outcomes were to assess the accuracy of AI-ECG to predict aCa and follow up these patients for all-cause mortality, new-onset acute myocardial infraction (AMI), and new-onset heart failure (HF) to validate the ability of AI-ECG-aCa for previvor identification.

**Results:** ECG-aCa had mean absolute errors (MAE) of 0.78/0.98 mg/dL and achieved an area under receiver operating characteristic curves (AUCs) 0.9219/0.8447 and 0.8948/0.7723 to detect severe hypercalcemia and hypocalcemia in the internal/external validation sets, respectively. Although <20% variance of ECG-aCa could be explained by traditional ECG features, the ECG-aCa was found to be associated with medical complexity. Patients with ECG-hypercalcemia but initially normal aCa were found to have a higher risk of subsequent all-cause mortality [hazard ratio (HR): 2.05, 95% confidence interval (CI): 1.55-2.70], new-onset AMI (HR: 2.88, 95% CI: 1.72-4.83), and new-onset HF (HR: 2.02, 95% CI: 1.38-2.97) in the internal validation set, which were also seen in external validation.

**Conclusions:** The AI-ECG-aCa may help detect severe dyscalcemia for decision support and ECG-hypercalcemia also provides prognostic value for future cardiovascular outcomes.

FR-PO570

Skimmed Milk as an Alternative Treatment for Hypophosphatemia

Kiara Marie H. Padua, Ivan Kenneth S. Zapanta, Christine D. Pascual, Maricar Esculto. Makati Medical Center, Makati City, Philippines.

**Background:** Mild and Moderate Hypophosphatemia (1-2.5 mg/dL) are generally treated with oral supplements. However, oral phosphate is not accessible in the Philippines. Skimmed milk which is known to have high phosphorus content is readily available but no studies yet were done to evaluate its efficacy in correcting phosphorus.

**Methods:** A non-inferiority, open-label, randomized controlled pilot trial was done to assess the efficacy of skimmed milk (150ml divided into three doses, 0.03 mmol

phosphorus: mL) compared to phosphate solution (60mL in three divided doses, 1mmol phosphorus: mL) in correcting mild and moderate hypophosphatemia. Mean percent change was used for the treatment difference, with the non-inferiority limit at 15%. Adverse events were noted and intention to treat was done.

**Results:** Skimmed milk was able to increase phosphorus but was not different from phosphate solution (p = 0.86). There were seven participants who showed no increase in phosphorus post treatment, five of which were admitted in critical units (p = 0.68). The mean percent change was (50.32% vs 30.93%, p = 0.12) hence the mean percent change difference was -19.39% and is not statistically significant, however was outside the non-inferiority margin thus skimmed milk failed to show non-inferiority. There was abdominal pain and vomiting with phosphate solution.

**Conclusions:** Although, skimmed milk failed to show non-inferiority to phosphate solution, this pilot study showed that skimmed milk is an effective, safe, and readily available alternative for non-critically ill hypophosphatemic patients in resource-limited areas.

Table 2. Pre-treatment and Post-treatment Serum Phosphorus (n= 40)

	Phosphate Solution (n = 20)	Skimmed Milk (n = 20)	P-value
Pre-treatment Phosphorus (mg/dL)	2.01 ± 0.23	1.99 ± 0.41	0.88 <sup>1</sup>
Post-treatment Phosphorus (mg/dL)	3.02 ± 0.94	2.62 ± 0.76	0.14 <sup>2</sup>
Mean Change (Mean, SD)	1.02 ± 0.85	0.60 ± 0.62	0.86 <sup>3</sup>
Mean Percent Change	50.32 ± 44.4	30.93 ± 32.3	0.12 <sup>2</sup>
Change in Serum Phosphorus level

FR-PO571

Ionized Magnesium Correlates With Total Magnesium in High-Risk Kidney Cohorts

Denise C. Hasson, James Rose, Kyle Merrill, Charles D. Varnell, Stuart Goldstein, Stefanie W. Benoit. Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

**Background:** Serum magnesium (Mg) abnormalities are common in critically ill children and kidney transplant (KTx) recipients; abnormal values are associated with poor outcomes including mortality. Mg homeostasis is affected by kidney function, acid-base status, calcium-vitamin D alterations, and medications (eg, immunosuppressants, citrate). The active form, ionized Mg (iMg), is not measured, and studies conflict regarding total (TMg) and iMg correlation. We hypothesized iMg and TMg concentrations will be categorized differently (i.e., low, normal, high) in patients (pts) after KTx and on continuous kidney replacement therapy (CKRT) with citrate, but ionized calcium (iCa) will correlate with iMg.

**Methods:** We collected whole blood from pts in a single center for iMg and iCa measurement. Each CKRT pt could contribute multiple samples as our timepoints would reset with each circuit change. Total Mg and Ca were collected as standard of care. Demographic, lab, and outcome data were recorded from the medical record. iMg and iCa were categorized using normal ranges of 0.44-0.65 mmol/L and 1.0-1.3 mmol/L, respectively, based on prior studies and clinical significance. Fisher's Exact test and Pearson correlation studies were used for statistical analysis.

**Results:** In 9 KTx pts (n= 28 samples), iMg and TMg had similar categorization (p<0.001) and correlated well (R=0.811, p<0.001, Table 1A, Figure 1A), but iCa did not differentiate normal from abnormal iMg concentrations (p=0.118). In 11 CKRT pts (n=70 samples), more time on CKRT resulted in more ionized hypomagnesemia despite 65/70

samples having normal tMGs: 17/30 (57%) of pre-CRRT, 15/19 (79%) of 1-2 hour, and 15/16 (94%) of 18-28 hour iMGs were low. On CKRT, there was category agreement ( $p=0.028$ ) and moderate correlation between iMG and tMG ( $R=0.54$ ,  $p<0.0001$ ), but poor category agreement ( $p=0.50$ ) and correlation between iMG and iCa ( $R=0.178$ ,  $p=0.138$ ).

**Conclusions:** iMG and tMG correlate in both groups, with greater category agreement in the KTx cohort, thus tMG likely represents active Mg in these pts. CKRT patients exposed to citrate had progressive ionized hypomagnesemia despite normal tMG and may benefit from supplementation. iCa should not be used as a surrogate for iMG concentrations.

**Funding:** Commercial Support - Nova Biomedical provided devices and disposables free of charge.

**Renal Proximal Tubular Dysfunctions in Primary Biliary Cholangitis**  
Xiaoxiao Shi,<sup>1</sup> Tianchen Guo,<sup>2</sup> Yubing Wen,<sup>1</sup> Xuemei Li,<sup>1</sup> Limeng Chen.<sup>1</sup>  
<sup>1</sup>Department of Nephrology, State Key Laboratory of Complex Severe and Rare Diseases, Peking Union Medical College Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Beijing, China; <sup>2</sup>Department of Internal Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Beijing, China.

**Background:** Renal involvement of primary biliary cholangitis (PBC) always presents as distal renal tubular acidosis. Proximal tubular (PT) dysfunctions in PBC have been rarely reported and their clinicopathological characteristics and renal prognosis remain unclear.

**Methods:** We recruited 935 inpatients of PBC from February 2003 to July 2021 and identified 11 cases with PT dysfunctions (PBC-PT). Their medical document, kidney pathology, and follow-up data were retrospectively reviewed and analyzed.

**Results:** The 11 PBC-PT patients were mainly middle-aged ( $57.8\pm5.2$  years) females (81.8%) with a mean estimated glomerular filtration rate (eGFR) level of  $46.54\pm23.03$  ml/min/1.73m<sup>2</sup>. They showed different degrees of PT dysfunctions, including hyperuricosuria (80.0%), hypouricemia (63.6%), normoglycemic glycosuria (63.6%), generalized aminoaciduria (62.5%), hyperphosphaturia (60.0%), and hypophosphatemia (54.5%). Compared to the PBC patients with non-proximal tubulointerstitial injuries, the PBC-PT patients had an older age at diagnosis and a lower ratio of severe hypokalemia. Their kidney pathology showed tubulointerstitial nephritis with lymphoplasmacytic infiltrates, brush border defects, and proximal tubulitis. After glucocorticoids (GCs) treatment, we observed the recovery of hypophosphatemia, hypouricemia, renal glycosuria, and the significant improvement of eGFR ( $43.24\pm19.60$  ml/min/1.73m<sup>2</sup> vs.  $55.02\pm21.14$  ml/min/1.73m<sup>2</sup>,  $P=0.028$ ).

**Conclusions:** We reported the largest single-center cases series of PBC-PT. The PT dysfunctions were not rare in PBC patients, and GCs treatment improved the eGFR and tubular functions.

**Use of Balanced Crystalloids vs. Isotonic Saline in Critically Ill Patients: A Meta-Analysis**  
Sara Alattal,<sup>1</sup> Si Yuan Khor,<sup>1</sup> Saif Al-Deen Alattal,<sup>1</sup> Abdullah Al-Abcha,<sup>1</sup> Yeshwanter Radhakrishnan,<sup>2</sup> Mohamed Hassanein.<sup>3</sup> <sup>1</sup>Michigan State University, East Lansing, MI; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>3</sup>The University of Mississippi Medical Center, Jackson, MS.

**Background:** Recent focus to compare resuscitation with balanced fluids and unbalanced solutions has emerged. However, the resuscitative fluid of choice and whether it affects patients' outcomes remains debatable. We aimed to perform a comprehensive meta-analysis to compare balanced crystalloids and isotonic saline outcomes in critically ill patients.

**Methods:** A systematic search of Pubmed, Embase and Cochrane was done through May, 2022 of all studies that compared any balanced fluids with isotonic saline and reported at least one of the following outcomes: acute kidney injury (AKI), mortality, and kidney replacement therapy (KRT). Primary outcome was the incidence of AKI. Secondary outcomes included the need for KRT and all-cause mortality. Pooled risk ratio (RR) with the corresponding 95% confidence intervals (CI) were obtained using a random-effect model.

**Results:** Thirty-one studies were identified and twenty-four studies were included with a total of 48,751 patients. The incidence of AKI was significantly lower in the balanced fluids group compared to the isotonic saline group (14.2% vs 15.2%,  $p=0.002$ ). There was a significant difference in all-cause mortality with lower incidence in the balanced fluids group compared to the isotonic saline group (16.9% vs 19.2%,  $p=0.006$ ). There was no significant difference in the incidence of KRT between balanced fluids and normal saline (5.6% vs 6.1%,  $p=0.06$ ).

**Conclusions:** Our study supports the use of balanced crystalloids over isotonic saline for fluid resuscitation in critically ill patients. Compared to normal saline, balanced fluids use resulted in lower mortality rate and incidence of AKI. However, it did not improve the incidence of KRT. Further large-scale clinical studies are needed to validate our findings.

FR-PO574

**The Use of Urine Biomarker-Creatinine Ratio as the Exposure in Epidemiological Studies Alters the Exposure-Outcome Relationships**  
Abu Mohd Naser,<sup>1</sup> Md Mahbubur Rahman,<sup>2</sup> Farjana Jahan,<sup>3</sup> Keiichi Sumida,<sup>2</sup> Prabin Shrestha,<sup>2</sup> Yamini Mallisetty,<sup>2</sup> Shejuti Paul,<sup>2</sup> Connie Rhee,<sup>4</sup> Kamyar Kalantar-Zadeh,<sup>4</sup> Csaba P. Kovessy.<sup>2,3</sup> <sup>1</sup>Division of Epidemiology, Biostatistics, and Environmental Health, University of Memphis, Memphis, TN; <sup>2</sup>The University of Tennessee Health Science Center, Memphis, TN; <sup>3</sup>VA Medical Center, Memphis, TN; <sup>4</sup>University of California Irvine, Irvine, CA; <sup>5</sup>International Centre for Diarrhoeal Disease Research, Bangladesh (icddr), Dhaka, Bangladesh.

**Background:** The use of urine biomarker-creatinine ratio as exposure is common in epidemiological studies that allows adjusting for the dilutional status of the urine under the assumption that individuals excrete same daily amount of creatinine. However, urine creatinine excretion varies based on an individual's muscle mass, gender, age, and ethnicity. Hence, the use of urine biomarker-creatinine ratio may lead to measurement error. Regression adjustment for creatinine could be a better strategy to assess effects of urine biomarkers. Our aim was to compare the association of urine sodium concentration with blood pressure, proteinuria, and calciuria, using urine sodium-creatinine ratio (UNaCrR) vs. urine sodium adjusted (UNaCrAdj) for urine creatinine as exposures.

**Methods:** We used 10,050 person-visits pooled data from the coastal Bangladesh population whose urine sodium, creatinine, total protein, calcium concentrations, and blood pressure were measured. We created restricted cubic spline plots to visualize the relationship between UNaCrR and UNaCrAdj with three health outcomes, using linear mixed models (blood pressure) or quantile mixed models (for proteinuria and calcium).

**Results:** For UNaCrR, we found a U-shaped relationship with SBP and DBP; an upward and then plateaued relationship with urine protein and calcium concentrations. For UNaCrAdj, we found an inverse U-shaped relationship with SBP and DBP; and an upward positive relationship with urine protein and calcium concentrations (Figure).

**Conclusions:** We find altered relationships for UNaCrR versus UNaCrAdj with three outcomes. The plots for UNaCrAdj are more aligned with the published literature on the relationship of urine sodium with proteinuria and calciuria.

**Funding:** Private Foundation Support

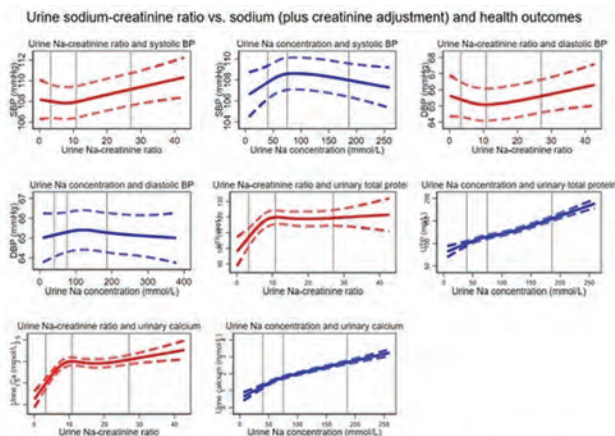

Figure: Restricted cubic spline plots visualizing the relationships of urine sodium-creatinine ratio vs. urine sodium with creatinine adjustment with blood pressure, urine total protein, and calcium concentrations. Red plots are for sodium-creatinine ratio and blue plots are for urine creatinine with regression adjustment. Dotted lines represent the lower and upper limit of the 95% confidence interval of the relationships. Vertical lines represent the 5<sup>th</sup>, 50<sup>th</sup>, and 95<sup>th</sup> percentiles of the exposures (urine sodium creatinine ratio or sodium concentration).

### Endothelial Cell Ferroptosis Promotes Renal Damage in ANCA-Induced Glomerulonephritis

Anthony Rousselle,<sup>1</sup> Dörte Lodka,<sup>1</sup> Lovis Kling,<sup>2,1</sup> Ralph Kettritz,<sup>2,1</sup> Adrian Schreiber.<sup>2,1</sup> <sup>1</sup>Experimental and Clinical Research Center, Max Delbrück Center for Molecular Medicine (MDC) and Charité, Berlin, Germany; <sup>2</sup>Charité Universitätsmedizin Berlin, Berlin, Germany.

**Background:** Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) are systemic autoimmune diseases characterized by inflammation of small blood vessels and organ damage, including necrotizing and crescentic glomerulonephritis (NCGN). ANCA are circulating immunoglobulin G (IgG) autoantibodies binding to and activating neutrophil granulocytes and monocytes. The persistent inflammation leads to renal cell necrosis. Ferroptosis is a form of programmed cell death characterized by the production of ROS- and iron-dependent lipid peroxidation leading to membrane rupture. The Acyl-CoA Synthetase Long Chain Family Member 4 (ACSL4) enzyme regulates the generation of lipid peroxides. We tested the hypothesis that endothelial cell ferroptosis contributes to ANCA-associated NCGN.

**Methods:** To analyse the biological significance of ferroptosis in endothelial cells in vivo, we generated MPO<sup>-/-</sup> ACSL4<sup>EC</sup> mice, which lack ACSL4 specifically in endothelial cells. MPO<sup>-/-</sup> ACSL4<sup>EC</sup> mice were immunized with murine MPO, irradiated and subsequently transplanted with hematopoietic cells from C/57BL/6J (WT) mice. Mice were sacrificed and analyzed 6-8 weeks following transplantation. Ferroptosis was investigated in vitro using human umbilical vein endothelial cells and ANCA-stimulated neutrophils. Cell death and lipid peroxidation were detected by flow cytometry. Ferrostatin-1 (Fer-1) and siRNA against ACSL4 were used to inhibit ferroptosis.

**Results:** We found increased lipid peroxidation (4-HNE staining) in kidney section of mice with AAV. MPO<sup>-/-</sup> ACSL4<sup>EC</sup> chimeric mice showed reduced renal damage as indicated by less necrotic and crescentic glomeruli supporting the notion that endothelial cell ferroptosis is important for the development of MPO-ANCA-induced NCGN. In vitro experiments revealed that ANCA-activated neutrophils induced endothelial cell death and this effect was prevented by ferroptosis inhibition with Fer-1 and siRNA against ACSL4. In contrast, inhibition of either necroptosis or apoptosis did not prevent endothelial cell death. Finally, ferroptosis inhibition alleviated the accumulation of lipid peroxides and endothelial dysfunction induced by ANCA-activated neutrophils.

**Conclusions:** ANCA-activated neutrophils induce ferroptosis in endothelial cells in vitro and endothelial cell ferroptosis contributes to ANCA-associated NCGN in a murine AAV model.

**Funding:** Government Support - Non-U.S.

### β2 Integrin-Dependent Adhesion Is Indispensable for Inflammatory HIF1α Activation in Human Neutrophils

Lovis Kling,<sup>1,2</sup> Claudia Eulenberg-Gustavus,<sup>1</sup> Uwe Jerke,<sup>1</sup> Anthony Rousselle,<sup>1</sup> Kai-Uwe Eckardt,<sup>2</sup> Adrian Schreiber,<sup>1,2</sup> Ralph Kettritz.<sup>1,2</sup> <sup>1</sup>Experimental and Clinical Research Center, Charité – Universitätsmedizin Berlin and Max Delbrück Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany; <sup>2</sup>Department of Nephrology and Medical Intensive Care, Charité – Universitätsmedizin Berlin, Berlin, Germany.

**Background:** Myeloid cells migrate from blood to inflammatory sites with high cytokine but low oxygen concentrations. Hypoxic but also pharmacologic prolyl hydroxylase inhibition induces hypoxia-inducible factor 1α (HIF1α), and thereby enhances myeloid cell performance. We tested the hypothesis that cytokines and β<sub>2</sub>-integrins co-operate in the HIF1α activation process.

**Methods:** We characterized HIF1α in human blood neutrophils and monocytes using immunoblotting and qPCR. Neutrophil suspension was achieved on polyhema, adhesion on fibronectin, and migration through transwells. Prolyl hydroxylases were inhibited with Roxadustat (ROX), and HIF1α translation with YC1. Signaling pathways were analyzed with β<sub>2</sub>-integrin antibodies and the JAK2 inhibitor AZD1480.

**Results:** We observed HIF1α activation in ROX-, but not cytokine-treated neutrophils and monocytes after 4h incubation in tubes. A 3-fold synergistic effect occurred in neutrophils but not in monocytes with combined GM-CSF and ROX treatment. Neutrophils that interacted with fibronectin showed high HIF1α protein abundance, whereas HIF1α protein was completely absent under stringent suspension conditions on polyhema that excluded cell-cell and matrix contacts. Consequently, pre-incubation with blocking β<sub>2</sub>-integrin antibodies prevented neutrophil HIF1α protein in both tubes and on fibronectin. GM-CSF induced strong HIF1α mRNA via JAK2/STAT but independent of adhesion. However, an additional β<sub>2</sub>-integrin signal was required for HIF1α protein upregulation. Adhesion did not accelerate transcription but rather involved post-transcriptional mechanisms stabilizing HIF1α protein as shown by YC1-mediated inhibitory effects. These novel synergistic mechanisms led to strong HIF1α protein in neutrophils that migrated towards GM-CSF and ROX in transwell experiments.

**Conclusions:** Human neutrophils are unable of activating HIF1α in suspension. In contrast, cytokine, β<sub>2</sub>-integrin, and prolyl hydroxylase co-operation at inflammatory sites enables strong HIF1α activation.

**Funding:** Government Support - Non-U.S.

## FR-PO577

### Enhanced Serum Levels of NF-κB-Regulated Immune Modulators in Lupus Nephritis Patients With TNIP1 Variant rs4958881

David W. Powell, Makayla Brady, Shweta Tandon, Dawn J. Caster. *University of Louisville School of Medicine, Louisville, KY.*

**Background:** Lupus nephritis (LN) is a prevalent and severe complication of systemic lupus erythematosus (SLE). Non-invasive diagnostics are limited and current therapies have inadequate response rates. This raises a great need for understanding the cellular and molecular mechanisms for LN development to identify novel diagnostics and therapeutic targets. We previously reported the TNIP1 variant rs4958881 as risks for LN. TNIP1 encodes the protein ABIN1, which is a polyubiquitin binding protein that negatively regulates the immune regulatory transcription factor NF-κB. NF-κB activation leads to the expression of inflammatory cytokines and chemokines. We hypothesize that patients with the risk variant for TNIP1 have increased serum levels of NF-κB-regulated cytokines and chemokines.

**Methods:** To test our hypothesis, we acquire serum from 30 LN patients in an active flare (UPCR > 500 mg/g) and 7 healthy control individuals. Of the 30 LN patients, 17 patients had the TNIP1 rs4958881 variant. These serum samples were analyzed with a bio-plex array containing antibodies for 48 human cytokine/chemokine regulated by NF-κB.

**Results:** We found 12 proteins (IL-18, SCF, IL-2Ra, HGF, M-CSF, TRAIL, IFN-γ, MIP-1α, IL-16, IL-8, MIG, and G-CSF) were significantly increased in serum from LN patients compared to control serum and 6 of these were significantly increased specifically in LN patients with the TNIP1 variant compared with controls (IFN-γ, MIP-1α, IL-16, IL-8, MIG, and G-CSF).

**Conclusions:** Our findings indicate that LN patients have an increased serum levels of a panel of specific inflammatory cytokines and chemokines and the presence of TNIP1 risk allele leads to a differential response. These data provide a list of candidate diagnostic markers and potential therapeutic targets and important insight into novel mediators of immune-phenotypes in LN.

**Funding:** NIDDK Support

## FR-PO578

### Enhanced Neutrophil Activity in Lupus Nephritis Patients With TNIP1 Variant rs4958881

David W. Powell, Makayla Brady, Shweta Tandon, Madhavi J. Rane, Michelle T. Barati, Dawn J. Caster. *University of Louisville School of Medicine, Louisville, KY.*

**Background:** There is need for understanding cellular and molecular mechanisms of lupus nephritis (LN) to define novel diagnostics and therapeutic. We previously reported the TNIP1 variant rs4958881 as risks for LN. TNIP1 encodes ABIN1, which negatively regulates the immune regulatory NF-κB. Glomerular neutrophil accumulation has been shown in LN patients and we have shown that transgenic mice with loss of ABIN1 function also develop glomerular influx of neutrophils. Release of neutrophil extracellular traps (NETs) is implicated in loss of immune tolerance in SLE and enhanced serum levels of NETs and antibodies against NET components have been reported in LN patients. Thus, we hypothesize that LN patients with the TNIP1 rs4958881 risk variant have increased NET production/release and recruitment of neutrophils due to NF-κB over activation.

**Methods:** We tested our hypothesis by performing in vitro transwell migration (chemotaxis) and supernatant DNA measurements (NET release) assays with neutrophils isolated from 6 LN patients with and 6 LN patients without the TNIP1 variant rs4958881 and 6 healthy control subjects. Neutrophil functions were measured in response to known positive activators (FMLF for chemotaxis and PMA for NET production). Interferon (IFN)-γ is prominent activator of neutrophils that was recently implicated in LN and we found that serum levels of IFN-γ are enhanced in LN patients with the rs4958881 variant. Thus, stimulation with IFN-γ was also assessed.

**Results:** IFN- $\gamma$  did not activate chemotaxis of neutrophils from healthy controls or LN patients without the TNIP1 variant rs4958881, but cells from LN patients with the TNIP1 variant had a robust response to IFN- $\gamma$ . NET production was enhanced in response to PMA and IFN- $\gamma$  in neutrophils from LN patients with the TNIP1 variant as compared to the response in cells from LN patients without the and healthy controls.

**Conclusions:** Our findings indicate that LN patients' neutrophils have an altered response to an LN relevant stimulus compared to healthy control individuals. These data also suggests that the presence of TNIP1 variant rs4958881 further exacerbates this altered response. This suggests this increased neutrophil activation is a contributing factor to inflammatory development in these patients and that targeting and suppressing neutrophil activity could potentially alleviate their LN.

## FR-PO579

### CC Chemokine Receptor 2 (CCR2) in ANCA Disease: Different Roles in Glomerulonephritis vs. Lung Granulomatosis in MPO-ANCA Induced Mouse Model

Peiqi Hu, Hong Xiao, Marco A. Alba, Shen-Ju Gou, Yanglin Hu, Ronald Falk, J. Charles Jennette. *University of North Carolina, Chapel Hill, NC.*

**Background:** Antineutrophil cytoplasmic autoantibody disease has a spectrum of necrotizing small vessel vasculitis, including necrotizing crescentic glomerulonephritis (NCGN) and lung granulomatosis (LG). Neutrophils and monocytes/macrophages are key players in the pathogenesis of ANCA disease. CC chemokine receptor 2 (CCR2) serves as the main receptor for CCL2, and modulates recruitment of monocytes/macrophages and neutrophils to sites of inflammation. CCR2 has dual pro-inflammatory and anti-inflammatory roles in inflammation. The aim of the present study was to elucidate the role of CCR2 in the pathogenesis of NCGN and LG in an animal model of MPO-ANCA disease.

**Methods:** A murine MPO-ANCA induced model was used to evaluate the in vivo role of CCR2 in ANCA GN and LG. CCR2<sup>-/-</sup> and B6 WT mice were treated with a single dose of anti-MPO IgG iv at day 0; or a dose of intratracheal LPS administration at day 0 plus two consecutive doses of anti-MPO IgG on day 0 and day1. Mice were sacrificed at day7 and kidneys and lungs collected for pathologic assessment.

**Results:** On day 7 after receiving a single dose of MPO-ANCA IgG, WT mice (n=8) had 13.9% mean crescents (crescent between arrows in Figure 1), whereas CCR2<sup>-/-</sup> mice (n=3) had less GN with 0.5% crescents. However, WT mice had no LG, whereas CCR2<sup>-/-</sup> mice had well defined LG often with a central core of neutrophils surrounded by macrophages (between arrows in Figure 2).

**Conclusions:** Our preliminary data indicate that CCR2 deficiency reduces the severity of necrotizing inflammation in glomeruli, whereas CCR2 deficiency facilitates granulomatous disease in lungs. Insights into the role of CCR2 in the pathogenesis of ANCA disease will help guide development of safe and effective therapies involving CCR2 and CCR2 ligand modulation for ANCA disease.

### Kidney Injury Molecule 1 (KIM-1): A Potential Biomarker of AKI and Tubulointerstitial Injury in Patients With ANCA-Glomerulonephritis

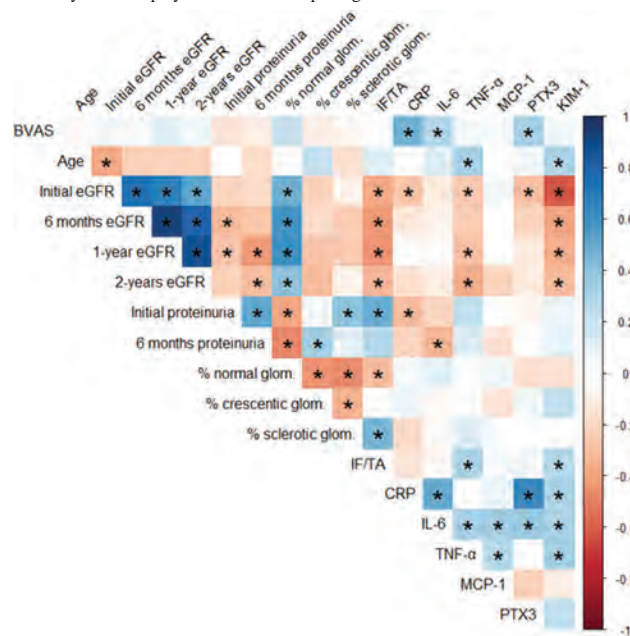

Benoit Brillard,<sup>1</sup> Charlotte Boud'hors,<sup>1</sup> Samuel Wacrenier,<sup>1</sup> Simon Blanchard,<sup>1</sup> Odile Blanchet,<sup>1</sup> Giorgia B. Piccoli,<sup>2</sup> Nicolas Henry,<sup>3</sup> Assia Ilham Djema,<sup>4</sup> Pascale Jeannin,<sup>1</sup> Yves Delneste,<sup>5</sup> Marie-Christine Copin,<sup>1</sup> Jean Francois Augusto.<sup>1</sup> <sup>1</sup>Centre Hospitalier Universitaire d'Angers, Angers, France; <sup>2</sup>Centre Hospitalier du Mans, Le Mans, France; <sup>3</sup>CH Laval, Laval, France; <sup>4</sup>Centre Hospitalier de Cholet, Cholet, France; <sup>5</sup>Universite Angers Faculte des sciences, Angers, France.

**Background:** Kidney injury molecule 1 (KIM-1) is a transmembrane glycoprotein expressed by proximal tubular cells, recognized as an early, sensitive, and specific urinary biomarker for kidney injury. Blood KIM-1 was recently associated with the severity of acute and chronic kidney damage but its value in ANCA-associated vasculitis with glomerulonephritis (ANCA-GN) has not been studied. Thus, we analyzed its expression at ANCA-GN diagnosis and its relationship with clinical presentation, kidney histopathology, and early outcomes.

**Methods:** We assessed KIM-1 levels and other pro-inflammatory molecules (CRP, IL-6, TNF- $\alpha$ , MCP-1 and PTX3) at ANCA-GN diagnosis and after 6 months in patients included in the Maine-Anjou registry, which gathers data patients from four French Nephrology Centers diagnosed since January 2000.

**Results:** Blood KIM-1 levels were assessed in 58 patients. Levels were elevated at diagnosis and decreased after induction remission therapy. KIM-1 was associated with the severity of renal injury at diagnosis and the need for KRT. In opposition to other pro-inflammatory molecules, KIM-1 correlated with the amount of interstitial fibrosis and tubular atrophy (IF/TA) on kidney biopsy, but not with glomerular involvement. In multivariable analysis, elevated KIM-1 predicted initial eGFR ( $\beta = -19 [-31, -7.6]$ ,  $p = 0.002$ ).

**Conclusions:** KIM-1 appears as a potential biomarker for acute kidney injury and for tubulointerstitial injury in ANCA-GN. Whether KIM-1 is only a surrogate marker for IF/TA or a key immune player in ANCA-GN pathogenesis remain to be determined.

## FR-PO581

### Intrarenal Synthesis of Complement C3 Localized to Distinct Vascular Compartments in ANCA-Associated Renal Vasculitis

Desiree Tampe, Samy Hakroush, Bjoern Tampe. *University Medical Center Göttingen, Göttingen, Germany.*

**Background:** The activation of the complement system contributes essentially to its pathogenesis by autoantibody-antigen recognition directed against host cells in anti-neutrophil cytoplasmic antibody (ANCA)-associated renal vasculitis. The measurement of serum complement C3 with immunoassays is routinely used in clinical practice to determine and monitor complement activation. Importantly, C3 hypocomplementemia is only present in a minor subset of ANCA-associated renal vasculitis. These observations suggest that intrarenal synthesis of distinct complement components might contribute to kidney injury in renal vasculitis.

**Methods:** Intrarenal complement C3c localized to distinct vascular compartments (including small-sized arteries, capillaries, and venules) was evaluated in a total number of 43 kidney biopsies with ANCA-associated renal vasculitis. Publicly available transcriptome array datasets for C3 expression (encoded by *C3*) from Nephroseq (www.nephroseq.org, May 2022, University of Michigan, Ann Arbor, MI).

**Results:** Immunostaining confirmed presence of C3c deposits localized to either the glomerular tuft, interlobular arteries, peritubular capillaries, or venules in ANCA-associated renal vasculitis. Glomerular C3c deposits correlated positively with serum levels of complement C3c ( $p=0.011$ ), further supporting intrarenal synthesis of complement C3. As compared to healthy controls, we observed a significant induction of *C3* mRNA transcripts in the tubulointerstitial ( $p<0.0001$ ) and glomerular compartments of renal vasculitis ( $p<0.0001$ ). Interestingly, intrarenal synthesis of C3 was significantly higher in renal vasculitis as compared to lupus nephritis for both compartments ( $p<0.0001$  and  $p<0.001$ , respectively). Intrarenal *C3* mRNA expression correlated with impaired kidney function in the tubulointerstitial and glomerular compartments of renal vasculitis. Gene set enrichment analysis linking intrarenal C3 synthesis to distinct inflammatory signaling pathways.

**Conclusions:** To our knowledge, this is the first report of a systematic analysis of intrarenal synthesis and vascular distribution of intrarenal complement C3 deposits in ANCA-associated renal vasculitis. This is especially relevant because clinical trials currently investigate inhibition of the complement system in ANCA-associated renal vasculitis.

## FR-PO582

**Reduced ANCA-Sialylation Increases Anti-Myeloperoxidase-Induced Necrotizing Crescentic Glomerulonephritis in a Mouse Model**

Dörte Lodka, Anthony Rousselle, Sylvia Lucke, Maximilian Ebert, Udo Schneider, Ralph Kettritz, Adrian Schreiber. *Charite Universitätsmedizin Berlin, Berlin, Germany.*

**Background:** The glycosylation of IgG and especially of autoantibodies is an important regulator of antibody functionality. It has already been described that IgG glycosylation affects the binding ability to Fc receptors. It is also known that the glycosylation pattern of ANCA is altered during active AAV. However, only a few studies showed a direct relationship between glycosylation patterns and cellular functionality in AAV-relevant processes. We tested the hypothesis that B cells from active AAV patients are hypoglycosylated and that hypoglycosylated ANCA trigger stronger neutrophil activation in vitro and more severe MPO-ANCA induced NCGN.

**Methods:** The glycosylation status of B cells from patients compared to healthy controls was analyzed by flow cytometry. IgG from patients with active AAV were sialylated and desialylated in vitro. These modified antibodies were used in neutrophil stimulation assays to investigate the influence of sialylation status on ROS production, NETs induction and IL-1b secretion. Anti-MPO NCGN was induced in WT mice by passive IgG-transfer from MPO-immunized mice. The administered IgG originated from either MPO<sup>+</sup> (normal IgG) or MPO<sup>-</sup>/St6gal1<sup>-/-</sup>-mice (hyposialylated IgG). Histological evaluation of renal sections as well as flow cytometric analyses of blood and kidney cells were performed.

**Results:** B cells from active patients showed about a third reduced levels of sialic acid, terminal galactose and fucose compared to healthy controls. In vitro sialylation of IgG from active patients resulted in about 64%, 70% and 55% decreased ROS production, NETs formation and IL-1b secretion, respectively. Finally, mice receiving hyposialylated IgG from MPO<sup>-</sup>/St6gal1<sup>-/-</sup>-mice showed worsened NCGN compared to mice receiving IgG from MPO<sup>+</sup>-mice, as evidenced by an increased proportion of crescentic (20.9% vs. 8.4%) and necrotic (10.7% vs. 4.27%) glomeruli.

**Conclusions:** Glycosylation, especially sialylation of IgG, affects the severity of AAV disease. Increased IgG-sialylation had a protective effect as shown by reduced ROS production, NETs formation and IL-1b secretion in vitro. Conversely, sialic acid deficiency aggravated MPO-ANCA induced vasculitis in a murine disease model.

**Funding:** Government Support - Non-U.S.

## FR-PO583

**CD19 CAR-T Cells Protect Against the Development of ANCA-Induced Necrotizing Crescentic Glomerulonephritis in a Mouse Model**

Dörte Lodka,<sup>1</sup> Anthony Rousselle,<sup>1</sup> Ralph Kettritz,<sup>1</sup> Maria Zschummel,<sup>2</sup> Mario Bunse,<sup>2</sup> Adrian Schreiber.<sup>1</sup> <sup>1</sup>Charite Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>Max-Delbrück-Centrum für Molekulare Medizin in der Helmholtz-Gemeinschaft, Buch, Germany.

**Background:** ANCA-induced vasculitis and NCGN are potentially life-threatening and current therapeutic approaches are largely based on cytotoxic drugs or B-cell-depleting antibodies. Chimeric antigen receptor T cells (CAR T cells) are genetically modified T cells that express a protein consisting of intracellular T cell receptor domains that are coupled to an extracellularly located antibody domain. The antibody specificity determines which target cells are recognized and destroyed by the CAR T cells. The use of CAR-T cells in autoimmune diseases is a promising new therapeutic approach. Since ANCA are implicated in ANCA-associated vasculitides (AAVs), depletion of ANCA-producing B cells may be an effective AAV therapy. We tested the hypothesis that CD19 CAR T cells deplete B cells, including MPO-ANCA-producing B cells, thereby protecting from MPO-ANCA induced necrotizing crescentic glomerulonephritis (NCGN).

**Methods:** Anti-MPO NCGN was induced by immunization of MPO<sup>-</sup>-mice with murine MPO, followed by irradiation and transplantation of hematopoietic cells from WT mice. In addition, CD19 CAR-T cells and SP6 CAR-T cells (control CAR) were administered. Effects on disease severity were analyzed by histological examination of kidney sections and by spleen, blood and bone marrow flow cytometry.

**Results:** CD19 CAR T cells showed efficient immigration and stable persistence in the transplanted animals, as they were detectable in bone marrow, spleen and peripheral blood after two and five weeks. In addition, mice receiving CD19 CAR T cells had significantly reduced amounts of CD19-expressing endogenous B cells compared to SP6 CAR T mice at 5 weeks in bone marrow (0.03% vs. 6.68%), spleen (0.05% vs. 60.7%) and peripheral blood (0.004% vs. 38.3%) accompanied by decreased anti-MPO titer. Finally, histology revealed a reduction in both crescentic (0.49% vs. 10.83%) and necrotic (0% vs. 6.04%) glomeruli in mice receiving CD19 CAR T cells compared to SP6 CAR T mice at 5 weeks, thus showing a protection from NCGN induction.

**Conclusions:** Our data suggest that depletion of CD19-expressing B cells by administration of CD19 CAR-T cells is an effective therapeutic option in murine anti-MPO-induced NCGN.

**Assessing Clinical Outcomes of ANCA Vasculitis in the Post PEXIVAS Era: A Single Centre Retrospective Analysis**

Ravindra Rajakariar,<sup>1</sup> Charles Hall,<sup>1</sup> Jack E. Carruthers,<sup>1,2</sup> James Wells.<sup>1</sup> <sup>1</sup>Barts Health NHS Trust, London, United Kingdom; <sup>2</sup>The Francis Crick Institute, London, United Kingdom.

**Background:** The PEXIVAS trial (2018) showed no outcome benefit with the routine use of plasma-exchange (PLEX) in patients with ANCA vasculitis and eGFR < 50mL/min. As a result, our clinical practice changed in favour of no PLEX and replacing a standard steroid wean with a fast steroid taper, thus altering the burden of immunosuppression in patients with ANCA vasculitis. We performed a retrospective analysis of a cohort of patients with ANCA vasculitis and renal involvement to determine whether this change in management impacted on patient outcomes and infections requiring hospitalisation.

**Methods:** We audited a cohort of ANCA vasculitis patients with renal involvement under follow-up at a tertiary centre diagnosed in the last 20 years. We collected demographic and clinical data including induction agent, PLEX regimen, and details of infections due to immunosuppression. The outcomes measured were patients who were in remission at one year and infections that required hospitalisation or CMV viraemia within 1 year of diagnosis

**Results:** A total of 134 patients were identified, 91 diagnosed pre-PEXIVAS and 43 post-PEXIVAS. 6 patients died from COVID-19 by 1 year in the post-PEXIVAS group, these patients were excluded from analysis. Pre- and post-PEXIVAS mean age (60.6 yrs and 59 yrs respectively) and sex ratio (54/91 (59%) and 24/43 (55%)) were similar. The preferred induction agent pre-PEXIVAS was cyclophosphamide (65/91 (75%)) whilst there was a move to Rituximab in the post-PEXIVAS cohort (13/43 (48%)). Pre-PEXIVAS, 27/91 (29%) patients underwent PLEX versus 2/43 (4%) post-PEXIVAS. Remission rates at 1 year after diagnosis were similar between the two cohorts (pre: 65/91 (71.4%); post: 23/37 (53%); p=0.18 by Fisher's exact test). Infections that required hospitalisation were not significantly different but there was a trend to lower rate of admissions (pre: 16/91 (17.6%); post: 5/37 (12.2%); p=0.61 by Fisher's exact test).

**Conclusions:** Our results suggest that change in clinical management after PEXIVAS was not associated with poorer outcomes in relation to treatment response and there was no significant difference in infections requiring hospitalisation at 1 year in patients with ANCA vasculitis. Our work complements recent findings that PLEX was not associated with improved rates of renal replacement therapy or mortality (Nezam et al. 2022).

## FR-PO585

**Proteomic Analysis of Glomeruli in Myeloperoxidase-ANCA Glomerulonephritis**

Amit Sethi,<sup>1,2</sup> Joseph P. Grande,<sup>1</sup> Ulrich Specks,<sup>1</sup> Fernando C. Fervenza.<sup>1</sup> <sup>1</sup>Mayo Foundation for Medical Education and Research, Rochester, MN; <sup>2</sup>University of Minnesota Twin Cities, Minneapolis, MN.

**Background:** Myeloperoxidase (MPO)-ANCA- associated vasculitis often involves the kidney resulting a severe necrotizing and crescentic glomerulonephritis (GN). Kidney biopsy shows varying percentages of glomeruli involved by necrotizing and crescentic lesions. Yet, a proportion of the glomeruli appear normal and uninvolved by the necrotizing and crescentic lesions. In this study, we compared the proteomic profile of involved and uninvolved glomeruli in MPO-ANCA-GN.

**Methods:** We performed laser microdissection of glomeruli involved by crescents/fibrinoid necrosis (CF), and glomeruli that appeared normal (N) on light microscopy in 6 cases of MPO-ANCA-GN. Equal number of glomeruli were dissected in each group/case. This was followed by mass spectrometry (MS/MS) to analyze the proteomic profile in the 2 groups. Sclerosed glomeruli were not dissected.

**Results:** Proteomic profile shows higher activation of complement pathways in CF glomeruli compared to N glomeruli with higher total spectral counts (TSC) of C3 (2-fold), C5 (7-fold), C7 (10 fold), C9 (6-fold). In addition, there is 3-7 fold increase in TSC of actinin 4, laminin subunit 2, fibrinogen a, fibrillin 1, agrin, nidogen-2, heat shock protein 90 in CF glomeruli compared to N glomeruli. On the other hand, there is 3-6 fold increase in TSC of desmoplakin, protein S100, and serpin B3 and B12 in N glomeruli compared to CF glomeruli.

**Conclusions:** Complement activation is greater in glomeruli involved by crescents and necrosis. There are also differences in proteins expressed in glomeruli with crescents/necrosis compared to uninvolved glomeruli. Overexpression of certain proteins in normal glomeruli may protect glomeruli from developing crescents/necrosis.

**Funding:** Private Foundation Support

## FR-PO586

**PRTN3 Polymorphism in Antineutrophil Cytoplasmic Antibody (ANCA) Vasculitis**

Dhruti P. Chen, Yichun Hu, Susan L. Hogan, Ronald Falk, Dominic J. Ciavatta. *University of North Carolina System, Chapel Hill, NC.*

**Background:** Patients with vasculitis associated with antibodies to proteinase-3 (PR3-ANCA) experience relapse frequently. We investigated whether a polymorphism (rs62132293) upstream of the *PRTN3* gene is associated with increased relapse among patients with PR3-ANCA.

**Methods:** Patients (n=401) and healthy controls (n=130) from the Glomerular Disease Collaborative Network were genotyped for the variant (G-allele). *PRTN3* mRNA was quantified by RT-qPCR from total leukocyte RNA of 298 (MPO and PR3) patients.

Plasma PR3 was quantified using enzyme-linked immunoassay and means compared using Wilcoxon test. Kaplan-Meier estimates and log rank test were used for time to relapse and multivariable Cox proportional hazards models with hazards ratios for relapse.

**Results:** Patients and healthy controls were genotyped, respectively: 179 (44%) and 62 (48%) who were non-carriers (C/C), 181 (45%) and 54 (41%) heterozygous carriers (C/G), 41 (10%) and 14 (11%) homozygous carriers (G/G). Among patients, 170 were PR3-ANCA, remainder had MPO-ANCA (n=197), dual positive (n=9) or seronegative (n=25). PR3-ANCA patients relapsed more than MPO-ANCA (HR 1.48, 95% CI 1.09, 2.02). Variant carriers with PR3-ANCA had reduced relapse free survival and increased risk of relapse compared to MPO-ANCA (HR 1.66, 95% CI 1.08, 2.54). The relapse risk for non-carriers was similar in PR3 and MPO-ANCA (Figure 1). Among patients, carriers had higher *PR3N3* gene expression compared to non-carriers (C/G vs. C/C and G/G vs. C/C,  $p=0.012$  and  $p=0.001$ , respectively). Gene expression correlated with plasma protein levels ( $p<0.005$ ) and patients with the variant had higher mean plasma PR3 levels compared to non-carriers (126.3ng/mL vs. 64.01 ng/mL,  $p=0.082$ , (Figure 2).

**Conclusions:** Our study highlights the clinical significance of the risk allele marked by rs62132293, and suggests increased relapse in PR3-ANCA may, in part, be explained by inheritance of the risk variant. Our results underscore disease phenotype in ANCA vasculitis may be contingent on autoantigen availability.

**Funding:** NIDDK Support

## FR-PO587

### Serum Sulfatide Level as a Marker for Differentiation and Activity Assessment in Renal Vasculitis Diseases

**Daiki Aomura, Makoto Harada, Takayuki Nimura, Yosuke Yamada, Koji Hashimoto, Yuji Kamijo.** Department of Nephrology at Shinshu University school of medicine *Shinshu Daigaku Igakubu Fuzoku Byoin, Matsumoto, Japan.*

**Background:** Sulfatides are glycosphingolipids associated with coagulation and platelet aggregation, suggesting a possible involvement in renal vasculitis (RV). However, research on this notion is extremely limited, with only one study on a small population of healthy individuals and patients with ANCA-associated vasculitis (AAV) revealing serum sulfatide (SS) level as a possible differentiation marker in AAV, especially with active crescentic findings on kidney biopsy. To further assess the association between SS and RV, we performed a retrospective study with a larger sample size including several RV diseases.

**Methods:** This cross-sectional investigation included patients admitted to the Nephrology Department of Shinshu University Hospital (Japan) after April 2008. Patients who were firstly diagnosed as having IgA vasculitis (IgAV), AAV, or anti-GBM disease (GBM) were included. As controls, donor candidates for living kidney transplantation (donors) were analyzed as well. SS levels were analyzed using stored frozen serum samples.

**Results:** The mean±standard deviation SS levels of donors (n=23), IgAV (n=26), AAV (n=64), and GBM (n=10) were  $8.30\pm1.68$ ,  $6.14\pm1.59$ ,  $5.30\pm2.02$ , and  $2.72\pm0.94$  nmol/mL, respectively. Regarding associations with kidney biopsy findings, SS levels were significantly higher in patients with a higher crescentic score (Oxford classification) in IgAV. In contrast, SS levels were significantly lower in patients with a crescent-type phenotype (Berdens classification) in AAV and negatively correlated with the percentage of glomeruli with cellular crescents in GBM ( $r=-0.76$ ,  $p=0.02$ ). Those associations of active pathological findings with SS level were stronger than with other possible markers including serum C-reactive protein level in all RV groups.

**Conclusions:** SS level is a possible marker for differentiation and activity assessment in RV diseases.

## FR-PO588

### Association Between ANCA Kinetic, Renal Survival, and Relapse Risk in ANCA-Glomerulonephritis

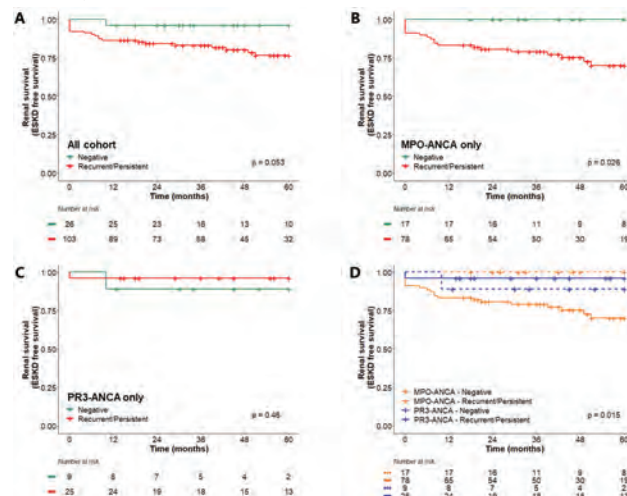

**Clément Samoreau,<sup>1</sup> Giorgia B. Piccoli,<sup>3</sup> Cecile Martin,<sup>5</sup> Philippe Gataut,<sup>6</sup> Emeline Vinatier,<sup>1</sup> Frank Bridoux,<sup>5</sup> Jérémie Riou,<sup>1</sup> Alice Desouche,<sup>1</sup> Pierre Jourdain,<sup>1</sup> Samuel Wacrenier,<sup>1</sup> Nicolas Henry,<sup>4</sup> Odile Blanchet,<sup>1</sup> Assia Ilham Djema,<sup>2</sup> Lise-Marie Pouteau,<sup>1</sup> Marie-Christine Copin,<sup>1</sup> Celine Beauvillain,<sup>1</sup> Jean Francois Augusto,<sup>1</sup> Benoit Brillard.<sup>1</sup>** <sup>1</sup>Centre Hospitalier Universitaire d'Angers, Angers, France; <sup>2</sup>CH de Cholet, Cholet, France; <sup>3</sup>Centre Hospitalier du Mans, Le Mans, France; <sup>4</sup>CH de Laval, Laval, France; <sup>5</sup>Centre Hospitalier Universitaire de Poitiers, Poitiers, France; <sup>6</sup>Centre Hospitalier Regional Universitaire de Tours, Tours, France.

**Background:** ANCA kinetic in ANCA-associated vasculitis with glomerulonephritis (AAV-GN) has been suggested to be associated with relapse. Few studies focused on its association with renal prognosis. Thus, we aimed to investigate the relationship between i) ANCA specificity and evolutive profile, and ii) renal outcomes.

**Methods:** This multicentric retrospective study included patients diagnosed with ANCA-GN since 01/01/2000. Patients without ANCA at diagnosis and with fewer than 3 ANCA determinations during follow-up were excluded. We analyzed eGFR variation, renal-free and relapse-free survival according to three ANCA profiles (negative, recurrent, persistent) and to ANCA specificity (MPO or PR3).

**Results:** Over a median follow-up of 56 months, 19 [13-25] ANCA determinations were performed for the 134 included patients. Patients with a recurrent/persistent ANCA profile had a lower renal- ( $p=0.053$ ) and relapse-free ( $p=0.019$ ) survival compared to those with negative ANCA profile. Patients with a recurrent/persistent MPO-ANCA profile had the worst renal survival ( $p=0.015$ ) and those with recurrent/persistent PR3-ANCA profile had the worst relapse-free survival ( $p=0.013$ ) compared to other profiles. In multivariate regression analysis, a negative ANCA profile was an independent predictor of positive 2-year eGFR percent variation ( $p<0.001$ ).

**Conclusions:** ANCA kinetic after ANCA-GN diagnosis is associated with outcomes. MPO-ANCA recurrence/persistence identifies patients with a lower potential of renal recovery and a higher risk of ESKD, while PR3-ANCA recurrence/persistence identifies patients with a greater relapse risk. Thus, ANCA kinetic may help identify patients with a smoldering disease.

## FR-PO589

### Histological Subtyping of Interstitial Infiltrates and Long-Term Validation of Renal Risk Score in ANCA-Associated Glomerulonephritis

**Aglaiia Chalkia,<sup>1</sup> Christos Koutsianas,<sup>3</sup> Panagiota E. Giannou,<sup>1</sup> Georgios Agelis,<sup>1</sup> Harikleia Gakiopoulou,<sup>2</sup> Alexandros G. Panagiotopoulos,<sup>3</sup> Konstantinos Thomas,<sup>3</sup> Dimitrios Vassilopoulos,<sup>3</sup> Dimitrios I. Petras.<sup>1</sup>** <sup>1</sup>Nephrology Department, Hippokraton General Hospital, Athens, Greece; <sup>2</sup>1st Department of Pathology, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece; <sup>3</sup>2nd Department of Medicine and Laboratory, Clinical Immunology - Rheumatology Unit, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece.

**Background:** Data on the prognostic significance of baseline renal histologic findings in ANCA-associated glomerulonephritis (AAGN) are limited.

**Methods:** Retrospective study of 38 patients with AAV and biopsy proven AAGN. Patients were categorized according to their histologic subtype and the composition of their interstitial inflammatory infiltrates as well as their risk for progression to end-stage renal disease (ESRD) according to their renal risk score were estimate.

**Results:** 38 patients (mean age: 68 years, males:50%, MPA: 60%, anti-MPO+: 76%, mean follow-up: 48 months) were categorized into focal (n=9, 24%), mixed (n=12, 32%), crescentic (n=6, 16%) and sclerotic (n=8, 21%) subtypes while 3 patients had isolated tubulointerstitial nephritis (8%). In terms of interstitial infiltrates, mixed type

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

biopsies (n=12) had more intense interstitial inflammation (67% vs 25%, p=0.029) with predominant eosinophilic (42% vs 13%, p=0.086) and macrophage (58% vs 16%, p=0.02) compared to the other types. Contrarily, in focal type we noticed absence of macrophage (0% vs 39%, p=0.053) and limited neutrophilic (11% vs 54%, p=0.053) infiltration, compared to the rest. Patients with focal type demonstrated the lowest (HR 0.027 95% CI 0.009-3.238, p=0.09) and those with sclerotic type the highest (HR 5.95 95% CI 1.494-18.059, p=0.010) risk for ESRD progression. According to the renal risk score, the cumulative renal survival at 1, 2 and 5 years was 100% in the low-risk, 94% in the medium-risk and 50%, 38% and 18% respectively in the high-risk (p<0.0001). The high-risk group presented the highest risk for progression to ESRD (HR 25.29, 95% CI 3.145-203.38, p=0.002), compared to low/medium risk groups.

**Conclusions:** Our real-life study confirmed the value of histologic subtyping and the renal risk score for predicting ESRD progression in patients with AAGN. It also demonstrated that the cellular composition of interstitial infiltrates differs significantly according to the histologic subtype. These findings may have important implications for the understanding of the pathogenesis and prognosis of AAGN.

FR-PO590

Histopathologic Prognostication of ANCA-Associated Vasculitis Using Banff Parameters

Jerome P. Givi, James L. Akers, Adriana Garrison, Khaled Shawwa, Dinesh Kannabhiran, Md. Shahrier Amin. *West Virginia University Health Sciences Center, Morgantown, WV.*

**Background:** ANCA-associated vasculitis (AAV) with renal involvement makes up 80% of rapidly progressive glomerulonephritis cases. Our objective was to determine whether histopathologic parameters adapted from Banff provide prognostic information.

**Methods:** Biopsy slides from patients with AAV from 2008-2021 at West Virginia University Hospitals were reviewed. The biopsies were scored using an expanded Banff scoring system by a renal pathologist blinded to clinical data. Each histopathologic parameter was analyzed both individually and as part of a composite score, to determine association with eGFR and ESKD. Generalized estimating equation model was used to evaluate the association between the parameters and eGFR during follow-up. Proportional hazard model was used to investigate the association between the parameters to end-stage kidney disease (ESKD) (estimated glomerular filtration rate (eGFR) less than 15 ml/min/BSA or need for renal replacement therapy).

**Results:** Slides were available for review in 79 of 155 patients with AAV during the study period. Patients had a mean age of 63 years, 32 (41%) were females and 48 (61%) were MPO-ANCA. Having a crescent score (C) of C1 or C2 was associated with an eGFR decline of 8.19 ml/min/BSA (95% CI: -15.8 to -0.5, p=0.036) during follow up compared to C0. Percent of globally sclerosed glomeruli >25% compared to <10% was also associated with eGFR decline of 17.3 ml/min/BSA during follow up (95% CI: -29.2 to -5.3; p=0.005). Using a single composite score including crescent, vasculitis and total inflammation (CVI) showed that CVI > 3 (median value) was associated with a significant decline of eGFR during follow up compared to CVI < 3 (-15.6 ml/min/BSA, 95% CI: -24.3 to -3.6; p<0.001). Parameters that showed significant association with increased risk of ESKD include - interstitial fibrosis (ci>1 vs ci<1, hazard ratio, HR:2.6, 95% CI: 1.1 to 6.4, p=0.03) and total inflammation (ti<1 vs ti>1; HR - 3.4, CI - 1.1 to 10.2, p=0.032).

**Conclusions:** A scoring system that reflects both active inflammation and chronicity provides prognostic information when considering treatment in patients with AAV. Further multicenter studies will be useful to further validate these parameters for clinical use.

FR-PO591

Predicting Death in Anti-Neutrophil Cytoplasmic-Antibody Vasculitis With Glomerulonephritis

Nicolas Fage,<sup>1</sup> Jérémie Riou,<sup>1</sup> Charlotte Boud'hors,<sup>1</sup> Alice Desouche,<sup>1</sup> Emeline Vinatier,<sup>1</sup> Clément Samoreau,<sup>1</sup> Samuel Wacrenier,<sup>1</sup> Nicolas Henry,<sup>2</sup> Assia Ilham Djema,<sup>4</sup> Lise-Marie Pouteau,<sup>2</sup> Marie-Christine Copin,<sup>1</sup> Giorgia B. Piccoli,<sup>3</sup> Jean Francois Augusto,<sup>1</sup> Benoit Brillard.<sup>1</sup> <sup>1</sup>Centre Hospitalier Universitaire d'Angers, Angers, France; <sup>2</sup>CH Laval, Laval, France; <sup>3</sup>Centre Hospitalier du Mans, Le Mans, France; <sup>4</sup>Centre Hospitalier de Cholet, Cholet, France.

**Background:** Several scores have been developed to predict death in Anti-Neutrophil Cytoplasmic-Antibody vasculitis (AAV). However, the performance of these scores in AAV with glomerulonephritis (AAV-GN) remains uncertain. We aimed to evaluate their prognostic value and developed our own death prediction risk model in a large cohort of AAV-GN.

**Methods:** This multicentric retrospective study included patients newly diagnosed with ANCA-GN in 4 French nephrology departments (Maine-Anjou Registry) between 2000 and 2021. Scores (Five Factors Score, FFS; Japanese Vasculitis Activity Score, JVAS; multivariable index for AAV, MVIA; Maldini Score) were assessed at diagnosis before any therapeutic intervention. Clinical, biological and histological characteristics at diagnosis were retrieved. A multivariable cox analysis was performed to determine a death prediction model. Performance (time dependent concordance with C-index and AUC, and prediction accuracy with Brier Score) of these scores and of our model were assessed.

**Results:** Among the 167 patients included, FFS (HR = 2.78 [2.08-3.73]), JVAS (HR = 1.42 [1.25-1.60]), MVIA (HR = 3.06 [1.66-5.64]) and Maldini [HR = 1.23 (1.10-1.37)] scores were significantly associated with death (with performance decreasing in that order) (**Figure 1**). In multivariable analysis, age, diabetes, need of early kidney replacement therapy or eGFR, and hemoglobin at diagnosis were associated with death. Two new models including these variables were fit (**Table 1**) and were found with better performance than the existing scores (**Figure 1**).

**Conclusions:** ANCA-GN-specific models perform better in predicting death than existing scores.

Figure 1. Time-dependent AUC (concordance) (A), C-index (concordance) (B) and Brier score (prediction accuracy) (C) of each score and of our models. NDD: non-dialysis-dependent patients, DD: dialysis-dependent patients.

	"DD" model			"NDD" model		
	HR	95 % CI	p-value	HR	95 % CI	p-value
Age (per 5 years increment)	1.65	1.41 - 1.92	< 0.001	1.62	1.38 - 1.90	< 0.001
Diabetes	1.91	0.98 - 3.75	0.059	1.73	0.90 - 3.36	0.10
Early KRT	2.16	1.24 - 3.75	0.006	-	-	-
eGFR (per 5 ml/min increment)	-	-	-	0.90	0.84 - 0.97	0.007
Hemoglobin (per 1 g/dl increment)	0.86	0.74 - 0.99	0.037	0.85	0.74 - 0.99	0.04

MC1R Deficiency Enhances Th1 Response and Impairs Regulatory T Cell Homeostasis in Nephrotoxic Serum Nephritis

Bohan Chen, Xuejing Guan, Yan Ge, Lance D. Dworkin, Rujun Gong. *The University of Toledo Medical Center, Toledo, OH.*

**Background:** The melanocortin neuropeptides, represented by adrenocorticotrophic hormone, have recently emerged as a novel therapeutic choice for treating refractory glomerular diseases. As a key cognate receptor of the melanocortin hormone system, melanocortin 1 receptor (MC1R) plays a pivotal role in regulating immune response and inflammation, and has become a novel therapeutic target for a number of diseases. However, its role in the pathogenesis of immune-mediated glomerular disease remains unknown.

**Methods:** Wild-type mice and the recessive yellow mice (e/e) with the naturally occurring loss-of-function null mutation of MC1R received injection of the rabbit anti-mouse nephrotoxic serum (NTS) to develop the NTS nephritis and were examined 2 weeks later.

**Results:** The e/e mice developed more severe crescentic glomerulonephritis than WT mice, marked by aggravated proteinuria, kidney dysfunction, and renal lesions like glomerular hypercellularity, crescent formation, and renal inflammation and fibrosis. The exacerbated NTS nephritis in e/e mice was associated with greater levels of autologous IgG2c and IgG3 either deposited in glomeruli or in sera. In addition, profiling of signature cytokines of Th immunity revealed that e/e mice with NTS nephritis exhibited higher renal expression of IFN-γ, and an increasing trend in renal expression of TNF-α, as compared with WT mice, consistent with a reinforced Th1 immune response. Moreover, shown by immunohistochemistry staining, the number of FoxP3+ regulatory T cells in the NTS nephritic kidneys was diminished in e/e mice, as compared with WT mice. Mechanistically, MC1R was evidently detected in diverse renal leukocytes prepared from the diseased WT mice, including T lymphocytes, suggesting that T cells may be direct effector cells of the melanocortin hormones via MC1R signaling.

**Conclusions:** MC1R-mediated melanocortinergic signaling represses Th1 immune response and is required for regulatory T cell homeostasis in murine models of NTS nephritis, resulting in renal protection in experimental crescentic glomerulonephritis.

FR-PO593

Inhibition of VEGFR3 by SAR131672 Decreases Renal Inflammation and Lymphangiogenesis in the Murine Lupus Nephritis Model

Wenjia Li,<sup>1,2</sup> Tian Wang,<sup>1,2</sup> Jihyun Yeom,<sup>1,2</sup> Kyung Pyo Kang,<sup>1,2</sup> <sup>1</sup>Jeonbuk National University Medical School, Jeonju, Jeollabuk-do, Republic of Korea; <sup>2</sup>Jeonbuk National University Hospital Biomedical Research Institute, Jeonju, Jeollabuk-do, Republic of Korea.

**Background:** Lupus nephritis (LN) is an immune complex glomerulonephritis that develops as a frequent and potentially dismal manifestation of SLE. Lymphangiogenesis is the proliferation of pre-existing lymphatic vessels (LVs), which regulate tissue fluid homeostasis and immune cell trafficking, responding to the tissue environment. In this study, we have evaluated the therapeutic effect of the VEGFR3 inhibitor, SAR 131672, on the murine lupus nephritis model by regulation of inflammation and lymphangiogenesis.

**Methods:** Seven to eight-week-old male BALB/c mice were used in this experiment. The back area's skin was shaved and treated topically three times per week, with 100 µg of resiquimod in 100 µl of acetone for eight weeks and concomitantly treatment of VEGFR3 inhibitor, SAR 131672 by oral gavage. We evaluated renal histology and immunofluorescent staining for inflammatory cells and lymphatic vessels. We also assessed inflammatory cytokines and, chemokines, lymphangiogenic factors by qRT-PCR.

**Results:** Eight weeks of topical treatment of resiquimod to Balb/c mice induces lupus-like symptoms such as weight loss, splenomegaly, and glomerular immune complexes deposit such as IgG, IgM, and C3 in immunofluorescent staining. Histologically, glomerular mesangial cell proliferation and increased inflammatory cells in tubulointerstitial areas were noted in the H&E stain. Inhibiting VEGFR3 by oral SAR131672 treatment decreases glomerular and tubulointerstitial inflammation and LYVE-1 positive lymphatic vessels. The proinflammatory cytokines and chemokines such as ICAM-1, VCAM-1, MCP-1, CCL19, CCL21, CCR7, CXCL13, and BAFF mRNA levels were increased compared with the vehicle-treated group. Treatment SAR131672 decreases proinflammatory cytokines and chemokine.

**Conclusions:** VEGFR3 inhibition by SAR131672 decreases the resiquimod-induced lupus nephritis model by regulating inflammation and lymphangiogenesis.

**Funding:** Government Support - Non-U.S.

## FR-PO594

### CD11b Activation Suppresses suPAR and Inflammatory Signaling to Ameliorate Lupus Nephritis in Murine Models

Veronica Villanueva,<sup>1</sup> Xiaobo Li,<sup>1</sup> Samia Q. Khan,<sup>4</sup> Viviana Jimenez,<sup>1</sup> Mehmet M. Altintas,<sup>1</sup> Hafeez Faridi,<sup>2</sup> Jochen Reiser,<sup>1</sup> Timothy B. Niewold,<sup>3</sup> Vineet Gupta,<sup>1</sup> <sup>1</sup>Rush University Medical Center, Chicago, IL; <sup>2</sup>Chicago State University College of Pharmacy, Chicago, IL; <sup>3</sup>Hospital for Special Surgery Department of Medicine, New York, NY; <sup>4</sup>Editas Medicine, Cambridge, MA.

**Background:** Lupus nephritis (LN) is a debilitating comorbidity of systemic lupus erythematosus (SLE). CD11b, the alpha-chain of integrin dimer CD11b/CD18, is highly expressed on myeloid cells and plays a critical role in their adhesion, migration, and signaling. Single nucleotide polymorphisms (SNPs) in the *ITGAM* gene, encoding CD11b, are significantly associated with LN and reduce integrin function. Additionally, levels of pro-inflammatory mediators, such as suPAR, are increased in the LN sera. We previously described CD11b activation using novel agonist LA1 as a novel modulator of integrin function. Here we investigated how CD11b-dependent signaling modulates such pro-inflammatory molecules.

**Methods:** We used a combination of in vitro and in vivo assays. We utilized macrophage cell lines and primary macrophages. Cells were treated with TLR agonists, pathway inhibitors, and CD11b agonist leukadherin-1 (LA1). Changes in protein expression were assessed by western blot and proinflammatory cytokine levels were assessed by ELISA. For complementary in vivo studies, we utilized wild type, CD11b knockout (KO) and a CD11b knockin (KI) expressing a constitutively activating mutation. We induced SLE and LN in these models and studied the efficacy of genetic and pharmacologic CD11b activation as a therapeutic strategy.

**Results:** TLR-stimulation increased inflammation and suPAR levels in vitro. Importantly, CD11b activation significantly reduced proinflammatory cytokines and suPAR, suggesting a novel mechanism for controlling inflammation in glomerular diseases. Mechanistically, CD11b activation reduced TLR-dependent activation of NFκB and NLRP3/Caspase-1 pathways. In vivo, CD11b activation significantly reduced levels of suPAR and proteinuria.

**Conclusions:** We demonstrate that CD11b activation reduced myeloid cell generated suPAR in models of lupus and lupus nephritis. These studies provide further support for CD11b activation as a therapeutic strategy for autoimmune diseases.

### Klotho Deficiency Induces Regulatory T Cells in Mice With Lupus Nephritis

Tsuneo Takenaka,<sup>1</sup> Tsutomu Inoue,<sup>2</sup> Takashi Miyazaki,<sup>2</sup> Toshiaki Miyazaki,<sup>2</sup> Matsuhiko Hayashi,<sup>3</sup> <sup>1</sup>Kokusai Iryo Fukushi Daigaku Kohokai Group, Minato-ku, Japan; <sup>2</sup>Saitama Ika Daigaku, Iruma-gun, Japan; <sup>3</sup>Keio Gijuku Daigaku Igakubu Daigakuin Igaku Kenkyuka, Shinjuku-ku, Japan.

**Background:** Recent studies demonstrate that klotho deficiency participates in various chronic kidney disease. However, it has not been fully assessed the influence of klotho in autoimmune kidney diseases. Klotho is known to binds transforming growth factor β (TGFβ) receptor to antagonize its pathophysiological actions including renal fibrosis. Alternatively, TGFβ is required to generate and maintain regulatory T cells with inducing FOXP3, an important cell population for immunological tolerance.

**Methods:** NZBWF1 mice were used as a model of lupus nephritis. NZBWF1 mice were housed separately in metabolic cage, and divided into two groups (n=10 for each): one group was treated with daily subcutaneous injection of klotho protein (20 µg/kg/day), and the other received vehicle alone. Systolic blood pressure (SBP) was measured by tail-cuff method. Glomerular filtration rate (GFR) was assessed using FITC-inulin. Four weeks later, the animals were killed to harvest the spleen and kidneys for analyses.

**Results:** Klotho supplementation suppressed SBP, 8-epi-prostaglandin F2a excretion and renal angiotensin II levels (p<0.05 for all) without changes in albuminuria and GFR in NZBWF1 mice. Exogenous klotho protein supplementation increased serum klotho levels, urine klotho excretion, and endogenous renal expression of klotho in NZBWF1 mice (p<0.05 for all). Surprisingly, anti-double strand DNA antibody was

slightly elevated in klotho-treated NZBWF1 mice (p<0.05). Glomerular pathology and interstitial cell infiltration were similar between 2 groups. The spleen tended to be greater in klotho-treated group, but statistical significance was not attained. In consistent, CD8+FOXP3+ T cells were unaltered between 2 groups. However, klotho supplementation reduced CD4+FOXP3+ T cells in spleen of NZBWF1 mice (p<0.05).

**Conclusions:** The present data indicated that klotho protein supplementation suppressed renal renin-angiotensin system, ameliorating blood pressure and oxidative stress. Our results suggest that klotho supplementation worsened auto-antibody, possibly by inhibiting TGFβ with resultant deterioration in regulatory T cells. The present findings implicate that while klotho may not suite for the management of autoimmune kidney diseases, klotho supplementation for dialysis patients could partly reverse the defect in cellular immunity and susceptibility to infections.

### IgE Double-Stranded DNA Antibody-Containing Serum From Systemic Lupus Erythematosus Patients With Nephritis Alters the Inflammatory Profile of Basophils, Neutrophils, and Eosinophils

Senka Sendic,<sup>1,2</sup> Ladan Mansouri,<sup>3</sup> Anna Nopp,<sup>3</sup> Iva Gunnarsson,<sup>4,5</sup> Stefan H. Jacobson,<sup>1,2</sup> Joachim Lundahl,<sup>3,6</sup> <sup>1</sup>Karolinska Institutet, Department of Clinical Sciences, Stockholm, Sweden; <sup>2</sup>Division of Nephrology, Danderyd University Hospital, Stockholm, Sweden; <sup>3</sup>Karolinska Institutet, Department of Clinical Science and Education Södersjukhuset, Stockholm, Sweden; <sup>4</sup>Division of Rheumatology, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden; <sup>5</sup>Rheumatology, Karolinska University Hospital, Stockholm, Sweden; <sup>6</sup>Karolinska University Hospital, Stockholm, Sweden.

**Background:** Lupus nephritis (LN) is characterized by primarily IgG autoantibodies against double stranded DNA (dsDNA). Recently, attention has been paid to the role of IgE dsDNA antibodies (auto IgE dsDNA) and the involvement of basophils and neutrophils in the pathogenesis. Therefore, we studied the prevalence of IgE dsDNA antibodies in patients with SLE and in healthy controls and the impact of sera on the phenotypic profile of basophils, neutrophils and eosinophils.

**Methods:** In this cross-sectional study 87 patients with SLE were included from the Dep. of Rheumatology, Karolinska University Hospital, Stockholm, Sweden. Disease activity was assessed using the British Isles Lupus Assessment Group (BILAG) index. Sixty-three patients with active nephritis (BILAG A-C) and twenty-four patients had previously active but currently quiescent renal SLE (BILAG D). Forty-one healthy controls were included. Serum levels of auto IgE dsDNA were measured with fluorescence enzyme immunoassay. In a subgroup including 10 patients (BILAG A) and 10 healthy controls, a whole blood method was applied to evaluate the impact of serum on granulocyte subpopulations. Cells were immune stained for markers related to degranulation, adhesion and immune modulation and analyzed by flow cytometry.

**Results:** Patients with active nephritis (BILAG A-C), but not patients with BILAG D, had a significant higher level of autoreactive IgEdsDNA compared to healthy individuals (p=0.030, p=1.0, respectively). Patient sera, but not healthy control sera, up-regulated CD69 on basophils (p=0.023) and patient sera down-regulated CD164 to a higher extent than sera from healthy controls (p=0.043). Patient sera, but not healthy control sera, down-regulated neutrophil expression of CD44 and CD15 (p=0.009 and p=0.029, respectively). CD88 on eosinophils was down-regulated by patient sera to a higher extent than sera from healthy individuals (p=0.001).

**Conclusions:** Patients with active LN, but not patients with currently quiescent renal SLE, have a significant higher level of circulating autoreactive IgEdsDNA than healthy controls and sera from these patients impact the phenotypic profile of basophils, neutrophils and eosinophils. These data indicate a role of these cells in the pathogenesis of LN and may impact treatment strategies.

## FR-PO597

### The Ion Transporter Na<sup>+</sup>-K<sup>+</sup>-ATPase Enables Pathological B Cell Survival in the Kidney Microenvironment of Lupus Nephritis

Irene Chernova, Joseph Craft. Yale University School of Medicine Department of Internal Medicine, New Haven, CT.

**Background:** The kidney is a unique microenvironment characterized by high sodium concentrations [Na<sup>+</sup>], yet susceptible to infiltration by lymphocytes in autoimmune diseases such as systemic lupus erythematosus. The mechanisms used by infiltrating lymphocytes to survive the high Na<sup>+</sup> environment of the kidney are not known.

**Methods:** We investigated how B cells from lupus-prone MRL<sup>lpr</sup> mice respond to Na<sup>+</sup> stress using cell culture and water deprivation experiments. The role of sodium potassium ATPase (Na<sup>+</sup>-K<sup>+</sup>-ATPase, NKA) in intrarenal B cell survival was investigated using small molecule studies, the generation of lupus-prone mice missing an NKA subunit and bone marrow (BM) chimera studies. Key findings regarding NKA expression were validated in additional murine lupus models and human lupus nephritis biopsies.

**Results:** We show that kidney infiltrating B cells in lupus adapt to elevated [Na<sup>+</sup>] and that NKA expression correlates with the ability of infiltrating cells to persist in the kidney. Compared to MRL<sup>lpr</sup> B cells, B cells from non-autoimmune mice had lower NKA expression, evidenced increased apoptosis when exposed to high [Na<sup>+</sup>] and did not take up residence in the kidney. NKA expression was induced by high [Na<sup>+</sup>] *in vitro* and was increased in kidney, as compared to spleen, B cells in several lupus-prone mouse strains. Pharmacological inhibition of NKA and genetic knockout of the NKA γ subunit, previously not known to be expressed in B cells, resulted in reduced kidney B cell infiltration and amelioration of proteinuria without affecting systemic B cells or

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

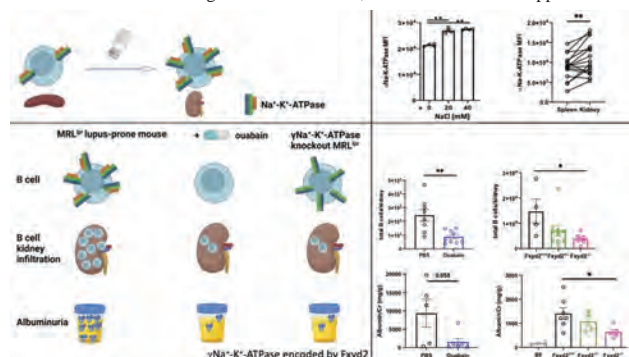

Underline represents presenting author.

other intrarenal immune cell populations. The  $\gamma$ NKA deletion effect was B cell-intrinsic as confirmed by BM chimera studies. B cells in biopsies of lupus nephritis patients also evidenced higher expression of NKA and its  $\gamma$  subunit than T cells.

**Conclusions:** We show that kidney-infiltrating B cells in lupus initiate a tissue adaption program in response to  $\text{Na}^+$  stress and identify  $\text{Na}^+\text{-K}^+\text{-ATPase}$  as a potential organ-specific therapeutic target in lupus nephritis.

### Inflammatory Dendritic Cell Drive Intra-Renal T Cells to Double-Negative T Cell in Lupus Nephritis

Latha Prabha Ganesan, Shane Bruckner, Noushin Saljoughian, James M. Turman, Murugesan Rajaram, Brad H. Rovin, Wael Jarjour, Samir V. Parikh. *The Ohio State University Wexner Medical Center, Columbus, OH.*

**Background:** The pathogenesis of lupus nephritis (LN) is incompletely understood stalling progress and resulting in suboptimal patient outcomes. We previously identified a novel inflammatory dendritic cells (InfDC) accumulating in the peri-glomerular space adjacent to CD3+ T cells forming an immunologic synapse in human kidney biopsies at LN flare. Here, we aim to describe the T cell phenotype(s) in cross-talk with these InfDC during LN flare. Characterizing these T cells will further our understanding of the major immune cells driving local inflammatory damage during LN.

**Methods:** Multi-color flow cytometry analysis was performed using antibodies against various immune cell markers, comparing proteinuria NZM 2410 mice and human-chimeric lupus mouse (Hu-lupus) mice with pre-proteinuric NZM (pre-prot-NZM) and humanized healthy (Hu-healthy) mice, respectively.

**Results:** FACS analysis of T cell phenotypes identified upregulation of double negative (CD4-CD8-) (DN) T cells, but not Th1 or Th17, in prot-NZM compared to pre-proteinuric. Also, the DN T cell frequencies paralleled InfDC in the intra-renal space and the expression of both cell types correlated with proteinuria. There was no correlation between InfDC and DN T cell kidney expression and proteinuria in lymph nodes or spleen. To relate our findings with human LN, we studied Hu-lupus mice and found significantly higher InfDC and DN T cell expression compared to Hu-healthy mice. Importantly, the majority of CD3+ cells in the Hu-lupus mice were TCR $\alpha$ b+TCR $\gamma$ d-CD4-CD8-PD1+, suggesting a subtype of DN T that are known to be self-reactive and proinflammatory.

**Conclusions:** In this study, we demonstrate an increase in a novel subtype of pro-inflammatory DN T adjacent to InfDC in NZM model of LN and in a humanized mouse model of LN. These InfDC, DN T cell subtype and their relationship have not been previously described. These findings enhance our understanding of the mechanisms that drive intra-renal inflammation during LN. Targeting InfDC or their associated DN T cell phenotype may attenuate renal inflammation and improve outcomes in LN.

## FR-PO599

### Atypical Chemokine Receptor 4 Is Expressed in Kidney Glomeruli and Mitigates the Severity of Experimental Glomerulonephritis

Katharina Artinger,<sup>1,2</sup> Elin Hub,<sup>2</sup> Alexander H. Kirsch,<sup>1</sup> Philipp Eller,<sup>3</sup> Alexander R. Rosenkranz,<sup>1</sup> Kathrin Eller,<sup>1</sup> Antal Rot,<sup>2</sup> <sup>1</sup>Clinical Division of Nephrology, Medical University of Graz, Graz, Austria; <sup>2</sup>Centre for Microvascular Research, William Harvey Research Institute, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom; <sup>3</sup>Intensive Care Unit, Department of Internal Medicine, Medical University of Graz, Graz, Austria.

**Background:** Besides ligating their cognate GPCRs, chemokines importantly interact with atypical chemokine receptors (ACKRs) that are characterised by mostly non-overlapping microanatomical expression and distinctive ligand specificities. ACKR4 is expressed in primary and secondary lymphoid organs, where it is involved in regulating cell migratory steps required for optimal immune responses and furthermore by a hugely varying types of cells in multiple parenchymal organs with hypothetical scenarios suggesting how ACKR4 scavenging its cognate chemokines might affect the pathophysiology of these organs. Here we investigated the expression of ACKR4 in murine kidney and assessed its contribution to nephrotoxic serum nephritis (NTSN), an experimental murine model of immune complex glomerulonephritis.

**Methods:** Expression of renal ACKR4 was evaluated in healthy ACKR4-eGFP reporter mice as well as after the induction of NTSN. To investigate the contribution of ACKR4 to the NTSN the ACKR4-deficient mice and WT controls were subjected to an anti-basal membrane immunization protocol and the parameters of immunopathogenesis and the ensuing kidney disease were evaluated at 7 and 14 days after the immunization.

**Results:** We found that ACKR4 is expressed in the kidney exclusively in the glomeruli by a discrete subset of parietal cells localising adjacently to the vascular glomerular pole. In mice with NTSN the expression of ACKR4 was diminished and ACKR4+ cells were even missing from some glomeruli, especially in those corresponding with the increased abundance of alpha-SMA, a marker of renal fibrosis. The ACKR4-deficient mice showed a delayed antibody response following immunisation. However, despite this, their NTSN parameters, including albuminuria, PAS-score and crescent formation were significantly increased as compared to the WT controls.

**Conclusions:** ACKR4 is expressed in the kidney by a small subpopulation of glomerular cells and it is decreased during NTSN. Reduced antibody titers following immunisation of ACKR4-deficient mice are in line with its contribution to the effective cell migratory steps within the immune organs. Conversely, the more severe appearance of NTSN in these mice, suggests that ACKR4 in the kidney plays a regulatory role limiting the development of this experimental disease.

## FR-PO600

### Immune Checkpoint Molecule BTLA Attenuates Experimental Glomerulonephritis by Directly Inhibiting T Effector Cells and Inducing Treg Differentiation

Paul Diefenhardt,<sup>1,2</sup> Marie Braumann,<sup>1,2</sup> Bastian Trinsch,<sup>1,2</sup> Thomas Schömgig,<sup>1,2</sup> Claudio Sierra Gonzalez,<sup>1,2</sup> Bernhard Schermer,<sup>1,2</sup> Thomas Benzing,<sup>1,2</sup> Paul T. Brinkkoetter,<sup>1,2</sup> Sebastian Braehler,<sup>1,2</sup> Braehler Lab <sup>1</sup>Uniklinik Köln, Köln, Germany; <sup>2</sup>Exzellenzcluster CECAD in der Universität zu Köln, Köln, Germany.

**Background:** Excessive, dysregulated inflammation mediated by T-cells in the kidney can lead to acute, crescentic Glomerulonephritis (GN). After T-cell receptor binding to a specific antigen, secondary and tertiary signals are required for successful T cell activation and differentiation. Accordingly, interference with these additional signals might represent a viable treatment option for GN. One of these secondary signal molecules, B and T Lymphocyte Attenuator (BTLA), was shown to mediate anti-inflammatory effects in other T-cell mediated disease models. Its role during glomerular inflammation, however, remains unclear.

**Methods:** Nephrotoxic nephritis (NTN) was induced in wild type (wt) and BTLA knock out (BTLA-KO) mice. For treatment evaluation, an agonistic anti-BTLA antibody was administered i.v. into wt mice after NTN induction. Functional readouts included albuminuria and BUN concentration. Histological damage was assessed 10 days after NTN induction in all groups using PAS stained tissue slides. Extensive immunophenotyping of renal and splenic immune cells was performed using IHC and flow cytometry. Additional *in vitro* assays revealed the impact of BTLA deficiency on the function of dendritic cells and T-cell subsets.

**Results:** Knockout of BTLA results in aggravation of NTN driven by an increase in pro-inflammatory Th1 cells. Systemically, nephritic BTLA-KO mice show a significant reduction of T regulatory cells. Activation of BTLA through administration of an agonistic anti-BTLA-antibody attenuate NTN by reducing the frequencies of Th1 and Th17 cells in the nephritic kidney and increasing systemic Treg numbers. *In vitro* Treg suppression assays reveal an evasion of Treg mediated suppression by BTLA deficient T effector cells. Suppressive capacity of BTLA deficient Tregs, on the other hand, is unchanged. Likewise, no impairment of T-cell activation by BTLA deficient DCs was detected.

**Conclusions:** BTLA attenuates inflammation in experimental GN through two mechanisms: 1) via Treg mediated suppression of BTLA+ T effector cells and 2) through induction of anti-inflammatory T regulatory cells. Activation of BTLA signaling by agonistic antibodies represents an effective treatment strategy in NTN.

## FR-PO601

### Urine Complement Activation Products in Lupus Nephritis

Nicholas Li,<sup>1</sup> Daniel J. Birmingham,<sup>2</sup> Laura Biederman,<sup>2</sup> Tibor Nadasdy,<sup>2</sup> Brad H. Rovin,<sup>2</sup> <sup>1</sup>University of Calgary, Calgary, AB, Canada; <sup>2</sup>The Ohio State University, Columbus, OH.

**Background:** Complement activation plays a critical role in the development of kidney injury during lupus nephritis (LN). Clinical trials targeting the complement pathway are now underway in LN. It is therefore important to understand the relationship between intra-renal complement activation and kidney histology in LN, and whether complement activation products (CAPs) can serve as biomarkers to guide complement-directed therapies. In this investigation, urine CAPs levels were measured, and associations with kidney injury were determined.

**Methods:** A cohort of 149 patients had urine and blood collected at the time of kidney biopsy for suspected LN. The CAPs C5a, C5b-9, and factor Ba were measured in the urine by ELISA. Biopsies were examined by routine histology, and the NIH activity and chronicity indexes (AI, CI) were calculated by two nephropathologists. CAPs levels were correlated with clinical and histologic data using the spearman correlation r.

**Results:** The results are summarized in the Table. The highest levels of CAPs were found in patients with proliferative or proliferative plus membranous LN, with lower levels in pure class II and V. All three urine CAPs correlated with AI, but the strongest correlation was between C5b-9 and AI. Only Ba and C5a correlated with CI, but this correlation was, at best, modest. All CAPs correlated with proteinuria, while only Ba and C5a correlated with serum creatinine.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** Urine C5b-9 was the best measure of histologic activity in LN. Given the size of the C5b-9 complex, it is unlikely to be filtered, even by glomeruli with a damaged glomerular permeability barrier. Urine C5b-9 therefore only reflects intra-renal complement activity. C5a and Ba associated modestly with active lesions, as well as kidney damage, likely accounting for their association with serum creatinine. We suggest levels of urine C5b-9 could be used to follow the success of anti-complement therapies in mitigating intra-renal complement activation in LN.

**Funding:** Private Foundation Support

FR-PO602

**Integration of Exostosin 1 and 2 Into a Clinical Care Pathway for Membranous Nephropathy**  
Jennifer A. Brown, Hyunjae Chung, Graciela Andonegui, Hallgrimur Benediktsson, Daniel A. Muruve, Justin Chun. *University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

**Background:** Membranous lupus nephritis (MLN), is a renal manifestation of systemic lupus erythematosus. The identification of biomarkers presents an avenue to better explain the pathogenesis, diagnosis, and prognosis of many heterogenous glomerulonephritides. Exostosin 1 and 2 (EXT1 and 2) are proteins that have recently been found in secondary membranous nephropathies including MLN. Exisiting literature suggests that EXT-associated membranous nephropathy represents a distinct clinical phenotype, with EXT-negative disease leading to higher risk of renal failure, but exactly how these groups differ has not yet been well described.

**Methods:** We evaluated a cohort of 28 patients reported as isolated MLN from the Biobank for the Molecular Classification of Kidney Disease in Calgary, Alberta with kidney biopsies performed between 2010 and 2020. Frozen kidney biopsies preserved in OCT (optimal cutting temperature) compound were subjected to immunohistochemistry to label EXT1 and 2. We then reviewed for correlation to renal function (serum creatinine) and proteinuria (urine protein to creatinine ratio) prior to biopsy, and up until 36 months post-biopsy.

**Results:** We detected both EXT1 and 2 in our cohort. Notably, we identified three distinct staining patterns. Negative/negative, positive/positive, and negative/positive, with respect to EXT1/EXT2 status. The pattern of negative/positive appears to be unique in comparison to previous studies with EXT1 and 2, which have shown uniform results between the two related proteins. Initial analyses show a trend towards resolving proteinuria for the EXT2 positive cohort.

**Conclusions:** Similar to prior reports using formalin fixed, paraffin embedded tissue, we demonstrate that frozen section staining can reliably detect EXT1/EXT2. Distinguishing EXT1/EXT2-positive patients may better predict outcomes with the potential to integrate into patient care. The significance of differential status between EXT 1 and 2 is yet to be determined but represents a distinctive finding that may assist in prognostication for this cohort.

FR-PO603

**Pure Membranous Lupus Nephritis (LN) and Renal Outcomes**  
Catherine Larned, Sarah M. Gordon, Stephen W. Olson, Robert Nee, Gillian Costa. *Walter Reed National Military Medical Center, Bethesda, MD.*

**Background:** Previous LN studies are mostly comprised of patients with proliferative LN (PLN) with only a small subgroup of membranous LN (MLN). Therefore, MLN is less well characterized. We sought to describe clinical characteristics, treatment, and renal outcomes in the largest and most diverse MLN cohort with the longest follow-up to date.

**Methods:** We used a Military Health System (MHS) ICD9/ICD10 code query to identify and an electronic record review to confirm 105 biopsy-proven adult MLN patients without concomitant PLN. We collected demographic, clinical, treatment and outcome data for each MLN case.

**Results:** Median follow-up was 93 months (7.75 years). The cohort was predominantly black (61%), female (74%), and young (median age 35 years). Median serum creatinine (Scr), estimated glomerular filtration rate (eGFR), urine protein/Cr ratio, and serum albumin at diagnosis were 0.80 mg/dL, 98 ml/min/1.73m<sup>2</sup>, 3.28 gm and 2.8 g/dL, respectively. Proteinuria at diagnosis was not associated with doubling of Scr (3.4 vs. 3.3gm, p=0.81) but reduction of proteinuria to <1gm was associated with lower likelihood of doubling Scr (36.4 vs. 83.0% p=0.001). Complete remission (CR,) reduction in proteinuria to <0.5gm and <15% reduction in eGFR within one year, was also associated with a lower likelihood of doubling Scr (8.3 vs. 55%, p=0.003) which remained significant after adjustment for age, race, and baseline eGFR [OR: 0.09 (CI: 0.01-0.80)], p=0.03]. Partial remission (PR,) at least 50% reduction in proteinuria to <3gm at one year, was not significantly associated with a lower likelihood of doubling Scr (54.6 vs. 66.7%, p=0.48). A majority of patients were on a renin-angiotensin system inhibitor (91.4%); 78.1% were treated with immunosuppressive therapy (7.8% treated with steroid only).

**Conclusions:** In this large MLN cohort with long follow up, reduction of proteinuria to <1gm or achievement of CR within one year of diagnosis was significantly associated with preservation of renal function, but partial remission alone was not. Despite overall superior renal prognosis of MLN compared to PLN, our findings suggest that providers should aim to achieve CR to preserve renal function. *Disclaimer: The views expressed in this Abstract are those of the authors and do not reflect the official policy of the Department of the Army/Navy/Air Force, the Department of Defense, or the United States government.*

FR-PO604

**Effect of Induction Therapy on Glomerular Morphometry in Lupus Nephritis**  
Warangkana Pichaiwong, Rajavithi Hospital, Bangkok, Thailand.

**Background:** Based on a series of randomized controlled trials (RCTs), the data have demonstrated an efficacy treatment response defined by clinical outcomes between intravenous cyclophosphamide (IVCYC) and mycophenolate mofetil (MMF) for induction therapy of lupus nephritis (LN). Only few studies have systematically examined glomerular morphometric responses to induction therapy. This study was aimed to assess the effect of induction therapy in the aspect of glomerular morphometry.

**Methods:** We have analyzed renal biopsies obtained from 20 patients with proliferative and membranous LN patients who underwent protocol renal biopsies after induction therapy. The glomerular morphometry was demonstrated by percentage of mesangial matrix expansion which was quantitated by silver methenamine and podocyte density was counted.

**Results:** Of the 20 patients included, the mean age was 32.20±13.19 years, 85% was female. The mean arterial blood pressure was 160.11±7.15 mm.Hg. The mean baseline estimation for glomerular filtration rate was 83.11±35.03 ml/min/1.73m<sup>2</sup> and the median urine albumin to creatinine ratio was 2.22 (1.60-3.93). The Median range of C3 concentration was 0.65 (0.54-0.85) g/L. The mean of total numbers of glomeruli obtained was 25.07±8.86 glomeruli/biopsy, disease activity and chronicity indices were 5.8/24 and 2.3/12, respectively. After completion of the induction therapy, glomerular tuft area occupied by silver-stained matrix was decreased (pre-induction 8.60±1.77% vs. post-induction 5.91±2.23%, p=0.954). There was an exhibited increase in podocyte number (pre-induction 238.64±117.33 vs. post-induction 268.00±121.52, p=0.388), podocyte density (pre-induction 74.45±25.87/x106 um<sup>3</sup> vs. post-induction 88.25±23.43/x106 um<sup>3</sup>, p=0.590) and decreased glomerular volume/podocyte (pre-induction 15,386.73±6,572.53 um<sup>3</sup> vs. post-induction 12,119.50±4,020.53 um<sup>3</sup>, p=0.575).

**Conclusions:** This study shows that there is a trend to improve glomerular morphometry particularly podocyte density following induction therapy with either IVCYC or MMF in patients with biopsy-proven proliferative LN. However, more sample sizes are needed to adequately assess these outcomes.

**Funding:** Government Support - Non-U.S.

FR-PO605

**Clinico-Pathological Associations of Serum CD44 Level in Patients With Lupus Nephritis**  
Yawen Gao, Susan Yung, Tak Mao D. Chan. *Department of Medicine, School of Clinical Medicine, the University of Hong Kong, Hong Kong SAR, Hong Kong.*

**Background:** Conventional serological markers do not always correlate with clinical activity in lupus nephritis (LN). CD44 is a transmembrane glycoprotein that is widely expressed in immune and non-immune cells, and has been implicated in tissue inflammation and fibrosis. CD44 also serves as a cell receptor for hyaluronan (HA), a glycosaminoglycan that contributes to inflammatory and fibrotic processes. We previously reported that serum HA level correlated with clinical and serological parameters in LN. This study investigated clinico-pathological associations of circulating CD44 level.

**Methods:** Serial serum samples from patients with biopsy-proven Class III/IV LN were collected at intervals of 3-4 months over 3 years. Sera from sex- and age-matched patients with non-renal SLE or non-lupus chronic kidney disease (CKD) or healthy subjects were included as Controls. Serum CD44 was measured by ELISA.

**Results:** Six hundred and sixty-two sera from 41 LN patients (31 female and 10 male, age 38.78±12.02 years) were included. Serum CD44 level was significantly higher

in active LN compared to remission, non-renal SLE, CKD, or healthy subjects ( $P<0.0001$ , for all). Serum CD44 level correlated with SLEDAI-2K and renal SLEDAI-2K scores, anti-dsDNA antibody titre, proteinuria, and serum HA level, and inversely correlated with eGFR and C3 level ( $P<0.0001$ , for all). All episodes of LN flare were accompanied by increased serum CD44 level, which decreased after treatment with immunosuppression. A temporal relationship was observed between CD44 level and SLEDAI-2K and renal SLEDAI-2K scores, anti-dsDNA antibody titre, C3 level, and proteinuria. ROC analysis showed that serum CD44 level distinguished active LN from healthy subjects (sensitivity 98.31%, specificity 100.00%), from LN in remission (sensitivity 86.44%, specificity 98.31%), from non-renal SLE (sensitivity 98.31%, specificity 98.00%), and from non-lupus CKD (sensitivity 98.31%, specificity 100.00%) ( $P<0.0001$ , for all).

**Conclusions:** Active LN is associated with increased serum CD44 level. Further studies are warranted to investigate whether CD44 may serve as a biomarker in the diagnosis and monitoring of LN activity.

## FR-PO606

### Comorbidities and Poor Long-Term Outcomes of Lupus Nephritis in Adult Patients in the United States

Isabelle Ayoub,<sup>1</sup> Janice Ma,<sup>2</sup> Konrad Pisarczyk,<sup>2</sup> Richard Leff,<sup>3</sup> Eunmi Park,<sup>3</sup> Li Long.<sup>3</sup> <sup>1</sup>The Ohio State University Wexner Medical Center, Columbus, OH; <sup>2</sup>Maple Health Group, New York, NY; <sup>3</sup>Kezar Life Sciences Inc, South San Francisco, CA.

**Background:** Lupus nephritis (LN) is a serious complication of systemic lupus erythematosus (SLE) associated with considerable morbidities, including but not limited to an increased risk of end-stage kidney disease (ESKD). There is a need to better understand clinical burden specific to LN. This study aimed to summarize evidence on long-term disease outcomes and comorbidities in adults with LN in the United States (US).

**Methods:** A comprehensive targeted literature review was conducted in MEDLINE and Embase to identify studies in patients with adult and juvenile onset of LN, published in English between March 2012 and 2022. The search included conference abstracts indexed in Embase since 2019.

**Results:** Of 4,216 records identified in the medical databases, 20 reported on long-term outcomes of disease and burden of comorbidities in adults with LN. The majority of studies were conducted on longitudinal cohorts and nationwide claims databases. Only 26% of LN adults achieved complete remission (CR) at 1 year and 40-59% achieved CR at 2 years, suggesting limited response to existing therapies. Those achieving CR after 2 years had a significantly lower mortality and ESKD risk compared with those who did not. LN adults suffered from hypertension (35-78%), cachexia (62%), serious infections requiring hospitalization (58%), and mental health disorders (29%). LN adults were more likely to experience cardiovascular (CVD) comorbidities compared to non-SLE, fractures compared to both non-SLE and SLE-only patients, and had 3-times higher odds of hospitalization due to posterior reversible encephalopathy syndrome compared to SLE-only adults. Causes of death were often CVD and serious infections requiring hospitalization. Deaths occurred in 20% of patients with serious infections requiring hospitalization with 49% of those occurring during hospitalization or up to 30 days after discharge. In LN-ESKD adults, 40% of patients died during follow-up, with CVD-related deaths as the most common (>40%) followed by infection-related deaths (14%).

**Conclusions:** LN is associated with poor long-term outcomes including increased risk of comorbidities compared to SLE only. Patients are often hospitalized or die due to comorbid CVDs and infections. There is a high unmet need for a therapy that can improve the long-term disease outcomes in LN.

## FR-PO607

### Poor Health-Related Quality of Life in Adult Patients With Lupus Nephritis

Yoe Kie Onno Teng,<sup>1</sup> Janice Ma,<sup>2</sup> Konrad Pisarczyk,<sup>2</sup> Richard Leff,<sup>3</sup> Eunmi Park,<sup>3</sup> Li Long.<sup>3</sup> <sup>1</sup>Leids Universitair Medisch Centrum, Leiden, Netherlands; <sup>2</sup>Maple Health Group, New York, NY; <sup>3</sup>Kezar Life Sciences Inc, South San Francisco, CA.

**Background:** Lupus nephritis (LN) is a serious complication of systemic lupus erythematosus (SLE) associated with considerable morbidity that has a devastating impact on a patient's life. However, little is known about true impact of LN on a patient's health-related quality of life (HRQoL) in an autoimmune disease that can affect several organ systems. The objective of this study was to summarize the evidence on the humanistic burden of LN in adult SLE patients.

**Methods:** A comprehensive targeted literature review was conducted in MEDLINE and Embase to identify studies in patients with adult and juvenile onset of LN, published in English between March 2012 and 2022. The search included conference abstracts indexed in Embase since 2019.

**Results:** Of 4,126 records identified in the medical databases, 9 reported on the HRQoL in adult patients with LN. The studies were conducted in the US (n=5), multiple countries worldwide (n=2), Latin America (n=1) and Europe (n=1). Active LN was significantly associated with poor scores in almost all domains of SF-36 suggesting a deterioration in multiple aspects of life, especially in physical and emotional functioning. The humanistic burden of active LN was more pronounced compared to SLE manifestations in other organ systems. Patients with active LN had significantly worse HRQoL measured by lupus-specific questionnaires such as LupusPRO and LupusQoL,

compared to subjects with inactive LN or those with SLE only, with the most profound impact of active renal disease on procreation, fatigue, physical and emotional health. Three studies examined the perspectives of LN patients on facilitators and satisfaction of disease control and treatment. Physician- and patient-reported dissatisfaction were reported by 33% of nephrologists and 25% of patients and were associated with LN severity and various signs and symptoms of disease. The key patient-relevant aspects of LN treatment were hope for being normal/healthy, improved quality of life, and effective patient-physician communication regarding benefits and harms.

**Conclusions:** LN significantly affects HRQoL across multiple domains of life such as physical and emotional functioning that are particularly affected during periods of active disease. Despite various therapies available, 25% of patients are dissatisfied with their options, indicating a high residual unmet need.

**Funding:** Commercial Support - Kezar Life Sciences, Inc.

## FR-PO608

### Substantial Economic Burden Associated With the Management of Lupus Nephritis in Adult Patients in the United States

Brad H. Rovin,<sup>1</sup> Janice Ma,<sup>2</sup> Konrad Pisarczyk,<sup>2</sup> Richard Leff,<sup>3</sup> Eunmi Park,<sup>3</sup> Li Long.<sup>3</sup> <sup>1</sup>The Ohio State University, Columbus, OH; <sup>2</sup>Maple Health Group, New York, NY; <sup>3</sup>Kezar Life Sciences Inc, South San Francisco, CA.

**Background:** Lupus nephritis (LN) is a serious complication of systemic lupus erythematosus (SLE) associated with considerable morbidity, including an increased risk of end-stage kidney diseases (ESKD) that may impose a substantial economic burden on the healthcare system. Recently, a systematic literature review showed increased costs and healthcare resource utilization (HCU) associated with LN globally but there is a need to better understand the economic impact of the disease in the United States (US). This study aimed to summarize the evidence on costs and HCU related to the management of LN in adult patients in the US.

**Methods:** A comprehensive targeted literature review was conducted in MEDLINE and Embase to identify studies in patients with adult and juvenile onset of LN, published in English between March 2012 and 2022. The search included conference abstracts indexed in Embase since 2019.

**Results:** Of 4,216 records identified in the medical databases, 8 US studies reported on costs and HCU in adults with LN. The majority of studies were conducted based on nationwide claims and inpatient databases. On average, patients with LN had significantly higher utilization of outpatient visits related to spectrum of care (e.g., primary care, neurology, nephrology, dermatology) and hospitalizations per year with approximately 6-day longer lengths of stay, compared to matched subjects without SLE or LN. The mean annual healthcare cost ranged from \$33,500 to \$51,000, being the highest in the first year following LN diagnosis (\$44,205), and 5-7-times higher than in matched non-SLE/LN controls ( $p<0.05$ ). The main cost drivers were related to inpatient care followed by ambulatory and pharmacy costs. LN-related ESKD and active LN led to excess costs compared to periods of low disease activity, with mean monthly healthcare cost of \$22,000 and \$6,600 vs \$1,100, respectively.

**Conclusions:** LN is associated with significant economic burden on the US healthcare system. The total cost of care is notably high in patients suffering active disease and those developing ESKD, which confirms the urgency of need for effective therapies to treat LN and prevent its complications.

**Funding:** Commercial Support - Kezar Life Sciences, Inc.

## FR-PO609

### Old Friend in Camouflage: Polyarteritis Nodosa With Thrombotic Microangiopathy

Waleed A. ElSheikhMohammed, Roberto Pisoni, Ruth C. Campbell. *Medical University of South Carolina, Charleston, SC.*

**Introduction:** PAN with TMA and AKI is an uncommon presentation rarely described in the literature. We report two cases below.

**Case Description:** 1) 33 male with HTN presented to ER with abdominal pain, HTN urgency and severe anemia 6 g/dl. Abdominal CT revealed a liver hematoma requiring embolization. He represented in 2 weeks with HTN emergency, AKI and new thrombocytopenia 60 K/uL. U/A no RBC,UPCR 0.5 g/g. Schistocytes present on peripheral smear, LDH elevated and haptoglobin low. PLEX was urgently started with steroids. Shiga toxin, anti-factor H Ab, ADAMTS13, HBsAg and HCV Ab were normal/negative. ANA 1: 1280 + anti SSA but C3, C4, ANCA, cryoglobulins and anti-GBM all negative. Lymph node biopsy unremarkable. Kidney biopsy showed TMA with negative IF and no immune complex deposits. Colonoscopy showed multifocal areas of ischemia concerning for vasculitis. A diagnosis of PAN was made. Cyclophosphamide was added. Hematological markers improved but kidney function did not. He remained HD dependent. 2) 57 female presented with anasarca, Raynaud's, HTN, anemia and AKI peak creatinine 2mg/dl with UPCR 0.3 g/g and albumin 3.7 g/L. Liver biopsy showed nodular regenerative hyperplasia. Viral hepatitis negative. Immunology + ANA 1:160, otherwise negative. Kidney biopsy revealed TMA. Patient was placed on ARB and underwent salpingo-oophorectomy for potential Meigs syndrome with no improvement in ascites, further complicated by spontaneous diverticular rupture. Conventional angiogram assessing for PAN was positive. Induction with steroids and cyclophosphamide followed with good clinical response. Creatinine at last follow up 1.2mg/dl.

**Discussion:** PAN first described in 1866 by Kussmaul and Maier has evolved from encompassing most vasculitides to a subset characterized by necrotizing inflammation of medium arteries. Its incidence and prevalence have declined due to improved hepatitis B prevention and vaccination. PAN may occur in the absence of hepatitis B. Kidneys are involved in 26-43% of cases and new or worsening HTN is a feature of renal involvement.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

Malignant HTN with TMA as presenting feature is reported only in a French case. Recognizing PAN as potential cause of TMA can be lifesaving as untreated, its 5-year survival is only 13%. CT angiography may be diagnostic but findings can be subtle. Renal failure requiring permanent dialysis is not common in PAN and impacts prognosis.

## FR-PO610

### A Case of IgA-Dominant Infection-Related Glomerulonephritis Caused by *Streptococcus mutans* Mimicking ANCA-Associated Vasculitis

Ana I. Stark, Swetha Rani Kanduri, Paula A. Medina, Ivo Lukitsch, Juan Carlos Q. Velez. Ochsner Nephrology *Ochsner Medical Center, New Orleans, LA.*

**Introduction:** Infection-related glomerulonephritis (IRGN) can manifest features similar to anti-neutrophilic cytoplasmic antibody (ANCA) associated vasculitis (AAV) in 10-30% of cases, posing a diagnostic challenge. IgA-dominant IRGN is typically observed in the setting of staphylococcal infections. Herein, we report an unusual case of IgA-dominant IRGN with ANCA positivity mimicking AAV in the setting of *Streptococcus mutans* endocarditis.

**Case Description:** A 73-year-old woman presented to clinic with a 6-month history of fatigue and a skin rash. Medical history was pertinent for chronic heart failure with preserved ejection fraction and mitral regurgitation. Laboratory data revealed elevated serum creatinine of 1.2 mg/dL (baseline 0.8 mg/dL), positive anti-proteinase-3 (PR3) antibodies (4.2 U) and low hemoglobin (8.4 g/dL). Patient was subsequently admitted to the hospital for further work up. Upon arrival, physical examination revealed a purpuric rash in lower extremities. Additional laboratory data showed positive antinuclear antibody (ANA) (1:640), low haptoglobin (<10), low C3 (30 mg/dL), low C4 (< 3 mg/dL), negative rheumatoid factor and cryoglobulins. Urinalysis revealed hematuria and leukocyturia. AAV was suspected and infectious workup was ordered in an attempt to clear her to initiate immunosuppression. Blood cultures were positive for *Streptococcus mutans* and transthoracic echocardiography demonstrated multiple vegetations along the anterior mitral leaflet suggesting infective endocarditis. Kidney biopsy was performed and a suboptimal specimen revealed mesangial and subendothelial IgA-dominant immune complex deposits, confirming a case of IgA-dominant IRGN. Following antibiotic initiation, kidney function recovered to a serum creatinine of 1 mg/dL and patient was discharged home. However, shortly after discharge, the patient was readmitted with bifrontal septic emboli, complicated by subarachnoid hemorrhage, and the patient expired.

**Discussion:** IRGN presenting with features of AAV is diagnostically challenging and warrants careful clinical evaluation and kidney biopsy interpretation. *Streptococcus mutans* should be considered as a causative organism for IgA-dominant IRGN along with the more commonly reported *Staphylococcus sp.*

## FR-PO611

### Gross Hematuria: Initial Atypical Manifestation of Anti-Glomerular Basement Membrane Disease

Juan P. Gomez Villarreal, Nayeli N. López Villa, Rita B. Aguilar, Elisa M. Guerrero Gonzalez, Lilia M. Rizo Topete, Giovanna Y. Arteaga Muller. *Hospital Universitario Dr Jose Eleuterio Gonzalez, Monterrey, Mexico.*

**Introduction:** Anti-glomerular basement membrane disease or Goodpasture syndrome is a rare disease that affects < 2/1,000,000 people annually. Goodpasture syndrome is a small vessel vasculitis that targets the  $\alpha 3$  chain of the type 4 collagen of the glomerular and alveolar membranes. Anti-GMB disease has a high morbidity with almost all patient leading to kidney failure. Our case presents a atypical symptom of Anti-GMB disease.

**Case Description:** A 31-year-old man with history of Hodgkin lymphoma in 2011 was admitted to the ER for hematuria, during his evaluation he mentions that has been with this symptom for one month without pain or tenesmus, he refers that 3 days ago start with hemoptoic coughing, during his assessment his blood pressure was 170/90 mmHg and the only relevant on the physical exploration was decreased breath sounds at lung bases. Admission: Hgb 10.50 g/dL WBC 11.10 K/uL Plt 221 K/uL SCr 11.3mg/dL, BUN 62mg/dL, Urinalysis had 612 mg/dL of proteinuria, hematuria 200 hem/uL, erythrocyturia > 100/ field, serologic anti-GMB 105.37 UR/mL. was positive. Treatment started with methylprednisolone for 3 days then switched to prednisone, cyclophosphamide and plasma exchange with albumin started. Hemodialysis started as support therapy and renal biopsy was performed.

**Discussion:** Anti-GMB disease is known for his aggressive course treatment is very hard to achieve in low income country's due de lack of equipment for plasma exchange, our patient was treated as mention above but the engaging part of the case is that we executed plasma exchange treatment using albumin without the frozen plasma at the end because the unavailability in our center; the literature mentions that patients with alveolar hemorrhage should use frozen plasma during de plasma exchange or if you use albumin give frozen plasma at the end of the exchange, even though we did the plasma exchange with albumin the patient had a good clinical response.

## FR-PO612

### Isolated Anti-GBM Disease and COVID-19 Vaccination

Atlee Baker, Maheen Khan, Athip Vatanapradith, Kenneth D. Abreo, Mary A. Buffington, Phani P. Morisetti. *LSU Health Shreveport, Shreveport, LA.*

**Introduction:** IgA nephropathy is the most reported glomerulonephritis post-COVID vaccination. Other reported cases include atypical anti-GBM nephritis, among others. Treatment consists of immunosuppressants and plasmapheresis with renal replacement therapy. Renal outcomes have varied. A case is presented of isolated anti-GBM nephritis in a patient whose renal injury occurred weeks after receiving a booster dose of COVID vaccine.

**Case Description:** A 59-year-old male with recent history of ureteral stones with stent placement, travel history in the last 6 months and use of doxycycline for suspected Lyme's disease in the last 3 months presented to the emergency department for decreased urine output, fevers, and arthralgias. He also received a Pfizer COVID vaccine booster 6 weeks ago. His symptoms had worsened in the last 2 weeks. On initial evaluation, he was noted to have stage 3 acute kidney injury (AKI) with creatinine 5.3 mg/dL. Although he had findings of nephrolithiasis, no ureteral obstruction or hydronephrosis were noted on imaging. He received extensive infectious work up which was all negative. Hemodialysis was initiated on day 7 for metabolic derangements and volume overload. After infectious work up was negative, renal biopsy was performed revealing linear IgG deposits. Serum anti-GBM antibodies were positive. Despite receiving plasmapheresis, cyclophosphamide and prednisone, the patient continued to require dialysis and was discharged on home hemodialysis.

**Discussion:** The development of AKI with systemic symptoms occurred about 6 weeks following his COVID vaccine, longer than previously reported cases. The patient also has a history of nephrolithiasis. At this time, direct association of this patient's anti-GBM disease with the COVID vaccine is unclear however remains a clinical consideration. The presentation of anti-GBM disease is unique as disease is limited to renal involvement.

Linear reaction to IgG

## FR-PO613

### Glomerular Microangiopathy in a Patient With Takayasu Arteritis

Makiko Fujii, Kensei Taguchi, Kei Fukami, Sakuya Ito. *Kurume Daigaku Igakubu Daigakuin Igaku Kenkyuka, Kurume, Japan.*

**Introduction:** Takayasu arteritis (TA) is a large vessel inflammation that predominantly involves aorta and its main arteries. TA-caused kidney injury is known to be mainly due to renal artery stenosis. However, glomerulonephritis has been histologically identified in some TA cases.

**Case Description:** A 69-year-old female presented with leg edema and refractory hypertension with nephrotic range proteinuria (17.0 g/gCr). She exhibited >10 mmHg blood pressure discrepancy between left and right upper limbs and severe aortic regurgitation. Lab test showed high level of erythrocyte sedimentation rate. Contrast-enhanced CT identified wall thickening of the left subclavian artery, which led to the diagnosis of TA. Renal biopsy demonstrated that double basement membrane, enlarged subendothelial space, and mesangiolysis with no immunoglobulin deposition. Although azilsartan and nifedipine had been prescribed, systolic blood pressure (sBP) was still >160 mmHg. Thus, while oral prednisolone was started to suppress TA-induced inflammation, azilsartan was replaced with sacubitril valsartan, an angiotensin receptor-neprilysin inhibitor (ARNI), for treating refractory hypertension. After a few weeks, sBP was decreased to 130 mmHg with sacubitril valsartan 200mg QD and proteinuria was dramatically improved to 0.5 g/gCr.

**Discussion:** TA commonly involves the renal artery, leading to stenosis and subsequent ischemic nephropathy. However, no stenosis and occlusion were observed in renal artery of this case. Small vessel inflammation in the kidney such as vessel wall necrosis and immune cells infiltration was not found. Serum levels of pro-inflammatory cytokines including VEGF and IL-6 were within the normal range. The results indicate that TA-caused hypertension, but not vessel inflammation induced by TA, plays a pathological

role for development of glomerular microangiopathy. A previous study showed that 70% of TA patients presenting with glomerular lesion has severe hypertension and intimal thickening in renal arterioles was observed more frequently in TA patients presenting with glomerular lesion when compared to those without glomerulonephritis, which supports our hypothesis. In the present case, ARNI significantly reduced sBP which might directly contribute to the improvement of proteinuria. ARNI can be potent to control hypertension more effectively than conventional hypertensive agents in TA patients.

## FR-PO614

### Rapidly Progressive Glomerulonephritis Associated With Recurrent Cryoglobulinemia in a Patient With Monoclonal Gammopathy of Undetermined Significance

Michael B. Neinst, Xueguang (Gary) Chen. *Southern Illinois University School of Medicine, Springfield, IL.*

**Introduction:** Mixed cryoglobulinemia is most often associated with HCV infection, and less commonly, monoclonal gammopathies. Rapidly progressive glomerulonephritis is a common pathway of disease in these patients and early diagnosis is imperative for renal recovery. We present the case of recurrent cryoglobulinemia in a patient with MGUS resulting in RPGN after rituximab suppression therapy.

**Case Description:** A 50-year-old male presented for evaluation of progressive abdominal pain and anorexia. He has a history of cryoglobulinemia and GN three years prior with renal biopsy showing tubular and interstitial inflammation with immune-complex deposition not completely consistent with either monoclonal gammopathy or cryoglobulinemia. It was treated successfully with three courses of rituximab with resultant CKD3b. Further workup revealed MGUS on SPEP and bone marrow biopsy. A repeat bone marrow biopsy two months prior showed normocellular bone marrow with minute population of kappa monocytic plasma cells consistent with his known MGUS. On current admission, his creatinine was 10.2 g/dL with severe proteinuria of 8,216g/24 hours. Other lab values were significant for persistent IgM kappa monoclonal gammopathy on SPEP, low C3 and C4, significantly elevated RF with negative anti-CCP, and cryoglobulin level of 6%, consistent with mixed type II cryoglobulinemia. Renal biopsy showed cryoglobulinemic glomerulonephritis with focal crescentic formation involving 25% of glomeruli, severe tubulointerstitial nephritis, moderate interstitial fibrosis, and tubular atrophy. The patient was started on nine total plasmapheresis sessions over three weeks and dialysis concurrently, with rituximab infusion weekly for four weeks. Repeat RF decreased from 922 to 142 and cryoglobulin level was negative after treatment was completed. Ultimate prognosis is yet to be determined. He is continued on dialysis at this time.

**Discussion:** MGUS is a well-established part of the monoclonal gammopathy spectrum. MGRS was a recently proposed portion of this spectrum in 2012 to underline the need for more aggressive treatment in this population. While this case re-demonstrates promise of rituximab treatment for initial cryoglobulinemia associated with MGUS, it further underlines the need for improved diagnosis of the renal significance in this spectrum to prevent further kidney damage and possible ESRD.

## FR-PO615

### Eosinophilic Granulomatosis With Polyangiitis (EGPA) Presents With Nephrotic Syndrome (NS) in the Course of the Disease

Nehemias Guevara,<sup>1,2</sup> Marjorie Mailing Flores Chang,<sup>1,2</sup> Mahmoud Ali,<sup>1,2</sup> Jamil Ibrahim,<sup>1,2</sup> Bessy Suyin Flores Chang.<sup>1,2</sup> *<sup>1</sup>St Barnabas Hospital, Bronx, NY; <sup>2</sup>Albert Einstein College of Medicine, Bronx, NY.*

**Introduction:** EGPA affects small and medium sizes vessels. Asthma, nasal, sinus symptoms, and peripheral neuropathy are hallmarks. Necrotizing pauci immune glomerulonephritis is the most common renal presentation seen in kidney biopsy, rarely associated with nephrotic range proteinuria (NRP). Here we are presenting a case of EGPA associated with NRP.

**Case Description:** A 54 year old male with a PMH HTN, EGPA, Jak 2+ myeloproliferative disorder, presented with 2 months of progressive dyspnea, nasal congestion, productive cough grey sputum with streaks of blood, palpitations, and fatigue. VS: BP: 177/138 mmHg, HR: 129 beats/min, RR:18 breaths/min, T: 98.4 F, SatO2: 97% on room air. PE: ill appearance, eyes anicteric, erythematous and edematous nasal turbinates, erythematous oropharynx with a non-bleeding ulcer on the right side, lungs: decreased breath sounds on bases, lower extremities with no edema, skin intact with no rashes. Works up remarkable for thrombocytosis of 765k, eosinophilia of 179k, elevated creatinine, and D-dimer (Table 1). CXR: unremarkable, EKG: sinus tachycardia, biatrial enlargement, left ventricular hypertrophy, concerning pulmonary embolism (PE), V/Q scan: matched defect in perfusion/ventilation at the left lower lobe superior segment; intermediate probability for PE, the patient was treated with therapeutic enoxaparin. CT Chest (Image 1) scattered bilateral centrilobular ill-defined ground glass nodules throughout the lungs. Course was complicated with worsening renal failure, a 50% drop in baseline renal function with NRP (3.5 gr first time presentation), concern for pulmonary/renal syndrome as an acute flare of EGPA. Renal biopsy showed: focal crescentic and diffuse sclerosing glomerulonephritis, pauci immune type (ANCA-associated), with no activity and mild chronicity. Immunosuppressive therapy with rituximab, mycophenolate mofetil, and steroids were initiated, with the slow recovery of renal function and decrease in proteinuria.

**Discussion:** EGPA and renal involvement are uncommon at 25%; it's associated with autoimmune activity, however, once renal is involved tubulointerstitial nephritis is the classical presentation, NS is rare in EGPA, final outcome and need for renal replacement therapy still unknown, our patient is still receiving immunosuppression with the slow recovery of renal function.

## FR-PO616

### A Case of Hydralazine-Induced ANCA-Associated Vasculitis

Waseem Obeid. *Ascension St John Hospital, Detroit, MI.*

**Introduction:** Hydralazine is a direct vasodilator that is widely used for treatment of hypertension and heart failure with reduced ejection fraction. This medication has been associated with autoimmune diseases including ANCA-associated vasculitis (AAV)

**Case Description:** A 73-year-old lady with a past medical history of uncontrolled hypertension and myelodysplastic syndrome presented to the hospital with an asymptomatic increase in serum creatinine on routine blood work that was 2.5 mg/dL. The patient had COVID-19 infection 3 weeks prior to blood work that required no treatment or hospitalization. Patient had been on hydralazine for years at 50 mg three times daily to treat hypertension. Basic metabolic panel showed creatinine of 2.60 mg/dL, BUN of 50 mg/dL. Urinalysis revealed a protein of 100 mg/dL. Microscopy showed RBCs of 90 per hpf and WBC of 11 per hpf. Spot urine protein/creatinine ratio was 1.6 g/g. C-ANCA was negative but P-ANCA was positive with a titers greater than 1:5120, PR-3 antibodies were negative with myeloperoxidase antibodies positive at 1.4 AI. Antihistone antibodies came back positive at 6.8 units. She was started on IV methylprednisolone 500 mg daily for 3 days. The kidney biopsy was performed and showed glomerulosclerosis of 20/70 glomeruli, cellular and fibrocellular crescents in 14 of 50 viable glomeruli. Immunofluorescence was completely negative for IgG, IgA, C3 and C1q with mild mesangial IgM deposition, (+2). Biopsy findings were compatible with ANCA-associated, pauci-immune proliferative glomerulonephritis with crescent formation. Following IV methylprednisolone she was switched to oral prednisone, 60 mg daily. The patient was also given one gram of IV rituximab and discharged with a creatinine level of 1.9 mg/dL.

**Discussion:** This case shows the importance of considering the diagnosis of hydralazine ANCA associated vasculitis when treating patients with nephritic syndrome. It also highlights the importance of reconsidering treatment with hydralazine for hypertension or heart failure and reserve it to certain groups of patients with few alternatives.

## FR-PO617

### Immune Checkpoint Inhibitors as Potential Triggers for ANCA Vasculitis

Faten F. Aqeel, Duvuru Geetha, Jose M. Monroy-Trujillo. *Johns Hopkins University, Baltimore, MD.*

**Introduction:** Immune checkpoint inhibitors (ICIs) have made a tremendous impact on the survival of patients with certain cancers. However, Immune-related adverse events (IrAEs) have been implicated in such therapies. Little is known about the relationship between ICIs and ANCA-associated vasculitis (AAV). We report a case of de-novo MPO ANCA positive AAV and a case of relapsing PR3 ANCA positive AAV following treatment with ICI. This observational report highlights two cases of AAV patients occurring after ICI therapy. We looked at the onset of AAV, type of ANCA, kidney biopsy results, and clinical outcomes.

**Case Description:** One patient developed de-novo MPO ANCA positive AAV 11 months after treatment with ICI, pembrolizumab. The second patient with relapsing PR3 ANCA positive AAV developed yet another relapse after 1 month of ICI. Both patients presented with kidney injury, proteinuria, and hematuria. Remission was achieved after rituximab and glucocorticoids treatment. (Table 1)

**Discussion:** ICIs, specifically PD-1 inhibitors could cause de-novo AAV or trigger a relapse of AAV. Close monitoring of disease relapse is critical in AAV patients undergoing ICI therapy.

Patient characteristics, type of cancer, ICI treatment, onset of vasculitis, ANCA type, and treatment

ID	Age (year)	Race	Sex	Type of cancer	ICI	Existing AAV before ICI	ANCA type	Timing of AAV after initiation of ICI (months)	Presenting findings	Treatment	Nadir sCr (mg/dL)	AAV status at last follow up
1	65	C	M	Squamous cell carcinoma of left palatine tonsil	Pembrolizumab	N	MPO	11	AKI (sCr 7.20), hematuria, proteinuria, foot drop	RTX + GC	1.5	Remission
2	67	C	F	Squamous cell cancer of the lung	Pembrolizumab	Y	PR3	1	AKI (sCr 2.2), hematuria, proteinuria	RTX + GC	1.8 (baseline sCr)	Remission

AAV: ANCA associated vasculitis, ANCA: anti-neutrophil cytoplasmic antibody, ICI: Immune checkpoint inhibitor, F: female, M: male, C: Caucasian, PR3: proteinase-3, MPO: myeloperoxidase, GC: glucocorticosteroids, RTX: rituximab, AKI: acute kidney injury, sCr: serum creatinine, N: no, Y: yes

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

## ANCA-Associated Vasculitis With Hypocomplementemia

Juan D. Diaz Garcia, Mario Alamilla Sanchez, Valeria Yanez Salguero, Martin B. Yama Estrella, Jose L. Ortega, Enrique F. Morales Lopez, Julio C. Nieto, Claudia B. López, Irving G. Ramirez, Francisco Velasco Garcia Lascrain. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.*

**Introduction:** It has been suggested that the role of complement activation, mainly of the alternate pathway, in the pathogenesis of ANCA vasculitis is significant. Although ANCA-related necrotizing and crescentic glomerulonephritis is often referred to as a "pauciimmune" process, in certain cases there is deposition of immune complexes and complement in the glomeruli detected by immunofluorescence. Complement deposits in the kidney of patients with ANCA vasculitis correlate with greater kidney damage, more significant proteinuria, and general disease activity.

**Case Description:** 3 patients are reported, 2 men and 1 woman, with histopathological diagnosis of pauciimmune glomerulonephritis and C3 deposits detected by immunofluorescence, positive ANCA PR3, negative ANAS, profoundly decreased C3 with values less than 20 mg/dl in all 3 patients and C4 decreased by less than 10 mg/dl. Active urinary sediment with dysmorphic erythrocytes 70%, proteinuria in 24 hours between 2 g to 2.5 g, progressive deterioration of renal function, requiring 2 of them renal replacement therapy. Management was started with methylprednisolone 1000 mg every 24 hours for 3 days and Rituximab 375 mg/m<sup>2</sup> every week for 4 weeks as induction therapy. 2 patients with a progressive decrease in serum creatinine reaching baseline renal function and one patient who required hemodialysis sessions without recovery of baseline renal function, being diagnosed with chronic kidney disease.

**Discussion:** According to reports, 25% of patients with ANCA vasculitis have low C3 levels at the time of diagnosis, which is associated with more severe kidney disease and worse renal outcomes, with complement deposits being reported in biopsies. In 25-54% of patients with ANCA vasculitis. C3 deposition was associated with proteinuria, higher creatinine, lower C3, and certain parameters of renal histopathology, such as a higher percentage of crescent formation. In our cases, the three patients presented decreased complement in both C3 and C4 with severe kidney disease; however, 2 patients with a favorable outcome thanks to timely management and another patient who ended up with chronic kidney disease on hemodialysis. This should be taken into account in therapeutic and follow-up strategies.

## FR-PO619

## ANCA Negative Pauci-Immune Necrotizing Glomerulonephritis in a Liver Transplant Patient

Arjun Kumar, Audrey McCartney, Nives Zimmermann, Latoya L. Brathwaite, Niralee Patel. *University of Cincinnati, Cincinnati, OH.*

**Introduction:** Pauci-immune necrotizing glomerulonephritis (PING), a common cause of rapidly progressive glomerulonephritis, is associated with antineutrophil cytoplasmic antibodies (ANCA); yet up to 10% of cases may be ANCA-negative. We present a case of ANCA-negative PING in a patient with an orthotopic liver transplant (OLT) on immunosuppressants.

**Case Description:** 40-year-old male with history of OLT 4 years ago from congenital cytomegalovirus cirrhosis and well-controlled post-transplant diabetes had an urgent kidney biopsy due to an acute rise in creatinine (Cr) from 2.5 to 3.5 mg/dL, new nephrotic range proteinuria (urine protein Cr ratio 3.8g/g), and microscopic hematuria. His immunosuppression was tacrolimus (FK) and mycophenolate mofetil (MMF). Kidney ultrasound showed small echogenic kidneys. Biopsy (Figure 1) revealed glomeruli with cellular crescents with focal necrotizing lesions with majority of glomeruli with global sclerosis, and 50% interstitial fibrosis and tubular atrophy. Immunofluorescence staining was negative for immunoglobulins, C3, C1q, and light chains. Electron microscopy did not exhibit any deposits. Serological labs, including ANCA, were negative except for a low (1:80) antinuclear antibody. Given active cellular crescents, despite the signs of chronicity, he was treated with 3 days of high dose methylprednisolone followed by prednisone taper and 2 doses of rituximab in 2 weeks, in addition to chronic FK and MMF. 2 months later, renal dysfunction persists.

**Discussion:** ANCA-negative PING tends to have poorer kidney prognosis, with 25% requiring dialysis at diagnosis and a high mortality compared to ANCA-positive PING. ANCA-negative PING may represent an entirely separate disease and has been associated with malignancy and bacterial infections. Data on the underlying pathophysiology is limited; yet ANCA-negative PING is managed similarly to ANCA-positive cases with corticosteroids, rituximab or cyclophosphamide. The unique *de novo* presentation of a patient on immunosuppressives suggests there may be an atypical underlying pathophysiology and further investigations are warranted.

Figure 1 Left: kidney biopsy with H&E stain showing hypercellular glomerulus with occluded glomerular capillary loops, and Right: Silver stain showing extracapillary proliferation (crescent formation).

## FR-PO620

## ANCA Glomerulonephritis With IgA Deposits

Elena Zidan,<sup>1</sup> Aaron M. Domm,<sup>2</sup> <sup>1</sup>Bridgeport Hospital Internal Medicine, Bridgeport, CT; <sup>2</sup>Bridgeport Hospital, Bridgeport, CT.

**Introduction:** We present a patient with antineutrophilic cytoplasmic antibody (ANCA) associated pauci-immune necrotizing crescentic glomerulonephritis (AAV) who was additionally found to have IgA deposits on immunofluorescence. Estimated prevalence of circulating ANCA in biopsy proven IgA nephropathy (IgAN) is approximately 1.4%. There are a limited number of cases in the literature of coexisting AAV and IgAN.

**Case Description:** A 36-year-old female from Peru presented to the hospital with gross hematuria and transient right third finger proximal interphalangeal joint arthritis. Physical exam was unremarkable and stable vital signs. On laboratory evaluation she was found to have kidney failure with serum creatinine of 1.7 mg/dL, no baseline labs available. Urinalysis revealed gross hematuria, and spot protein creatinine ratio revealed nephrotic range proteinuria 3.69 mg/mg Cr (normal <=0.10 mg/mg Cr) with serum albumin 2.7 mg/dL (normal 0.4-1.3 mg/dL). Further serology was remarkable for ANCA titer >1:1280 (normal <1:20) with perinuclear pattern, elevated anti-myeloperoxidase antibody 50.7 (normal <1.0 AU). Anti-glomerular basement membrane and proteinase-3 antibodies were undetectable. Ultrasound guided right renal biopsy was performed after she was started empirically on pulse dose methylprednisolone. Renal biopsy revealed pauci-immune necrotizing crescentic glomerulonephritis and immunofluorescence showed concomitant mesangial IgA deposits. After initial three doses of pulse steroid, she was transitioned to high dose oral prednisone and two one-gram doses of rituximab (14 days apart), with full recovery of renal function. Gross hematuria persisted for 5 weeks after steroid initiation. Renal imaging was unremarkable.

**Discussion:** This is a unique case of AAV with concurrent mesangial IgA staining immune deposits, whereas typically, AAV is a pauci-immune process without significant staining on immunofluorescence. Persistent gross hematuria is unusual for ANCA GN and does raise suspicion that the IgA deposits may be clinically relevant. The clinical significance of the IgA staining in this case of AAV is unclear, as many kidney transplant donors without kidney disease have incidental IgA deposits. Alternatively, this may represent a form of crescentic glomerulonephritis where both ANCA and IgA contribute to pathogenesis. Fortunately, patient had an excellent response to course of steroids and rituximab, with normalization of renal function.

## FR-PO621

## The Great Clinical Masquerade of ANCA Vasculitis

Aditi Singh, Stephen N. Simeone, Duha A. Jweehhan, Mamta Shah. *UConn Health, Farmington, CT.*

**Introduction:** Early recognition and treatment of anti-neutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis (GN) is paramount to halt progression to end stage renal disease. We present a case of new-onset ANCA positive renal-limited vasculitis in an elderly female with failure to thrive.

**Case Description:** A 78-year-old female presented to our institution with altered mental status and poor oral intake. Over the past several months, she had progressive clinical decline with recurrent admissions for suspected interstitial pneumonia, urinary tract infections (UTI) and dysphagia with failure to thrive. Chemistry demonstrated a serum creatinine of 2.5 mg/dL elevated from a baseline of 0.8 mg/dL. The patient received intravenous crystalloid resuscitation and antimicrobial therapy for clinical hypovolemia and suspicion of UTI. Urinalysis revealed large proteinuria with a urine protein-creatinine ratio of 3.35, hematuria, pyuria, and fine granular casts. Further evaluation revealed positive speckled antinuclear antibodies with titers of 1:160, positive perinuclear-ANCA with a titer of 1:1280 and positive myeloperoxidase antibodies. Renal biopsy demonstrated active crescentic necrotizing glomerulonephritis (Figure 1), significant interstitial inflammation with vascular involvement and negative immunofluorescence. High dose corticosteroid and cyclophosphamide therapy was initiated with rapid improvement in her renal function and resolution of hematuria. She clinically improved and was discharged on prednisone and cyclophosphamide with a plan to transition to rituximab.

**Discussion:** We present a case that highlights the diagnostic challenge of ANCA-associated vasculitis with its protean symptoms and multisystem involvement in an aging population where multiple comorbidities co-exist. ANCA positive GN is the most common new onset GN in adults over the age of 50 and yet studies show a significant delay between initial presentation and diagnosis. A high degree of clinical suspicion is required in this challenging population to reduce the morbidity and mortality associated with this disease.

**Renal Limited ANCA-Associated Vasculitis Associated With Cardiac Tamponade Following Pfizer-BioNTech SARS-CoV-2 Vaccination**

Yasmin N. Mahmoud,<sup>1,2</sup> Omar N. Elhawary,<sup>1,2</sup> Mary C. Mallappallil,<sup>1,2</sup> Sonalika Agarwal,<sup>1,2</sup> Isha Puri,<sup>1,2</sup> *SUNY Downstate Health Sciences University, New York City, NY; <sup>2</sup>Kings County Hospital Center, Brooklyn, NY.*

**Introduction:** While short-term side effects of COVID-19 vaccine resemble those of other vaccines, long-term side effects remain unknown. We report a case of new-onset renal-limited ANCA-associated vasculitis in an elderly woman who developed acute kidney injury with nephrotic range proteinuria after receiving the Pfizer-BioNTech COVID-19 vaccine.

**Case Description:** 74-year-old woman with history of Hypertension, Diabetes presented with generalized fatigue and occasional cough after getting Pfizer-BioNTech covid vaccine in June 2021. She had nephrotic range proteinuria with UPC of 4 g/g, serum positive for MPO-ANCA antibody with a titer of 1:160. CT chest showed moderate to large pericardial effusion which was subsequently confirmed on Echocardiogram. Kidney biopsy was done and showed MPO-ANCA mediated crescentic focal necrotizing and focal sclerosing glomerulonephritis. The patient later developed transient episode of SVT which required higher level of care and a pericardiocentesis was done for cardiac tamponade and impending cardiac collapse.

**Discussion:** Six cases of ANCA-associated glomerulonephritis after SARS-CoV-2 vaccination have been reported to date. We report a case of ANCA-associated vasculitis associated with cardiac tamponade following Pfizer-BioNTech SARS-CoV-2 vaccination. Since April 2021, increased cases of myocarditis and pericarditis have been reported in the United States after mRNA COVID-19 vaccination and reported cases have occurred predominantly in male adolescents and young adults 16 years of age and older. To our knowledge this is the first case of renal limited MPO-ANCA-associated vasculitis following Pfizer-BioNTech covid vaccine with association of cardiac tamponade in an elderly female. Diagnosis is often challenging, and post-marketing surveillance systems must continue to assess vaccine safety.

Crescents and Necrosis

## FR-PO623

**Belimumab and Multitarget Therapy, Mycophenolate Mofetil, and Tacrolimus as Induction Therapy of Severe Active Lupus Nephritis: Case Series From China**

Min Min,<sup>1</sup> Jiong Zhang,<sup>2</sup> *<sup>1</sup>National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing Medical University, Nanjing, China; <sup>2</sup>National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.*

**Introduction:** To assess safety and generate preliminary efficacy data on multitarget therapy (MT) and standard care followed by belimumab (BLM) for severe active Chinese LN patients, a case series were investigated. Four patients with severe active LN were treated with standard care [mycophenolate mofetil (MMF) / tacrolimus (FK506)] or MT, followed by BLM infusions. BLM were given 10mg/kg every 2 weeks for 3 times, then every 4 weeks till Week 24. Primary renal response index, SLEDAI and safety data were analyzed.

**Case Description:** The patients (3 females) affected by LN ISN/RNP Class III/IV±V with high disease activity are 2 de novo LN, 2 refractory LN. At baseline, the SLEDAI score were 20,17,16,15 respectively. Three of them accepted intravenous (IV) methylprednisolone, followed by standard care or MT, one patient started standard care immediately after admission. Within 2 weeks of starting treatment, IV BLM was introduced. The initial oral prednisone doses were 30-45mg/day. At Week 24, the SLEDAI score decreased to 2,8,10,2 respectively. Two patients who accepted MT achieved complete renal remission, the other two achieved partial renal remission (Figure 1). MT and BLM therapy reduced SLEDAI more rapidly than MMF or FK506 regimen (Figure 2). Prednisone reduced to 10-15mg/day. No adverse events occurred.

**Discussion:** The addition of belimumab to MT or standard therapy was safe. This regimen leads to renal remission in severe active LN patients and diminishes SLEDAI. Further studies are needed to evaluate the benefits of belimumab combined with MT in severe active LN.

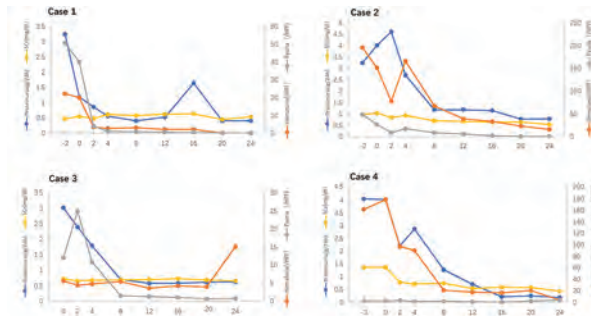

Figure 1. Changes of urinary protein, urinary red blood cells, urinary white blood cells and serum creatinine in 4 patients during the treatment with belimumab and multitarget therapy/standard therapy. 0 week is the time to start the belimumab. Case 1 and Case 4 accepted belimumab and multitarget therapy. Case 2 accepted belimumab and mycophenolate mofetil. Case 3 accepted belimumab and tacrolimus.

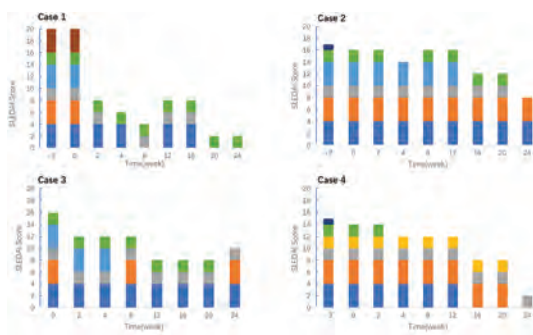

Figure 2. The details of 4 patients' Systemic Lupus Erythematosus Disease Activity Index (SLEDAI). The graph shows the patients' overall scores along with the SLEDAI components with their respective weights during the treatment with belimumab and multitarget therapy/standard therapy. 0 week is the time to start the belimumab. Case 1 and Case 4 accepted belimumab and multitarget therapy. Case 2 accepted belimumab and mycophenolate mofetil. Case 3 accepted belimumab and tacrolimus.

## FR-PO624

**Renal Limited PR3-ANCA Vasculitis due to Abiotrophia defectiva Infective Endocarditis**

Leonardo Pozo Garcia, Jeryl P. Varughese, Sehrish Ali, Pascale Khairallah. *Baylor College of Medicine, Houston, TX.*

**Introduction:** *Abiotrophia defectiva* (*A. defectiva*) is a rare cause of infective endocarditis (IE) and in some cases, it can lead to glomerulonephritis (GN). There is only one report in the literature associating this organism with ANCA-positive vasculitis with renal involvement. This entity is scarcely described.

**Case Description:** A 25-year-old gentleman with a history of type 1 diabetes mellitus and tetralogy of Fallot with multiple repairs including surgical pulmonary valve replacement, tricuspid annuloplasty, and two prosthetic implants on the right ventricle outflow tract was admitted to the ICU for decompensated right heart failure and night sweats with plans for surgical repair. Received further workup, inotropes, IV diuretics, and CVP monitoring. Initial imaging was consistent with diffuse lung and heart nodularity. Blood cultures grew gram-positive cocci, later identified as *A. defectiva*. Antibiotics adjusted. CTA consistent with pulmonary valve and artery vegetations and pulmonary septic emboli. The patient underwent re-replacement of the pulmonary valve, pulmonary artery patch, and tricuspid valve replacement. Valve cultures consistent with *A. defectiva*. Renal function deteriorated from baseline 0.8 mg/dL to 1.4 mg/dL. Urinalysis had 2+ protein, 3+ blood, and 50-100 RBC/HPF. UPC 3 gm/gm. PR3 ANCA elevated 249 with repeat 323 (NL <19 AU/mL). He was started on pulsed-dosed steroids empirically. Renal biopsy revealed pauci-immune GN with mesangial IgM2+ and C3 staining at the vascular pole. The patient was discharged on ceftriaxone and steroid taper.

**Discussion:** The patient developed renal limited PR3-ANCA GN due to *A. defectiva* IE. GN associated with IE is a well-documented entity commonly found in patients with IE caused by staphylococci and streptococci. Only one other case has been previously reported with *A. defectiva* as the pathogenic organism causing both IE and biopsy-proven PR3-ANCA vasculitis. It is unclear if heavy induction immunosuppression followed by maintenance immunosuppression is needed in these rare cases. Individualized treatment is recommended from our experience.

## FR-PO625

**Monoclonal Tissue ANA as an Initial Clue to Lupus Podocytopathy**

Gilad S. Guez, Nicole Fernandez, Abdelaziz A. Elsanjak. *LewisGale Medical Center, Salem, VA.*

**Introduction:** Lupus podocytopathy (LP) is a rare renal manifestation of lupus without immune complex-mediated pathogenesis. By electron microscopy (EM), there is diffuse podocyte foot process effacement (PFPE), without glomerular capillary wall

immune complexes. By light microscopy (LM), glomeruli may be normal or may exhibit mesangial hypercellularity or focal segmental glomerulosclerosis (FSGS); however, proliferative lupus nephritis (LN) is absent. LP is currently not included in the LN classification and may not be recognized without careful clinic-pathologic correlation. This case displays the FSGS variant of LP with monoclonal tissue ANA as the first finding of lupus with good treatment response.

**Case Description:** 19-year-old female was admitted for generalized edema. Labs showed anemia, proteinuria (urine protein/Cr=10.3), microhematuria, hypoalbuminemia, and normal renal function. Renal biopsy LM showed the tip lesion variant of FSGS (Fig. 1A). By IM, there was low level mesangial IgG/IgM staining. Tubular cell nuclei stained for IgG (Fig.1B) with IgG1 heavy chain and kappa light chain restriction. EM showed extensive PFPE (Fig. 1C) and tubuloreticular inclusions (Fig. 1D), but no capillary wall deposits. The findings were suspicious for LP. Serologies were positive for ANA and dsDNA. Skin biopsy showed lupus dermatitis. She was started on prednisone, tacrolimus and hydroxychloroquine. Prednisone was replaced with mycophenolate mofetil for maintenance, and remission was achieved.

**Discussion:** The FSGS variant of LP has low rates of remission with steroids alone. This case shows that robust immune suppression may improve prognosis. LP has histologic similarities with minimal change disease and primary FSGS, so clues from the IF/EM and clinical history help in diagnosis. Monoclonal tissue ANA is a rare finding and was helpful in diagnosing LP in this biopsy.

Fig. 1

## FR-PO626

### A Case of Histiocytic Glomerulopathy With Features of Thrombotic Microangiopathy With Features of Atypical Sarcoidosis and Lupus Anticoagulant

MD S. Alom, Catherine A. Moore, Hae Yoon Grace Choung, *Strong Memorial Hospital, Rochester, NY.*

**Introduction:** Hemophagocytic Syndrome (HPS) is a rare, potentially fatal disease, characterized by unrestrained immune activation resulting in hypercytokinemia and multiorgan failure

**Case Description:** We present a case with subacute progressive renal dysfunction, hematuria and proteinuria in a 73-year-old female with a congenital solitary kidney, hypertension, and primary hyperparathyroidism. She was admitted with serum creatinine (s.cr) of 4.1 g/dl up from baseline (0.9 mg/dl). Additional findings included pancytopenia, hypermetabolic lymphadenopathy, mild hypercalcemia, and fatigue. She underwent extensive work up including PET scan and biopsies of the kidney, lymph node and bone marrow. Biopsy of the kidney showed histiocytic glomerulopathy with features of thrombotic microangiopathy (TMA) while LN exhibited non-necrotizing granulomas typical of sarcoidosis. Bone marrow was diagnosed clonal hematopoiesis of indeterminate potential (CHIP). Laboratory values of note included positive IgM for Beta-2-glycoprotein and anti-cardiolipin, random urine total protein/creatinine ratio (UPCR) 2.2 gm/gm, soluble IL2 receptor 1652 U/mL, CRP 156 mg/L, LDH 365 U/L, CPK 294, Ferritin 618 ng/ml, and normal serum protein electrophoresis and serum immunofixation. 1,25 Di-Hydroxy Vitamin D was normal. She was placed on prednisone with initial robust improvement in renal parameters: s.cr decrease to 2.1 mg/dL and UPCR to 660 mg/gm. Course was complicated by legionella pneumonia leading to reduction in steroids, and she initiated infliximab infusions. Unfortunately renal function failed to improve with infliximab and s.cr increased to 5 mg/dL

**Discussion:** Histiocytic glomerulopathy (HG) has been associated with Macrophage Activation Syndrome/HPS following viral infections or hematologic malignancies. Glomerular involvement is rare and usually manifests as either a podocytopathy, TMA, or rarely HG. HG has not been reported with sarcoidosis. The pathogenic role of her positive

lupus anticoagulant, given the features of TMA on renal biopsy, and CHIP on LN biopsy is an additional factor under consideration. Findings of CHIP may indicate worse renal prognosis; this association needs further study.

## FR-PO627

### Lupus Nephritis Complicated by Multi-Organ Arterial Thrombosis

Noor Bazerbashi, Nisarg Gandhi, Elise Ewing, Angelina Edwards, *Houston Methodist, Houston, TX.*

**Introduction:** Thrombosis is a known complication of Nephrotic Syndrome (NS) and results in significant morbidity and mortality. While thrombotic events (TE) in Lupus Nephritis (LN) are often related to antiphospholipid syndrome, an imbalance between thrombotic and antithrombotic factors in those with nephrotic-range proteinuria (NRP) leads to NS-related hypercoagulability. Here, we report an unexpected case of multi-organ arterial thrombosis in a patient (pt) with LN.

**Case Description:** A 23-year-old woman with active systemic lupus erythematosus underwent kidney biopsy for evaluation of 7.7 g proteinuria on 24-hour urine collection. While serum creatinine was stable at 0.73 mg/dL, her serum albumin was low at 2.7 g/dL, and autoimmune markers including anti-nuclear antibody, anti-dsDNA antibody, ribonucleoprotein, and anti-smith antibody were reactive. Outpatient kidney biopsy showed Class IV and V LN, with global diffuse proliferative and membranous lesions with crescentic formation. Before initiation of therapy, she presented with sudden onset of diffuse abdominal pain, headache, and positional chest discomfort. CT abdomen/pelvis with contrast showed multifocal splenic and renal infarcts, and CT head showed lacunar infarcts. Evaluation of chest pain showed no valvular lesions on transthoracic echocardiogram, but further assessment with transesophageal echocardiogram showed a large thrombus in the descending aorta, confirming the embolic source. A comprehensive hypercoagulable workup was collectively unrevealing. The hypercoagulable state was thought to be secondary to underlying inflammatory disease and likely acquired protein C/S deficiency in the setting of NRP. Anticoagulation therapy was initiated, and aggressive management of LN was pursued. Follow-up imaging showed resolution of the thrombus, and the pt continues to show reduction in proteinuria and improvement in serum albumin.

**Discussion:** Venous TE is well-described in NS, but arterial TE is rare and more reported in membranous glomerulonephritis. The cumulative effect of imbalance of antithrombin III, protein C/S, fibrinolytic activity, fibrinogen, and von Willebrand factor increases thrombotic risk. Initiation of thrombotic prophylaxis with appropriate risk stratification guided by pt's serum albumin level is recommended to prevent these detrimental complications.

## FR-PO628

### Hydralazine-Induced Antinuclear Antibody (ANA) Negative “Lupus-Like Nephritis” With Normal Complements

Hema Balina, Edva Noel, Rizwan Rabbani, Iris J. Lee, Christine P. Bastl, *Temple University Hospital, Philadelphia, PA.*

**Introduction:** Isolated severe lupus nephritis from hydralazine without systemic manifestations of vasculitis is rare. Hydralazine can trigger autoimmune disease, and most of these cases have positive ANA and anti-histone antibodies. This case describes the presentation of ANA negative isolated lupus-like nephritis from hydralazine with normal complements, but positive anti-histone and anti-phospholipase A2 antibodies (Anti-PLA2R).

**Case Description:** A 65-year-old female with hypertension, and diabetes who was on hydralazine for two years presented with acute kidney injury and edema. Labs include Creatinine 5.38mg/dl, BUN 42 mg/dl, WBC 8.2K/mm<sup>3</sup>, Hemoglobin 7.5g/dl, Platelets 284K/mm<sup>3</sup>. The urine protein creatinine ratio was 16 grams. ANA, Anti-ds DNA, ANCA, Rheumatoid factor, hepatitis panel, kappa lambda ratio, serum electrophoresis, urine electrophoresis, and immunofixation were negative. Anti-histone antibodies and anti-PLA2R were positive. Renal biopsy showed membranoproliferative glomerulonephritis with the crescent formation, membranous glomerulopathy, and “full-house” staining on immunofluorescence. A diagnosis of hydralazine-induced lupus-like nephritis was made based on her medication history, positive anti-histone antibody, lack of criteria fulfilling SLE, and findings of lupus nephritis on biopsy. Treatment with mycophenolate mofetil and prednisone led to improvement in proteinuria and renal function.

**Discussion:** The incidence of hydralazine-induced lupus is approximately around 5-8%. The diagnosis is made based on the temporal relationship between drug exposure and at least one clinical characteristic of SLE. Hydralazine-induced lupus usually presents with arthralgias, myalgias, fever, rash, and/or serositis. In severe cases, vasculitis, glomerulonephritis, or respiratory failure can be seen. The main serological findings in drug-induced lupus include a positive ANA (In 90-95% cases), anti-histone antibodies (90-95%), anemia, leukopenia, and positive Coombs test. Hypocomplementemia can be seen in 50% of the cases. Our patient had a unique presentation of hydralazine-induced lupus-like nephritis with no other systemic manifestations, normal complements, and a negative ANA. In addition, our patient had anti-PLA2R antibodies which are usually associated with primary membranous and rarely seen in membranous disease due to lupus.

## FR-PO629

**Bamboozled: Concomitant Lupus Nephritis and Systemic Thrombotic Microangiopathy**

Margaret Spolnik, Corey J. Cavanaugh, Helen P. Cathro. *University of Virginia, Charlottesville, VA.*

**Introduction:** Lupus nephritis (LN) and thrombotic microangiopathy (TMA) are rare diseases rarely occurring together. Both can have devastating outcomes of kidney failure, neurological demise, and even death.

**Case Description:** A 31-year-old African-American woman with history of lupus and idiopathic thrombotic thrombocytopenic purpura (TTP) presented with malaise, swelling, emesis and diarrhea for 1 week. Initial testing- Cr 8.7 mg/dL (baseline 1.1), pLts 30 k/uL, haptoglobin <8, LDH 938 U/L, Hgb 6.7 g/dL, uPr/Cr 2.89 g/g, low C3/C4, ANA >1:640, positive dsDNA, Smith, and SSA antibodies. Shiga toxin neg. Peripheral smear showed schistocytes. Urine microscopy had granular casts, but no RBC casts and no dysmorphic RBCs. Given concern for possible TTP, plasmapheresis (PLEX) occurred for 5 sessions until ADAMTS-13 returned with 57% activity. She was also given eculizumab and solumedrol for concern of complement-mediated TMA. Kidney biopsy showed membranous pattern glomerulopathy with 64% cellular crescents and 63% globally sclerotic glomeruli, acute tubular damage, mild interstitial fibrosis and mild tubular atrophy. IF staining was positive for IgG 1+, IgM trace, kappa 2+, lambda 2+, but negative for C1q and IgA and without evidence of TMA. She was treated as proliferative LN given high clinical suspicion with lupus history and active cellular crescents. She started IV cyclophosphamide at 500 mg every 2 weeks for a total of 6 doses per Euro-lupus protocol with corticosteroids. Repeat labs with Cr 1.3, uPr/Cr decreased to 0.14 g/g, and C3/C4 normalized. Peripheral smear without schistocytes and improved LDH/haptoglobin levels. With a negative atypical HUS genetic panel, eculizumab was terminated after two months. She is currently on low-dose steroids and mycophenolate mofetil 1000mg BID.

**Discussion:** Two rare and severe diseases presented concomitantly in a patient with acute kidney injury. She was treated with multiple agents for immunosuppression including cyclophosphamide, steroids and eculizumab as well as five plasmapheresis sessions with no apparent adverse events. Definitive data for cessation of eculizumab is not available, but cessation has not resulted in a recurrent flare. Despite a biopsy without typical characteristic full-house staining for LN, the patient responded well to the Euro-lupus protocol and remains with stable kidney function and minimal proteinuria.

## FR-PO630

**Bartonella Endocarditis With Crescentic Glomerulonephritis Mimicking Lupus Nephritis**

Mohammad A. Sohail, Kristen Tomaszewski, Juan C. Calle. *Cleveland Clinic, Cleveland, OH.*

**Introduction:** Distinguishing an infectious from an autoimmune cause of glomerulonephritis (GN) is critical in diagnostic challenges such as culture negative infective endocarditis (IE) to avoid exposing patients to inadvertent immunosuppression (IS). Although Bartonella IE appears to be frequently associated with ANCA/PR3 positivity, our case illustrates that Bartonella IE can also cause crescentic GN with positive anti-dsDNA and antiphospholipid (aPL) antibodies, mimicking lupus nephritis.

**Case Description:** A 74-year-old man presented with fevers, night sweats, weight loss, dyspnea and left upper quadrant abdominal pain. Initial evaluation revealed pancytopenia, acute kidney injury with creatinine of 2.1 mg/dl from baseline 0.8 mg/dl, severe aortic stenosis (AS) on echocardiography and a splenic infarct on abdominal imaging. Urine protein/creatinine ratio was 1.0 and sediment showed normomorphic RBCs. Blood cultures were negative. Serologic testing showed positive ANA/anti-dsDNA/MPO-ANCA, low C3/normal C4 and triple positive aPL profile. Bone marrow biopsy was unrevealing. The patient was initiated on steroids and hydroxychloroquine for possible diagnosis of systemic lupus erythematosus (SLE), and underwent a transcatheter aortic valve replacement (TAVR) for severe AS. Subsequent kidney biopsy revealed crescentic GN with IgM and C3 codominant deposits. The patient's history of AS requiring TAVR raised the possibility of a subacute culture-negative IE as a potential cause for GN. Bartonella was detected by blood PCR testing with positive IgG for Bartonella henselae. Subsequent histopathology of the explanted prosthetic aortic valve under Warthin-Starry stain revealed bacillary organisms in fibrinous vegetations. Anti-dsDNA and aPL antibodies turned seronegative after treatment with ceftriaxone and doxycycline.

**Discussion:** Anti-dsDNA and aPL antibodies are not typical of Bartonella IE-associated GN. However, the patient's lack of response to IS, IgM dominant pattern on kidney biopsy, positive Bartonella PCR/serology, and resolution of anti-dsDNA and aPL antibodies following antibiotic therapy, supported Bartonella IE over SLE as the cause of the GN. Although determining the etiology of GN in culture negative IE can be challenging with positive autoimmune serologies, reaching a prompt accurate diagnosis is crucial to prevent inadvertent IS and valve replacement procedures.

## FR-PO631

**A Unique Case of Scleroderma Renal Crisis**

Nickolas Coombs, Mythri Anil Kumar, Jarrod B. Post. *Hartford Hospital, Hartford, CT.*

**Introduction:** Scleroderma renal crisis (SRC) occurs in 5-20% of patients with diffuse cutaneous systemic sclerosis (SSc). Early initiation of angiotensin converting enzyme inhibitors (ACEi) can promote renal stabilization or recovery. We present a case of SRC in amyopathic dermatomyositis (DM) with overlap syndrome.

**Case Description:** A 76-year-old female with hypertension (HTN) presented with months of bilateral lower extremity edema, arthralgias, myalgias, and dyspnea. A transthoracic echocardiogram (TTE) was normal and nuclear stress testing revealed two-vessel coronary artery disease. CT chest showed non-specific interstitial pneumonia. Antinuclear antibody (Ab), PL12 Ab and C-Reactive protein were elevated; mycophenolate mofetil (MMF) and methylprednisone were started for DM. She was admitted to the hospital for pulmonary edema secondary to malignant HTN complicated by acute kidney injury (AKI). Her urinalysis, renal ultrasound and TTE were unremarkable. Respiratory status improved with aggressive diuresis and her AKI was thought to be cardiorenal; serum creatinine (SCr) stabilized at 1.8 mg/dl (baseline 0.6). MMF was thought to precipitate pulmonary edema and she was discharged on hydroxychloroquine. She was readmitted 2 weeks later with similar symptoms and SCr 2.3 mg/dl. Despite diuresis, kidney function declined; right heart catheterization was done and normal. Given a recent diagnosis of DM, accelerated HTN, and worsening AKI this raised suspicion for SRC. Interestingly, sclerodactyly was noted in bilateral fingers as well. Further testing revealed RNA polymerase III Ab positivity; renal biopsy was suggestive of SRC. Hemodialysis (HD) was initiated, and she was discharged on lisinopril, steroid taper, and MMF.

**Discussion:** We describe a case of amyopathic DM with overlap of SSc in which the use of steroids and cessation of ACEi precipitated SRC. In 20% of cases, SRC precedes the clinical findings of SSc making diagnosis challenging. As polymyositis and DM commonly overlap with SSc, clinical suspicion for SRC is required when presented with accelerated HTN and AKI. In the absence of skin changes, RNA polymerase Ab positivity should raise suspicion for SRC. Prolonged ACEi in SRC may reconstitute renal function for up to 18 months after onset of SRC; ACEi should continue even in patients on long-term dialysis. However, while ACEi have decreased mortality by >60%, outcomes in SRC remain poor with 42% requiring HD.

## FR-PO632

**Thrombotic Microangiopathy as a Presentation of Paroxysmal Nocturnal Hemoglobinuria and Lupus Nephritis**

Clementina Elizabeth Calderon Garcia,<sup>1</sup> Guillermo Navarro Blackaller,<sup>1,2</sup> Jonathan Chavez.<sup>1,2</sup> *<sup>1</sup>Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico; <sup>2</sup>Universidad de Guadalajara Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico.*

**Introduction:** Thrombotic microangiopathy (TMA) characterized by thrombocytopenia, microangiopathic hemolytic anemia, and organ injury. Paroxysmal nocturnal hemoglobinuria (PNH) characterized by intravascular hemolytic anemia, thrombosis, bone marrow dysfunction and hypercoagulability. Systemic lupus erythematosus (SLE) is an autoimmune multisystemic disease. SLE associated with PNH is very rare. We present the case of a man who presented TMA, secondary to lupus nephritis (LN) with PNH both entities coexisting.

**Case Description:** A 48-year-old man with acute kidney injury with creatinine 13mg/dl, urea 148mg/dl, hemoglobin 6g/dl and 56,000 platelets, with peripheral blood smear showing the presence of schistocytes, COOMBS direct negative, low haptoglobins, ANAs 1:640, low C3 and normal C4 levels. ADAMS 13 activity >17%, Shiga toxin and ANCAS negative. Anti-double chain, Anti-SM, lupus anticoagulant, anti cardiolipins, and anti B2 glycoprotein antibodies negatives. HBV, HCV, and HIV serologies negatives. Kidney ultrasound was normal. SLE was diagnosed, requiring hemodialysis. Renal biopsy was performed, reporting class II LN with acute tubulointerstitial nephritis and autoimmune TMA (Image). Given the persistence of anemia and thrombocytopenia, PNH phenotype was addressed, and monocytes were identified as CD59 8.7% TYPE II, CD59 23.3% TYPE III.

**Discussion:** PNH has reduced or absent glycosylphosphatidylinositol (GPI)-anchored proteins on the cell surface. Loss of the GPI-linked complement inhibitors, CD55 and CD59 on erythrocytes leads to chronic or paroxysmal intravascular hemolysis. In our patient, we found a deficient CD59 pattern that can also be observed in SLE or hemolytic anemias. Therapeutics can be directed by targeting complement protein C5, eculizumab is a treatment option that has been shown to significantly reduce hemolysis and thus hemolysis-related side effects in PNH cases.

## FR-PO633

## It's Not Always Lupus Nephritis

Maris Hardee,<sup>1</sup> Carter V. Schwartz,<sup>2</sup> Neville R. Dossabhoy,<sup>2</sup> Tiffany Caza,<sup>3</sup> Mohammad Atari.<sup>2</sup> <sup>1</sup>University of Mississippi School of Medicine, Jackson, MS; <sup>2</sup>The University of Mississippi Medical Center, Jackson, MS; <sup>3</sup>Arkana Laboratories, Little Rock, AR.

**Introduction:** Systemic lupus erythematosus (SLE) is a complex immunological disease, with a plethora of manifestations. While lupus nephritis commonly affects patients with SLE, other renal diseases may also involve the kidney in SLE patients. Here, we describe a rare case of chronic sclerosing IgA nephropathy in a patient with SLE.

**Case Description:** A 31-year-old African American female with a history of SLE and secondary Sjogren syndrome presented with dyspnea and pleuritic chest pain. On exam, she had severe hypertension and peripheral edema. Labs were significant for pancytopenia, and creatinine elevated to 2.4 mg/dL (up from a baseline of 1 mg/dL). The urine protein-to-creatinine ratio was 6.57 g/g. Antinuclear antibodies, SSA antibodies, and chromatin antibodies were positive, with a low C3 complement but normal anti-double-stranded DNA antibodies. Kidney biopsy revealed chronic sclerosing IgA nephropathy and arterionephrosclerosis. Global (15/31) and segmental glomerulosclerosis with collapsing features were present. Immunofluorescence showed granular mesangial staining for IgA (+3), IgG (+1), IgM (+2), C3 (+3), kappa and lambda (+2), and negative C1q. Electron microscopy showed focal subendothelial and numerous mesangial electron-dense deposits. The patient declined testing for APOL-1.

**Discussion:** The incidence of IgA nephropathy in the setting of SLE is unknown. However, secondary IgA nephropathy has been well described in the setting of Sjogren syndrome. The patient described here presented with nephrotic range proteinuria, elevated creatinine and active systemic lupus, raising concern for lupus nephritis at the time. Kidney biopsy revealed an unexpected glomerular pathology of IgA nephropathy. This case emphasizes the importance of consideration of other etiologies as a cause of renal impairment in SLE patients even with active systemic lupus.

## FR-PO634

## Correlation of Urinary Waxy Casts With Renal Pathology

Muner Mohamed, Vipin Varghese, Dustin Chalmers, Juan Carlos Q. Velez. Ochsner Nephrology Ochsner Medical Center, New Orleans, LA.

**Background:** Urinary waxy casts (uWxC) are traditionally described in textbooks as indicative of chronic renal parenchymal disease. However, data supporting this contention is lacking. uWxC can be seen in the context of various renal syndromes, including acute kidney injury, chronic kidney disease, rapidly progressive glomerulonephritis (GN) and nephrotic syndrome. Thus, we investigated the correlation between identification of uWxC and renal pathological findings.

**Methods:** We prospectively collected data of patients seen in nephrology consultation with a urine specimen subjected to microscopic examination of the urinary sediment (MicExUrSed) over a 3-year period. Within this cohort, we identified cases in which a kidney biopsy was concomitantly performed. We assessed the association of uWxC with glomerular or tubular pathology and with chronicity [interstitial fibrosis and tubular atrophy (IFTA) and glomerular obsolescence (GO)].

**Results:** Among 683 patients with MicExUrSed, 103 (15%) underwent kidney biopsy and were included. Mean age was 55 years, 51% women, 50% white and 38% self-identified black. Median serum creatinine was 3.2 (0.7-15.6) mg/dL and not significantly different between those with and without uWxC (4.7 vs 3.8 mg/dL,  $p=0.13$ ). uWxC were identified in 35 (34%) cases. A glomerulopathy was diagnosed in 79 (77%). Among those with uWxC ( $n=35$ ), a glomerulopathy was more likely to be found with concomitant acute tubular injury (ATI) than without ATI (57% vs 23%,  $p=0.0006$ ), whereas among

those without uWxC, glomerulopathies were found with or without concomitant ATI with similar frequency (41% vs 34%,  $p=0.48$ ). Overall ( $n=103$ ), more patients with uWxC had  $\geq 20\%$  IFTA compared to those without uWxC (74% vs 51%,  $p=0.03$ ). Among those with glomerulopathy ( $n=79$ ), more patients with uWxC had  $\geq 20\%$  IFTA compared to those without uWxC (89% vs 56%,  $p=0.004$ ). uWxC did not correlate with GO.

**Conclusions:** Identification of uWxC denotes greater likelihood of finding evidence of ATI superimposed with a glomerulopathy rather than finding an isolated glomerular lesion. uWxC are associated with greater probability of finding  $\geq 20\%$  IFTA in a kidney biopsy specimen, particularly in those with a glomerular pathology. This observation may help clinicians weigh on suitability of a kidney biopsy when chronicity or coexistence of ATI are in question.

## FR-PO635

## Urinary White Blood Cell Casts Are Commonly Associated With Glomerulonephritis Rather Than Acute Interstitial Nephritis

Dustin Chalmers,<sup>1</sup> Swetha Rani Kanduri,<sup>1,2</sup> Vipin Varghese,<sup>1</sup> Jay R. Seltzer,<sup>3</sup> Juan Carlos Q. Velez.<sup>1,2</sup> Ochsner Nephrology <sup>1</sup>Department of Nephrology, Ochsner Health, New Orleans, LA; <sup>2</sup>Ochsner Clinical School, The University of Queensland, Brisbane, QLD, Australia; <sup>3</sup>Missouri Baptist Medical Center, St. Louis, MO.

**Background:** Urinary white blood cell casts (uWBCC) are traditionally thought to be indicative of acute interstitial nephritis (AIN). However, clinical data supporting this contention is lacking. uWBCC has also been described in glomerulonephritis (GN) and pyelonephritis (PN). Herein, we investigated the diagnostic performance of uWBCC in differentiating the etiology of kidney disease.

**Methods:** We prospectively collected data of patients seen in nephrology consultation who had a urine specimen subjected to microscopic examination of the urinary sediment (MicExUrSed) as part of the clinical evaluation. Within this cohort, we identified cases in which a kidney biopsy was performed. We assessed the performance of uWBCC in the diagnosis of GN and AIN. To specifically assess for immune-mediated and/or proliferative GN (uWBCC are plausible), podocytopathies (e.g., collapsing glomerulopathy, diabetic nephropathy) were grouped separately. In addition, we pooled cases in which uWBCC were identified, with and without kidney biopsy confirmation, at our site and at an additional contributing site where MicExUrSed is routinely performed.

**Results:** Among 683 patients with MicExUrSed, 103 (15%) underwent kidney biopsy and were included. Mean age was 55 years, 51% women, 50% white and 38% self-identified black. Median serum creatinine was 3.4 (0.7-15.6) mg/dL. Biopsy diagnosis was GN in 42 (41%) and non-GN in 61 cases (59%). The sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of uWBCC for diagnosis of GN were 26%, 85%, 55% and 62%, respectively, whereas the sensitivity, specificity, PPV and NPV of uWBCC for diagnosis of AIN were 8%, 79%, 5% and 87%. Thus, the PPV of uWBCC to diagnose GN was greater than that for AIN. In addition, out of 37 cases total with uWBCC, 27 (73%) had GN [16 (59%) of them with acanthocytes also present], 3 (8%) had PN, 6 (16%) had others and only 1 (3%) had AIN, further substantiating the observation that uWBCC are more likely to be associated with GN.

**Conclusions:** Identification of uWBCC predominantly reflected a diagnosis of GN rather than AIN. This finding challenges the current paradigm, traditional teaching, and standardized testing on this topic, all of which should be revisited.

## FR-PO636

## Association of Obesity With Cardiorenal Outcomes in the CureGN Cohort

Evan Zeitler, Yichun Hu, Susan L. Hogan, Dorey A. Glenn, Ronald Falk, Amy K. Mottl. UNC Kidney Center, Chapel Hill, NC.

**Background:** Obesity is a risk factor for cardiorenal outcomes in patients with CKD, but its relevance in glomerulonephropathy (GN) is less known.

**Methods:** Participants  $\geq 16$ yr from CureGN were categorized by age-appropriate BMI status at enrollment: normal (20-24 in adults; 5-85 %ile in children), overweight (25-29 for adults, 85-95th %ile in children), obese (30-34 in adults,  $\geq 95$ th %ile in children) or morbidly obese ( $\geq 35$  in adults and children). Composite kidney (40% decline in eGFR/end-stage kidney disease) and composite cardiovascular (myocardial infarction/heart failure diagnosis/stroke/death) outcomes were evaluated. Baseline characteristics and frequency of outcomes were compared between weight status groups using Chi-square and Kruskal-Wallis tests. A log rank test was used to compare Kaplan-Meier curves of time-to-event for the kidney outcome.

**Results:** Characteristics and outcomes are shown in the **Table**. The cohort was 44% female with a median age of 44 and median (IQR) follow up of 3.74 (2.06, 5.21) years. GN diagnoses were 28% IgAN, 26% FSGS, 31% MN and 14% MCD. Higher baseline BMI was associated with higher blood pressure ( $p < 0.0001$ ) and urine protein-to-creatinine ratio (uPCR,  $p = 0.006$ ), and lower eGFR ( $p = 0.0002$ ) at enrollment compared to those with a lower BMI. More kidney events occurred in the highest weight category, and the time to kidney event was shorter (**Figure**), but this was not true for cardiovascular events.

**Conclusions:** BMI is an important mediator of major kidney outcomes in GN, stressing the importance of this modifiable risk factor in its management.

## FR-PO637

## Epidemiology of Rapidly Progressive Glomerulonephritis in Iceland

Magnus T. Sigurdarson,<sup>1</sup> Asta D. Jonasdottir,<sup>2,1</sup> Sverrir Hardarson,<sup>2,1</sup> Konstantin Shcherbak,<sup>2</sup> Runolfur Palsson,<sup>2,1</sup> Olafur S. Indridason.<sup>2</sup> <sup>1</sup>Haskoli Islands, Reykjavik, Iceland; <sup>2</sup>Landspítali–The National University Hospital of Iceland, Reykjavik, Iceland.

**Background:** Rapidly progressive glomerulonephritis (RPGN) is a serious presentation of glomerulonephritis (GN), defined as deteriorating kidney function over few days to three months. The average yearly incidence of RPGN in Iceland was 0.6/100,000 in the period 1983–2002. The aim of this study was to examine the epidemiology of RPGN in Iceland over the last two decades with regard to incidence and outcome.

**Methods:** This was a retrospective, population-based study of the period 2002–2021. We identified cases by searching SNOMED diagnosis codes in the database of the Department of Pathology at Landspítali – The National University Hospital of Iceland (LUH). We also searched for ICD-10 diagnosis codes indicative of RPGN in the LUH data warehouse. Nephrology services in Iceland are centralized at LUH, where all kidney biopsies in the country are performed. Demographic and clinical data were obtained from patients' medical records. Annual incidence was calculated based on the population of Iceland each year (numbering 376,248 on January 1, 2022).

**Results:** Eighty-seven cases of RPGN were identified, 80 from biopsy data and additional seven by search for ICD-10 diagnosis codes. The median age was 58 years (range, 8–89) and 51 (59%) were men. Pauci-immune GN accounted for 41 (47.1%) cases, 36 of which were positive and 5 negative for ANCA. Eighteen patients (20.7%) had anti-GBM disease and 25 (28.7%) immune-complex GN. The mean annual incidence of RPGN was 1.3/100,000 population. Increase in the incidence (per 100,000/year) from the first 5-year period to the last was noted for ANCA-associated vasculitis (from 0.41 to 0.67), ANCA-negative vasculitis (from 0.07 to 0.17) and for anti-GBM disease (from 0.21 to 0.33). The incidence decreased for immune-complex GN (from 0.55 to 0.11). Acute dialysis was needed in 30 cases (34.5%). At 6 months from diagnosis, 23 patients (26%) were dialysis-dependent and 11 (13%) had died.

**Conclusions:** The study suggests an increase in RPGN incidence in Iceland in the past 20 years. Since most patients with clinical presentation of RPGN are likely to be referred to nephrology and undergo a kidney biopsy, aging of the population or a true increase in incidence are the most likely explanations. Prognosis remains relatively poor and a high proportion of patients requires kidney replacement therapy.

## FR-PO638

## Are Immunosuppression Treatments for Glomerular Disease Associated With Increased Cardiovascular Risk?

Mohammad Atiquzzaman,<sup>1</sup> Mark Canney,<sup>2</sup> Yuyan Zheng,<sup>1</sup> Lee Er,<sup>1</sup> Yinshan Zhao,<sup>3</sup> Dilshani Induruwage,<sup>1</sup> Sean Barbour.<sup>3</sup> <sup>1</sup>BC Provincial Renal Agency, Vancouver, BC, Canada; <sup>2</sup>University of Ottawa, Ottawa, ON, Canada; <sup>3</sup>The University of British Columbia, Vancouver, BC, Canada.

**Background:** The risk of cardiovascular disease (CVD) associated with immunosuppression (IS) treatments for glomerular disease is currently unknown. This was investigated in a population-level cohort of patients with glomerular diseases from British Columbia, Canada after adjusting for eGFR and proteinuria over time as measures of disease activity.

**Methods:** All adults with IgA nephropathy, FSGS, membranous nephropathy or minimal change disease on a kidney biopsy between January 2000 & December 2012 were identified from a provincial registry, excluding those with ESKD prior to the biopsy date or no available follow-up. IS medications were categorized as antimetabolites, calcineurin inhibitors, corticosteroids or cyclophosphamide, and quantified using defined daily doses (DDD) or grams, as appropriate. The primary outcome was acute cardiovascular events and urgent revascularization after biopsy date, evaluated using extended Cox regression models to determine the association with time-varying IS exposure after adjusting for eGFR & proteinuria over time, type of glomerular disease & CV risk factors.

**Results:** Amongst 1,912 patients with median follow-up 6.8 years, 212 (11.1%) patients developed a CV outcome event. In multivariable models, prednisone and antimetabolite exposures were not associated with CV risk. However, modest (150–300 DDD) & high (≥300 DDD) cumulative doses of calcineurin inhibitors were both associated with >2-fold higher risk of CV events, and each 10g of cumulative cyclophosphamide exposure was associated with a 1.5-fold higher risk of CV events (Table).

**Conclusions:** Calcineurin inhibitors and cyclophosphamide used for the treatment of glomerular diseases are both associated with increased risk of CV events independent of treatment effects on disease activity. These results can inform the selection of therapies in clinical practice with less CVD morbidity.

Results from extended Cox regression analysis modeling the relationship between time-varying immunosuppression medication exposure and the risk of cardiovascular diseases (CVD)				
Exposure to immunosuppression medications	Univariable model		Multivariable model	
	Unadjusted HR (95% CI)	P-value	Adjusted <sup>a</sup> HR (95% CI)	P-value

## FR-PO639

## NURTURE-INS: A Biobank of United Kingdom Idiopathic Nephrotic Syndrome Patients to Enable Research and Disease Stratification

Liz Colby,<sup>1</sup> Melissa Benavente,<sup>2</sup> Maarten W. Taal,<sup>2,3</sup> Elaine M. Davies,<sup>4</sup> Michael L. Nation,<sup>4</sup> Tim S. Johnson,<sup>5</sup> Lorna J. Hale,<sup>6</sup> Uwe Andag,<sup>7</sup> Philipp Skrobilin,<sup>7</sup> Robert J. Unwin,<sup>8</sup> Ania B. Koziell,<sup>9</sup> Gavin I. Welsh,<sup>1</sup> Moin Saleem.<sup>1</sup> <sup>1</sup>University of Bristol Faculty of Health Sciences, Bristol, United Kingdom; <sup>2</sup>University of Nottingham School of Medicine, Nottingham, United Kingdom; <sup>3</sup>Royal Derby Hospital, Derby, United Kingdom; <sup>4</sup>Kidney Research UK, Peterborough, United Kingdom; <sup>5</sup>The University of Sheffield, Sheffield, United Kingdom; <sup>6</sup>UCB Pharma, Slough, United Kingdom; <sup>7</sup>Evotec AG, Hamburg, Germany; <sup>8</sup>AstraZeneca PLC, Cambridge, United Kingdom; <sup>9</sup>King's College London, London, United Kingdom.

**Background:** Idiopathic Nephrotic Syndrome (INS) is a heterogeneous disease and current classification is based on observational responses to therapies. The NURTURE-INS cohort has been established as part of the UK-first standardised renal-biorepository with linked clinical data to develop novel methods to stratify patients for better disease management. Funding and governance was achieved via a unique collaborative partnership between Kidney Research UK, industry and academic investigators.

**Methods:** Patients are being recruited from 14 adult and 8 paediatric centres throughout Great Britain. Detailed longitudinal clinical data will be collected alongside long-term outcomes with respect to end stage kidney disease and survival. Serum, plasma, urine, RNA and DNA samples are collected and processed according to strict industry standards. Clinically stained histology slides will be digitally scanned, and any surplus biopsy tissue blocks will be cut for additional immunohistochemistry.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Results:** Recruitment commenced in October 2017 and 664 patients have been recruited with recruitment expected until December 2022. A summary of the cohort is presented in the table. All patients will have SNP array genotyping and exome sequencing and 74% of the cohort have had a kidney biopsy (46.4% FSGS, 50.1% Minimal Change, 3.5% Other). We are currently analysing the data for detailed molecular stratification, and further research studies are invited.

**Conclusions:** NURTuRE-INS is a unique resource of high-quality patient samples alongside clinical data to mechanistically investigate INS patients. This will result in better disease management and help develop new treatments, as stratifying patients prior to clinical trial entry is likely to increase their success. Access to the data and biosamples will be available by application to an independent Strategic Oversight and Access Committee next year.

Long-Term Use of Voclosporin in Patients With Class V Lupus Nephritis: Results From the AURORA 2 Continuation Study

Dawn J. Caster,<sup>1</sup> Amit Saxena,<sup>2</sup> Salem Almaani,<sup>3</sup> Amber Rosales,<sup>4</sup> Henry Leher.<sup>4</sup> <sup>1</sup>University of Louisville, Louisville, KY; <sup>2</sup>NYU Langone Health, New York, NY; <sup>3</sup>The Ohio State University Wexner Medical Center, Columbus, OH; <sup>4</sup>Aurinia Pharmaceuticals Inc, Victoria, BC, Canada.

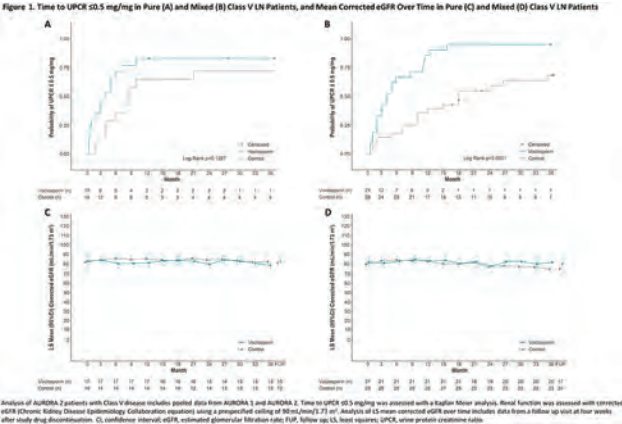

**Background:** Persistent proteinuria increases risk of comorbidities in lupus nephritis (LN) and rapid reductions in protein are predictive of improved long-term renal health. Patients (pts) with Class V LN may take longer to respond to therapy and treatments that efficiently reduce proteinuria in this population are needed. We report on a post-hoc analysis of voclosporin in Class V LN using three years of data from the Phase 3 AURORA 1 and AURORA 2 studies.

**Methods:** AURORA 1 enrolled pts with biopsy-proven active LN, UPCR ≥1.5 mg/mg (≥2.0 mg/mg for pure Class V), and eGFR >45 mL/min/1.73 m<sup>2</sup>. Pts completing AURORA 1 were eligible to enter AURORA 2 on the same blinded therapy (voclosporin or placebo) in combination with MMF and low-dose steroids. Hazard ratios (HR) for the time to UPCR ≤0.5 mg/mg and mean eGFR levels were assessed in pts with mixed and pure Class V LN.

**Results:** A total of 80 Class V pts continued treatment into AURORA 2. Baseline UPCR was 3.7 and 3.4 mg/mg in control and voclosporin arms, respectively. Differences between treatment arms in UPCR reductions were apparent within the first month and sustained at three years; the median time to UPCR ≤0.5 mg/mg was 3.7 and 16.3 months in the voclosporin and control arms, respectively (HR 2.54; p=0.0004). Results were similar in pure and mixed Class V voclosporin arms; control arms took longer to reach the endpoint (Figure 1). Mean corrected eGFR levels were similar in all treatment arms and stable throughout the study (Figure 1).

**Conclusions:** Voclosporin-treated pts with Class V LN saw substantial reductions in UPCR that occurred faster than in pts treated with MMF and low-dose steroids alone. Voclosporin may be beneficial in limiting the negative long-term impact of proteinuria in this population.

The Value of Repeat Kidney Biopsy-Based Directed Management of Lupus Nephritis: A Pilot Study in a Single Centre

Li Jin Ooi, U Zhe Ding, Arvind Ponnusamy. Royal Preston Hospital, Preston, United Kingdom.

**Background:** The duration of maintenance therapy for lupus nephritis (LN) has no fixed guidance at present. It has also been established that there is a discordance between clinical and histological remission. Studies have suggested using histological findings from a repeat renal biopsy as an adjunct to clinical parameters to guide treatment. We undertook a pilot study in a tertiary centre to assess the feasibility of repeat kidney biopsy in directing the management of LN.

**Methods:** Patients with biopsy-proven active lupus nephritis which include class 3,4,5 who had a subsequent planned elective biopsy at our centre (n=7). Disease activity was assessed using the NIH activity (AI) and chronicity indices (CI). Therapeutic management was then modified based on activity and chronicity index from second renal biopsy. AI > 2 was considered for continuation of immunosuppression and maintenance therapy to be reduced or stopped for those with lower AI index.

**Results:** The mean age of the first presentation of lupus nephritis was 51±14.1 years, 6 of whom were female. The median period between the first and subsequent biopsy was 29.9 months. Mean eGFR at first biopsy was 56.2±21.4, 70.5±19.5 at second biopsy and 65±21 at last follow up. uPCR at first biopsy was 666.3±393.2 mg/mmol, 80.6±134.3 mg/mmol at second biopsy and 57.7±88.6 mg/mmol at last follow up. Mean activity index was 7.5±3.3 at first biopsy and 0.67±0.82 (p<0.05) at second biopsy whilst the mean chronicity index was 1.17±0.98 at the first biopsy and 2.17±1.17 (p<0.05) at the second biopsy. Following the results from the second biopsy, Immunosuppression therapy was escalated for 1 patient, reduced for 4 patients, and stopped for 2 patients of whom both had no further relapse at the last follow up.

**Conclusions:** Our pilot study suggests that renal biopsy is a valuable tool alongside clinical parameters. Repeat kidney biopsy may prevent unnecessary continuation of immunosuppression without the risk of relapse. The data also showed that induction immunosuppression and rapid control of clinical disease activity did not necessarily prevent chronic damage in LN suggesting that there may be a role for anti-fibrotic agents. No adverse events were associated with the biopsies done in this cohort suggesting that this is safe. The data above was limited by its single-centre retrospective nature and small sample size.

FR-PO642

Characteristics and Outcomes of a Lupus Nephritis Cohort From Latin America

María F. Zavala Miranda,<sup>1,2</sup> Abril A. Pérez Arias,<sup>1,3</sup> Sofia E. M. Macedo,<sup>1,2</sup> Luis E. Morales-Buenrostro,<sup>1,2</sup> Roque A. Comunidad Bonilla,<sup>1</sup> Juan M. Mejía-Vilet.<sup>1,2</sup> <sup>1</sup>Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; <sup>2</sup>Universidad Nacional Autonoma de Mexico, Mexico City, Mexico; <sup>3</sup>Universidad Autonoma de Baja California, Mexicali, Mexico.

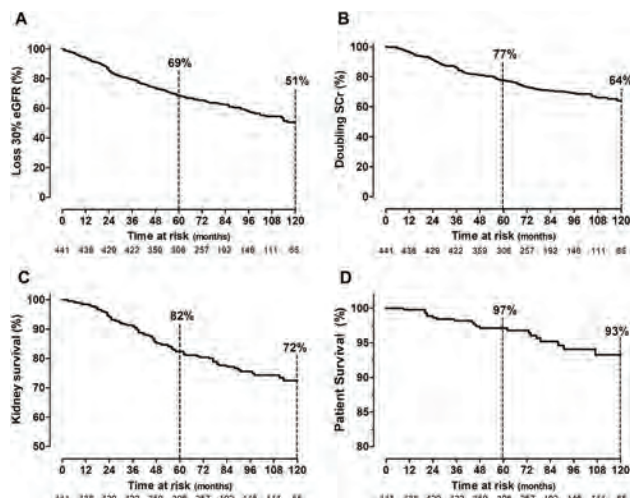

**Background:** Differences in Lupus nephritis (LN) presentation, prognosis, and rates of progression to end-stage renal disease (ESRD) have been described among patients from different genetic backgrounds, ethnicities, and geographic regions. Our aim was to characterize the clinical presentation and outcomes of a Hispanic population from Latin America.

**Methods:** We studied 441 subjects with systemic lupus erythematosus and biopsy-proven LN followed for >36 months. We obtained demographic, clinical, laboratory, histopathological, and treatment variables. All outcomes were analyzed by survival analysis and included the response to therapy, renal relapses, progression of kidney disease (decline in eGFR≥30%, doubling of serum creatinine, ESRD), and patient survival.

**Results:** The median age of the study cohort was 29 years (IQR 23-37), and 96% were female. The median eGFR at inclusion was 81mL/min/1.73m<sup>2</sup> (IQR 48-118), and 24h-uPCR was 3.4g/g (IQR 1.9-5.6). Mixed class LN (III/IV+V) was the most frequent. Over a median follow-up of 79 months, complete response rates were 22.3%, 41.7%, and 51.7%, at 6-, 12-, and 24-months, respectively. Renal relapse rates were 32.2% and 50.6% at 3- and 5-years. By 3- and 5-years, 20.9% and 31.5% had decline in eGFR ≥30%, 13.8% and 22.8% doubled their serum creatinine, and 8.6% and 17.7% progressed to ESRD. The factors associated with adverse kidney outcomes were age, eGFR at presentation, the histologic chronicity index, and the response to therapy. Patient survival was 98.2% and 97.1% at 3- and 5-years.

**Conclusions:** The response to treatment and patient survival in our cohort is comparable to that observed in other regions, there is a high rate of renal relapses and progression to ESRD.

Rates of progression to loss of kidney function by response status at different months of follow up.

### FR-PO643

#### Trends in Lupus Nephritis: The Co-Management Conundrum

Ryan Rex, Denise Foy. *Spherix Global Insights, Exton, PA.*

**Background:** With new lupus nephritis (LN) treatment options available, patient management is more complex and co-management between nephrologists and rheumatologists presents challenges.

**Methods:** Nephrologists (n=50) and Rheumatologists (n=50) have been surveyed monthly beginning in Feb. 2021 regarding their use of belimumab and voclosporin in LN. Between Aug. 30 and Oct. 30, 2021, we conducted a retrospective, HIPAA-compliant chart audit (n=954 charts for pts with Class III, IV +/-V LN) in collaboration with 92 nephrologists and 110 rheumatologists.

**Results:** Longitudinal tracking of voclosporin and belimumab highlight increased rate of initiation and utilization among rheumatologists and nephrologists for both agents, however notable differences are emerging. Additionally, a potential gap in care is noted as 65% of nephrologists and 72% of rheumatologists agree "Co-management between rheumatologists and nephrologists for patients with LN could be vastly improved." As of May 2022, the percent of physicians prescribing voclosporin is higher among nephrologists than rheumatologists (52% vs. 40%), however, patient initiations by rheumatologists are beginning to outpace those by nephrologists. While both groups used calcineurin inhibitors (CNIs) in about 10% of patients in the chart audit, rheumatologists were more likely to use voclosporin than nephrologists who reported higher use of traditional CNIs (Figure 1 uploaded). Rheumatologists have decades-long experience using belimumab in SLE which translates to greater experience in LN for rheumatologists vs. nephrologists (92% vs. 74%). Rheumatologists report managing over three times as many LN patients on belimumab to date (9.4 vs. 2.6). Further, nephrologists report more than half of their patients on belimumab were initiated by the rheumatologist whereas the converse tends not to occur.

**Conclusions:** Our data suggests rheumatologists are taking increased ownership of treatment initiation and LN patient management. In addition to vast experience with belimumab in SLE, rheumatologists' experience with biologic agents and in-office administration helps them navigate the prior authorization process. It is likely rheumatologists will refer patients to nephrologists later than in the past now that new treatment options are available.

Figure 1.

	Nephro	Rheum
% of LN pts on CNIs	10.2%	10.2%
voclosporin	24%	44%
tacrolimus	60%	46%
cyclosporine	16%	10%

### FR-PO644

#### Lymphangiogenesis in Biopsy-Proven Lupus Nephritis

Jihyun Yeom, Kyung Pyo Kang. *Jeonbuk National University Hospital, Jeonju, Jeollabuk-do, Republic of Korea.*

**Background:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by immune complex deposits, inflammatory cell infiltrations in multiple organs, and approximately half of the patients affected kidneys. The histological class and degree of activity/chronicity affected the therapeutic plan and prognosis in lupus nephritis. Thus, we intend to elucidate the correlation between lymphangiogenesis and activity indices in LN patients.

**Methods:** This study was reviewed and approved by the Institutional Review Board of Jeonbuk National University Hospital (CUH- 2020-07-032-001). We reviewed medical records for the biopsy-proven lupus nephritis and immunohistochemistry for D2-40

was performed. D2-40 positive lymphatic vessels were counted in the whole cortex of biopsy specimens, and the density of lymphatics was determined by computer-assisted morphometric analysis (magnification x200).

**Results:** Table 1 shows the clinical characteristics of the patient in our study. All 6 patients were women, demonstrating a female predominance in lupus, and renal manifestation occurred firstly in 2 patients at the time of diagnosis of lupus. In addition, 4 patients were proliferative lupus nephritis and showed high ANA titer, lower C3 levels, and higher activity indices. Figure 1 describes the correlation between the expression of D2-40 positive lymphatic vessels and lupus activity indices, and two factors have a positive correlation. (p value=0.0302)

**Conclusions:** Our study shows the higher the activity indices, the more the expression of lymphatic vessels in lupus nephritis, which may help set treatment target in the future.

### FR-PO645

#### Safety and Tolerability of Avacopan During the Early Access Program for ANCA-Associated Vasculitis

Jolijn R. van Leeuwen, Yoe Kie Onno Teng. *Leids Universitair Medisch Centrum, Leiden, Netherlands.*

**Background:** ANCA-associated vasculitis (AAV), a rare and severe disease, is associated with a high risk of complications from AAV and the treatment's toxic effects. Avacopan, a selective C5aR inhibitor, was recently approved for the adjunctive treatment of AAV. As part of the Early Access Program (EAP), the safety and tolerability of thirty patients treated with avacopan were analyzed.

**Methods:** Safety data was recorded in a global safety database between February 2019 and November 2021. All participating physicians were ADVOCATE investigators with previous avacopan experience and safety training, including recognizing adverse events (AEs). The safety and tolerability of avacopan during the EAP are described below.

**Results:** Thirty AAV patients had avacopan exposure during three years of EAP. Twenty-four AEs were reported in eight individual case safety reports (ICSRs) from eight patients (27%). Seventy-three percent (22 patients) of patients did not report any AEs. No deaths were reported. Fifteen events in five patients (16.7%) were considered serious AEs (SAEs) and are listed by System Organ Class in Table 1. Four SAEs were categorized as infection-related events occurring in two patients (6.7%), resulting in three hospitalizations. Six SAEs in 2 patients were assessed as related to avacopan by the reporter, leading to the discontinuation of Avacopan.

**Conclusions:** Serious Adverse Events occurred in five patients (16.7%). The most frequently reported SAEs were observed in the Infections and infestations and Renal and Urinary disorders SOCs. Seventy-three percent (22 patients) of patients did not report any AEs.

Serious Adverse Events reported in 30 AAV patients enrolled in the EAP

System Organ Class (Preferred Term)	SAE n (%); #	SAEs related to Avacopan® n (%); #
Infections and infestations (Klebsiella infection, Staphylococcal bacteremia, Ursosepsis, COVID 19)	2 (6.7%); 4	1 (3.3%); 3
Renal and urinary disorders (Acute kidney injury, End-stage renal disease, Renal failure, Renal impairment)	3 (10%); 4	1 (3.3%); 1
Eye disorders (Age-related macular degeneration, Visual acuity reduced, Metamorphopsia, Retinal edema)	1 (3.3%); 4	1 (3.3%); 1
Blood and lymphatic system disorders (Lymphopenia)	1 (3.3%); 1	-

FR-PO646

**Maintenance of ANCA Vasculitis Remission by Intermittent Rituximab Dosing Based on B Cell Reconstitution vs. Serologic ANCA Flare**  
Reza Zonozi,<sup>1</sup> Frank B. Cortazar,<sup>2</sup> Pravart Nithagon,<sup>1</sup> Noah Huizenga,<sup>1</sup> Anushya Jeyabalan,<sup>1</sup> John Niles.<sup>1</sup> <sup>1</sup>Massachusetts General Hospital, Boston, MA; <sup>2</sup>Vasculitis and Glomerular Disease Center, Albany, NY.

**Background:** Fixed-schedule rituximab dosing over 2 years is effective at maintaining remission for patients with ANCA vasculitis. However, rituximab is associated with adverse events. The ideal dosing strategy for long-term maintenance of remission remains unknown.

**Methods:** This is an open-label, single center, randomized and two-arm controlled trial. Inclusion criteria were AAV, in remission on fixed-rituximab for at least 2 years, and off other immunosuppression including steroids. Exclusion criteria were IgG level < 300 mg/dL and another disease with life expectancy < 36 months. BVAS, B cells and ANCA titers are monitored every 3 months. In the B cell arm, rituximab 1000 mg is reinfused once peripheral B cells are > 10 B cells/mm<sup>3</sup>. In the ANCA arm, rituximab 1000 mg is reinfused x 2 for significant ANCA titer increase. Randomization was stratified by ANCA serotype. The primary outcome measured was clinical relapse, defined by BVAS-WG ≥ 2. Secondary outcomes of interest included SAEs.

**Results:** 57 subjects were randomized to the ANCA arm, and 58 patients to the B cell arm. The median follow-up time was 4.1 years (IQR, 2.5 - 5.0). At 3 years 4.1% (95% CI, 1.0 - 15.6) of patients in the B cell arm experienced a clinical relapse, compared to 20.5% (95% CI, 11.9 - 34.1) of patients in the ANCA arm (log-rank p = 0.045). 22 SAEs occurred in the ANCA arm, compared to 21 in the B cell arm (NS). Discontinuation rate of rituximab due to any SAE/AE(s) was 13.6% (95% CI, 6.7 – 26.4%) in the B cell arm, and 0% in the ANCA arm, at 3 years after entry (log-rank p = 0.02).

**Conclusions:** In patients with AAV in remission after 2 years of continuous rituximab, tailoring rituximab to B cell return is associated with lower rates of clinical relapse, but higher rates of drug discontinuation due to an adverse event, compared to tailoring rituximab to ANCA rise.

Figure 1. Kaplan-Meier curve to time to clinical relapse.

FR-PO647

**Impact of Immunosuppressive Therapy on Vascular and Vasogenic Alterations of the Central Nervous System in Patients With ANCA-Associated Vasculitis With Renal Involvement**  
Arkadiusz Lubas, Artur Maliborski, Anna Grzywacz, Grzegorz Splocharski, Stanislaw Niemczyk. *Wojoskwy Instytut Medyczny, Warszawa, Poland.*

**Background:** The data concerning the prevalence of CNS vasculitis in patients with ANCA-associated vasculitis (AAV) with renal involvement is limited. Moreover, the efficacy of systemic immunosuppressive therapy (IS) on CNS alterations in this

population of patients was not clearly evidenced. This study aimed to prospectively estimate the occurrence of CNS vascular alterations and the influence of 1-year IS in patients with AAV with renal involvement.

**Methods:** Patients with acute onset of AAV with renal involvement qualified for the intensive IS were prospectively included in the study. As the treatment, an induction and a maintenance IS were provided. BVAS, creatinine, MPO-ANCA, PR3-ANCA, and non-contrast brain MRI angiography were estimated initially and after 12 months. Vascular alterations in the form of alternating narrowing and dilatation (aND) in secondary and tertiary cerebral artery branches (CAB) were investigated. Moreover, the number of focal ischemic white matter lesions (WML) was estimated. McNamara test was used to compare dependent categorical variables and Wilcoxon's test for continuous dependent variables comparison.

**Results:** In total, 17 patients who completed both brain MRI assessments were included in the study. Initially, aND was found in 12/17 (70.5%) patients, but after treatment, these alterations were investigated in 7/12 (41.2%) participants (p=0.074). In the secondary CAB IS resulted in 50% decrease of aND (10/17 vs. 5/17; p=0.074). Moreover, the reduction of aND in tertiary CAB was significant (9/17 (52.9%) vs. 3/17 (17.6%); p=0.041). In all participants, WML were detected before and after the IS, and the IS did not change the number of these lesions. A significant decrease in BVAS (7.76 ±3.49 vs. 0.65 ±0.86; p<0.001) and MPO-ANCA (60.2 ±46.5 vs. 24.5 ±36.0 p<0.001) after IS was investigated. The decrease of creatinine and PR3-ANCA was not important.

**Conclusions:** The occurrence of brain vasculitis lesions is frequent in patients with a flare of ANCA-associated vasculitis with renal involvement. Immunosuppressive treatment decreases CNS vascular alterations, which corresponds with the decrease of MPO-ANCA and clinical activity of the disease.

**Funding:** Government Support - Non-U.S.

FR-PO648

**Do the Benefits of Subcutaneous Immunoglobulin Therapy for Secondary Hypogammaglobulinemia in ANCA Vasculitis Extend Beyond Infection Prevention?**  
Bryce M. Churilla, Faten F. Aqeel, Duvuru Geetha. *Johns Hopkins University School of Medicine, Baltimore, MD.*

**Background:** Rituximab (RTX) is an effective treatment for induction and maintenance of remission in ANCA-associated vasculitides (AAV). However, hypogammaglobulinemia and increased infection risk remain a concern. Subcutaneous immunoglobulin (SCIG) therapy has been shown to improve this RTX induced side effect, but its impact on disease remission is not known.

**Methods:** This observational report highlights a single-center series of 5 AAV patients treated with RTX for remission induction. These individuals received SCIG for moderate to severe IgG deficiency. We examined the effects of SCIG on serum IgG level, disease remission, rituximab use, relapses and infections in this cohort.

**Results:** The median age was 68 yrs, 3 had relapsing disease and 3 were PR3 ANCA positive. At baseline, 4 patients had experienced recurrent infections. Serum IgG levels improved with SCIG administration in all patients and recurrence of infection markedly improved (Table 1). Post SCIG, RTX was either no longer needed or ultimately discontinued. All patients remained in disease remission with SCIG administration with no relapses noted.

**Conclusions:** SCIG therapy has been shown to improve hypogammaglobulinemia in RTX treated AAV. However, our report highlights a potential benefit in minimizing relapses in these patients. This finding which is of significance in management of AAV needs to be confirmed in clinical trials.

ID	Age, Sex	Maintenance Treatment		Number of Infections		Number of AAV Relapses		Current Immunosuppression
		Before SCIG	After SCIG	Before SCIG	After SCIG	Before SCIG	After SCIG	
1	68, F	RTX every 6 months and then every 4 months	RTX stopped	5	1	2	None	Prednisone
2	79, F	None	None	4	None	None	None	None
3	69, F	AZA, Prednisone	None	5	None	None	None	Prednisone
4	16, M	AZA, LEF, Prednisone, RTX 1000 mg every 6 months	RTX dose and duration decreased initially and then stopped	None	None	6	None	None
5	50, M	RTX every 6 months	RTX duration decreased initially and then stopped	3	None	1	None	None

ANCA: anti-neutrophil cytoplasmic antibody, AAV: ANCA-associated vasculitis, SCIG: subcutaneous immunoglobulins, F: female, M: male, RTX: Rituximab, AZA: Azathioprine, LEF: Leflunomide

FR-PO649

**Combined Activity and Chronicity Score for Prognostic Assessment in ANCA-Associated Vasculitis With Glomerulonephritis (AAV-GN)**  
Marta I. Casal Moura, Fernando C. Fervenza, Ulrich Specks, Sanjeev Sethi. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

**Background:** Previous studies have shown that chronic changes on kidney biopsy are useful for stratifying the risk of kidney failure in patients with AAV-GN. We aimed to evaluate the impact of inflammatory activity for the prediction of renal outcomes.

**Methods:** A retrospective cohort study of MPO- or PR3-ANCA positive patients with AAV and active renal disease. Inflammatory activity was assessed by the Activity Index (AI): a ratio between the number of crescents and/or necrosis and the total number of glomeruli

(in percent). We calculated the AI score (AIS): 0-5 = 0; 6-10 = 1; 11-15 = 2; 16-20 = 3; 21-25 = 4; 26-37.5 = 5; 37.6-50 = 6; 51-65 = 7; 66-80 = 8; 80-90 = 9; 90-100 = 10. Chronicity was evaluated with the Mayo Clinic Chronicity Score (MCCS). For the combined score, we summed the MCCS and the AIS.

**Results:** We analyzed 326 patients with kidney biopsies available to score. The biopsies had in median (IQR), 13 glomeruli (9-20), 4 crescents (2-6) and an AI of 28.6% (15.3-47.6). The population was classified according with the risk of progression to kidney failure (KF) in 3 classes as (i) low (0-6) – 114 (35%), (ii) intermediate (7-11) – 152 (46.6%), and (iii) high ( $\geq 12$ ) – 60 (18.4%). Median eGFR at baseline correlated with the overall risk categories: 42.2 vs. 22.1 vs. 13.4 mL/min/1.73 m<sup>2</sup>,  $p < 0.0001$ . Renal recovery was more frequent in patients at low risk of progression: 87.7% vs. 64.6% vs. 36.6%,  $p < 0.0001$ , whereas kidney failure at 12 months and dialysis were more frequent in patients at higher risk (36.7% vs. 12.4% vs. 3.8%,  $p < 0.0001$ ; 35.6% vs. 13.0% vs. 2.9%,  $p < 0.0001$ , respectively). The combination of AIS with MCCS independently predicted the risk of KF at 12 months (HR 1.916, 95%CI 1.210 - 3.033,  $p = 0.006$ ), particularly increased in patients classified as high risk (HR 3.124, 95%CI 1.224 - 7.970,  $p = 0.017$ ) and in patients with PR3-ANCA (HR 1.896, 95%CI 1.012 - 3.551,  $p = 0.046$ ) independently of eGFR at AAV-GN diagnosis and adjusted for severity of renal involvement and age.

**Conclusions:** The combined assessment of acute inflammatory activity and chronic changes on kidney histology independently predicted renal outcomes in patients with AAV-GN. The impact of the inflammatory activity is cumulative to the chronic changes.

## FR-PO650

### Development of a Radiomic-Clinical Nomogram to Predict the Treatment Resistance of Myeloperoxidase ANCA-Associated Vasculitis

Zhong Yong, Xiangya Hospital Central South University, Changsha, China.

**Background:** We aimed to develop a radiomics nomogram to predict the treatment resistance of MPO-AAV patients.

**Methods:** MPO-AAV patients were randomly assigned to a training cohort and a test cohort. Treatment-resistance related features were selected using multivariate logistic regression to obtain the radiomic score (Rad-score). Two models were built. The clinical utility of the good models was assessed by decision curve analysis (DCA). The calibration of combined radiomics nomogram was evaluated.

**Results:** Serum creatinine and 9 radiomics features were selected, which were related to the treatment resistance of MPO-AAV. The accuracy of Model 2 (radiomics nomogram) for the prediction of treatment resistance was 0.948 and 0.913 in the training and test cohorts, which was higher than Model 1 (radiomics) with the AUC of 0.824 ( $p = 0.039$ ), and 0.898 ( $p = 0.043$ ) respectively. The DCA curve demonstrated that Model 2 had a higher net clinical benefit than that of Models 1. The calibration curves of Model 2 closely aligned with the true treatment resistance rate in the training ( $p = 0.28$ ) and validation sets ( $p = 0.70$ ). Furthermore, the validation cohort gained a good AUC of 0.929 in the Model 2.

**Conclusions:** The radiomics nomogram is a useful for predicting the treatment resistance of MPO-AAV.

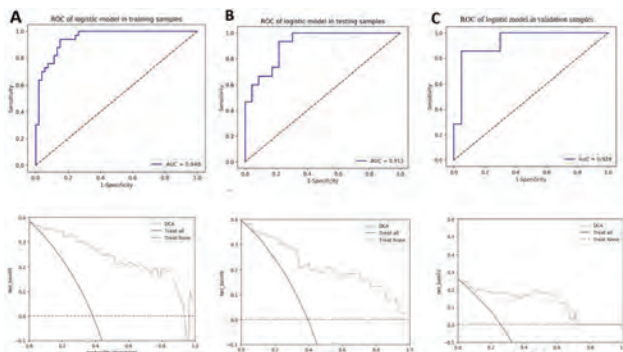

Figure 1: ROC curves of radiomics nomogram and decision curve analysis to detect the presence of treatment resistance in the training (A), test (B) and validation (C) cohort, respectively.

Figure 2: A Diagnostic accuracy of the rad-score in the training set and B diagnostic accuracy of the rad-score in the test set.

## FR-PO651

### Renal Recovery for Patients With Baseline eGFR $\leq 20$ in Avacopan ADVOCATE Trial

Frank B. Cortazar,<sup>1</sup> David R. Jayne,<sup>2</sup> Annette Bruchfeld,<sup>3</sup> Pirow Bekker.<sup>4</sup>  
<sup>1</sup>Saint Peter's Hospital, Albany, NY; <sup>2</sup>University of Cambridge, Cambridge, United Kingdom; <sup>3</sup>Karolinska Institutet, Stockholm, Sweden; <sup>4</sup>ChemoCentryx Inc, San Carlos, CA.

**Background:** In the 330-patient ADVOCATE trial, where 81% of patients with ANCA-associated vasculitis had renal involvement, estimated glomerular filtration rate (eGFR) increased on average 7.3 mL/min/1.73 m<sup>2</sup> with avacopan and 4.1 in the prednisone group ( $P = 0.029$ ) at Week 52 (Jayne et al. 2021).

**Methods:** The aim of this post hoc analysis was to evaluate changes in eGFR in the 50 patients in ADVOCATE who approached the dialysis threshold, i.e., eGFR  $\leq 20$  mL/min/1.73 m<sup>2</sup>.

**Results:** The mean age was similar to the overall study population (66 vs. 61 years), but with a higher proportion of newly diagnosed (88 vs. 69%), MPO+ (84 vs. 57%) and MPA patients (72 vs. 45%), and higher cyclophosphamide use (50 vs. 35%; Table). eGFR increased on average 16.1 and 7.7 mL/min/1.73 m<sup>2</sup> at Week 52 in the avacopan and prednisone groups, respectively ( $P = 0.003$ ). More patients in the avacopan group had an increase in eGFR of  $\geq 2$ -fold ( $P = 0.030$ ) and above 20 mL/min/1.73 m<sup>2</sup> ( $P = 0.024$ ), and a higher number of patients had increases in eGFR above 30 and 45 mL/min/1.73 m<sup>2</sup>. eGFR in one patient in the avacopan group increased to 65 at Week 52 (baseline 17). Serious adverse events occurred in 13/27 patients (48%) in the avacopan group (1 death due to bronchopneumonia) and 16/23 patients (70%) in the prednisone group (1 death due to pleural effusion).

**Conclusions:** In ADVOCATE eGFR improved more in the avacopan vs. control group, with greater proportional GFR recovery in those with the most severe renal involvement. Reference: Jayne et al. NEJM 2021;384:599-609.

**Funding:** Commercial Support - ChemoCentryx

### eGFR Results

	Avacopan (N=27)	Prednisone (N=23)
Age (years), mean (SD)	67.1 (11.13)	64.8 (17.22)
Newly diagnosed / Relapsed AAV	23 (85%) / 4 (15%)	21 (91%) / 2 (9%)
Myeloperoxidase+ / Proteinase 3+ AAV	22 (81%) / 5 (19%)	20 (87%) / 3 (13%)

### Analysis of Clinical Outcomes in ANCA-Associated Glomerulonephritis Treated With Rituximab: A Single Center Experience in Japan

Soko Kawashima, Shinya Kaname, Kyorin Daigaku Igakubu Fuzoku Byoin, Mitaka, Japan.

**Background:** Contrary to many Western countries, MPO-AAV is dominant in Japan. The therapeutic response to rituximab (RTX) might differ. Therefore, we conducted a retrospective analysis of the clinical database of the 80 ANCA associated glomerulonephritis (ANCA-GN)-patients in our hospital.

**Methods:** All patients met the CHCC classification criteria for MPA and GPA at disease onset. Eighty patients [53(66%) females] followed for at least six months since 2014 (up to Mar 2022) were analyzed. Remission was defined as BVAS 0. We divided the ANCA-GN patients into the 4 groups [Group 1 (RTX induction+, maintenance+): 18 cases), Group 2 (RTX induction+, maintenance-): 13), Group 3 (immunosuppressant+): 23) and Group 4 (glucocorticoid only): 26)], and their clinical features and renal prognosis were compared.

**Results:** Of the 80 patients (53 MPO-MPA, 21 MPO-GPA, and 6 PR3-GPA), patients [25 newly diagnosed or 6 relapsing diseases] received a remission induction with RTX therapy. The frequencies of RPGN in ANCA-GN were 69%, 72% in group 1, 85% in group 2, 22% in group 3 and 73% in group 4, respectively. The average ages at onset were 64.5  $\pm$  15.6, 79.5  $\pm$  5.1, 74.5  $\pm$  8.1, 81.7  $\pm$  5.5 years. The mean ages at the initiation of RTX were 65.8  $\pm$  14.8 in group 1, 80  $\pm$  5.2 in group 2, of which 33%, 92% were over 75 years. Maintenance therapy was given more often based on changes in CD19+ counts and/or ANCA titer in 81%, as compared to scheduled administration every 6 months. The BVAS were 14.3  $\pm$  6.2, 17.9  $\pm$  2.8, 12.2  $\pm$  4.2, 13.8  $\pm$  5.8. Serum creatinine levels (mg/dl) were 1.9  $\pm$  1.1, 2.7  $\pm$  1.5, 1.7  $\pm$  1.8, 3.1  $\pm$  2.7. Group 1 had high survival and renal survival, which was better than group 3. Most of the deaths in group 2 and 4 were within 1 year,

and renal death had already occurred at the intervention within 3 months during induction therapy. Infection was the most common cause of death in all groups. In group 1 and 2, there was a tendency for recovery of renal function 1 year after the induction of remission, indeed, the dialysis withdrawal rates were 88%. The remission rates at 6/12 months were 85/77, 73/55, 92/67, 58/58%. The achievement rates of daily PSL dose of 10mg at 6 months/5mg at 12 months were 62/54, 64/45, 25/8, 26/11%.

**Conclusions:** These results showed that RTX is effective and has an acceptable safety profile in relatively elder AAV-GN patients in daily practice.

## FR-PO653

### Interstitial ANCA-Associated Vasculitis Associates With Severe Kidney Injury Independent of Glomerulonephritis

Desiree Tampe, Samy Hakroush, Bjoern Tampe. *University Medical Center Göttingen, Göttingen, Germany.*

**Background:** Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a small vessel vasculitis affecting multiple organ systems, including the kidney. Small vessels in the kidney include small-sized arteries (interlobular artery, afferent and efferent arteriole), capillaries (glomerular and peritubular capillary) and venules. Although crescentic ANCA glomerulonephritis (GN) is a common histological finding reflecting glomerular small vessel vasculitis, it is reasonable that manifestation of AAV could also contribute to interstitial small vessel vasculitis.

**Methods:** A total number of 49 kidney biopsies with confirmed renal involvement of AAV were retrospectively included, a renal pathologist evaluated all biopsies and was blinded to clinical data collection and analysis.

**Results:** Among all active and chronic tubulointerstitial lesions analogous to the Banff scoring system, the only association between severe kidney injury requiring kidney replacement therapy (KRT) was observed for interstitial vasculitis in AAV reflected by peritubular capillaritis (ptc,  $p=0.0002$ ) and arteritis (v,  $p=0.0069$ ), affecting 5/49 (10.2%) and 11/49 (22.4%) of renal biopsies, respectively. Interestingly, no association between interstitial vasculitis (ptc and v correlating with severe kidney injury) and any glomerular lesion in ANCA GN (also correlating with severe kidney injury) was observed, thereby confirming that interstitial vasculitis contributes to severe kidney injury independent of ANCA GN. By contrast, short-term renal recovery from KRT was equal in both groups, suggesting a distinct association with acute decline of kidney function at disease onset.

**Conclusions:** Taken together, by using the Banff scoring system we here expand our current knowledge of renal interstitial lesions in AAV revealing peritubular capillaritis and arteritis as important histological alterations associated with severe kidney injury in a considerable subset of AAV. Furthermore, our findings that interstitial vasculitis did not correlate with crescentic ANCA GN implicate that the characteristics of each vasculitis manifestation are independent and could further improve our understanding of mechanisms contributing to renal injury.

## FR-PO654

### Comparison of Outcomes Between Rituximab and Cyclophosphamide for Primary Membranous Nephropathy: A Single Center Experience

Azm U. Hussain, Nadia Sarween. *University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

**Background:** Rituximab is increasingly being considered first-line treatment for Primary membranous nephropathy. While treatment outcomes have been compared to Calcineurin inhibitors there is no randomized controlled trial to date comparing Rituximab with a Cyclophosphamide-based regime. We aimed to review the outcomes of both treatments at our centre.

**Methods:** All patients with a diagnosis of Primary Membranous Nephropathy made between 2011 and 2020 were included in the study and identified through histology records. The follow-up period was until December 2021. Data were extracted from hospital electronic patient records. Secondary Membranous nephropathy and disease occurring in renal transplant recipients were excluded. Any patient who received Rituximab or cyclophosphamide were included and their clinical outcomes were compared. Complete remission was defined as a reduction in proteinuria to less than 300mg/day while the partial remission was defined as a reduction in proteinuria of  $\geq 50$  per cent from baseline and to  $>300$  mg/day and  $<3.5$  g/day. Statistical analysis was performed using Pearson-Chi square and One way ANOVA tests.

**Results:** 50 patients were identified with a diagnosis of primary membranous nephropathy and received treatment with either or both Cyclophosphamide, and Rituximab. The mean age of participants was 53 years with 30% males, 72% ( $n=32$ ) were PLA2R positive at the point of diagnosis. Response rates between the two treatment groups were not significantly different with 20% achieving full remission in Cyclophosphamide versus 17% in the Rituximab treated group ( $p = 0.40$ ). There were significantly more partial remissions observed in the Cyclophosphamide versus Rituximab group (57% vs 24% respectively,  $p 0.003$ ). Time to favourable response was shorter in the Cyclophosphamide versus Rituximab group (7 vs 12.6 months respectively,  $p = 0.003$ ).

**Conclusions:** In our study, there is a suggestion that those treated with Cyclophosphamide versus Rituximab were more likely to respond to treatment. Patients treated with Rituximab also appear to take longer to respond. A trial comparing both treatments and reviewing short and long term responses is warranted.

## FR-PO655

### Outcomes of Idiopathic Membranous Nephropathy: A Single Centre Experience

Christina Bell, Anna K. Forbes, Benjamin Low, Sumaya Huque, Alexander F. Gardner, David Mäkanjuola, Bhriagu Raj Sood. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

**Background:** The immunosuppressive approach to treat idiopathic membranous nephropathy is highly variable and outcomes are inconsistent in the published literature.

**Methods:** We conducted a retrospective review of outcomes in patients with high-risk idiopathic membranous nephropathy treated with immunosuppression at a tertiary renal centre in London.

**Results:** We identified 44 patients, comprising 33 males and 11 females. Mean age was 58.6 years (standard deviation 13.4 years) and 82.6% were Caucasian. PLA2R antibody status was assessed in 59.1% (26/44 patients); of these 69.2% were positive. At treatment initiation median urine PCR was 962 mg/mmol (IQR 702 – 1277 mg/mmol), median albumin 21 g/L (IQR 16-28 g/L), median creatinine 136  $\mu$ mol/L (IQR 98 – 180  $\mu$ mol/L) and median eGFR 47 ml/min/1.73 m<sup>2</sup> (IQR 26 -60 ml/min/1.73 m<sup>2</sup>). First line therapy comprised of either IV cyclophosphamide in combination with oral prednisolone (C+P) (70.5%) or Tacrolimus monotherapy (Tac) (29.5%). We found a higher response rate in the Tac group at all time points (6,12 and 24 months) but these findings were not statistically significant. At 6 months, of those who received C+P 11.5% (3/26 patients) achieved complete remission (CR) and 46.2% (12/26 patients) achieved partial remission (PR). With Tac 45.5% (5/11 patients) achieved CR and 36.4% (4/11 patients) achieved PR. Relapse rates within 24 months of treatment initiation were higher in patients who received Tac at 23.1% compared with 12.9% in those treated with C+P. However, this finding was not statistically significant. 7 patients progressed to ESKD and required renal replacement therapy, including 4 on C+P and 3 on Tac.

**Conclusions:** We have been unable to identify a difference in outcomes between C+P and Tac immunosuppression treatment regimens. Published literature suggest Rituximab is superior in patients who are PLA2R antibody positive and we are in the process of analysing this in our population.

## FR-PO656

### Associations Between Biomarkers of Complement Activation, Galactose-Deficient IgA1 Antibody, and the Updated Oxford Pathology Classification of IgA Nephropathy

Yunting Juan,<sup>1</sup> Yen-Ling Chiu,<sup>1,2</sup> <sup>1</sup>*Far Eastern Memorial Hospital, New Taipei City, Taiwan;* <sup>2</sup>*Yuan Ze University, Chung-Li, Taiwan.*

**Background:** Our prior study indicates a close relationship between alternative complement pathway activation, Galactose-Deficient IgA1 (Gd-IgA1) concentration, and clinical severity of IgA nephropathy (IgAN). Nonetheless, the relationship between complement factors and the updated Oxford classification of IgAN remains unclear.

**Methods:** This study enrolled eighty-four previously-untreated, biopsy-diagnosed IgAN patients from two medical centers in Taiwan. The clinical and laboratory findings were collected at the time of biopsy. Plasma levels of complement factor C5a, factor Ba and Gd-IgA1 were measured and analyzed.

**Results:** It was found that levels of proteinuria positively correlated with the updated Oxford classification of mesangial hypercellularity (M), endocapillary hypercellularity (E), tubular atrophy/interstitial fibrosis (T), and crescents (C). In addition, plasma Gd-IgA1 titer was significantly elevated in IgAN patients with tubular atrophy/interstitial fibrosis (T). Factor Ba, a biomarker of the alternative pathway, is also significantly elevated in IgAN patients with tubular atrophy/interstitial fibrosis (T). A similar change was detected for factor C5a but the difference did not reach statistical significance. Levels of factor Ba also negatively correlated with eGFR and positively correlated with proteinuria.

**Conclusions:** The results indicate that both levels of Gd-IgA1 antibody and factor Ba reflect the Oxford classification on IgAN. Whether these biomarkers can be used to guide therapeutic decisions requires further study.

## FR-PO657

### Prevalence of Optimal Conservative Therapy Implementation Among CureGN Participants With IgA Nephropathy

Arun Rajasekaran,<sup>1</sup> Maria Larkina,<sup>2</sup> Bruce A. Julian,<sup>1</sup> Laura H. Mariani,<sup>2</sup> Dana Rizk.<sup>1</sup> <sup>1</sup>*The University of Alabama at Birmingham School of Medicine, Birmingham, AL;* <sup>2</sup>*University of Michigan Michigan Medicine, Ann Arbor, MI.*

**Background:** Immunoglobulin A nephropathy [IgAN] is the most common primary glomerulonephritis in many countries; 20-40% of patients progress to kidney failure by 20 yr after diagnosis. Optimized supportive care is pivotal in addressing modifiable risk factors for progression, including hypertension and proteinuria. Through the Cure Glomerulopathy [CureGN] study, we sought to ascertain prevalence of optimal BP and proteinuria control, and maximal renin angiotensin aldosterone system inhibitor [RAASi] use among IgAN adults at enrollment and longitudinally.

**Methods:** CureGN, an observational longitudinal study, enrolled 458 adults  $\geq 18$  yr with primary IgAN within 5 yr of initial diagnostic kidney biopsy. BP was measured annually and urine protein-to-creatinine ratio [UPCR] values were obtained within 60 d of study visit. RAASi prescription patterns and dosing were ascertained at enrollment and longitudinally. Enrollment visits were classified as incident [ $< 6$  mo of biopsy] or prevalent [ $\geq 6$  mo post biopsy]. Goals for BP and proteinuria control were the 2012 KDIGO guidelines at study inception.

**Results:** At enrollment [median 359 d from initial biopsy], 41% patients had optimal supportive care for BP and proteinuria. Of the 59% patients with suboptimal BP and proteinuria: 7% were not on RAASI, 28% were on sub-maximal RAASI, and 24% were on maximal RAASI not at BP goal. At enrollment, only 36% incident and 45% prevalent patients had achieved optimal supportive care. Longitudinal data after initial biopsy showed > 50% participants had sub-optimal BP [ $\geq 125/75$  mm Hg] and UPCR [ $\geq 1$  g/g] up to 5.5 yr after diagnosis. [Figure 1]

**Conclusions:** Suboptimal control of BP and proteinuria was common in adults with IgAN in the 5 yr after diagnosis. Application of the more stringent 2021 KDIGO guidelines would likely indicate more at-risk patients. These findings highlight the need to continue education about the importance of conservative management. Many participants had proteinuria despite optimal BP, a group that would benefit from enrollment in clinical trials testing therapies that could mitigate disease progression.

## FR-PO658

### Practice Patterns in IgA Nephropathy: A Questionnaire-Based Survey

**Bhavik Bansal**,<sup>1</sup> Amritesh Grewal,<sup>1</sup> Hernan Trimarchi,<sup>2</sup> Boon Wee Teo,<sup>3</sup> Yuko Shima,<sup>4</sup> Madhivanan Sundaram,<sup>5</sup> Haidong He,<sup>6</sup> Arunkumar Subbiah,<sup>7</sup> Dipankar M. Bhowmik,<sup>7</sup> Sanjay K. Agarwal,<sup>7</sup> Soumita Bagchi.<sup>7</sup> <sup>1</sup>Medical Student, All India Institute of Medical Sciences, New Delhi, New Delhi, India; <sup>2</sup>Nephrology Service, Hospital Británico Buenos Aires Argentina, Buenos Aires, Argentina; <sup>3</sup>Division of Nephrology, Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Queenstown, Singapore; <sup>4</sup>Pediatrics, Wakayama Medical University, Japan, Wakayama, Japan; <sup>5</sup>Department of Nephrology, Royal Darwin Hospital, Darwin, Australia, Darwin, NT, Australia; <sup>6</sup>Division of Nephrology, Fudan University, Minhang Hospital, Shanghai, China, Shanghai, China; <sup>7</sup>Nephrology Department, All India Institute of Medical Sciences, New Delhi, India, New Delhi, India.

**Background:** IgA nephropathy (IgAN) is a common primary glomerular disease with ethnic differences in phenotype. The Kidney Disease Improving Global Outcomes (KDIGO) has provided guidelines for management of IgAN but the actual practice patterns among nephrologists is not known.

**Methods:** An online questionnaire-based survey was conducted focussing on treatment strategies practiced by nephrologists in management of IgAN.

**Results:** Among 402 responders, 76.9% treat adults, 9.2% paediatric patients and 13.9% both. 61.2% respondents were from Asia, 18.4% from South America, 9.7% from North America, 7.2% from Europe and 3.5% from Australia. MEST-C score was not reported in 12.7% centres, mainly in Australia (28.6%) and South America (23.0%). 97% nephrologists use initial supportive therapy by renin angiotensin system (RAS) blockade with ACEi /ARB; ramipril (20.8%) and losartan (23.6%) being most preferred. Also, 26.1% use dual RAS blockade and 56.7% aldosterone blockers. Other treatments used are fish oil (45.0%), SGLT-2 inhibitors (49.5%) and hydroxychloroquine (13.4%). Though 59.5% target blood pressure <130/80 mm Hg, 37.1% target <120/80 mm Hg. Most nephrologists wait 3-6 months (42.4%) or >6 months (26.6%) before starting immunosuppression. For starting immunosuppression, 92.8% consider degree of proteinuria, 79.1% eGFR and 65.7% MEST-C score. 40.6% start immunosuppression immediately if proteinuria is >3g/day. 31.1% use immunosuppression in non-crescentic IgAN with eGFR <30 ml/min/1.73m<sup>2</sup>. 89.1% use steroids as first line immunosuppression, while 6.5% use mycophenolate mofetil (MMF). 86.6% use second line immunosuppression in steroid resistant patients, MMF (50%) being most commonly prescribed. 99.2% use immunosuppression for C2 lesions: steroids + cyclophosphamide is the most commonly used regimen (66.7%). 43.5% use immunosuppression in all cases with C1 lesions, 47% individualize therapy based on eGFR and proteinuria while 9.5% do not use immunosuppression.

**Conclusions:** Although most nephrologists agree on the parameters to assess disease status, there is heterogeneity in type of supportive therapy and immunosuppression used especially in difficult to treat cases.

## FR-PO659

### Updated Interim Results of a Phase 1/2 Study of BION-1301 in Patients With IgA Nephropathy

**Jonathan Barratt**,<sup>1</sup> Laura Kooienga,<sup>2</sup> Irfan Agha,<sup>3</sup> Hanna Thomas,<sup>3</sup> Biruh Workeneh,<sup>4</sup> Sai Prasad N. Iyer,<sup>5</sup> Rangaraj Narayanan,<sup>5</sup> Taher Sathaliya,<sup>5</sup> Bess Sorensen,<sup>5</sup> Brian S. Schwartz,<sup>5</sup> Andrew J. King.<sup>5</sup> <sup>1</sup>University of Leicester, Leicester, United Kingdom; <sup>2</sup>Colorado Kidney Care, Denver, CO; <sup>3</sup>Dallas Renal Group, Dallas, TX; <sup>4</sup>The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>5</sup>Chinook Therapeutics Inc, Seattle, WA.

**Background:** BION-1301 is a novel humanized monoclonal antibody that blocks a proliferation-inducing ligand (APRIL), a soluble factor that is elevated in patients with IgAN. APRIL promotes the production of pathogenic galactose-deficient IgA1 (Gd-IgA1), leading to immune complex deposition and kidney injury. Blocking APRIL with BION-1301 is a potential disease-modifying approach to directly target the pathogenesis of IgAN. In a Phase 1/2 study (NCT 03945318) in healthy volunteers and patients with IgAN, BION-1301 was well-tolerated with no SAEs and durably reduced free APRIL, IgA, Gd-IgA1, IgM and to a lesser extent, IgG. Here we present updated interim results in BION-1301-treated patients transitioned from IV to subcutaneous (SC) administration (Cohort 1) as well as novel data from IgAN patients with *de novo* SC administration (Cohort 2).

**Methods:** For the ongoing phase 1/2 open-label, multicohort trial, eligibility criteria include adults with biopsy-proven IgAN, eGFR  $\geq 30$  mL/min per 1.73 m<sup>2</sup>, baseline urine protein excretion  $\geq 0.5$  g/24 hrs or UPCR  $\geq 0.5$  g/g, and on stable/optimized RASi (or intolerant). Cohort 1 (n= 10) received 450 mg of BION-1301 administered IV every 2 weeks, transitioning to SC at 600 mg every 2 weeks after at least 24 weeks. Cohort 2 (n= 10) receives 600 mg of BION-1301 SC every 2 weeks.

**Results:** In patients with IgAN who transitioned from IV to SC (Cohort 1), BION-1301 was generally well-tolerated, with no SAEs or terminations due to AEs as of last observation (May 23, 2022). Durable reductions in serum levels of free APRIL and immunoglobulins were observed. As previously reported, clinically meaningful reductions in proteinuria were seen as early as 12 weeks (30.4% geometric mean UPCR reduction, n=7), were sustained through 52 weeks (70.9% geometric mean UPCR reduction, n=6), and were associated with reduced Gd-IgA1 levels. Preliminary response is consistent in patients transitioning from IV to SC. Updated data from Cohort 1 and novel data from Cohort 2 will be reported at the time of presentation.

**Conclusions:** BION-1301 offers disease-modifying potential by directly targeting the initiating pathogenesis of IgAN. Interim biomarker and clinical activity responses support advancement of BION-1301 into later-stage development for patients with IgAN.

**Funding:** Commercial Support - Chinook Therapeutics, Inc

## FR-PO660

### Long-Term Outcomes of Patients Treated With Tacrolimus as First Line Therapy for Minimal Change Disease

**Charlotte Seneschall**,<sup>1,2</sup> Rakesh Dattani,<sup>1</sup> Tom Cairns,<sup>1,2</sup> Stephen P. McAdoo,<sup>1,2</sup> Nicholas R. Medjeral-Thomas,<sup>1,2</sup> Megan Griffith,<sup>1,2</sup> <sup>1</sup>Imperial College London, London, United Kingdom; <sup>2</sup>Imperial College Healthcare NHS Trust, London, United Kingdom.

**Background:** Steroids are first line treatment for Minimal Change Disease (MCD) but have significant side effects. Increasingly, alternative immunosuppression such as tacrolimus is used, but there is no data on long term outcomes. This single centre retrospective study reviews long-term outcomes of patients treated with tacrolimus as first line therapy for MCD.

**Methods:** Adult patients with MCD followed up at Imperial College Hospitals NHS Trust were identified from the biopsy database. Clinical data was extracted from records of patients given tacrolimus monotherapy as initial treatment for MCD with >1yr follow up. Statistics were performed using GraphPadPrism.

**Results:** 50 patients had tacrolimus monotherapy as initial MCD treatment from 2004-2021. 21 were female, 29 male; 21 white, 2 Black, 16 Asian & 11 other/not stated. Median age 50.5yrs (17-83). Initial median albumin 13 (5-26), eGFR 90 (10-90). Median follow up 55.5 months (14-162). 44/50 remitted on tacrolimus, median 1 month (0.5-10). 6/50 failed to remit or were intolerant and were then changed to alternative therapy after median time 3.5 months (1-9). In total, 22/44 treated initially with tacrolimus relapsed. 4/44 relapsed on tacrolimus, including 2 noncompliant before relapse. 1 patient was lost to follow up. 39 had tacrolimus weaned or stopped. 17/39 subsequently relapsed: 5 relapsed on weaning & 12 relapsed after stopping. Median time from stopping tacrolimus to relapse was 3 months (1-55). 18/22 patients who relapsed were retreated with tacrolimus monotherapy and all entered remission. 10/18 patients had a 2nd relapse, 6 had a 3rd relapse, 4 had a 4th. There was no significant change in median eGFR for patients only treated with tacrolimus after 1, 3 and 5 years (p=0.73, 0.11, 0.27). No patients reached end stage renal failure.

**Conclusions:** Tacrolimus is an effective treatment for MCD that avoids steroids' side effects. As for steroids, relapse rates in adults are high. Low therapeutic levels increase relapse risk. Patients who initially respond to tacrolimus re-enter remission after 1st relapse. Subsequent relapse rates remain high. eGFR is generally maintained but should be monitored for individual patients.

## FR-PO661

**Long-Term Complications in Patients With Childhood-Onset Nephrotic Syndrome: A Report From a Tertiary Care Center in India**

Joyita Bharati,<sup>1,2</sup> <sup>1</sup>Post Graduate Institute of Medical Education and Research, Chandigarh, India; <sup>2</sup>North Shore University Hospital, Manhasset, NY.

**Background:** Childhood-onset nephrotic syndrome (NS), although commonly steroid-sensitive, is associated with long-term complications such as obesity, osteoporosis, growth failure, and hypertension. Reports on long-term complications of childhood-onset NS are mostly from developed countries not representing South-Asian ethnicities. Further, data on cardiovascular health among older children and young adults with childhood-onset NS are limited.

**Methods:** This was an observational study involving patients attending a tertiary care center. Patients aged 15 years or older, identified from the database of childhood-onset NS attending an adult renal clinic, were examined for long-term complications and long-term remission of NS at their visit in December 2021. Childhood-onset NS meant onset of NS before 10 years of age. Long-term complications included obesity, growth failure, low bone mineral density (BMD) Z score, hypertension, and increased carotid intima-media thickness (cIMT). Long-term remission was defined as no relapse for the last 3 consecutive years without immunosuppressive medication to maintain remission.

**Results:** Of 101 patients studied (~80% with frequent relapsing (FR)/steroid-dependent (SD)NS), the mean age was 17.6 (2.4) years at the time of the study. Long-term complications were noted in 89.1% of patients which included one or more of the following- obesity (22.7%), growth failure (31.7%), low BMD Z score (53.5%), hypertension (31.7%), and high cIMT (50.5%). Thirty-nine (38.6%) patients were in long-term remission at the time of the study. Growth failure and low BMD Z scores were less frequent in patients with long-term remission compared to those without long-term remission.

**Conclusions:** In Indian patients with childhood-onset NS (predominantly FR/SDNS) who were studied at 15 years of age, ~90% had long-term complications which included high cIMT in 50%. Only ~40% were in long-term remission.

## FR-PO662

**Predictors of Progression to Kidney Failure in Patients With Focal Segmental Glomerulosclerosis**

Katherine R. Tuttle,<sup>1,2</sup> Kenn B. Daratha,<sup>1</sup> Cami R. Jones,<sup>1</sup> Lindsey M. Kornowski,<sup>1</sup> Radica Z. Alicic,<sup>1,2</sup> Martin C. Bunke,<sup>3</sup> Kamlesh M. Thakker,<sup>3</sup> Diana T. Amari,<sup>3</sup> Lionel Pinto,<sup>3</sup> Kaijun Wang,<sup>3</sup> Keith C. Norris,<sup>4</sup> Susanne B. Nicholas,<sup>4</sup> CURE-CKD <sup>1</sup>Providence St Joseph Health, Spokane, WA; <sup>2</sup>University of Washington, Seattle, WA; <sup>3</sup>Traverse Therapeutics Inc, San Diego, CA; <sup>4</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; <sup>5</sup>Genesis Research LLC, Hoboken, NJ.

**Background:** Focal segmental glomerulosclerosis (FSGS) is a glomerular disease that often progresses to kidney failure. The study aim was to evaluate clinical predictors associated with progression to kidney failure from real-world data.

**Methods:** Electronic health records from the Center for Kidney Disease Research, Education, and Hope (CURE-CKD) Registry were used to derive the study population from Providence and UCLA Health systems. Demographics, clinical characteristics, and prescription medications were obtained for adults ≥18 years old with FSGS in 2016-2020. Cox proportional hazards modeling was used to evaluate predictors of a primary composite outcome of 40% eGFR decline or eGFR <15 mL/min/1.73 m<sup>2</sup> (≥2 measures ≥90 days apart).

**Results:** Adults with FSGS (N=384) were 45% women and 51±18 (mean±SD) years old. At baseline, median CKD-EPI 2021 eGFR was 49 (interquartile range 30-77) mL/min/1.73 m<sup>2</sup>; UACR/UPCR were 1155 (323-2605) mg/g & 1.9 (0.8-3.4) g/g; systolic blood pressure was 130±15 mm Hg. Prescription medications included: ACE inhibitors/ARBs 72%, glucocorticoids 42%, calcineurin inhibitors 19%. Primary outcome events occurred in 118 (31%) patients. Median (IQR) follow-up time was 2 (1-3) years. Higher baseline eGFR, older age, and longer follow-up time were associated with lower risk of the primary outcome. Predictors of higher risk were hospitalization, treatment at Providence, ACE inhibitor/ARB use, and more outpatient visits (Figure). In a sensitivity analysis adding those with baseline UACR/UPCR measures (n=219), UACR >300 mg/g & UPCR >0.5 g/g yielded a HR=4.41 (1.65-11.80) and overall model stability.

**Conclusions:** Nearly one third of adults with FSGS progressed to 40% eGFR decline or kidney failure over a median of 2 years. Higher risks reflected in intensity of health care utilization and system, as well as by ACE inhibitor/ARB use, may reflect more severe illness.

**Funding:** Commercial Support - Traverse Therapeutics

**Predictors of 40% eGFR decline or eGFR <15 mL/min/1.73m<sup>2</sup> in patients with FSGS in 2016-2020**

## FR-PO663

**Defining Immunosuppression Treatment Futility Indicators in Focal Segmental Glomerulosclerosis: A CureGN Study**

Brooke A. Blazius,<sup>1</sup> Shawn P. Sullivan,<sup>1</sup> Mahmoud Kallash,<sup>2</sup> Jason M. Kidd,<sup>3</sup> Howard Trachtman,<sup>1</sup> Rebecca Scherr,<sup>1</sup> Noelle E. Carlozzi,<sup>1</sup> Debbie Gipson,<sup>1</sup> <sup>1</sup>University of Michigan, Ann Arbor, MI; <sup>2</sup>Nationwide Children's Hospital, Columbus, OH; <sup>3</sup>Virginia Commonwealth University School of Medicine, Richmond, VA.

**Background:** Due to the heterogeneity of focal segmental glomerulosclerosis (FSGS) and potential for immunosuppressive therapy (IST) associated risks or non-responsiveness, decisions to initiate and to stop IST is relevant to practice but not evidence based. Physician perspectives on indicators of IST treatment futility in patients with FSGS at diagnosis (Never Start) and after a period of IST (Permanently Stop).

**Methods:** The study used a modified Delphi approach, including an expert panel of nephrologists to elicit Never Start and Permanently Stop concepts and key population subgroups for whom futility indicators may vary. Responses were coded and combined into futility concepts. An electronic survey was developed to elicit additional futility concepts to rate degree of agreement with each Expert Panel concepts using a Likert scale (strongly disagree to strongly agree), enriched by novel concepts reported by the responder. Survey 1 was distributed to practicing nephrologists via email.

**Results:** Four domains were elicited from the expert panel: biopsy findings, lab findings, complications/conditions, patient preference. A total of 109 responded to Survey 1. Pre-specified concepts that reached a threshold of 60% agree included 8/25 Never Start concepts and 14/26 Permanently Stop concepts (Fig). An additional six Never Start and six Permanently Stop concepts reached the 60% threshold for agree plus neutral responses and were included in Survey 1.

**Conclusions:** We found a high degree of conceptual agreement in FSGS IST futility indicators at diagnosis and when discontinuing therapy. Precise indicator thresholds will be confirmed in Survey 2. Future research will compare quantitative assessment of IST practice patterns by physician reported futility concepts at each clinical juncture.

**Funding:** NIDDK Support

Figure 1. Conceptual Model of IST Futility at FSGS Diagnosis and After a Period of Therapy

## FR-PO664

**Direct Oral Anticoagulants for Prophylaxis Against Thromboembolism in Patients With Nephrotic Syndrome**

Omar Osman, Luba Muaddi, Swati Arora. Allegheny Health Network, Pittsburgh, PA.

**Background:** Nephrotic Syndrome (NS) is associated with an increased risk of arterial and venous thromboembolic (VTE) complications when serum albumin is below 2.5 g/dL. Few case reports discussed the use of direct oral anticoagulants (DOACs) as treatment and prophylaxis for thromboembolism in patients with NS. The importance of this case series is to add to the existing literature on the experience of using DOACs in NS.

**Methods:** Charts of 9 patients with NS on DOACs were reviewed. Seven patients had biopsy proven membranous nephropathy, one patient had Class IV Lupus Nephritis and one had primary FSGS. Seven patients were using DOACs purely for VTE prophylaxis, one patient was already on DOAC for atrial fibrillation and one patient was on DOAC for treatment of an acute VTE. Demographic data along with baseline proteinuria, serum albumin and bleeding events were obtained for all patients.

**Results:** Of the 9 patients identified, 1 patient was given rivaroxaban for treatment of IVC thrombus which was extending into the renal veins. The remaining patients used apixaban as a form of prophylaxis for VTE. Follow up for patients on apixaban varied 3 to 24 months during which none of the patients developed VTE. DOACs were discontinued once serum albumin became greater than 2.5g/dL. Only one patient remained on a DOAC for an alternative indication.

**Conclusions:** The importance of our results highlight the use of DOACs for treatment and prophylaxis for VTE. Prior literature identifies successful use of DOACs for prophylaxis in 2 patients illustrated by Sexton et. al. Concern for use of DOACs in patients with nephrotic syndrome is based on data that they are highly protein bound and

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

so this questions the efficacy of DOACs in NS. However, given that there are real world examples of successful use of DOACs for treatment and prophylaxis of VTE in nephrotic syndrome patients, we recommend further studies to evaluate the efficacy of DOACs in prevention of VTE compared to the current standard of care.

## FR-PO665

### Refractory Membranous Nephropathy With Anti-Rituximab Antibodies Treated Successfully With Obinutuzumab

**Sumit Kumar**,<sup>1,2</sup> <sup>1</sup>Texas Kidney Institute, Dallas, TX; <sup>2</sup>Nephrotox Research Group, Dallas, TX.

**Introduction:** Membranous nephropathy results from IgG deposition in glomerular capillaries. A precision-medicine based anti-CD 20 approach has continued to evolve. Rituximab (RTX), has become the cornerstone for treatment after it's demonstration to be noninferior to cyclosporine. Here, we report anti-rituximab antibodies causing rapidly refractory disease, successfully treated with Obinutuzumab (OZB)

**Case Description:** A 65 yr old Caucasian male presented in Nov 2017 with shortness of breath. An acute pulmonary embolism and renal vein thrombosis was diagnosed with 25 g proteinuria and normal renal function. Kidney Biopsy demonstrated Idiopathic membranous nephropathy with No crescents, fibrinoid necrosis, thrombosis or endocapillary hypercellularity. Initial treatment was pulse steroids in Jan 2018 and 1 dose of RTX 1 gram. 2nd dose was never given. He went into a remission and came to our care in Oct 2019. In Mar 2020, he relapsed and underwent RTX infusion 1 g every 2 weeks for 2 doses. His initial response over the next few months was favorable, but he relapsed 4 months later. Other than trace to 1+ edema, he remained asymptomatic. **Anti-RTX Antibody was 158 ng/mL.** He was treated with OZB – Day 1 – 100 mg; Day 2 – 900 mg and Day 8 – 1000 mg, along with hypersensitivity prophylaxis. His Anti PLA 2R Ab became undetectable in 3 months and UPCR dropped steadily. He has remained asymptomatic, without any recurrence of proteinuria in extended follow-up.

**Discussion:** Our patient presented a unique conundrum with steady clinical improvement after being treated with rituximab, and then developing rapid relapse with detection of **anti-rituximab antibodies**. In our review, this has not been described previously. Obinutuzumab, fully humanized type II anti-CD 20 monoclonal antibody produces greater CD20 depletion and is superior to rituximab. While the use of Obinutuzumab has been described in limited case reports for the treatment of refractory membranous nephropathy, anti-rituximab antibodies have not been described in refractory disease.

Patient Course

## FR-PO666

### IgG4 Related Membranous Nephropathy Treated With Anti-CD 20 Therapy

**Arjun L. Kalaria**, Bo Chen, Syeda B. Ahmad. *UPMC, Pittsburgh, PA.*

**Introduction:** Primary Membranous nephropathy (MN) is associated with autoantibodies against phospholipase A2 receptor (PLA2R) in the majority of cases. MN is associated with up to 10-15% of Immunoglobulin G4 (IgG4)-related kidney diseases. IgG4-related disease is an immune-mediated condition that can involve multiple organs and appear with lymphoplasmacytic infiltrations of IgG4+ plasma cells, storiform fibrosis, obliterative phlebitis, mild to moderate eosinophilia, and remarkably high serum IgG and IgG4. We report a rare case of IgG4-related MN treated with Rituximab.

**Case Description:** Our patient is a 66-year-old woman with hypertension, allergic rhinitis, and osteopenia who was referred to nephrology for new-onset edema. She denied NSAID use and had been up to date on her cancer screening. A 24hr urine protein was noted to have nephrotic range proteinuria of 5518 mg/24h. Labs showed a creatinine 0.8 mg/dL, BUN 12 mg/dL, serum albumin 2.3 g/dL and an absolute eosinophil count 2.1. Serological work-up notable for anti-neutrophil antibody level +1:40 in an equivocal pattern, normal C3 and C4, hepatitis B/C and anti-PLA2R antibody negative, free kappa lambda ratio 1.01, and serum immunofixation electrophoresis showing a faint IgG kappa. Further workup showed elevated serum IgG4 level 377 mg/dL (normal 4.0-86.0 mg/dL). Imaging demonstrated mediastinal and retroperitoneal lymphadenopathy with normal-sized kidneys. She underwent a native kidney biopsy which showed membranous glomerulopathy, PLA2R negative, basement membrane IgG4 staining by paraffin immunohistochemistry, small subepithelial electron-dense deposits with minimal to mild interstitial fibrosis, and tubular atrophy. She was treated with rituximab 1000 mg 2 weeks apart and a follow-up dose of 1000 mg in 6 months. Repeat imaging showed decreased size of lymphadenopathy. Follow up labs 3 months from last rituximab dose showed BUN 10 mg/dL, Cr 0.75 mg/dL, Alb 3.2 g/dL and urine protein/creatinine ratio of 0.3g/g.

**Discussion:** IgG4-related MN disease is an extremely rare disease entity. The standard treatment option is high-dose prednisone. We opted for steroid-sparing therapy due to patient preference and history of osteopenia. There is limited data on the use of anti-CD 20 blockade for the treatment of IgG4-related MN. We demonstrate in this case that Rituximab, as dosed per the Mentor trial, is an effective treatment option for IgG4-related MN.

## FR-PO667

### Remission of Secondary Membranous Nephropathy From Sjogren Syndrome After Treatment With Hydroxychloroquine

**Dina R. Al-Tuhafy**, Jean H. Ancion, Saira Sajid, Katerina Hysi, James Drakakis. *NYU Langone Hospital - Long Island, Mineola, NY.*

**Introduction:** Membranous nephropathy (MN) is a common cause of proteinuria. It can be divided into primary and secondary forms. The primary form is characterized by nephrotic syndrome and accounts for 70% of cases of MN. The other 30% may be secondary, attributed to underlying causes, such as infections, drugs, malignancies, or autoimmune diseases. The treatment of secondary MN is targeted to the etiologic cause and when effectively administered, can lead to a remission or cure of MN. While treatment options are well defined for underlying SLE or RA in the setting of MN, those for Sjogren's are much less so.

**Case Description:** 69 year old female with PMHx of Sjogren's syndrome (sicca symptoms, +ANA/SS-B), initially presented with anasarca and proteinuria quantified at 7 g/day. Kidney biopsy was performed showing membranous nephropathy, with negative staining for PLA2R. In addition, serum PLA2R Ab neg, favoring secondary form (likely Sjogren's related). At first immunosuppression was held. Renal function remained stable (serum creatinine 1.3 mg/dL). After several months, due to lack of improvement, she received two doses of 1000 mg of Rituximab. Proteinuria reached nadir of 3.5 g/g, but 6 months after the infusion, rose back up to 8 g/g. At this point, she started Hydroxychloroquine 400 mg per day. Improvement in proteinuria followed after 6 months of this therapy (down to 3.7 g/g). After an additional 8 months, the urine protein quantification was 561 mg/g and by 1 year later down to <200 mg/g.

**Discussion:** Renal involvement in Sjogren's syndrome is typically rare, only affecting <10% of patients. When present, this is usually in the form of tubulointerstitial nephritis and renal tubular acidosis. However, MN (secondary) has also been reported as a cause of renal disease in patients with Sjogren's, as high as in 36% in one cohort. Those patients with glomerular involvement are said to carry a worse prognosis. In fact, little data is available about the effectiveness of steroids or other immunosuppression to slow progression of renal disease and improve proteinuria. Our case is illustrative in that it showed a complete remission of secondary MN from Sjogren's syndrome only after treatment with Hydroxychloroquine. This strategy was enacted only after Rituximab proved ineffective.

## FR-PO668

### Screening for Anti-Rituximab Antibody in Management of Rituximab Refractory PLA2R-Associated Membranous Nephropathy

**Ayotunde Ositelu**, Andrew Vissing, Wadah J. Ayoub, Yonatan A. Peleg, Yashpal S. Kanwar, Vikram Aggarwal. *Northwestern Memorial Hospital, Chicago, IL.*

**Introduction:** Phospholipase A2 receptor associated Membranous Nephropathy (PLA2R-MN) accounts for 80% of primary MN (pMN). High titers of anti-PLA2R-Ab and non-remission of Nephrotic syndrome (NS) are associated with poor renal outcomes.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

Rituximab (RTX), a chimeric monoclonal antibody (mAb) targeting CD20 on B-cells, is a first-line agent for moderate to high-risk pMN. However, 20-40% of pMN remain refractory to RTX. We report an approach to manage RTX refractory PLA2R-MN based on the use of the anti-RTX Ab assay.

**Case Description:** A 78 year-old male presented to our Nephrology clinic to manage severe N.S. He was on high dose of diuretics and ACEI for 3 months. Evaluation revealed proteinuria of 15 g/day, serum albumin (S. A) of 2 g/dl, eGFR=47 ml/min and anti-PLA2R Ab level was 751.6 RU/mL (positive test > 20 RU/ml). Renal biopsy findings were consistent with MN. He met high-risk criteria for pMN and received RTX 1g i.v twice within 2 weeks. 3 months later, anti-PLA2R levels decreased to 48.1 RU/mL. At 6 months he had partial remission (PR) of proteinuria, improvement in edema and S.A remained 3-3.3 g/dl. Overall suggesting RTX-responsive course however due to lack of immunologic remission (LR) he received RTX(1g) at 6 months. We noticed worsening of proteinuria and edema at 8 months. Anti-PLA2R level had risen serially up to 794.6 RU/mL at 10 months. Lack of I.R (refractory pMN) and worsening N.S prompted us to investigate factors contributing to RTX resistance and reduced bioavailability. We screened him for neutralizing Abs against RTX and his anti-RTX Ab level was elevated: 1,432 ng/mL (normal < 25 ng/mL) and he had undetectable RTX level. We obtained approval and he received Obinutuzumab (OBI, fully humanized mAb) at 12 months. OBI is directed to a different epitope on CD20 and has higher affinity for CD20 than RTX. Within a month of OBI, anti-PLA2R Ab came down to 25 RU/mL. UPCR was 2.19 g/g & S.A 3.5 g/dL at 14 months thus denoting PR and near complete LR.

**Discussion:** This case report highlights the clinical utility of anti-RTX Ab screening when managing patients with refractory PLA2R-MN. The presence of anti-RTX should prompt the use of new generation (more humanized) anti-CD20 therapy to achieve immunologic and clinical remission.

### FR-PO669

#### Novel Treatment Option for PLA2R-Positive Membranous Nephropathy

Aditi A. Sen,<sup>1</sup> Nidhi Aggarwal,<sup>1,2</sup> Sarvari Yellapragada,<sup>1,2</sup> John E. Mbue,<sup>2</sup> Maulin Shah,<sup>1,2</sup> <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>Michael E DeBakey VA Medical Center, Houston, TX.

**Introduction:** B-cell depletion with rituximab has been shown to be effective in treating anti-phospholipase A2 receptor (aPLA2R) antibody-associated membranous nephropathy (MN). While rituximab is generally well tolerated, some patients may develop serious side effects limiting its use. Novel anti-CD20 agents are now available, but evidence of their effectiveness in aPLA2R-MN is limited. We present a case of aPLA2R-MN treated with ofatumumab.

**Case Description:** A 45-year-old man presented with recurrence of MN. He had Hodgkin's lymphoma at age 14 and underwent splenectomy and chemotherapy (MOPP/ABVD regimen) which caused neuropathy. Sixteen years later, he developed polymorphous large cell lymphocytosis, a complication of prior chemotherapy and splenectomy. He first developed membranous nephropathy in 2014 (age 38), which was successfully treated with rituximab. He had recurrent membranous nephropathy (2017) with biopsy revealing aPLA2R (serum level 37 RU/mL) and again achieved remission with rituximab. Subsequently, he developed worsening neuropathy, likely due to rituximab. He had another recurrence (2020), initially treated with cyclosporine but was not effective (aPLA2R level 110.5 RU/mL). Given prior response to anti-CD20 therapy and given high risk of side-effects with cyclophosphamide, we opted to treat with ofatumumab (no known reports of neuropathy) guided by B-cell depletion confirmation. Three months after treatment, he has achieved serological remission and shown significant improvement in proteinuria.

**Discussion:** This case highlights that novel anti-CD20 agents may be considered for aPLA2R-MN when use of rituximab is prohibitive. Rituximab, a chimeric monoclonal antibody, may cause development of human anti-chimeric antibodies, which can affect efficacy and tolerability. Novel agents, such as ofatumumab, being fully human or humanized, decrease immunogenicity. Many of them have boosted efficacy due to increased binding affinity to Fc receptor on B-cells with increased complement-dependent cytotoxicity and/or antibody-dependent cellular cytotoxicity. It remains to be seen if our patient achieves complete and persistent remission. Further studies are needed to investigate the ability of these agents to achieve and maintain serological and clinical remission in aPLA2R-MN and understand their overall tolerability.

### FR-PO670

#### Can PLA2R Antigen in Kidney Tissue Turn Positive After Recent COVID-19 Infection in Membranous Nephropathy?

Syed A. Bukhari,<sup>1,2</sup> Omar N. Elhawary,<sup>1,2</sup> Isha Puri,<sup>1,2</sup> Mary C. Mallappallil,<sup>1,2</sup> Sonalika Agarwal,<sup>1,2</sup> <sup>1</sup>Kings County Hospital Center, Brooklyn, NY; <sup>2</sup>SUNY Downstate Health Sciences University, New York City, NY.

**Introduction:** COVID-19 infection has been associated with variety of kidney diseases including glomerulopathies. To our knowledge, only 8 cases of membranous nephropathy post COVID infection have been reported so far out of which 3 were PLA2R antigen positive. We report another case of such a rare association.

**Case Description:** 33 y/o AA obese male admitted with worsening anasarca for 1 month. His labs showed normal kidney function, hypoalbuminemia and nephrotic range proteinuria of 4 g/d. Urinalysis was otherwise bland. Serology including ANA, ANCA, C3, C4, Anti-PLA2R, Hepatitis panel, HIV were all negative. USG showed normal kidneys. Kidney biopsy was done which showed membranous nephropathy. There were no signs of virus in the kidney tissue. He stained positive for PLA2R antigen. Further history revealed that he had mild COVID infection 2 weeks before the swelling started.

He did not require hospital admission. For his kidney disease, he is started on losartan and diuretics. He is being observed for 6 months for possible spontaneous resolution.

**Discussion:** Based on the clinical presentation and serology it would suggest that the patients with COVID-19 infection may be associated with subsequent membranous nephropathy. The clinical presentation of the infection two weeks prior may be the stimuli for the PLA2R antigen and the membranous nephropathy, while the serum anti-PLA2R antibody was negative.

### FR-PO671

#### Novel Target Antigens in Sarcoidosis-Associated Membranous Nephropathy

Luca Nardelli,<sup>1</sup> Dalia Zubidat,<sup>1</sup> Benjamin J. Madden,<sup>1</sup> Satoru Kudose,<sup>2</sup> Vivian C. Negron,<sup>1</sup> Louann Gross,<sup>1</sup> Samih H. Nasr,<sup>1</sup> Fernando C. Fervenza,<sup>1</sup> Sanjeev Sethi,<sup>1</sup> <sup>1</sup>Mayo Foundation for Medical Education and Research, Rochester, MN; <sup>2</sup>Columbia University, New York, NY.

**Background:** Kidney involvement occurs in 10-20% patients with sarcoidosis. Membranous nephropathy (MN) is the most frequent glomerular disease in patients with sarcoidosis. Previous small case series have shown that greater than 50% of MN diagnosed in patients with sarcoidosis are positive for Phospholipase A2 receptor (PLA2R). However, no target antigens have been identified in the remaining sarcoidosis-associated MN.

**Methods:** We performed a retrospective study of 19 patients diagnosed with sarcoidosis and biopsy-proven MN. We performed laser microdissection of glomeruli followed by mass-spectrometry (MS/MS) to detect MN antigens. This was followed by immunohistochemistry (IHC)/ immunofluorescence microscopy (IF) staining to confirm and localize the antigens.

**Results:** Using MS/MS, we identified PLA2R in 7/19 (37%), neural epidermal growth factor-like 1 protein (NELL1) in 4/19 (21%), and 1/19 (5%) each of thrombospondin type 1 domain-containing 7A (THSD7A) antigen, protocadherin 7 (PCDH7) and Proprotein Convertase Subtilisin/Kexin Type 6 (PCSK6/abstract submitted) (Fig 1). IHC/IF confirmed MS/MS findings and showed PLA2R, NELL1, THSD7A and PCDH7 staining along the GBM (Fig 2). Segmental NELL1 staining was noted in 2 of the 4 NELL1-positive MN. No known antigen was detected in the remaining 5/19 (26%) MN cases.

**Conclusions:** The presence of PLA2R antigen in renal biopsy should not exclude a secondary cause of MN, particularly sarcoidosis. The incidence of PLA2R-negative MN associated with sarcoidosis is probably higher than what has been previously reported. NELL1, PCDH7, THSD7A, and PCSK6 represent new antigens in sarcoidosis-associated MN.

Target antigens in Sarcoidosis-associated MN.

IHC showing granular GBM staining for (A-E) NELL1 in 4 cases, panel C shows segmental GBM staining, arrow points to few loops showing no staining (C and D are same case) and (F) PCDH7.

### FR-PO672

#### Hydrocarbons to Pulmonary Renal Syndrome: A Risky Road

Martha Catalina Morales-Alvarez,<sup>1</sup> Samuel T. Eley,<sup>2</sup> Isaac E. Stillman,<sup>1</sup> Bhavna Chopra,<sup>1</sup> <sup>1</sup>Beth Israel Deaconess Medical Center, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA.

**Introduction:** Anti-GBM syndrome is rare small vessel vasculitis with an incidence of <2 cases/million population and a bimodal age distribution in the third and sixth decades of life. Environmental factors such as URIs, smoking, and inhalation of hydrocarbons in genetically susceptible individuals are associated with increased anti-GBM antibodies production. We present a rare case of a young patient with Toluene exposure manifesting anti-GBM syndrome in a background of PLA2R membranous nephropathy (MN).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Case Description:** A 23-year-old man with new onset HTN and headaches presented to the ED with hemoptysis for 2 days. He was hemodynamically stable with normal oxygen saturation. Initial laboratory results revealed a Hb of 5.7 g/dL and SCr of 19.7 mg/dL. CXR revealed bilateral diffuse infiltrates and urine sediment showed several dysmorphic RBCs. Total urine Pr/Cr ratio was 6.2 g/g. Due to concern for pulmonary-renal syndrome with diffuse alveolar hemorrhage and hypoxic respiratory failure he was initiated on pulse dose steroids, plasmapheresis (total x5), and hemodialysis within 1 day of admission. Serologies returned positive only for anti-GBM antibodies. A kidney biopsy showed active crescentic GN with minimal IFTA and granular staining of PLA2R in the capillary loops by IF (Fig 1). Oral cyclophosphamide was initiated on day 5. He reported repeated high exposure to toluene since childhood while repairing bikes. During a 3-mo follow up, he was still HD dependent.

**Discussion:** This case exhibits a unique presentation of anti-GBM syndrome following repeated hydrocarbon exposure in a setting of underlying MN. Inhaled toxins promote recurrent localized inflammation and increased capillary permeability unmasking hidden epitopes and allowing antibody formation, potentially manifesting as anti-GBM syndrome. Early diagnosis and appropriate use of immunosuppressive and extracorporeal therapies is necessary to prevent morbidity and to improve survival of this rare condition.

#### FR-PO673

##### A Unique Case of Atypical Anti-Glomerular Basement Membrane Disease

Muhammad Rawala, Hania Kassem, Nidal Alhosainat, Marjan Afrouzian. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

**Introduction:** Classic anti-glomerular basement membrane (GBM) nephritis is clinically and pathologically the most aggressive form of glomerulonephritis. The binding of the autoimmune antibodies to GBM leads to crescent formation and rapidly progressive glomerulonephritis (RPGN). We present a case of a 56-year-old female with atypical features of anti-GBM disease who did not require immunosuppression.

**Case Description:** A 56-year-old female with a history of chronic kidney disease (CKD) stage III, diabetes mellitus type II, smoking, hypertension, chronic obstructive pulmonary disease, hepatitis C-related cirrhosis presented to the hospital with a 2-month history of worsening ascites that did not respond to diuretics. Large volume paracentesis was performed, after which the patient developed acute kidney injury, which was initially thought to be secondary to decreased effective circulating volume. However, work-up identified nephrotic range proteinuria and dysmorphic RBCs on urine microscopy. This prompted a renal biopsy for evaluation of glomerulonephritis (GN). The biopsy was reported as atypical Anti-GBM disease with proliferative GN and diabetic glomerulosclerosis. The patient's anti-GBM antibody was negative. She was managed conservatively as creatinine stabilized around 1.2-1.4 mg/dL.

**Discussion:** The incidence of atypical anti-GBM is reported to be 11.8%. Our patient exhibited IgG linear staining along the glomerular and tubular basement membranes, the pathologic hallmark of the anti-GBM disease. But the clinical characteristics of our patient having nephrotic range proteinuria and mild nonprogressive worsening in kidney function, differed from the traditional presentation of pulmonary symptoms and RPGN found in anti-GBM disease. Also, similarly to other cases of atypical anti-GBM, the patient was a smoker, had a negative anti-GBM antibody, and histologically had evidence of endocapillary proliferation. The objective of the case is to delineate that anti-GBM disease can present atypically with a less aggressive phenotype, variable histologic changes, and undetectable anti-GBM antibody. This subset of patients has an overall better prognosis and may be managed conservatively.

##### From ESRD to CKD5: An Unlikely Path for an Anti-Glomerular Basement Membrane (Anti-GBM) Patient

Christopher F. Middleman, Maura A. Watson. *Walter Reed National Military Medical Center, Bethesda, MD.*

**Introduction:** Anti-GBM is a rare small vessel vasculitis with estimated fewer than two cases per one million population. The disease is caused by circulating antibodies directed against the glomerular basement membrane and alveolar basement membrane, leading to glomerulonephritis (GN) and/or alveolar hemorrhage.

**Case Description:** A 60 year old female was admitted for acute renal failure with a rapidly rising serum creatinine. Lab work-up revealed a highly elevated anti-GBM titer. Kidney biopsy revealed 100% crescentic disease with 15% interstitial fibrosis and tubular atrophy due to anti-GBM. Plasmapheresis plus immunosuppressive therapy (cyclophosphamide and steroids) vs. IV steroids followed by oral taper were considered. Given her biopsy findings conveyed low likelihood of renal recovery the patient elected treatment with IV, followed by oral, steroids and initiated chronic dialysis May 2020. Her anti-GBM antibody activity was monitored monthly (peak of 153 units May 2020) and down-trended over time. She reported increased urine output in early summer 2021 and 24 hour urine studies, completed between dialysis sessions, revealed an up-trending creatinine clearance. Her dialysis needs decreased to twice-weekly and she was ultimately liberated from dialysis entirely 16 months after initiation.

**Discussion:** Necrotizing anti-GBM associated GN with 100% crescent formation carries a poor renal prognosis and it is not unreasonable to forgo immunosuppressive therapy and plasmapheresis, as risks of these therapies often outweigh potential benefits. This case illustrates a patient who, not having received PLEX or cyclophosphamide, eventually recovered enough renal function to become a dialysis-free CKD5 patient. Other such case reports exist in literature and beckon us to ask: should we change our perspective of crescentic disease in anti-GBM and more strongly consider available therapies? Further research is needed to determine optimal treatment in anti-GBM patients with 100% crescent formation on biopsy. The views expressed in this Abstract are those of the authors and do not reflect the official policy of the Department of the Army/Navy/Air Force, the Department of Defense, or the United States government

##### Immune Complex-Mediated Membranoproliferative Glomerulonephritis in TAFRO Syndrome: A Case Report

Alaa S. Hrizat, Jaime Eberle-Singh, Li Li. *Thomas Jefferson University, Philadelphia, PA.*

**Introduction:** TAFRO syndrome is a clinical subset of idiopathic multicentric Castleman disease (iMCD) characterized by thrombocytopenia, anasarca, fever, reticulin fibrosis or renal dysfunction, and organomegaly. Renal involvement is a significant complication of TAFRO syndrome; however, only a small number of cases have been reported.

**Case Description:** A 42-year-old woman presented with hypertensive crisis and dyspnea. She was incidentally found to have a large mediastinal mass (11cm), pericardial and bilateral pleural effusions, and extensive multifocal hypermetabolic lymphadenopathy. The anterior mediastinal mass biopsy was diagnosed with iMCD with negative serologies for HIV and HHV-8. The patient was treated with 16 cycles of Siltuximab (anti-IL-6). While her dyspnea and metabolic activity of adenopathy improved, she continued to have anasarca and worsening hypergammaglobulinemia. This inflammatory state was consistent with TAFRO syndrome of iMCD and treatment was changed to Rituximab. Shortly after, the patient developed acute decompensated heart failure and worsening renal function with a Cr of 2.30 mg/dL (baseline Cr 1.5 mg/dL), BUN 65 mg/dL. Renal biopsy revealed that most of the glomeruli had membranoproliferative glomerulonephritis (MPGN) injury patterns without thrombi or fibrinoid necrosis. Immunofluorescence study revealed (all 1-2+) mesangial and capillary loop granular IgG, C3, kappa and lambda light chain deposits. Electron microscopy identified subendothelial electron-dense immune-type immune deposits. Overall the findings are consistent with immune deposit-associated MPGN.

**Discussion:** We present an iMCD patient with TAFRO syndrome with renal insufficiency secondary to immune deposit-mediated MPGN. Amyloidosis MPGN and thrombotic microangiopathy (TMA) have been reported in MCD. Further research is needed to elucidate the roles of VEGF and IL-6 and their impact on renal pathology in TAFRO syndrome.

A. Representative glomerulus shows MPGN injury pattern (H&E, 40X).

FR-PO676

Images of Sea Blue Histiocytosis in Lupus Nephritis  
Jin Wen. Hunan Provincial People's Hospital, Changsha, China.

**Introduction:** Sea blue histiocytosis (SBH) is a rare disease characterized by the deposition of abundant sea-blue histiocytes in various organs, most of which is regarded as a hereditary disorder. The association between SBH and lupus nephritis (LN) has never been reported before. Herein, we present a series of images of the deposition of SBH in the bone marrow of an adult woman with LN.

**Case Description:** A 32-year-old Chinese female was diagnosed with systemic lupus erythematosus (SLE) and LN for twelve years. The significant manifestations were recurrent fever with rash, proteinuria, hematuria, blood cell reduction (leukopenia, thrombocytopenia, and hemolytic anemia), and strong positive ANA and ds-DNA antibodies. She has also suffered from paravertebral infection with mycobacterium xenopi for two years, which was detected by the next-generation sequencing with paravertebral tissue. She has been under anti-mycobacterial therapy for two years. One month ago, the deposition of SBH was obtained in the bone marrow. The whole-exome sequencing (WES) of the patient and her parents has been done by Kindstar Global Company to exclude the primary hematologic hereditary disease.

**Discussion:** To our knowledge, this is the first case of SBH and LN. Secondary SBH could be diagnosed according to the typical images of SBH in the bone marrow and the negative result of the WES examination. However, the association between SBH and LN remains unknown, and there is another possibility that SBH is associated with non-tuberculous mycobacterial infection.

FR-PO677

ANCA-Systemic Lupus Erythematosus Overlap Syndrome: Case Series  
Nitpriya Paliwal, Gaia M. Coppock. University of Pennsylvania, Philadelphia, PA.

**Introduction:** Systemic lupus erythematosus (SLE) is characterized by development of autoantibodies against nuclear components. ANCA-associated vasculitides (AAV) are characterized by a small-sized vessel vasculitis & ANCA positivity. SLE & AAV are rarely associated as vasculitis may occur during SLE but rarely fits AAV classification criteria. A clinical entity that fulfills criteria for both SLE & AAV was first described in 2008.

**Case Description:** All 3 patients presented with hematuria, proteinuria & AKI. Case 1: 71 y/o F. Renal biopsy revealed glomerulonephritis (GN) with dominant IgA deposits and crescents. P-Anca titers were 44. Treated with steroids with improvement &

maintained on MMF for 6 months with complete remission. She had a recurrence 6 years after stopping all therapy & repeat renal biopsy revealed crescentic GN with immune complex deposits & near full-house pattern on immunofluorescence (IF). P-ANCA remained positive. She was treated with steroids and started on MMF with her creatinine now stable at 1. Case 2: 69 y/o F with high ANA titers (1:10240) & + MPO (57). Renal biopsy showed crescentic GN with full house staining on IF & intramembranous & subepithelial immune-type deposits on electron microscopy (EM). Treated with steroids & Cytoxan, followed by maintenance therapy with azathioprine & prednisone. Currently off maintenance therapy for 6 months with stable renal function. Case 3: 39 y/o F with high ANA titers (1:5120), normal complements, elevated MPO (66) & anti-ds DNA of 344. Prelim biopsy results revealed marked endocapillary cellularity with few crescents. Treated with solumedrol x3 followed by MMF. Final biopsy report showed full house IF & diffuse crescentic GN, so her treatment was switched to Cytoxan & steroid taper with clinical improvement.

**Discussion:** We discuss 3 cases of overlap with different presentations & approaches to treatment. Incidence of SLE & ANCA vasculitis overlap syndrome has increased over the last decade. The largest case series to our knowledge was of 8 patients reviewed between 1995-2014. The low number of cases prompts the question of underdiagnosis & significance of ANCA positivity in lupus nephritis. We recommend that ANCA testing be performed in all patients with lupus nephritis who have crescents on biopsy to test for overlap syndrome. Further studies are needed to identify the standard approach to treatment or if treatment should be tailored to individual patient presentation.

FR-PO678

Collapsing Glomerulopathy and Systemic Lupus Erythematosus: Case Series  
Fernando L. Strufaldi, Mateus J. Luvizotto, Gabriela C. Segura, Viktoria Woronik, Cristiane B. Dias, Livia B. Cavalcante, Luis Yu, Leticia Jorge. Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.

**Introduction:** Collapsing glomerulopathy is a clinical entity characterized by massive proteinuria, elevated serum creatinine, and rapid progression to end-stage renal disease. It is associated with autoimmune diseases, viral infections, and medications. Here we report 5 cases, which had the association between collapsing glomerulopathy (CG) and systemic lupus erythematosus (SLE).

**Case Description:** Clinical features of the patients are summarized in Table 1. At the beginning of the clinical presentation, 4 patients had nephrotic syndrome, with creatinine values ranging from 0.9 up to 3.37 mg/dL, without complement consumption. Regarding clinical manifestation of SLE, all patients had arthritis as the main symptom. Histological findings showed that the patients had focal to moderate focal fibrosis and tubular atrophy. One also had diabetic nephropathy. Another male patient, whose renal outcome was worse, had class IV lupus nephritis. The mean follow-up time of patients was 138 months, with 2 patients achieving complete remission, 1 patient partial remission, and 1 patient reached the combined endpoint of doubling creatinine and progression to end-stage renal disease. Of the 5 patients, one still does not have sufficient follow-up

**Discussion:** The pathogenesis of cases of CG associated with SLE remains unclear. Humoral and/or cellular immunity factors seem to be involved in the development of the disease. Due to the relative rarity of prevalence, there is currently no treatment based on clinical evidence

Table 1. Clinical and laboratory findings at the time of biopsy											
	Age(year)	Gender	Ethnic	Creatinine (mg/dL)	Cd3-EPI (ml/min)	Proteinuria (g/d)	Albumin (g/dl)	ANA pattern	Anti-dsDNA (U/ml)	Complement (mg/dl)	Clinical Symptoms
1	64	Woman	White	3.17	11	<0.6	3.3	Nuclear homogeneous 1:640	>200	C3=51 C4=13	Arthritis, rash, Raynaud
2	28	Woman	White	0.9	84	9.22	2.4	Nuclear fine speckled 1:640	Negative	C3=133 C4=39	Arthritis and serositis
3	60	Woman	White	1.05	58	1.09	3.3	Nuclear coarse speckled 1:320	Negative	C3=188 C4=16	Arthritis
4	35	Man	White	1.15	80	6.22	4.1	Nuclear fine speckled 1:640	Negative	C3=152 C4=38	Arthritis and neurological symptoms
5	85	Woman	White	2.1	26	8.8	2.5	Nuclear fine speckled 1:160	Negative	C3=188 C4=39	Arthritis

Table 2. Renal histopathological findings						
	Glomeruli	Tubular Intercept	Interstitial fibrosis	Tubular atrophy	Immunofluorescence	Other Findings
1	75	Yes	Focal	Focal	IgM 1+2 C3 2+3	No
2	8	No	Focal	Focal	IgM 1+3 C3 1+3	No
3	14	Yes	Focal	Moderate	Negative	Diabetic Nephropathy
4	12	Yes	Focal	Moderate	IgG trace IgM 1+3 C3 1+3	Class IV Lupus Nephritis
5	18	No	Diffuse	Moderate	IgM 2+3 C3 2+3	No

Table 3 - Follow-up data

Patient	Time from SLE diagnosis to collapsing glomerulopathy	Follow-up (months)	Treatment	CRP EPI (mg/min)	Complete remission (proteinuria <0.5 g/dl and eGFR >30 ml/min/1.73 m <sup>2</sup> )	Optimization of creatinine in HD
1	Simultaneous	108	Steroids and MMF <sup>a</sup>	22	No	No
2	8 years	144	Steroids, MMF <sup>a</sup> , AZA <sup>a</sup> , and tacrolimus	90	Yes	No
3	12 years	168	AZA <sup>a</sup>	56	Yes	No
4	13 years	192	Steroids, CYC <sup>a</sup> , MMF <sup>a</sup> and AZA <sup>a</sup>	5.98	No	Yes
5	18 years	03	Steroids, MMF <sup>a</sup> and CYC <sup>a</sup>	20	No	No

<sup>a</sup>Complete remission was defined by KDIGO criteria as proteinuria <0.5 g/day and eGFR >30 ml/min/1.73 m<sup>2</sup> (morphological remission). AZA: azathioprine, CYC: cyclophosphamide.

## FR-PO679

### Messenger RNA COVID-19 Vaccine-Associated Collapsing Focal and Segmental Glomerulosclerosis

Duha A. Jweehhan. UConn Health, Farmington, CT.

**Introduction:** A novel coronavirus (SARS-CoV-2) mRNA vaccine was invented as a mitigation strategy to control COVID-19 pandemic and as a promising approach to reduce the spread of COVID-19 infection among population worldwide with impressive reduction in new COVID-19 infection cases. We report a first case of collapsing focal and segmental glomerulosclerosis (FSGS) was diagnosed post-second dose of SARS-CoV-2 Moderna vaccine.

**Case Description:** A 75-year-old Caucasian female with unremarkable medical history who was admitted anasarca started 6 weeks after receiving the second dose of SARS-CoV-2 Moderna vaccine. She was found to have anuric acute kidney injury, blood pressure 210/110 mmHg. Laboratory results showed serum creatinine 8.2 mg/dl, serum albumin 2.6 g/dl. Urine microscopic showed numerous granular casts and tubular epithelial cells. 24 hr. urinary collection revealed proteinuria of 6.9 g. Transthoracic echocardiogram was normal. Kidneys were normal in size with increased cortical echogenicity on renal ultrasound. Unremarkable comprehensive workup. Kidney biopsy showed segmental sclerosis with associated hyperplastic visceral epithelial cells with intracytoplasmic protein reabsorption droplets. The associated capillary loops appeared collapsed. Immunofluorescence showed segmental glomerular staining for IgM, C3 and C1q (3+).

**Discussion:** Several case reports have been published suggesting a temporal association between glomerular disease and relapsing glomerular disease after receiving SARS-CoV-2 RNA (mRNA) vaccines of either Pfizer-Bio-Tech or Moderna mRNA-1273. SARS-CoV-2 mRNA vaccines generate humoral and cell-mediated immune response by CD4 and CD8 expansion to T helper-based response with production of interferon-gamma, tumor necrosis factor- $\alpha$ , interleukin-2 and antibody production predominantly of immunoglobulin G1 and IgG subclass. That suggests cell-mediated immune reaction that may cause podocyte injury or recurrence of glomerular disease. Potential mechanism of podocyte injury post SARS-CoV-2 mRNA vaccine may be triggered by cytokine-mediated response, direct toxic effect or a rapid T cell-mediated immune response and lead to podocytopathy. Further investigations are needed to establish the causal relationship between SARS-CoV-2 and glomerular injury in susceptible individuals. Increase awareness in that regard might help to expand database of those cases.

## FR-PO680

### Minimal Change Disease Superimposed on Diabetic Nephropathy: A Very Rare Clinical Occurrence

Tanazul T. Pariswala, Khawaja A. Bashir, Hitesh H. Shah. Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.

**Introduction:** Diabetic nephropathy (DN) is a leading cause of ESKD in the US. Patients with DN usually develop progressive proteinuria and kidney failure over the years. A subset of patients with DN may develop nephrotic syndrome. However, sudden onset of nephrotic syndrome in patients with history of diabetes mellitus (DM) may suggest the presence of nondiabetic kidney disease. Here, we present an interesting and challenging case of minimal change disease superimposed on DN.

**Case Description:** 78-year-old male with type 2 DM presented to our hospital for worsening bilateral LE swelling and significant weight gain. Of note, pt. was seen in another hospital approximately 3 months ago for similar complaints. During that hospital stay, pt. was found to have nephrotic syndrome. Kidney biopsy performed at the time showed diffuse effacement of epithelial foot processes consistent with minimal change disease (MCD) and mild diffuse diabetic glomerulosclerosis. Pt. was not initiated on oral corticosteroid therapy for MCD at the time as he had lab findings of latent TB. Pt. was initiated on oral rifampin as outpatient. Pt. however took rifampin for only 2 weeks as he felt that it contributed to his worsening LE swelling. On presentation to our hospital, pt. found to have significant bilateral LE edema and nephrotic syndrome. Urine TP/CR ratio was 10 and serum albumin was 1.5. Scr was elevated at 2.9 on admission, peaked to 4.8 during hospital stay. Pt. initiated on IV diuretic therapy with good clinical response. ID was initially consulted for concerns for latent TB. Pt. found to have abnormal lung findings on CT scan hence pulmonary team was also consulted. Pt. underwent bronchoscopy. BAL fluid studies were negative for AFB and active TB was ruled out. Pt. subsequently initiated on oral rifampin (for latent TB) and oral prednisone therapy (for MCD). Scr decreased to 4.2 prior to discharge. Pt. was discharged on oral diuretics, rifampin, and prednisone with advice to follow-up in nephrology clinic.

**Discussion:** While nephrotic syndrome has been described in patients with DN, MCD superimposed on DN has been rarely reported. Sudden onset of nephrotic syndrome

should raise suspicion for nondiabetic kidney disease in patients with DM. Our case also highlights the importance of kidney biopsy in diabetic patients presenting with sudden onset nephrotic syndrome and kidney failure.

## FR-PO681

### A Case of Proteinuria Associated With Thrombotic Microangiopathy in a Patient With Sickle Cell Disease

Sachin V. Pasricha,<sup>1,2</sup> Richard Ward,<sup>1,2</sup> Christopher J. Patriquin,<sup>1,2</sup> Rohan John,<sup>1,2</sup> Tushar S. Malavade.<sup>1,2</sup> <sup>1</sup>University Health Network, Toronto, ON, Canada; <sup>2</sup>University of Toronto, Toronto, ON, Canada.

**Introduction:** Thrombotic microangiopathy (TMA) causes renal dysfunction. Classic causes include thrombotic thrombocytopenic purpura, atypical haemolytic uremic syndrome, pregnancy, malignancy, drugs, transplant, autoimmune disease, infection, malignant hypertension, antiphospholipid (APLA) syndrome. We describe the case of patient with SCD with TMA shown on renal biopsy when evaluated for proteinuria.

**Case Description:** A 25 year-old male with SCD (HbSS) had proteinuria (1+ on dipstick, urine PCR of 212 mg/mmol, 24-hour protein of 2.75 g) with normal renal function (creatinine 83  $\mu$ mol/L) on screening. He had no known renal disease, diabetes, or nephrotoxic medications (including no NSAIDs). Routine blood-work was unremarkable, aside from baseline haemolytic indices. Autoimmune, vasculitis and infectious workup was negative. Morphological review was done to confirm schistocytes were not being mistaken for sickled RBC. Renal biopsy showed changes suggestive of SCN/hypertension (Fig 1a), and TMA (Fig 1b). Work-up for TMA causes was negative - normal ADAMTS13 levels (>98%), negative blood cultures, and no APLA antibodies. Genetic studies did not show any TMA pathogenic variants in complement or coagulation genes. The TMA was thus attributed to SCD in the absence of acute pain episodes.

**Discussion:** Case reports describe SCD-associated TMA, but these are in the setting of vaso-occlusive pain episodes, which are hypothesized to trigger TMA. Our case of SCD-associated TMA, without a pain crisis, is thus novel and proposes that SCD itself may be a secondary cause of renal TMA. Our case highlights the importance of renal biopsy for patients with SCD and proteinuria to identify if entities aside from SCN are contributory. Patients with SCD-associated TMA have responded to plasma exchange and/or RBC exchange transfusion in the setting of a pain crisis. Whether patients like ours, presenting outside a pain crisis, also respond to these therapies remains to be studied.

### Detection of Acid-Fast Bacillus, Interstitial Granulomatous Inflammation, and Infection-Associated Glomerulonephritis in a Patient With Tuberculosis

Supriya Gerardine,<sup>1</sup> Victoria Gutgarts,<sup>1,2</sup> Steven Salvatore,<sup>2</sup> Aisha Shaikh.<sup>1,2</sup> <sup>1</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>2</sup>Weill Cornell Medicine, New York, NY.

**Introduction:** Mycobacterium tuberculosis (TB) can affect the urinary collecting system and the kidney. Direct renal TB infection can cause glomerulonephritis (GN) and interstitial granulomatous nephritis. Extra-renal TB infection can lead to infection-associated GN. We report a case of infection-associated GN, interstitial granulomatous inflammation, and the presence of acid-fast bacillus in the kidney in a patient with disseminated TB.

**Case Description:** A 70-year-old man with laryngeal cancer presented to the hospital with fever, cough, and blood-tinged secretions from the tracheostomy. He had acute kidney injury (creatinine 1.7 mg/dL), hematuria, pyuria, and severe proteinuria (UPCR 8 g/g). Blood and urine cultures showed no growth. CT chest revealed small bilateral nodules consistent with miliary TB, and bronchial secretions grew mycobacterial TB. Kidney biopsy showed IgA-dominant immune complex GN with sub-epithelial hump-shaped deposits suggestive of infection-associated GN. The kidney biopsy also showed an interstitial non-caseating granuloma with an acid-fast bacillus (Image). Anti-tuberculosis therapy was initiated for disseminated TB infection involving the lungs and kidneys.

**Discussion:** This report describes a rare case of infection-associated GN and interstitial granulomatous inflammation due to disseminated TB. The presence of acid-fast bacillus in the kidney suggests renal TB infection. The combination of isoniazid, rifampin, pyrazinamide, and ethambutol is used to treat disseminated TB. A favorable response to anti-tuberculosis therapy in TB-associated infectious GN has been reported, but such findings are limited to a small number of cases. Knowledge of the renal manifestations of TB infection can lead to early diagnosis and timely initiation of anti-tuberculosis therapy.

Kidney biopsy findings. A. Proliferative GN, B. Non-caseating granuloma, C. Acid-fast bacillus

FR-PO683

Pronase Digestion to the Rescue

Matthew R. Johnson, Pravir V. Baxi, William L. Whittier, Stephen M. Korbet. Rush University Medical Center, Chicago, IL.

**Introduction:** Pronase digestion of paraffin-embedded kidney biopsy tissue is a valuable salvage technique used when glomeruli are not present on tissue reserved for routine immunofluorescence (IF). An additional advantage for this technique is that it can “unmask” immunoglobulin (Ig) deposits not seen on routine IF which has both diagnostic and treatment implications. Here, we present three cases in which pronase digestion was utilized to make unanticipated alternate diagnoses.

**Case Description:** *Case 1:* A 70-year-old woman with HTN and follicular lymphoma in remission presented with AKI, subnephrotic proteinuria, and hypercalcemia with an IgG lambda on serum and urine immunofixation. Standard biopsy techniques revealed normal glomeruli and interstitial nephritis. *Case 2:* A 50-year-old woman with HTN presented with AKI, hematuria, and nephrotic-range proteinuria with an IgG lambda on serum immunofixation. Standard biopsy methods revealed idiopathic MPGN. *Case 3:* A 60-year-old man with HTN presented with nephrotic-range proteinuria and serum and urine immunofixation (-) for monoclonal proteins. Standard biopsy techniques revealed idiopathic immune-complex mediated MPGN. See Table 1 for details of pronase digestion & final diagnosis.

**Discussion:** MGRS encompasses a wide spectrum of kidney lesions, and a diagnosis is essential in guiding treatment which is directed towards a clonal disorder. In these cases, routine IF failed to provide a tissue diagnosis and pronase digestion was vital in unmasking a paraprotein-related lesion which ultimately led to appropriate treatment. Pronase digestion should be considered in all cases where there is a high index of clinical suspicion for MGRS despite negative routine IF findings to facilitate early recognition and treatment for these patients.

	Presentation	Pathology	Diagnosis Pre Pronase Digestion	Pronase Digestion	Diagnosis Post Pronase Digestion	Follow Up
1	AKI, hypercalcemia, IgG lambda in serum and urine Urine P/C 1.5 g/g	AJN, normal glomeruli. IF: casts with equal kappa and lambda	Interstitial nephritis	Casts with lambda light chain restriction	Follicular Lymphoma, crystalline light chain cast nephropathy	Treatment with rituximab, significant reduction in lambda light chain load
2	AKI, hematuria, serum with IgG lambda, normal serum kappa/lambda ratio Urine P/C 18 g/g	MPGN pattern IF: Glomeruli with IgG, equal kappa and lambda	Idiopathic immune-complex MPGN	IgG and lambda restriction	Light and heavy chain deposition disease	Died prior to the start of chemotherapy
3	AKI, no monoclonal in serum or urine Urine P/C 11.3 g/g	MPGN pattern IF: Glomeruli with IgG, equal kappa and lambda	Idiopathic immune-complex MPGN	Monoclonal IgG3 kappa deposits	PGNMD	Treatment with CyBorD resulted in complete remission

Table 1: Use of Pronase Digestion Unmasks the Diagnoses

FR-PO684

Cell Cycle and Senescence Regulation by Podocyte Histone Deacetylases 1 and 2

Paulina Medina Rangel, Shuta Ishibe. Yale University, New Haven, CT.

**Background:** The loss of integrity of the glomerular filtration barrier results in proteinuria which is often attributed to the loss of podocytes. Despite the rising prevalence of proteinuric diseases, it is still unclear how podocytes are lost following damage. Senescence has been implicated to occur in age-related or by genomic stress such as DNA damage. Podocyte histone deacetylases (HDAC) are essential in maintaining a normal glomerular filtration barrier by modulating DNA-damage and preventing senescence.

**Methods:** Germline podocyte specific *Hdac1* and *2* double knockout (DKO) mice were generated.

**Results:** Our research describes that podocyte-specific loss *Hdac1* and *2* in mice results in severe proteinuria, collapsing glomerulopathy and sustained DNA damage, likely caused by deficient DNA damage repair in the absence of these enzymes. DNA damaged-podocytes not only re-entered the cell-cycle as studied with the FUCCI (Fluorescence-Ubiquitination-based Cell Cycle Indicator) system, but also exhibited p21-mediated cell-cycle arrest, which has been associated with cellular senescence. Consistent with these findings, podocyte senescence was demonstrated *in vivo* and *in vitro* by senescence-associated  $\beta$ -galactosidase activity and lipofuscin aggregates in the podocyte cell body. Through the senescence secretory associated phenotype, we evaluated that senescent podocytes secrete matrix metalloproteinases that may contribute to their detachment. Moreover, senescent podocytes were observed in the urine from these mutant mice.

**Conclusions:** Our findings suggest that *Hdac1* and *2* are essential in podocytes development, as the deletion of these genes lead to sustained DNA damage, senescence and loss of podocytes. The role of HDACs in cell cycle regulation and senescence may provide important clues in our understanding of how podocytes are lost following injury.

**Funding:** NIDDK Support

**Figure 1.** Loss of podocyte *Hdac1* and *2* in mice results in (A) collapsing glomerulopathy, (B) DNA damage (green) co-localized with WT-1 (red), (C) cell cycle re-entry, studied by FUCCI (WT-1 in blue, G1 phase in red) and (D) lipofuscin (blue granules), a marker of senescence.

FR-PO685

Glomerular-Tubular Cells Cross-Talk Mediated by Soluble RARRES1, a Podocyte-Secreted Protein

Ye Feng, John C. He, Kyung Lee. Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Retinoic acid receptor responder protein 1 (RARRES1) is a transmembrane protein whose expression is found mainly in podocytes and its expression is correlated with human glomerular disease progression. Our previous study also showed that extracellular cleavage of RARRES1 results in soluble form (sRARRES1), which is taken up via endocytosis to cause podocyte injury. Importantly, sRARRES1, but not full-length RARRES1, is pathogenic, as RARRES1 mutant with cleavage defect fails to induce podocyte injury. Therefore, we further determined the mechanism of RARRES1 cleavage to injure podocytes in an autocrine manner and whether podocyte-secreted sRARRES1 may injure tubular cells in a paracrine manner.

**Methods:** Human primary tubular epithelial cells were treated with sRARRES1 obtained from the supernatants of human podocytes with RARRES1 overexpression. Mice with podocyte-specific overexpression of human wildtype RARRES1 or RARRES1 cleavage mutant were generated and used for the study.

**Results:** We previously demonstrated that RARRES1 is cleaved by the MMP protease family. Among MMPs, multiple kidney scRNAseq datasets identified MMP23b to be highly and uniquely expressed in podocytes. In cultured human podocytes, TNF- $\alpha$  leads to enhanced MMP23b mRNA and protein expression, and MMP23b knockdown partially blocked RARRES1 cleavage. Treatment of tubular cells with purified sRARRES1 from podocyte supernatants induced tubular cell injury following its endocytic uptake. Interestingly, KIM-1 knockdown reduced tubular uptake of sRARRES1. Markers of ER stress were enhanced in tubular cells with sRARRES1 uptake *in vitro*. Consistently, kidneys of aged mice with podocyte-specific RARRES1 overexpression showed marked increase in ER stress and tubular injury markers, in the absence of significant proteinuria, suggesting that podocyte-derived sRARRES1 induces tubular cell ER stress and injury via glomerulo-tubular crosstalk.

**Conclusions:** Increased podocyte RARRES1 expression in glomerular disease results increased cleavage and uptake of sRARRES1 that results in autocrine podocyte injury as well as significant paracrine tubular cell injury, suggesting an important role of RARRES1 in podocyte-tubular cell crosstalk in kidney disease.

**Funding:** NIDDK Support, Veterans Affairs Support

**Background:** Terminally differentiated podocytes are highly susceptible to stress. Nucleotide excision repair (NER) genes are regulated in FSGS patient glomeruli. To study NER in podocytes, we generated a podocyte-specific *Erccl* knockout mouse (pko), which develops FSGS and shows activation of mTORC1 and inflammation, the latter shown here. Rapamycin treatment ameliorates the phenotype of *Erccl* pko mice. We present a calorie restriction study, known to inhibit mTORC1 and suppress inflammation and aging.

**Methods:** At 9 weeks of age, spleens and kidneys of *Erccl* pko and control mice were harvested and single-cell suspensions were prepared. T-cell and mononuclear phagocyte (MNP) populations were analyzed by flow cytometry using the BD LSRFortessa 2 cell analyzer. Immunohistochemistry for CD3 and MAC-2 was performed on kidneys of 12-week-old mice. 4-week-old *Erccl* pko mice were fed with 3.5 g standard diet over 4 weeks (CR). Two control groups were fed once daily with 4 g (SD) or *ad libitum* (AL). Histology as well as serum and urine analysis was performed at the end of the intervention period.

**Results:** 9-week-old *Erccl* pko mice showed an increased leukocyte count, mainly represented by Th1 cells. Systemically, Th17 cells were significantly decreased in *Erccl* pko-spleens with no changes in other immune cell populations. However, at 12 weeks *Erccl* pko mice showed a strong increase in glomerular macrophages, whereas glomerular T-cell-counts were unchanged. Albuminuria and glomerulosclerosis in *Erccl* pko mice were significantly reduced after 4 weeks of calorie restriction in line with a decrease of glomerular pS6RP signal, a downstream target of mTORC1.

**Conclusions:** *Erccl* deficiency causes progeroid syndromes in humans and mice. Podocyte-specific deletion of *Erccl* leads to glomerulosclerosis and early death, accompanied by mTORC1 activation and inflammation. Calorie restriction and rapamycin ameliorated disease progression. Next to inhibition of mTORC1 and deceleration of aging, calorie restriction is known to reduce inflammation. We show that renal inflammation is increased in *Erccl* pko mice. Interestingly, T-helper cell infiltration proceeds MNP infiltration into the kidneys. This influx and activation of immune cells might be regulated by calorie restriction and thus might explain the attenuation in the intervention group.

**The E3 Ubiquitin Ligase HUWE1 Is a Central Regulator of Podocyte Homeostasis**

Linus A. Volker,<sup>1,2</sup> Paul T. Brinkkoetter,<sup>1,2</sup> Bernhard Schermer,<sup>1,2</sup> Thomas Benzing,<sup>1,2</sup> Martin Höhne.<sup>1,2</sup> <sup>1</sup>*University Hospital of Cologne, Cologne, Germany;* <sup>2</sup>*Exzellenzcluster CECAD in der Universität zu Köln, Köln, Germany.*

**Background:** Terminal differentiation is a hallmark of renal podocytes. As terminally differentiated cells, podocytes need tight control of homeostasis. This is achieved through various signaling cascades such as mTOR, MAP-kinase signaling, AKT, and Wnt/Notch acting on diverse processes like proteostasis, DNA-damage repair, energy homeostasis and others. We identified the ultra-large E3 HECT-type ubiquitin-ligase HUWE1 as an interactor of the slit diaphragm associated protein complex. HUWE1 features a circular protein-protein interaction domain rendering it highly context-sensitive and versatile as a central modifier of intracellular signaling events via ubiquitination.

**Methods:** A podocyte-specific knockout mouse model of HUWE1 and shRNA- and CRISPR/Cas9-engineered podocyte cell-lines were used to elucidate the effects of HUWE1 on kidney function, podocyte homeostasis, and intracellular signaling. We employed a three-tiered multiomics approach including transcriptomics, proteomics, and ubiquitinomics to unravel the profound changes in podocyte homeostasis induced by HUWE1-deficiency.

**Results:** HUWE1-deficient mice develop albuminuria and progressive kidney failure at week 4. They develop severe glomerular damage and foot process effacement on the ultrastructural level. Huwe1-deficient mice die at week 7 to 14. Huwe1-deficient podocytes show decreased migratory activity and a general reduction in protein turn-over in the 26S proteasome fluorogenic peptidase assay, indicating defects in proteostasis. All three tiers of the multiomics approach demonstrated profound alterations in response to HUWE1-deficiency. An integrated analysis revealed podocyte-specific defects in mitochondrial energy metabolism, cell cycle and differentiation control, and actin cytoskeleton rearrangement. Moreover, a HUWE1-protein interaction network overlapped significantly with targets of mir193b-3p, a microRNA closely related to mir193a-3p, a known inducer of podocytopathy and FSGS.

**Conclusions:** HUWE1-deficiency causes a disruption of podocyte homeostasis via interaction with microRNA-associated networks and global changes in proteostasis, energy metabolism, cell cycle control, and actin cytoskeleton regulation.

## FR-PO688

**Farnesoid X Receptor Agonist Obeticholic Acid Reduces Kidney Disease in a Mouse Model of Alport Syndrome**

Bryce A. Jones,<sup>1</sup> Priscilla E. Perry,<sup>1</sup> Shania R. Davidson,<sup>1,2</sup> Isabel Lopez Santiago,<sup>1,3</sup> Sharmila Adapa,<sup>1</sup> Katherine C. Allen,<sup>1</sup> Katelyn Dial,<sup>1</sup> Emma Rowland,<sup>1</sup> Komuraiah Myakala,<sup>1</sup> Xiaoxin Wang,<sup>1</sup> Moshe Levi.<sup>1</sup> <sup>1</sup>*Georgetown University Medical Center, Washington, DC;* <sup>2</sup>*Howard University College of Arts and Sciences, Washington, DC;* <sup>3</sup>*Johns Hopkins University, Baltimore, MD.*

**Background:** Alport syndrome is a rare hereditary kidney disease caused by a mutation in the collagen IV  $\alpha3(\alpha4\alpha5)$  heterotrimer. The farnesoid X receptor (FXR) is a nuclear hormone receptor that is activated by bile acids. FXR agonism has been shown to protect the kidney in preclinical models of kidney disease, but no study thus far has investigated FXR agonism in an orphan kidney disease. Obeticholic acid is an FXR agonist approved for clinical use, and this greatly increases the translational value of preclinical studies with OCA. In this study, we test the hypothesis that obeticholic acid protects the kidney in a mouse model of Alport syndrome.

**Methods:** Male Col4a3<sup>tm1Jhm</sup> mice on 129S1/SvImJ were fed control diet (PicoLab 5053) alone or admixed with OCA (30 mg/kg BW) between 3 and 10 weeks of age. Col4a3<sup>-/-</sup> mice were the diseased mice, and Col4a3<sup>+/-</sup> and Col4a3<sup>-/-</sup> were the control mice. Plasma, urine, and organs were harvested at time of euthanasia for biochemical analyses.

**Results:** As expected, vehicle-treated Col4a3<sup>-/-</sup> mice had increased blood urea nitrogen (P < .0001), plasma creatinine (P < .0001), and urinary albumin-to-creatinine ratio (P < .0001) compared to control mice. Compared to vehicle-treated Col4a3<sup>-/-</sup> mice, OCA-treated Col4a3<sup>-/-</sup> mice had lower blood urea nitrogen (P < .05), plasma creatinine (trend, P < .06), and urinary albumin-to-creatinine ratio (P < .05) compared to vehicle-treated Col4a3<sup>-/-</sup> mice. Immunostaining for fibronectin and polarized imaging of picrosirius red (PSR) stained kidneys showed that OCA treatment prevented renal fibrosis compared to vehicle-treated mice (P < .05).

**Conclusions:** Obeticholic acid reduces kidney disease in a mouse model of Alport syndrome. Reduced renal fibronectin and PSR-positive staining suggests an OCA-mediated antifibrotic mechanism underlies at least part of the observed benefit.

**Funding:** NIDDK Support

## FR-PO689

**Increased Glomerular Elasticity Corresponds to Podocyte Injury and Loss in Alport Mice**

R. Tyler Miller,<sup>1,2</sup> Zhenan Liu,<sup>1</sup> Joonho Yoon,<sup>1</sup> Leslie A. Bruggeman,<sup>3</sup> Chao Xing,<sup>1</sup> Adwait Sathe,<sup>1</sup> Paul A. Janmey,<sup>4</sup> Joel M. Henderson,<sup>3</sup> Audrey N. Chang.<sup>1</sup> <sup>1</sup>*UT Southwestern Medical Center* <sup>2</sup>*The University of Texas Southwestern Medical Center, Dallas, TX;* <sup>3</sup>*VA North Texas Health Care System, Dallas, TX;* <sup>4</sup>*Case Western Reserve University, Cleveland, OH;* <sup>5</sup>*University of Pennsylvania, Philadelphia, PA;* <sup>6</sup>*Boston University School of Medicine, Boston, MA.*

**Background:** In primary glomerular renal disease, podocyte injury leads to proteinuria, hematuria, and later fibrosis with loss of tubular function. Podocyte injury causes disruption of cytoskeletal architecture with loss of foot processes and podocyte loss. We used Col4a3 KO Alport model mice to understand early steps in podocyte injury and loss.

**Methods:** Col4a3 knockout (KO) mice (Alport Syndrome model, C57Bl/6j) are born with normal renal function and progress to ESRD by 7 months. Activation of the unfolded protein response (UPR) in podocytes, attributed to accumulation of misfolded collagen heterotrimers, is a potential cause of podocyte injury in Alport nephropathy. We studied the structural and biophysical properties of podocytes in glomeruli from WT, KO, and tauroursodeoxycholic acid (TUDCA)-treated KO mice using microindentation, confocal microscopy, transmission EM, and bulk- and single-cell RNAseq to evaluate gene expression differences. We tested the hypotheses that 1) glomerular biophysical properties reflect podocyte injury and reduced cell number and 2) alleviation of the UPR reduces podocyte injury and preserves podocyte cell number and glomerular function.

**Results:** Increased glomerular deformability precedes proteinuria and increased serum creatinine that corresponds to increased podocyte loss that is associated with reduced podocyte adhesion. This period is followed by glomerular stiffening, reduced renal function, proteinuria, and fibrosis. Treatment with TUDCA reduced podocyte loss, normalized glomerular elasticity, and slowed progression of renal disease by functional and morphologic criteria. Bulk RNAseq and qRT-PCR showed patterns of fibrosis and inflammation that intensified with glomerular stiffening, proteinuria and reduced renal function, and that was reduced by TUDCA. scRNAseq of podocytes early in the course of disease before significant podocyte loss demonstrated injury pathway activation, with compensation by podocytes to resist injury and enhance cytoskeletal structure and adhesion.

**Conclusions:** Significant podocyte injury and loss occur before proteinuria and renal function deteriorates and fibrosis is a late event. Therapeutic efforts might be most effective when directed at early podocyte injury and loss.

## FR-PO690

**miR-193a and Nanoparticle Technology: A Novel Therapeutic Target in Alport Syndrome**

Laura Perin,<sup>1,2</sup> Astgik Petrosyan,<sup>1</sup> Sinem Kargin,<sup>1</sup> Paola Aguiari,<sup>1</sup> Qi Zhang,<sup>1</sup> Xiaogang Hou,<sup>1</sup> Roger E. De Filippo,<sup>1</sup> Kevin V. Lemley,<sup>1</sup> Eun ji Chung,<sup>2</sup> Stefano Da Sacco.<sup>1</sup> <sup>1</sup>Children's Hospital Los Angeles, Los Angeles, CA; <sup>2</sup>University of Southern California, Los Angeles, CA.

**Background:** Significant molecular and functional changes within the glomerulus, and specifically in podocytes, the cells in charge of the ultrafiltration, are responsible for the initiation and progression of renal damage. Our data indicate that elevation of miR-193a plays a key role in regulating podocyte biology by controlling podocyte cell cycle phases. Using different tools (glomerulus-on-a-chip: GOAC, human COL4-defective podocytes, FUCCI mice, nanoparticles, and spatial transcriptomics), we have identified miR-193a as a possible specific disease target in our model of CKD, Alport Syndrome (AS).

**Methods:** GOAC was seeded with human glomerular endothelial cells and podocytes derived from amniotic fluid of AS and healthy patients to recapitulate the function and structure of the glomerular filtration barrier. miR-193a studies were performed using mimics and inhibitors. Nanoparticles (micelle) containing miR-193a inhibitor were designed to specifically target podocytes. AS FUCCI mouse model (cell cycle indicator mouse model) was used to track podocyte miR-193a cell cycle modulation. Biopsies of Alport patients were used to confirm miR-193a expression by in situ hybridization and to perform Digital Spatial Profiling (DSP) using Nanostring technology.

**Results:** Spatial transcriptomics identified in human AS glomeruli altered gene expression for podocyte structure (foot process and slit diaphragm), GEC structure (glycocalyx), matrix turnover proteins, miR-193a targets, and cell cycle. Generated AS-GOAC presented impaired permselectivity, and proteomics revealed a distinctive AS signature. In AS-GOAC, miR-193a inhibition, delivered with innovative nanoparticles designed targeting podocytes, restored to normal the altered podocyte cell cycle, and regulated downstream miR-193a targets (WT1, ItgaVβ3/osteopontin, and VEGF) necessary for podocyte homeostasis.

**Conclusions:** We show that upregulating of miR-193a induces changes in gene expression and alteration of the cell cycle phases specifically in AS podocytes. Inhibiting miR-193a using micelle technology may re-establish glomerular function by modulating important molecular pathways responsible for podocyte survival representing a therapeutic target in AS settings.

## FR-PO691

**Extracellular Vesicle and Modulation of miR-93 in Kidney Disease**

Laura Perin, Charmi Dedhia, Paolo Neviani, Paola Aguiari, Valentina Villani, Astgik Petrosyan, Xiaogang Hou, Benedetta Bussolati, Sargis Sedrakyan. *Children's Hospital Los Angeles, Los Angeles, CA.*

**Background:** Modulation of miRNA expression in glomerular cells is associated with renal diseases. Our data indicate that miR-93 is down-regulated in glomeruli of mice with Alport syndrome (AS, our model of the renal disease characterized by a mutation in *coll4a5* gene) and in glomeruli of AS patients. Here, we investigated the role of hEVs derived from human amniotic fluid stem cells (hAFSC) in disease-modifying activity in vitro and in vivo by regulation of miR-93.

**Methods:** Isolated hEVs were characterized by cytometry, Exoview, immunomodulatory activity, RNA-seq, and proteomics. KO hEVs for miR-93 were generated by the use of an antagomir. Transfer and modulation of miR-93 (and its targets) in damaged human glomerular cells were evaluated in vitro. hEV disease-modifying activity was evaluated in AS mice by biodistribution, renal function, survival, and spatial transcriptomics (ST, Visium 10X Genomics Platform).

**Results:** By in situ analysis, we determined that miR-93 expression is decreased in mouse and human AS glomeruli. Cell specific damage decreases expression of miR-93 and its target expression (as VEGF) in human glomerular endothelial cells and podocytes. Expression of miR-93 was restored to normal levels only by normal hEVs and not KO hEVs. Proteomics and miR-seq data identified the specific hEV cargo fingerprint and that between the hEV and KO EV, a total of 59 proteins and 75 miRs were DE. GO and KEGG analysis of these cargo differences between hEVs and KO hEVs identified pathways central to disease progression, thus suggesting the central role of miR-93a in glomerular damage. When injected in AS mice, hEVs localized in the kidney, corrected proteinuria and prolong the lifespan. No side effects were noted. We defined spatial transcriptomics maps of kidneys from WT mice, AS mice, AS mice injected with hEVs and sacrificed after 5d and after 2m. Analysis of ST data on glomeruli showed that both early and late injections restored to normal important pathways responsible for AS progression (collagen formation, extracellular matrix alteration, fatty acid alteration) including miR-93 target pathways

**Conclusions:** hEVs regulated pathways that are central to glomerular homeostasis by modulation of miR-93. This suggests the possibility of using hEVs as a new therapeutic option for treating AS.

**Funding:** NIDDK Support

## FR-PO692

**Ramipril Therapy in Integrin  $\alpha$ 1-Null ARAS Mice Triples Lifespan: Mechanistic Clues From RNA-Seq Analysis**

Dominic E. Cosgrove,<sup>1</sup> Jacob D. Madison,<sup>1</sup> Daniel T. Meehan,<sup>1</sup> Kevin O. Wilhelm,<sup>2</sup> MichaelAnne Gratton,<sup>1</sup> Gina C. Samuelson,<sup>1</sup> John A. Fascianella.<sup>1</sup> <sup>1</sup>Boystown National Research Hospital, Omaha, NE; <sup>2</sup>Baylor College of Medicine, Houston, TX.

**Background:** The standard of care for patients with Alport syndrome is ACE inhibitors. In ARAS mice, the ACE inhibitors double lifespan. In humans, ACE inhibitor treatment extends life as well. Any therapy developed must provide significant benefit over ACE inhibition alone. Here we show that integrin  $\alpha$ 1-null Alport (DKO) mice treated with ramipril live 3X longer than untreated ARAS mice. This effect may be the result of laminin 211-mediated suppression of the transcriptional regulator FOXC2, which reduces expression of nephrin and podocin.

**Methods:** DKO mice were treated with vehicle or ramipril starting at 4 weeks of age. Proteinuria and glomerular filtration rates were measured at 5-week intervals. Glomeruli were analyzed for laminin 211 deposition in the GBM and GBM ultrastructure analyzed by TEM. RNA-seq was performed on isolated glomeruli at various timepoints, and cultured podocytes were overlaid with recombinant laminin 211 or not and RNA analyzed by RNA-seq.

**Results:** GFR in DKO mice decline between 10 and 15 weeks of age and in ramipril-treated DKO mice at 30 to 35 weeks. Proteinuria followed these same patterns with normalization of GBM architecture in ramipril-treated DKO mice. RNA-seq analysis showed that alteration of gene expression and pathways were similar comparing DKO with ramipril-treated DKO mice with delayed effects in ramipril-treated DKO mice. Decline in expression of nephrin and podocin mRNA and protein occurred but was delayed in the ramipril-treated DKO mice. GBM accumulation of laminin 211 was delayed in ramipril-treated Alport mice, and laminin 211 treatment of podocytes reduced expression of FOXC2 nephrin, and podocin.

**Conclusions:** Ramipril synergizes with integrin  $\alpha$ 1 blockade slowing the progression of glomerular disease and tripling the lifespan compared to untreated ARAS mice. The slowed progression involves similar genes and pathways, particularly the transcriptional regulator FOXC2, nephrin, and podocin. Reduced accumulation of laminin 211 in the GBM in treated mice. *In vitro*, Cultured podocytes exposed to laminin 211 show changes similar to Alport glomeruli.

**Funding:** Other NIH Support - NIDCD

## FR-PO693

**Altered Podocytes and Glomerular Stiffness in Alport Syndrome Occurs in Association With Increased SMPDL3b Expression**

Margaret Z. Gurumani,<sup>1,2</sup> Shamroop Kumar Mallela,<sup>1,2</sup> Alla Mitrofanova,<sup>1,2</sup> Jeffrey D. Pressly,<sup>1,2</sup> Vincent T. Moy,<sup>1</sup> Sandra M. Merscher,<sup>1,2</sup> Alessia Fornoni.<sup>1,2</sup> <sup>1</sup>University of Miami School of Medicine, Miami, FL; <sup>2</sup>University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL.

**Background:** Alport Syndrome (AS) is a hereditary disease caused by mutations in different chains of collagen IV, a component of the Glomerular Basement Membrane (GBM). While alterations in the composition of GBM that occur during pathogenesis has been extensively studied, less is known about the immediate cellular consequences occurring in podocytes contacted with an altered GBM. Sphingolipids are essential plasma membrane (PM) constituents, and the PM sphingolipids composition regulates the mobility of integrins, thereby promoting cell adhesion. We, and others have identified sphingomyelin-phosphodiesterase-acidlike-3b (SMPDL3b), an enzyme expressed in lipid raft domains of podocytes, where it regulates receptor assembly in caveolin-rich PM domains and where it regulates the availability of active sphingolipids such as ceramide 1 phosphate (C1P). With this study, we test the hypothesis that increased SMPDL3b expression in podocytes in the context of AS contributes to altered glomerular/podocyte stiffness.

**Methods:** Human podocyte cell lines transfected with a thermosensitive SV40- T construct and AS podocytes established from AS and wild type (WT) control mice were used for analysis. Atomic force microscopy (AFM) was used to assess the stiffness of podocyte in vitro and of micro dissected glomeruli ex vivo. RT-PCR was used to determine SMPDL3b expression in sieved glomeruli. PM fluidity was determined using a membrane fluidity kit from ABCAM.

**Results:** The expression of SMPDL3b was increased in AS podocytes and glomeruli when compared to WT. AS podocytes and glomeruli are associated with a significant decrease in stiffness when compared to WT. However, no changes in PM fluidity were observed in SMPDL3b OE podocytes when compared to control. SMPDL3b OE podocytes are also associated with a decrease in cell stiffness. C1P replenishment restores cell stiffness in SMPDL3b OE podocytes.

**Conclusions:** Our data demonstrate that SMPDL3b expression is increased in AS podocytes and glomeruli. Both SMPDL3b OE and AS podocytes and glomeruli are characterized by decrease in stiffness. Further studies are required to determine if SMPDL3b mediates cells and glomerular stiffness in AS and to determine how changes in stiffness affect the interaction with other components of filtration barrier.

**Funding:** NIDDK Support, Private Foundation Support

## FR-PO694

**SMPDL3b Regulates Proteinuria in Experimental Alport Syndrome via Sphingosin-1-Phosphate**

Alla Mitrofanova,<sup>1</sup> Annapurna Pamreddy,<sup>2</sup> Antonio M. Fontanella,<sup>1</sup> Matthew Tolerico,<sup>1</sup> Shamroop Kumar Mallela,<sup>1</sup> Margaret Z. Gurumani,<sup>1</sup> Judith T. Molina David,<sup>1</sup> Jin Ju Kim,<sup>1</sup> George W. Burke,<sup>1</sup> Sandra M. Merscher,<sup>1</sup> Kumar Sharma,<sup>2</sup> Alessia Fornoni.<sup>1</sup> <sup>1</sup>University of Miami School of Medicine, Miami, FL; <sup>2</sup>The University of Texas Health Science Center at Houston, Houston, TX.

**Background:** Alport Syndrome (AS) is caused by mutations in the gene coding for type IV collagens and is characterized by progressive loss of kidney function, where podocytes play the central role. We previously reported that cholesterol and sphingolipids are major determinants of podocyte function, and that sphingomyelin phosphodiesterase acid-like 3b (SMPDL3b), a lipid raft associated protein, plays an important role in podocyte survival and regulates the availability of bioactive sphingolipids such as sphingosine-1-phosphate (S1P). We tested the hypothesis that altered podocyte SMPDL3b expression affects the generation of S1P thus contributing to the renal failure in AS.

**Methods:** Illumina sequencing RNA data analysis, qRT-PCR and Western blot analysis were used to characterize differentiated immortalized murine podocytes isolated from AS mice. Kidney cortices from 8-week-old AS mice were used for LC-MS analysis. Kidneys from 20-weeks-old podocyte-specific Smpdl3b deficient AS mice (DKO) mice and their controls were processed for in-depth phenotypical analysis, including urinary albumin-to-creatinine ratio (ACR) and matrix-assisted laser desorption/ionization mass spectrometry imaging (MALDI-MSI). 16-weeks-old AS and DKO mice were intraperitoneally injected with 100 nM S1P for 4 weeks. Two-tailed t-test or One-Way ANOVA followed by Tukey's post-test were used to detect statistical changes.

**Results:** SMPDL3b expression is significantly higher in isolated podocytes and in kidney cortices from AS mice. Moreover, decreased expression of S1P phosphatase 1, an enzyme that catalyzes S1P dephosphorylation, in isolated podocytes was observed in association with S1P and ceramide accumulation in kidney cortices from AS mice. Podocyte specific SMPDL3b deletion in DKO mice resulted in decreased ACR levels and increased number of podocytes foot processes. S1P injections in DKO mice caused worsened albuminuria.

**Conclusions:** Our data indicate that SMPDL3b expression may affect availability of S1P, thereby regulating proteinuria levels in experimental AS. Thus, targeting SMPDL3b expression levels in the podocytes may represent a novel approach to improve renal outcomes in patients with AS.

**Funding:** NIDDK Support, Private Foundation Support

## FR-PO695

**Therapeutic Blockade of the SLIT/ROBO Signaling Pathway Alleviates Podocytopathy Defects in Integrin-Linked Kinase Podocyte-Specific Knockout Mice**

Sudhir Kumar,<sup>1</sup> Xueping Fan,<sup>1</sup> Emily Zaltz,<sup>1</sup> Hui Chen,<sup>2</sup> Joel M. Henderson,<sup>1,2</sup> David J. Salant,<sup>1,2</sup> Hongying Yang,<sup>3</sup> Stephen Berasi,<sup>3</sup> Weining Lu.<sup>1,2</sup> <sup>1</sup>Boston University, Boston, MA; <sup>2</sup>Boston Medical Center, Boston, MA; <sup>3</sup>Pfizer Inc, Cambridge, MA.

**Background:** The SLIT/ROBO signaling pathway negatively regulates podocyte adhesion and actin polymerization. Podocyte-specific deletion of integrin-linked kinase (ILK) in mice (ILK cKO) causes a podocytopathy reflecting FSGS with severe proteinuria, podocyte loss, and renal failure. We hypothesized that therapeutically blocking the SLIT/ROBO pathway with a ROBO2-IgG-Fc fusion protein would improve the podocytopathy phenotype in adult ILK cKO mice.

**Methods:** Seven-week-old ILK cKO homozygous mice were generated and treated with the ROBO2-IgG-Fc fusion protein or control IgG at 25 mg/kg every 2-3 days for 16 weeks. The survival probability of ILK cKO mice was calculated using the Kaplan Meier estimator. Urine samples were collected every two days to measure the urine albumin-to-creatinine ratio (UACR). Renal function (BUN measurement), kidney histology (PAS staining), podocyte number (P57 staining), podocyte foot process width (FPW), and slit diaphragm (SD) density of ILK cKO mice were assessed after three weeks of the treatment.

**Results:** Median survival was significantly longer in ROBO2-IgG-Fc treated than control IgG treated ILK cKO mice (105 days versus 52 days). After 3-weeks of treatment, significant mean UACR reductions were observed on day 18 (46%) and day 21 (50%) in ROBO2-IgG-Fc treated ILK cKO mice compared to control IgG treated mice. In addition, BUN was considerably lower in ILK cKO mice treated with the ROBO2-IgG-Fc (88 mg/dL) than the control IgG (124 mg/dL). Finally, podocyte loss, podocyte FPW, SD density, and renal tubular injury in ILK cKO mice were significantly improved by the ROBO2-IgG-Fc treatment compared to control IgG.

**Conclusions:** Therapeutic inhibition of the SLIT/ROBO signaling pathway ameliorates the podocytopathy phenotype and significantly extends the life span of adult ILK podocyte-specific knockout mice via preventing podocyte loss, reducing albuminuria, and improving renal function. Our studies provide additional confidence in rationale for blocking the ROBO/SLIT signaling pathway for treating podocytopathies and proteinuric kidney diseases. A phase 2 (NCT03448692) clinical trial testing the efficacy of a ROBO2-Fc fusion protein (PF-06730512) in FSGS patients is ongoing.

**Funding:** NIDDK Support, Commercial Support - Pfizer Inc.

## FR-PO696

**Therapeutic Blocking of NPRC, a Podocyte-Expressed Target, Is Kidney Protective in ZSF1 Rats**

Mark Lal,<sup>1</sup> Dina Dabaghie,<sup>2</sup> Emmanuelle Charrin,<sup>2</sup> Pernilla Tonelius,<sup>1</sup> Birgitta E. Rosengren,<sup>1</sup> Anna Granqvist,<sup>1</sup> Jaakko Patrakka.<sup>2</sup> <sup>1</sup>AstraZeneca Pharmaceuticals LP, Gothenburg, Sweden; <sup>2</sup>Karolinska Institutet, Stockholm, Sweden.

**Background:** Increasing natriuretic peptide (NP) levels can be achieved by neprilysin inhibition and is a clinically validated therapeutic strategy for heart failure, when combined with an angiotensin receptor blocker. An equally important and fundamental determinant of NP levels is contributed to by the NP clearance receptor, NPRC, a membrane protein abundantly expressed in the kidney. In this study, we aimed to elucidate the role of NPR3 in the pathogenesis of glomerulopathies.

**Methods:** Renal expression of NPR3 was studied using qPCR, scRNAseq and immunohistochemistry. The functional role of NPRC was analyzed using a novel mouse line in which NPRC was genetically inactivated specifically in podocytes (NPRC podKO). NPRC was targeted pharmacologically using an NPRC blocking peptide in a rat model of DN (uninephrectomized obese ZSF-1 rats (UNx ZSF-1 rats)), followed by studies in a mouse glomerulopathy model.

**Results:** NPRC was highly and specifically expressed by podocytes of the glomerulus. NPRC podKO mice showed normal kidney morphology and function and NPRC-deficiency did not readily affect the outcome of an acute mouse glomerulopathy model. In diabetic UNx ZSF-1 rats, pharmaceutical blocking of NPRC activity resulted in increased urinary and plasma cGMP levels, indicative of successful target engagement and elevated NPs. Diabetic rats treated only with NPR3 blocker showed limited impact on readouts of renal injury. However, when NPRC blocking was combined with losartan (angiotensin receptor blocker), it potentiated significantly the ameliorative effects on albuminuria and glomerular sclerosis. In line with this, NPRC blocking showed reno-protective effects in a mouse glomerulopathy model as shown by decreased glomerulosclerosis and reduced podocyte loss.

**Conclusions:** NPRC is highly expressed by podocytes and blocking its clearance activity appears to contribute to reno-protective effects in DN. Additional studies are needed to understand the molecular mechanisms of NP-signaling in the glomerulus and to explore the extent to which local paracrine and systemic NPRC blocking may contribute to functional benefit in kidney disease.

**Funding:** Commercial Support - AstraZeneca

## FR-PO697

**High-Throughput, Prospective Discovery of Splice-Disruptive Variants (SDVs) in the Nephrotic Syndrome (NS) Gene WT1**

Jennifer Lai Yee, Cathy Smith, Ian A. Dunn, Bala Bharathi B. Burugula, Jacob O. Kitzman. *University of Michigan, Ann Arbor, MI.*

**Background:** SDVs contribute to a fraction of nearly every human genetic disorder. Frasier Syndrome, a syndromic NS, is caused by SDVs near *WT1* exon 9 splice donor site (SD), which decrease the ratio between two natural splice forms of *WT1* called +KTS and -KTS. Beyond a few known Frasier Syndrome SDVs, accurately predicting other *WT1* variants' effects on splicing remains a challenge. *In vitro* minigene assays provide one means to test variant effect on splicing in highly multiplexed fashion. Thus, we coupled minigene assays with saturation mutagenesis across *WT1* exon 9 to systematically identify *WT1* SDVs in a high-throughput manner.

**Methods:** *WT1* exon 9 plus 200 bases of the flanking introns were cloned into an established minigene plasmid, in between constant synthetic exons. Saturation mutagenesis was performed to generate a variant library including every single nucleotide variant across the cloned region, each associated with a unique barcode present in the constant downstream exon. This variant library was then transfected into 293T cells, and 24 hours later, RNA was harvested from those cells and spliced transcripts from the minigene library were read by target RNA-seq. The splicing patterns associated with each *WT1* exon 9 variants were quantified from the aligned reads.

**Results:** Every possible single-base mutation was generated in the library, with a high degree of redundancy. Among spliced reads, +KTS and -KTS were the most highly represented isoforms and normally present at roughly 1:1 ratio. We identified 19 single-nucleotide variants near the +KTS SD which disrupt the normal splicing pattern of +KTS and -KTS isoform, favoring the expression of -KTS. Among these we detected all 8 known Frasier Syndrome variants. We also identify 16 single-nucleotide variants clustering near the -KTS SD which increased the expression of +KTS isoform.

**Conclusions:** Our saturation screen identifies all known Frasier syndrome SDVs in *WT1* exon 9. We also nominate an additional 11 variants which similarly decrease the +KTS/-KTS ratio, and these represent possible yet unseen Frasier Syndrome variants. We also discovered a set of variants which increase +KTS expression, which require further study. In summary, high throughput functional analyses can prospectively score genetic variants in NS and guide the functional classification

**Combining Multiphoton Microscopy With Super-Resolution Microscopy to Investigate Podocyte Injury in Acute Murine Kidney Slices**

Eva Wiesner, Julia Binz, Agnes Hackl, David Unnersjö-Jess, Thomas Benzing, Matthias Hackl. *Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany.*

**Background:** Maintenance of low intracellular calcium levels is important for podocyte health, as impairments in its homeostasis lead to kidney disease. However, it remains unclear what effects increasing calcium signals have on the actin cytoskeleton and the slit diaphragm. To combine functional measurements with a high-resolution structural readout, we established a novel co-imaging approach using two distinct microscopy techniques: multiphoton and STED microscopy, in an acute murine kidney slices (AKS) model.

**Methods:** For disease induction, nephrotoxic serum was injected into 5-week old C57BL/6 mice expressing GCaMP3 under the Pod:Cre promoter exclusively in podocytes. 5 days after injection the animals were sacrificed. The kidneys were removed and cut into slices of 300 µm thickness. The first imaging step was conducted at a multiphoton microscope to measure the fluorescence intensity of the GCaMP3 sensor. During acquisition, the slice was burned at several points in the kidney interstitium, later used as hallmarks. The AKS was fixed and prepared by anti-nephrin staining for follow-up STED microscopy. During STED imaging previously recorded glomeruli were identified by the burning points and high-resolution images of the slit diaphragm were acquired.

**Results:** Imaging of control animals showed low intracellular calcium levels in podocytes and an intact slit diaphragm architecture. In animals after induction of a nephrotoxic serum nephritis, the combination of multiphoton with STED microscopy revealed higher intracellular calcium levels in podocytes and a destruction of the slit diaphragm and demonstrated a correlation between intracellular calcium levels of podocytes and changes in the slit diaphragm morphology of different glomeruli in a single animal.

**Conclusions:** This new co-imaging approach combines the technical advantages of the individual imaging techniques and enables us to image the same glomerulus sequentially to correlate intracellular calcium levels with ultrastructural impairments of the slit diaphragm in a podocyte disease model. Our established co-imaging protocol using AKS can be applied to several research questions, providing both functional and ultrastructural information.

**Synuclein Alpha Accumulation Mediates Podocyte Injury in Fabry Nephropathy**

Fabian Braun,<sup>1</sup> Ahmed Abed,<sup>2</sup> Oystein Eikrem,<sup>3</sup> Nicola Wanner,<sup>1</sup> Soeren W. Gersting,<sup>1</sup> Ania C. Muntau,<sup>1</sup> Oliver Kretz,<sup>1</sup> Behzad Najafian,<sup>4</sup> Camilla Tøndel,<sup>5</sup> Michael Mauer,<sup>6</sup> Tillmann Bork,<sup>2</sup> Florian Grahmmer,<sup>1</sup> Thorsten Eierhoff,<sup>7</sup> Winfried Römer,<sup>2</sup> Hans-Peter Marti,<sup>3</sup> Victor G. Puelles,<sup>1</sup> Christoph Schell,<sup>2</sup> Tobias B. Huber.<sup>1</sup> <sup>1</sup>Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; <sup>2</sup>Albert-Ludwigs-Universität Freiburg, Freiburg im Breisgau, Germany; <sup>3</sup>Universitetet i Bergen Det medisinsk-odontologiske fakultet, Bergen, Norway; <sup>4</sup>University of Washington, Seattle, WA; <sup>5</sup>Haukeland Universitetssjukehus, Bergen, Norway; <sup>6</sup>University of Minnesota, Minnesota, MN; <sup>7</sup>University Hospital Münster, Münster, Germany.

**Background:** Anderson-Fabry disease is an X-linked lysosomal disorder characterized by a multisystemic globotriaosylceramides (Gb3) accumulation due to reduced alpha-galactosidase activity (GLA). Current therapies for Fabry disease are based on reversing intra-cellular accumulation Gb3 by enzyme replacement therapy (ERT) or chaperone-mediated stabilization of the defective enzyme, thereby alleviating lysosome dysfunction. However, their effect in the reversal of end-organ damage, like kidney injury and chronic kidney disease remains unclear.

**Methods:** We employed CRISPR/CAS9 to generate GLA knock out lines of immortalized human podocytes *in-vitro*. These cells were investigated by (ultra-) structural, transcriptome and proteome as well as functional analyses in the presence and absence ERT. The acquired data sets were integrated through network analysis and connectivity mapping. These data were complemented by the investigation of human biopsies taken sequentially before and after a period of ERT.

**Results:** Ultrastructural analysis of sequential renal biopsies showed that ERT use reduced Gb3 accumulation in podocytes but did not reverse foot process widening. The α-Galactosidase knockout podocyte cell line confirmed ERT-mediated reversal of Gb3 accumulation without resolution of lysosomal dysfunction. Transcriptome-based connectivity mapping and SILAC-based quantitative proteomics identified alpha-synuclein (SNCA) accumulation as a key event mediating podocyte injury. Genetic and pharmacological inhibition of SNCA improved lysosomal structure and function in Fabry podocytes, exceeding the benefits of ERT.

**Conclusions:** Together, this work reconceptualizes Fabry-associated cell injury beyond Gb3 accumulation, and introduces SNCA modulation as a potential intervention, especially for patients with Fabry nephropathy.

## FR-PO700

**Sarcomere-Like Structures Prevent Podocyte Detachment and Template Synaptopodin-Positive Extensions**

Shumeng Jiang,<sup>1</sup> Jeffrey H. Miner,<sup>2</sup> Guy M. Genin,<sup>1</sup> Hani Suleiman.<sup>2</sup> <sup>1</sup>Washington University in St Louis, St Louis, MO; <sup>2</sup>Washington University in St Louis School of Medicine, St Louis, MO.

**Background:** Podocyte injuries can cause chronic kidney disease, which is widespread and incurable. The biophysical mechanisms underlying podocyte responses to injury are unclear, in part because materials systems for mimicking the microenvironment of relevant kidney cells are limited.

**Methods:** We developed an *ex vivo* micropatterned hydrogel culture system that allows the control of the podocyte microenvironment, including ECM substrate types, stiffness, and cell shapes. This approach allows us to study the primary podocyte cytoskeleton immediately after their migration from isolated glomeruli of both mouse and human origins.

**Results:** In this culture system, primary podocytes upregulated a mat of sarcomere-like structures (SLs), with striations composed of alternating clusters of α-actinin 4, synaptopodin and myosin IIA in the early stages of spreading. These structures are reminiscent of the SLs observed in pathological podocytes *in vivo*. The periodic synaptopodin-positive clusters nucleated peripheral, foot process-like extensions, suggesting a role for SLs in guiding the formation and proper spacing of these processes. SLs were not found in a podocyte cell line, either before or after differentiation. Functionally, podocytes presenting SLs were highly contractile. The SLs were dissembled when we reduced their contractility either by inhibiting myosin, decreasing substrate stiffness, or inhibiting RhoA, ROCK or formins to target the Rho signaling pathway. In addition, our experiments revealed faster detachment of podocytes that lost SLs, emphasizing the need for SLs in injured podocytes to prevent podocyte loss as part of an adaptive mechanism after injury.

**Conclusions:** We show that SLs may have a dual role in podocyte biology: providing sufficient contractility that helps maintain adhesion to the GBM after injury; and templating the formation of foot process in immature podocytes or those recovering from injury. Therefore, the SLs in injured podocytes may serve as potential therapeutic targets.

## FR-PO701

**Plasma From Patients With Focal Segmental Glomerulosclerosis Triggers an Abnormal Kidney Organoid Development With Specific Alteration in the Glomerular Structures and Podocytes**

Lorenzo G. Gallon,<sup>1</sup> Ashwani K. Gupta,<sup>3</sup> Jason Wertheim.<sup>2</sup> <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>The University of Arizona College of Medicine Phoenix, Phoenix, AZ; <sup>3</sup>The University of Arizona College of Medicine Phoenix, Phoenix, AZ.

**Background:** Focal segmental glomerulosclerosis (FSGS) is a frequently acquired kidney disorder resulting in end-stage renal disease and it is associated with a high rate of recurrence after renal transplantation. Clinical and experimental evidence has shown that a circulating factor is involved in the pathogenesis of FSGS and its recurrence. We hypothesized that FSGS plasma could trigger an FSGS-specific abnormality in the glomerular structures and podocytes of kidney organoids.

**Methods:** The hPSCs were induced to differentiate in kidney organoids. On day 16, kidney organoid media was changed with fresh medium containing 10% healthy plasma, recurrent FSGS plasma, non-recurrent FSGS plasma, or primary FSGS plasma. On day 23, organoids were evaluated under a stereomicroscope, and organoids were stained for podocytes specific proteins, extracellular matrix (ECM) proteins, and injury molecules.

**Results:** Kidney organoids generated with organoid media and healthy plasma showed typical developmental phenotype with intact and tightly packed tubular clusters whereas organoids generated with FSGS plasma showed abnormal or damaged tubular clusters (Fig1. A-E). Podocalyxin staining for podocytes showed the organoids generated in organoid media and healthy plasma had intact presumptive glomerular structures (Fig1. F, G). Recurrent FSGS plasma-treated organoids and primary FSGS plasma-treated organoids showed damaged presumptive glomerular structures and scattered podocalyxin expression patterns (Fig1. I-J). Gene expression analysis by qPCR of kidney organoids cultured with recurrent FSGS plasma or primary FSGS plasma vs media, healthy plasma, or non-recurrent FSGS plasma showed alteration of podocytes specific proteins.

**Conclusions:** FSGS plasma can trigger FSGS specific abnormality in the glomerular structures and podocytes. FSGS plasma induce podocyte and proximal tubule injury. Our kidney organoid model could be a useful tool to study the pathophysiology of primary FSGS.

**Funding:** Other U.S. Government Support

Phenotypic changes to kidney organoids after FSGS plasma treatment.

## FR-PO702

### In Vivo High-Content Zebrafish Screening Identifies Podocyte-Protective Drugs

Maximilian Schindler,<sup>1</sup> Florian Siegerist,<sup>1</sup> Jochen Gehrig,<sup>2</sup> Sheraz Gul,<sup>3</sup> Nicole Endlich,<sup>1</sup> Endlich Lab <sup>1</sup>Universitätsmedizin Greifswald, Greifswald, Germany; <sup>2</sup>Acquifer Imaging GmbH, Heidelberg, Germany; <sup>3</sup>Fraunhofer-ITMP, Hamburg, Germany.

**Background:** Podocyte injury is the major cause of FSGS and no curative drugs are currently available. Therefore, identification of small molecules/compounds protecting podocytes is of high relevance. Since zebrafish larvae develop a size-selective filtration barrier within 4 days and we recently established a larval FSGS-like model, this organism is ideally suited for *in vivo* high-content screenings.

**Methods:** A transgenic screening strain expresses the nitroreductase and the fluorescent dye mCherry exclusively in podocytes. Additionally, a 78-kDa circulating eGFP-vitamin D-binding fusion protein is expressed. After incubation of larvae with 80 μM metronidazole (MTZ) for 24 hours, podocyte depletion and glomerular clearance of the eGFP fusion protein is induced. For the screening, larvae were co-treated with MTZ and compounds of a drug library at 4 days post fertilization (dpf) for 24 hours. After washout, the vascular eGFP as well as the podocyte mCherry was imaged at 5 and 6 dpf. The fluorescence ratios depict robust readouts for the degree of podocyte depletion and proteinuria.

**Results:** The screening of a drug library consisting of 138 compounds provided 9 potential hits with a protective effect on podocytes. These compounds significantly reduced the loss of vascular and/or podocyte fluorescence compared to the injury control group. Subsequent validation experiments with n=288 larvae per compound confirmed or rejected a protective effect of the drugs.

**Conclusions:** Our group established an *in vivo* high-content screening that identified potential drugs to treat FSGS.

**Funding:** Private Foundation Support, Government Support - Non-U.S.

## FR-PO703

### Flotillin Mediates Raft-Dependent Turnover of Fly Nephlin Within Slit Diaphragms in Drosophila Nephrocytes

Konrad Lang,<sup>1</sup> Julian Milosavljevic,<sup>1</sup> Helena Heinkel,<sup>1</sup> Martin Helmstädter,<sup>1</sup> John N. Poulton,<sup>2</sup> Tobias F. Hermle,<sup>1</sup> <sup>1</sup>Universitätsklinikum Freiburg Abteilung Innere Medizin IV Nephrologie und Allgemeinmedizin, Freiburg, Germany; <sup>2</sup>The University of North Carolina at Chapel Hill, Chapel Hill, NC.

**Background:** Evidence from *in vitro* studies and murine knockout models support a role of endocytosis for the glomerular filtration barrier. Two endosomal regulators, *GAPVD1* and *TBC1D8B*, were discovered as a monogenetic cause of nephrotic syndrome in humans. However, the mechanistic role of endocytosis at the slit diaphragm remains unclear. The nephrocyte model of *Drosophila* provides an accessible, molecularly conserved podocyte model to study slit diaphragm dynamics.

**Methods:** Using acute gain- and loss-of function strategies for endosomal regulators in *Drosophila* nephrocytes, we studied their impact on the trafficking of slit diaphragm proteins in fixed samples and live imaging. Endocytic turnover was investigated by live antibody labeling after genome editing of fly nephlin.

**Results:** Sns, the *Drosophila* ortholog of nephrin, exhibits a half-life of about two days after acute knockdown and the architecture of slit diaphragms appears stable in live imaging short term. However, live antibody labeling of fly nephrin revealed a near complete turnover after two hours, confirmed by FRAP analysis. This suggests that slit diaphragms form a stable yet very dynamic structure. Acute knockdown of Rab5, a small GTPase and key regulator of early endosomes, caused the formation of ectopic slits as well as a severely diminished Sns turnover. Silencing of the early endosomal protein Hrs phenocopied Rab5-RNAi. Diminished endocytosis further altered characteristics of the filtration barrier, selectively reducing passage of tracers close to the upper size limit. Silencing of *Rab11*, which promotes recycling, led to a slower turnover of Sns. Rab7, a regulator of degradation, had no overt impact on slit diaphragm formation or turnover, suggesting that degradation is dispensable for maintenance. To study the endocytic routes of entry, we acutely blocked dynamin-dependent endocytosis, which caused ectopic slits but a normal Sns turnover. Conversely, exposure to Cyclodextrin or inhibition raft-mediated flotillin endocytosis reduced the turnover significantly.

**Conclusions:** Dynamin-dependent endocytosis prevents the formation of ectopic slit diaphragms in nephrocytes. Flotillin-dependent endocytosis dominates turnover of nephrin within the slit diaphragm.

**Funding:** Government Support - Non-U.S.

## FR-PO704

### Using Drosophila melanogaster to Characterize Potentially Pathogenic Patient Mutations Associated With Nephrotic Syndrome and Focal Segmental Glomerulosclerosis

Johanna Odenthal, Bodo B. Beck, Bernhard Schermer, Thomas Benzing, Paul T. Brinkkoetter, Malte P. Bartram. Uniklinik Köln, Köln, Germany.

**Background:** Regulation of actin cytoskeleton organization is at the center of podocyte morphology and homeostasis during health and disease. The actin-binding and -crosslinking protein Alpha-actinin 4 (ACTN4) has been shown to play an essential role in this context, as mutations in the *ACTN4* gene are leading to an autosomal-dominant form of focal segmental glomerulosclerosis (FSGS). Here, performing gene panel sequencing in a pediatric patient presenting with steroid resistant nephrotic syndrome and FSGS, a *de novo*, potentially disease causing variant of *ACTN4* was identified, which was previously undescribed and not found in available genome or exome databases. Our aim is to elucidate the pathogenic potential of this variant for podocytes and FSGS progression.

**Methods:** To investigate the pathogenic potential of the newly identified ACTN4 variant (ACTN4-M240T), we employed the genetic toolbox of *Drosophila*. The fly holds podocyte-equivalent cells called nephrocytes, which are responsible for filtration and detoxification of the hemolymph. Cell-specific genetic manipulation enabled us to analyze RNAi-mediated knockdown of Actinin, the single fly homolog, in nephrocytes and its impact on cell morphology and function. Rescue experiments with the novel human ACTN4 variant will now give indication about possible pathogenic consequences of the mutation when compared to wildtype as well as previously described disease-associated variants of ACTN4.

**Results:** Knockdown of *Drosophila* Actinin in nephrocytes leads to severe functional and morphological defects, as seen by impacted filtration capacity and reduced nephrocyte diaphragm length. Transgenic expression of wildtypic human ACTN4 resulted in partial rescue of the Actinin-knockdown associated phenotypes. In contrast, expression of ACTN4-M240T as well as other FSGS-associated ACTN4-mutant proteins neither ameliorated functional nor morphological defects.

**Conclusions:** Our results underline the importance of Actinin and actin cytoskeleton regulation for nephrocyte/podocyte biology. As ACTN4-M240T was not able to rescue Actinin-knockdown associated phenotypes, but in contrast, showed similar results to other pathogenic variants of ACTN4, we conclude that also ACTN4-M240T is a pathogenic variant of ACTN4.

## FR-PO705

### Mitochondrial ROS Sensitize Podocytes to Insulin Resulting in mTOR Activation

Johanna Odenthal, Katrin Reitmeier, Lucas Kuehne, Bernhard Schermer, Thomas Benzing, Paul T. Brinkkoetter. Uniklinik Köln, Köln, Germany.

**Background:** Beyond their contribution to maintaining cellular ATP levels, mitochondria have been recognized as signaling hubs regulating podocyte function in states of health and disease. Recently, we established podocyte specific Phb2 deficient mice as *in vivo* model to study dysfunctional mitochondria and their impact on podocyte metabolism. PHB2 acts as scaffold protein at the inner mitochondrial membrane and is required for proper fusion and function of mitochondria. Loss of PHB2 resulted in hyperactive Insulin/IGF1 signaling and increased mTOR activation in podocytes (Ising et al. EMBO Mol Med 2015).

**Methods:** To further elucidate the molecular mechanisms by which mitochondria orchestrate the podocytes' response to insulin, we employed *Drosophila melanogaster* as a model and studied nephrocytes, podocyte-equivalent cells of the fly, responsible for filtration of the hemolymph. Cell-specific RNAi-mediated knockdown and simultaneous overexpression of candidate genes enabled us to investigate genetic interactions to identify the mitochondrial signaling cascade leading to the observed insulin hypersensitivity and subsequent mTOR activation.

**Results:** Knockdown of *Drosophila* Phb2 in nephrocytes leads to severe functional and morphological defects mimicking the published mammalian phenotype and confirming the feasibility of this approach. Simultaneous overexpression of a dominant-negative form of the Insulin-Receptor ameliorated both, functional and morphological defects in Phb2 deficient nephrocytes emphasizing the impact of hyperactive insulin signaling on the disease phenotype. Last, we tested the hypothesis, that increased mitochondrial ROS might lead to an autophosphorylation of the Insulin-Receptor and thereby enhance the intracellular insulin cascade upon binding of exogenous insulin. To this end, we overexpressed *Drosophila* Sod1 in the Phb2-knockdown background and observed a significant rescue effect.

**Conclusions:** Our results underline the importance of mitochondria as signaling hubs for nephrocyte/podocyte biology. The impact of mitochondria on metabolic signaling events can be recapitulated in *Drosophila* and appears to be conserved throughout evolution. Using *Drosophila* nephrocytes, we could identify mitochondrial ROS as important intracellular signal component leading to hyperactivation of the Insulin-Receptor and mTOR activation.

## FR-PO706

**mTOR-Dependent Autophagy Regulates Slit Diaphragm Density in Podocyte-Like *Drosophila* Nephrocytes**

Dominik Spitz,<sup>1</sup> Maria Comas Soberats,<sup>1</sup> Lea Gerstner,<sup>1</sup> Séverine Kayser,<sup>1</sup> Martin Helmstädter,<sup>1</sup> Gerd Walz,<sup>1,2</sup> Tobias F. Hermle.<sup>1</sup> <sup>1</sup>Renal Division, Department of Medicine, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany; <sup>2</sup>CIBSS - Centre for Integrative Biological Signalling Studies, Freiburg, Germany.

**Background:** Both mTor signaling and autophagy are important modulators of podocyte homeostasis, regeneration and aging, and have been implicated in glomerular diseases. However, the mechanistic role of these pathways for the glomerular filtration barrier remains poorly understood.

**Methods:** *Drosophila* presents a well-established model to study mTor signaling and autophagy with versatile genetic tools like tissue-specific RNAi-mediated knockdown or overexpression of wild type or functionally modified proteins. We used *Drosophila* nephrocytes as a podocyte model to investigate the connection of mTor signaling and autophagy and the homeostasis and maintenance of the nephrocyte ultrastructure and function as a storage kidney.

**Results:** We found that in the podocyte-like nephrocytes, mTor signaling positively controls cell size, survival and the extent of the subcortical actin network. Surprisingly, the inhibition of mTor signaling resulted in increased slit diaphragm spacing, whereas gain-of-function of mTor signaling did not affect slit diaphragm spacing, suggesting that additional cues limit the maximal density. Interestingly, both activation and inhibition of mTor signaling led to decreased nephrocyte function indicating that a fine balance of signaling activity is needed for proper function. We showed that basal autophagy in nephrocytes is required for survival and limits expression of *sns* (nephrin), but does not directly affect slit diaphragm formation or endocytic activity. However, using a genetic rescue approach, we demonstrated that excessive autophagy associated with loss of mTor function is primarily responsible for slit diaphragm misspacing.

**Conclusions:** Utilizing the *Drosophila* nephrocyte model to study the mechanistic role of mTor signaling and autophagy for the glomerular filtration barrier, we discovered a direct regulatory impact on the slit diaphragm architecture.

## FR-PO707

**Podocytes Respond to Mechanical Forces to Spatially Orient Their Processes on Glomerular Capillaries**

David Unnersjö-Jess,<sup>1,2</sup> Amer Ramdendovic,<sup>1</sup> Linus Butt,<sup>1</sup> Ingo Plagmann,<sup>1</sup> Martin Höhne,<sup>1</sup> Hans Blom,<sup>2</sup> Agnes Hackl,<sup>1</sup> Bernhard Schermer,<sup>1</sup> Thomas Benzing.<sup>1</sup> <sup>1</sup>Uniklinik Köln, Köln, Germany; <sup>2</sup>Kungliga Tekniska Hogskolan, Stockholm, Sweden.

**Background:** It has recently been proposed by our group that the main role of podocyte foot processes is to counteract forces resulting from filtration pressure in order to compress the basement membrane, thereby optimizing sieving properties. We here expand on these models by studying the role of spatial orientation of foot processes on glomerular capillaries.

**Methods:** We apply novel imaging protocols which allow for confocal in-situ 3D imaging of intact glomerular capillaries at a resolution sufficient to resolve foot processes. This allows for analyzing several thousands of podocyte processes and quantitatively determine their spatial orientation with regards to the capillary orientation.

**Results:** We report the novel finding that podocyte processes display a non-random distribution on glomerular capillaries, which is lost in different types of kidney disease. This finding suggests that the orientation of foot processes is important for the function of the filtration barrier. We further observe a more prominent orientation preference in elongated and more cylindrical capillary segments, where the difference between circumferential and longitudinal wall stress is highest. This strongly indicates that podocytes possess a machinery to regulate and maintain the spatial orientation of their processes based on the forces acting on them.

**Conclusions:** We consider the various forces that foot processes are exposed to and conclude that the observed orientation of foot processes in parallel with the orientation axis of capillaries is likely to ensure that slit diaphragm molecules (e.g. nephrin, NEPH1) are preferably aligned in parallel with the axis of highest wall stress. This adds further evidence to the theory that foot processes and the slit diaphragm act to mechanically counteract lateral wall stress, but also possesses a mechanosensory machinery for maintaining orientation on capillaries.

**Funding:** Private Foundation Support, Government Support - Non-US.

New imaging protocols allow for determining the orientation of foot processes based on nephrin staining (green).

## FR-PO708

**The Redundant and Unique Interactors of YAP and TAZ in Podocyte Homeostasis and Disease**

Lioba Ester,<sup>1</sup> Inês Cabrita,<sup>1</sup> Michel T. Ventzke,<sup>1</sup> Thomas Benzing,<sup>1</sup> Sandra Habbig,<sup>2</sup> Bernhard Schermer.<sup>1</sup> <sup>1</sup>Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; <sup>2</sup>Paediatric Nephrology, Children's University Hospital Cologne, Faculty of Medicine, University of Cologne, Cologne, Germany.

**Background:** The two effector proteins of the Hippo signaling pathway, YAP and TAZ, play a pivotal role in the cellular homeostasis of podocytes and the pathogenesis of focal segmental glomerulosclerosis (FSGS). The two proteins share 46% amino acid identity and are often regarded as homolog proteins. However, the podocyte-specific knockout of TAZ results in milder proteinuria and FSGS than the podocyte-specific YAP knockout. We aim to unravel the unique and redundant functions of YAP and TAZ in podocytes by identifying podocyte-specific interactors in health and disease.

**Methods:** We used immortalized podocytes (hMPs) and co-immunoprecipitated YAP or TAZ with specific antibodies. To overcome drawbacks resulting from these two proteins' homology, we generated hMPs expressing FLAG-tagged YAP or TAZ using TALEN-based genome editing. For in vivo purposes, we generated transgenic mice expressing 3xFLAG.YAP and TAZ.3xFLAG using CRISPR/Cas9. YAP or TAZ were pulled down in vitro from podocytes and in vivo from isolated glomeruli, followed by mass spectrometry analysis. Further, we generated YAP or TAZ podocyte-specific knockout mice as well as double knockouts, to shed light on common, distinct, and possible compensatory roles of YAP and TAZ in podocyte disease.

**Results:** Within the interactome analyses of the hMPs, we identified shared and non-shared interacting proteins between YAP and TAZ. Of all interactors, 60% overlapped for both, while 40% were unique. These results comprise known and novel interactors, including Fat1, Actn4, or Nephl. Interactome analysis of the nuclear fraction identified specifically nuclear interactors of YAP and TAZ, including known transcription factors (e.g. TEADs) and also ~30% of new nuclear interacting proteins. Currently, we are investigating the mechanistic role of novel candidates in FSGS while we are working on the in vivo models.

**Conclusions:** YAP and TAZ are critical proteins in the podocyte's homeostasis with divergent functions and interactors. Overlapping and distinct candidates identified in interactome analyses conducted both in vitro and in vivo systems suggest both shared and unique podocyte-specific functions. These novel unique and shared interactors of YAP and TAZ in podocytes will help to understand the specific impact of YAP and TAZ in the development of FSGS and recovery from podocyte injury.

## FR-PO709

**Mutation in Transient Receptor Potential Cation Channel Subfamily C Member 6 (TRPC6) Regulates Yes-Associated Protein 1(YAP1) Phosphorylation**

Chia An Chou,<sup>1,2</sup> Moin Saleem,<sup>1</sup> Gavin I. Welsh.<sup>1</sup> <sup>1</sup>Bristol Renal, Department of Translational Health Sciences, Bristol Medical School, University of Bristol, Bristol, United Kingdom; <sup>2</sup>Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung, Taiwan.

**Background:** Transient receptor potential cation channel, subfamily C member 6 (TRPC6), is a cation channel associated with hereditary focal segmental glomerulosclerosis. Angiotensin II (Ang II) activates TRPC6 and its downstream signalling. We investigated signalling regulated by TRPC6 in podocytes to understand the disease pathogenesis.

**Methods:** We developed conditionally immortalized wild-type and TRPC6-knockout (T6K) podocytes. Lentiviral transduction was used to express GFP-tagged TRPC6 in T6K cells. Phosphoproteomic analysis was used to identify changes in signalling pathways mediated by knocking out TRPC6. Immunoblotting and quantitative reverse transcription PCR (RT-qPCR) were applied for validation.

**Results:** T6K podocytes showed increased phosphorylation of Yes-associated protein (YAP) compared with the control. Ang II treatment increased YAP phosphorylation in control podocytes but not in T6K. RT-qPCR showed decreased expression of connective tissue growth factor (CTGF) and cellular communication Network Factor 1 (CCN1), YAP

downstream transcriptional targets, which returned to control levels upon expression of TRPC6GFP in T6K.

**Conclusions:** TRPC6 regulates the YAP phosphorylation and its downstream targets' level in podocytes. YAP is a transcriptional factor controlling cell proliferation. Our experiments suggest that knocking-out TRPC6 increases YAP phosphorylation and inhibits YAP-induced transcription.

**Funding:** Private Foundation Support

Immunoblotting of p-YAP in T6K and control podocytes.

Cells were treated by 0.1  $\mu$ M ANG II with various duration.

RT-qPCR of CTGF and CCN1 levels in WT, T6K and T6K+TRPC6GFP cell lines. Graphs represent mean $\pm$ SEM. WT: wild-type; T6K: TRPC6 Knockout, T6K+TRPC6GFP: T6K transduced with GFP-tagged TRPC6.

## FR-PO710

### The Mechanosensitive Ion Channel Piezo Activates Rho1 in Drosophila Nephrocytes

Sybilie Koehler,<sup>1,2</sup> Maja Lindenmeyer,<sup>1</sup> Tobias B. Huber,<sup>1</sup> Barry Denholm.<sup>2</sup>  
<sup>1</sup>University Medical Center Hamburg-Eppendorf, Hamburg, Germany;  
<sup>2</sup>Biomedical Sciences, University of Edinburgh, Edinburgh, United Kingdom.

**Background:** Podocytes constantly face biomechanical forces such as shear stress and hydrostatic pressure. Increasing forces result in morphological changes, detachment from the glomerular basement membrane and loss into the primary urine. This highlights a requirement for podocytes to sense changes in their physical environment and induce a response to react to increased biomechanical force.

**Methods:** Here, we investigated the functional role of the mechano-sensitive ion channel Piezo in *Drosophila* nephrocytes.

**Results:** First, we confirmed Piezo expression and localisation at the nephrocyte diaphragm. Acute activation of the channel with the chemical compound YODA revealed significantly increased  $Ca^{2+}$  signalling and Rho1 activation, suggesting a functional role of Piezo in nephrocytes and delineating the putative Piezo mechanosensitive pathway. For further analysis, we used knockout flies and observed a filtration phenotype, while morphology and GTPase activation was not altered. In addition, we also studied the impact of elevated Piezo levels and could show, that in line with the YODA effect, Piezo overexpression revealed severely increased Rho1-GTP levels and FITC uptake, while morphology was not changed. Because of this severe pathological phenotype, we tried to rescue the effects of Piezo overexpression with pharmacological inhibition by using tarantula toxin. Intriguingly, treatment with tarantula toxin reversed the elevated Rho1-GTP levels observed upon Piezo overexpression. Moreover, we were able to confirm Piezo1 and Piezo2 expression in mammalian podocytes and observed an upregulation of Piezo2 in glomerular disease tissue including Lupus, FSGS and hypertension.

**Conclusions:** Taken together, our data confirms the functional expression of Piezo in nephrocytes, its role in regulating GTPases and the beneficial effect of tarantula toxin to reverse the pathological effects caused by increased Piezo levels.

## FR-PO711

### Legumain Attenuates Podocyte Injury by Cleaving Transgelin and Stabilizing Cytoskeleton

Yang Qiu, Chun Zhang, Huazhong University of Science and Technology Tongji Medical College, Wuhan, China.

**Background:** Legumain is a protease which functions diversely in various cell types. It plays significant role in renal tubular cells pathology. However, its participation in podocyte pathology has been rarely explored

**Methods:** We induced podocyte injury with adriamycin injection to mimic human FSGS in mice. In vivo, global legumain knockout mice, podocyte-specific legumain knockout mice and podocyte-specific legumain overexpression mice were applied. In vitro, lentivirus and adenovirus vectors were used to knockdown and overexpress legumain in podocytes. The substrate of legumain, transgelin, was exogenously expressed and then assayed for cleavage. Fragments effects were explored by importing plasmids expressing different transgelin protein domains into podocytes

**Results:** Firstly, legumain was upregulated in podocytes in FSGS model both in vivo and in vitro. Secondly, the knockout of legumain aggravated proteinuria, glomerular sclerosis and podocyte loss. The podocytes showed less nephrin, podocin and F-actin fibers, but higher desmin expression. The overexpression of legumain alleviated these pathologies. Furthermore, we found that transgelin, an actin binding protein, was negatively regulated by legumain. Its cleavage fragments showed less affinity to actin. Compared to full length transgelin, the fragments inactivated RhoA/Rock pathway and upregulated F-actin and paxillin in podocytes

**Conclusions:** Legumain protects podocytes by cleaving transgelin and stabilizing cytoskeleton. This strongly suggests a therapeutic role of legumain in FSGS

## FR-PO712

### Consensus Draft of the Mouse Podocyte-Ome

Arvid D. Hutzfeldt,<sup>1</sup> Yifan Tan,<sup>2</sup> Léna L. Bonin,<sup>2</sup> Moritz Lassé,<sup>1</sup> Fatih Demir,<sup>2</sup> Markus M. Rinschen.<sup>1,2</sup> <sup>1</sup>Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; <sup>2</sup>Aarhus Universitet, Aarhus, Denmark.

**Background:** We aim to establish a common, simplified knowledgebase for the mouse "podocyte-ome" by integrating bulk RNA sequencing and bulk proteomics of sorted podocytes and single cell transcriptomics.

**Methods:** Three datasets of each omics type from three different laboratories, respectively, were integrated, visualized and bioinformatically analyzed.

**Results:** The procedure sheds light on conserved processes of podocytes, but also on limitations and specific features of the used technologies. High expression of glycan GPI anchor synthesis and turnover, and retinol metabolism was identified as a relatively understudied features of podocytes, while there are both podocyte-enriched and podocyte-depleted actin binding molecules. We compiled aggregated data in an application that illustrates the features of the dataset and allows for exploratory analyses through individual gene query of podocyte identity in absolute and relative quantification towards other glomerular cell types, keywords, GO-terms and gene set enrichments.

**Conclusions:** This consensus draft is a first step towards common molecular omics knowledge of kidney cells.

**Funding:** Government Support - Non-U.S.

### Synaptopodin Enables Podocyte Focal Adhesions to Resist Perpendicular Force

Chengqing Qu, Shumeng Jiang, Guy M. Genin, Hani Suleiman, Jeffrey H. Miner. Washington University in St Louis, St Louis, MO.

**Background:** Focal adhesions resist shear forces in nearly all cell types. Kidney podocytes are unusual in that they must resist stresses perpendicular to their basement membrane. We hypothesized that synaptopodin, a unique actin-associated protein that is highly expressed in podocytes, serves as a linker to enable focal adhesions to resist such perpendicular forces.

**Methods:** We developed an in vitro system to study the effect of perpendicular forces on cells cultured on hydrogels of defined stiffness, coated with defined extracellular matrix (ECM) proteins. By varying these factors, culture conditions, and the centrifugal forces applied, this setup allowed us to simulate the perpendicular forces that podocytes experience in their native glomerular microenvironment. We used primary podocytes taken from control (WT) mice as well as mice lacking synaptopodin (Synpo KO). We compared these cells to 3T3 cells as well as immortalized mouse podocytes cultured in both undifferentiated and differentiated conditions. We assessed the cellular responses to the centrifugal forces using morphological analysis as well immunostaining for integrins, synaptopodin,  $\alpha$ -actinin-4, myosin II and actin.

**Results:** Whereas perpendicular forces caused 3T3 cells to detach or become spindle-like, they caused WT primary podocytes to spread and form a continuous skirt of integrins at their periphery. Synpo KO primary podocytes and podocyte cell lines did not show this continuous integrin b1 pattern at the cell periphery but rather showed a diffuse pattern and were model likely to detach.

**Conclusions:** We uncover a mechanical role for synaptopodin in podocytes. When centrifugal force is applied, WT primary podocytes were able to resist these perpendicular forces through a major rearrangement of the focal adhesions. Lack of synaptopodin weakened podocyte responses to these forces and was associated with more podocyte

detachment. This function of synaptopodin could be important for podocyte adhesion to the basement membrane during their responses to elevated stresses and injury.

## FR-PO714

### Tight Junction Protein Claudin-5 Protects the Podocytes After Injury in Proteinuric Renal Diseases

Sonali Choudhury, Christine V. Behm, Heather A. Riddle, Stephen C. Parnell, Alan S. Yu. *University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS.*

**Background:** Focal and segmental glomerulosclerosis (FSGS) is characterized by podocyte injury and impairment of the glomerular filtration barrier causing proteinuria, nephrotic syndrome and kidney failure. Podocytes respond to injury by foot process effacement and “fusion”, with loss of slit diaphragms and replacement by tight junctions (TJ) between neighboring podocytes. Why TJs appear, and their role is unknown. Claudins are membrane proteins which are necessary to form TJs, and claudin-5 (Cldn5) is specifically expressed at the plasma membrane in adult podocytes and migrates to TJs upon injury.

**Methods:** To study the role of Cldn5, we generated Cldn5 homozygous Floxed (fl/fl) mice and crossed them to NPHS2-Cre mice to achieve podocyte-specific deletion of Cldn5 (Cre+). Glomeruli were isolated for Western blotting and immunofluorescence staining. Urine was collected from Cre+ mice and Cre- control littermates (N= 17-18 per group) at 5, 8, 15, 25, 35 and 45-weeks for measurement of albumin, by ELISA, and creatinine. Data was analyzed by linear mixed models with repeated measures over time.

**Results:** Podocyte-specific Cldn5 knockout mice (Cre+) were born at normal Mendelian ratios. Cldn5 was detected in podocytes of control mice by immunofluorescence and Western blotting and was absent from Cre+ mice indicating complete Cre excision. Cre+ mice developed increasing urine albumin/creatinine ratio (UACR) with age, compared to Cre- (P = 0.011), and male mice had increasing UACR with age compared to females (P = 0.015).

**Conclusions:** Cldn5 has a protective role in the glomerular filtration barrier at baseline. Since podocyte foot process effacement and TJ formation is common to all nephrotic disorders, Cldn5 may be critical in the adaptive response to FSGS and other podocytopathies. Ongoing studies are testing the role of Cldn5 in Adriamycin-induced podocyte injury.

### Lack of Complement Factor H Contributes to Endothelial Cell Injury in Shiga Toxin Haemolytic Uraemic Syndrome

Emily E. Bowen,<sup>1,2</sup> Jenny Hurcombe,<sup>1</sup> Fern Barrington,<sup>1</sup> Louise K. Farmer,<sup>1</sup> Carolina G. Ortiz-Sandoval,<sup>2</sup> Valentina Bruno,<sup>2</sup> Niyousha Rostam Shirazi,<sup>2</sup> Gavin I. Welsh,<sup>1</sup> Christoph Licht,<sup>2</sup> Moin Saleem,<sup>1</sup> Richard Coward.<sup>1</sup> *University of Bristol Faculty of Health Sciences, Bristol, United Kingdom; <sup>2</sup>SickKids Research Institute, Toronto, ON, Canada.*

**Background:** Haemolytic uraemic syndrome (HUS) is a thrombotic microangiopathy that has a predilection for the kidney. In 90% of cases, HUS follows gastroenteritis secondary to infection with Shiga toxin (Stx) producing bacteria such as *Escherichia coli*. STEC HUS is the leading cause of acute kidney injury in children with a mortality of 5%. We have previously shown endothelial cell complement activation in a PodGlb3 mouse model of STEC HUS. Here we build upon these findings to show that a reduction in glomerular endothelial CFH occurs both in our animal model and *in-vitro* co-culture models.

**Methods:** To demonstrate that the podocyte Stx receptor (Gb3) is sufficient to trigger the development of HUS, we used conditional gene targeting to engineer human Gb3 expression specifically in the podocytes of mice (PodGlb3). Using an *in-vitro* human glomerular cell co-culture model we evaluated the effects of Stx on endothelial cell injury, complement activation (C3b, C5b-9) and regulation (CD46, CD55, CFH).

**Results:** Following intraperitoneal Stx, PodGlb3 mice recapitulate all of the histopathological features of HUS. Further interrogation demonstrated glomerular endothelial cell complement activation, loss of CFH protection and rescue of the HUS phenotype following C5 inhibitor treatment. Interestingly, in co-culture studies Stx caused a reduction in glomerular endothelial CFH that was only seen in the presence of co-culture with podocytes.

**Conclusions:** These observations provide compelling evidence for the importance of podocyte-glomerular endothelial cell cross-talk in the development of STEC HUS and suggest a possible therapeutic role for complement inhibition in patients with this devastating disease.

**Funding:** Other NIH Support - Kidney Research UK, Academy of Medical Sciences, BMSA foundation Grant

### Lack of Complement Factor H contributes to endothelial cell injury in Shiga toxin Haemolytic Uraemic Syndrome (HUS): supporting Figure 1.

**Figure 1:** PodGlb3 mice given intraperitoneal Shiga toxin show evidence of endothelial complement activation (C3b) and loss of CFH protection.

Day 10 post-IP Stx glomerular immunofluorescence analysis for C3b and complement factor H (green) with co-staining for nephrin (red) in PodGlb3 mice and controls. Scale bar, 25  $\mu$ m.

Fold change in corrected total glomerular fluorescence intensity (CTGF) was calculated using Image J analysis for C3b and complement factor H deposition in the glomerulus. PodGlb3 n=3, controls n=3 with 30 glomeruli per mouse analysed. Unpaired T-test p value \*\*\*<0.0001.

## FR-PO716

### Fluorescence Resonance Energy Transfer (FRET) Based Visualization of cGMP Signaling in Glomerular Endothelial Cells and Podocytes

Nelli Rutkowski,<sup>1,2</sup> Frederik Görlitz,<sup>3</sup> Martin Höhne,<sup>1,2</sup> Bernhard Schermer,<sup>1,2</sup> Thomas Benzing,<sup>1,2</sup> Matthias Hackl,<sup>1,2</sup> *<sup>1</sup>Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; <sup>2</sup>CECAD, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; <sup>3</sup>Advanced Bioimaging Center, Berkeley, CA.*

**Background:** Cyclic guanosine-3',5'-monophosphate (cGMP) is an ubiquitous intracellular second messenger and is generated by the nitric oxide (NO)/soluble guanylate cyclase (sGC) and natriuretic peptide (NP)/particulate guanylate cyclase (pGC) signaling cascades. Drugs targeting this pathway have been used successfully in the treatment of vascular disease and sparked interest in translation to renal disease. In the kidney field, the literature relies on cell culture and biochemical methods, and lacks both temporal and spatial resolution to reveal the interplay and potential divergence between cell layers of a glomerulus e.g. endothelial cells and podocytes.

**Methods:** Acute kidney slices from mice expressing the genetically encoded fluorescent FRET-based cGMP biosensor cGi-500 exclusively in the cytosol of glomerular endothelial cells or podocytes were prepared. Binding of free cGMP leads to a decrease in FRET efficiency, as evidenced by a simultaneous change in donor and acceptor emission intensity in opposite directions. The donor/acceptor emission ratio (CFP/YFP) reflects the change in cGMP concentration over time. Agents modulating the cGMP pathway were applied with a superfusion system to record intensity measurements of a time series with confocal microscopy.

**Results:** Both endothelial cells and podocytes respond to stimulation with ANP (via pGC) and SNAP (NO donor, via sGC) with an increase in cytosolic cGMP concentrations. While cGMP concentrations decrease rapidly after incubation with an NO donor in the washout phase, cGMP concentrations remain high for a prolonged period after NP incubation. Simultaneous stimulation with ANP and SNAP leads to an additive response in endothelial cells, whereas cGMP concentrations in podocytes evolve in the opposite direction. Preliminary data suggest that enhanced activation of cGMP-degrading phosphodiesterases (PDE) contribute, as demonstrated by the use of the nonspecific inhibitor IBMX.

**Conclusions:** Levels of cGMP in glomerular endothelial cells and podocytes respond to stimulation of the NO-sGC and NP-pGC pathways. Additive stimulation leads to a further increase in cGMP levels in endothelial cells but a decrease in cGMP levels in podocytes. This is most likely due to increased PDE activity in podocytes.

## FR-PO717

**Angiotensin II Induces Mitochondrial Oxidative Stress in Podocyte**

Tae-Sun Ha,<sup>1,2</sup> *<sup>1</sup>Chungbuk National University Hospital, Cheongju, Chungcheongbuk-do, Republic of Korea; <sup>2</sup>Chungbuk National University, Cheongju, Chungcheongbuk-do, Republic of Korea.*

**Background:** Angiotensin II induces glomerular and podocyte injury via systemic and local vasoconstrictive or non-hemodynamic effects including oxidative stress. The release of reactive oxygen species (ROS) from podocytes may participate in the development of glomerular injury and proteinuria. We studied the roles of oxidative stress in angiotensin II-induced podocyte injury.

**Methods:** Mouse podocytes were incubated in media containing various concentrations of angiotensin II and at different incubation times and transfected by Nox4 or negative control scrambled siRNA for 24 h. The changes of the intracellular and mitochondrial ROS production were measured using respective assays and observed by confocal imaging and western blotting according to the presence of angiotensin II.

**Results:** Angiotensin II increased NADH/NADPH oxidase 4 protein and expression in a transcriptional mechanism that was also reversed by probucol. In addition, the suppression of NADH/NADPH oxidase 4 by siRNA reduced the oxidative stress induced by angiotensin II. Angiotensin II also significantly increased the generation of superoxide anions and suppressed the superoxide dismutase (SOD) activity that were significantly recovered with probucol. Furthermore, angiotensin II increased the intracellular ROS levels in dose- and time-dependent manners that were also recovered with probucol. The quantitative data of MitoSOX index demonstrated that mitochondrial superoxide production was significantly higher in angiotensin II -treated condition compared with that in untreated conditions with or without probucol at 24 h. When angiotensin II increased mitochondrial superoxide production by more than 2-fold, it was significantly recovered with probucol. We also found that cytoplasmic 8-oxo-dG immunoreactivity was significantly increased in angiotensin II -treated condition by 2-fold compared with that in untreated conditions with or without probucol at 24 h that was significantly recovered with probucol.

**Conclusions:** Our findings suggest that angiotensin II increased the generation of mitochondrial superoxide anions and ROS levels via the downregulation of the SOD activity and via the upregulation of NADH/NADPH oxidase 4 that were reversed by an antioxidant, probucol.

**Funding:** Government Support - Non-U.S.

## FR-PO718

**Geranylgeranylation of Small GTPase Is Critical to Preserving the Glomerular Filtration Barrier Integrity**

Roberto Boi, Lovisa Bergwall, Kerstin Ebefors, Jenny C. Nystrom, Lisa Buwall. *University of Gothenburg, Institute of Neurosciences and Physiology, Gothenburg, Sweden.*

**Background:** Actin cytoskeleton maintenance in podocytes is carefully and yet dynamically regulated by RhoGTPases Rac1, Cdc42, and RhoA and other small GTPases such as Rap1. These GTPases are commonly post-translational modified by geranylgeranyltransferase type-I (GGTase-I) or farnesyltransferase (FTase), which covalently transfer respectively a geranylgeranyl or a farnesyl to their target GTPases. These modifications are known as prenylation and are known to have a regulatory activity on small GTPases. Our hypothesis is that prenylation plays an important role in the regulation of normal glomerular permselectivity and that dysregulation leads to proteinuria and progression of glomerular disease.

**Methods:** The glomerular expression of GGTase-I was localized using immunofluorescence. Podocyte-specific GGTase-I and FTase knockout mice were generated. Albuminuria and foot process effacement (TEM) were used to investigate filtration barrier function. Depletion of GGTase-I was studied also *in vitro* using an inhibitor or with knockdown of gene expression. Immunofluorescence was used to analyze modifications of the actin cytoskeleton and  $\beta$ 1 integrin localization.

**Results:** GGTase-I was found to be expressed mainly by the podocytes in the human glomerulus. *In vivo* experiments in mice showed that GGTase-I knockout caused early-onset progressive albuminuria, accompanied by foot process effacement, while littermate controls and FTase knockout mice did not. *In vitro*, GGTase-I knockdown or inhibition markedly increased RhoA, Rac1, Cdc42, and Rap1 activation. This caused actin cytoskeleton disruption and altered  $\beta$ 1 integrin distribution.

**Conclusions:** In podocytes, geranylgeranylation was shown to be important in maintaining the balance of RhoGTPases and Rap1 and to be crucial for maintaining glomerular integrity and function.

**Funding:** Government Support - Non-U.S.

## FR-PO719

**Oxidative Stress Is a Mediator of Slit Diaphragm Defects Initiated by Disruption of Endocytosis**

John S. Poulton, Gang Xi. *University of North Carolina System, Chapel Hill, NC.*

**Background:** Studies in podocytes and fly nephrocytes suggest that disruption of endocytosis leads to loss of slit diaphragms. Previous studies indicate that slit diaphragm integrity also requires redox balance. Therefore, we hypothesized that disrupting endocytosis may lead to oxidative stress, which in turn perturbs slit diaphragm integrity.

**Methods:** Genes were knocked down or overexpressed in *Drosophila* nephrocytes using the Gal4-UAS system. ROS levels were measured using a ROS reporter (GstD>GFP) or DHE dye. To assess slit diaphragm integrity, localization of the slit diaphragm protein

ZO-1 was determined by confocal microscopy. In cultured human podocytes, endocytosis was disrupted by Dynasore, an inhibitor of Dynamin. ROS levels were determined using DHE or Nrf2 levels. Slit diaphragm integrity was indirectly assessed using Western Blot and immunoprecipitation to examine Nephrin's association with ZO-1 or Podocin.

**Results:** In fly nephrocytes, knockdown of regulators of endocytosis (e.g., Rab5, Cubn, Amn, Dlg) all led to significant loss of slit diaphragms, as previously reported. Depletion of these proteins also led to increased oxidative stress and activation of the Nrf2 antioxidant response pathway. Overexpression of the Nrf2 targets and antioxidant enzymes G6PD or Catalase significantly restored slit diaphragm integrity in these cells (as indicated by correct surface localization of ZO-1). Conversely, knockdown of G6PD or Nrf2 significantly enhanced the loss of slit diaphragms in Dlg knockdown cells. Dynasore treatment in human podocytes induced ROS generation within hours, evidenced by DHE staining and Nrf-2 activation. Long-term (e.g., over 6 hr) Dynasore treatment disrupted Nephrin/ZO-1 and Nephrin/Podocin associations, as well as ZO-1 plasma membrane localization. Similar results were obtained when high dose or long-term treatment of hydrogen peroxide was applied. We are currently investigating whether antioxidant reagents, such as Catalase, can rescue the alterations in Nephrin's protein interactions during long-term Dynasore treatment.

**Conclusions:** Our data indicate that disruption of endocytosis leads to increased ROS levels, which disrupt slit diaphragm integrity. Thus, in addition to its direct role in the trafficking of slit diaphragm proteins, endocytosis also affects slit diaphragm integrity by promoting redox balance.

## FR-PO720

**Proteasomal Processivity Influences the Endocytic Activity of Glomerular Cells**

Wibke Sachs, Lukas Heintz, Stephanie Zielinski, Markus M. Rinschen, Oliver Kretz, Desiree Loreth, Catherine Meyer-Schwesinger. *Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

**Background:** Glomerular injury is accompanied by intra- and extracellular protein accumulations. Degradation of proteins assures protein quality and prevents the cellular accumulation of unwanted proteins. Whether proteostatic mechanisms of glomerular cells assures the integrity and patency of the glomerular filter by preventing pathological protein accumulations is unknown. The two main intracellular proteolytic systems (ubiquitin-proteasome system (UPS), and autophagosomal-lysosome pathway (ALP)), are both ubiquitin dependent and thereby interconnected. We dissected the physiological cell-type significance of the UPS and ALP for glomerular protein accumulations, and filtration barrier function.

**Methods:** Human and murine glomerular cell-type specific UPS and ALP expression and activity was assessed by proteomic, histologic, and biochemical approaches. The impact of proteasomal or lysosomal inhibition on glomerular cell proteostasis, filtration barrier function, and endocytosis was analyzed clinically, morphologically, and biochemically in BALB/c mice and mechanistically in primary culture podocytes.

**Results:** Podocytes and endothelial cells express distinct active proteasome subtypes, while mesangial cells show a high lysosomal abundance. Treatment with a pan-proteasomal but not with a lysosomal inhibitor result in albuminuria and glomerular tuft enlargement with ultrastructural podocyte and endothelial cell alterations. Tuft enlargement in proteasome-inhibited mice is the result of intra- and extracellular glomerular protein accumulations, especially at the filtration barrier. Mechanistically, a downregulation of endocytic receptors in podocytes and an impaired endocytic uptake of extracellular proteins contributes to the glomerular protein accumulation upon proteasomal inhibition.

**Conclusions:** Proteasomal impairment alters glomerular filtration barrier function and protein clearance in a cell-type specific manner, partly due to a differential regulation of endocytic receptors.

**Funding:** Government Support - Non-U.S.

## FR-PO721

**Nampt Deficiency in Podocyte Causes Severe Glomerular and Tubular Damage Which Is Reversed by NAD<sup>+</sup> Supplementation**

Xiaoxin Wang, Komuraiah Myakala, Moshe Levi. *Georgetown University, Washington, DC.*

**Background:** Nicotinamide adenine dinucleotide (NAD<sup>+</sup>) plays critical roles in the conversion of fuel substrate to energy and as a substrate for important enzymes that regulate cellular homeostasis. The salvage pathway is responsible for most NAD<sup>+</sup> production in mammalian cells. As its rate-limiting enzyme, nicotinamide phosphoribosyltransferase (Nampt) deficiency in proximal tubules resulted in renal peritubular fibrotic changes, indicating the importance of NAD<sup>+</sup> metabolism in kidney disease. However, the exact role of Nampt in podocyte has not been explored yet.

**Methods:** Nampt podocyte conditional knockout mice, established by crossing the podocyte specific Nphs2-cre and Nampt-flox mice, were followed from birth until 8 months of age. To examine if NAD<sup>+</sup> is responsible for the phenotype in the podocyte Nampt deficient mice, nicotinamide was given to 8-month-old mice at 500mg/kg body weight in drinking water for 2 weeks.

**Results:** The podocyte Nampt deficiency caused progressive proteinuria and renal damage. The mild proteinuria noticeable at 3-month-old mice was escalated to more than 100-fold increase in proteinuria compared to wild type mice at 8-month-old in both males and females, with massive glomerulosclerosis, tubular atrophy and fibrosis, and inflammation observed in the podocyte Nampt knockout kidneys (Figure 1). 2-week nicotinamide treatment was able to normalize the proteinuria and significantly decrease the urinary kidney injury molecule (Kim-1) level in 8-month-old podocyte Nampt knockout mice.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Conclusions:** Our study shows that Namp1 plays a critical role to maintain podocyte homeostasis, with its deletion in the podocyte causing severe proteinuria and renal damage. This effect is dependent on NAD<sup>+</sup> as its supplementation rapidly corrects the increase in proteinuria, supporting a reversible mechanism through NAD<sup>+</sup> metabolism instead of impairment during development.

**Funding:** NIDDK Support

Figure 1. Histology staining shows the severe damage in the kidneys of 8-month-old podocyte-specific Namp1 knockout mice.

## FR-PO722

### Ezetimibe Restores the Communication Between Lipid Droplets and Mitochondria via Modulation of Plin5

Jin Ju Kim,<sup>1</sup> Judith T. Molina David,<sup>2</sup> Flavia Fontanesi,<sup>1</sup> Jeffrey H. Miner,<sup>2</sup> Sandra M. Merscher,<sup>1</sup> Alessia Fornoni.<sup>1</sup> <sup>1</sup>University of Miami School of Medicine, Miami, FL; <sup>2</sup>Washington University in St Louis School of Medicine, St Louis, MO.

**Background:** Alport Syndrome (AS) is a hereditary disease caused by mutations in collagen type IV. Pathogenic renal lipid droplets (LD) and triglyceride (TG) accumulation have been demonstrated in experimental AS (Col4a3KO mice). FFA catabolism resulting from excessive lipolysis of TG is a major contributor to cell lipotoxicity. Perilipin 5 (PLIN5) is an LD-related protein that plays a critical role in regulating TG lipase activity and the interactions between LD and mitochondria, where it protects mitochondria from excessive exposure to FFA. Here we test the hypothesis that PLIN5 expresses in podocytes and that PLIN5 deficiency in AS causes excessive TG breakdown and the loss of LD-mitochondrial contact, thus contributing to kidney failure.

**Methods:** *In vitro*, immortalized AS podocytes and WT podocytes were established and characterized in our laboratory by breeding the Col4a3KO mice (Jackson Laboratory) to H-2b-tsA58 transgenic mice (Charles River). PLIN5 expression was determined by RT-PCR and western blot analysis in podocytes from Col4a3KO mice when compared to controls. TG lipolysis and FFA quantification were determined and normalized to protein content. LD-Mitochondrial contact was determined by TEM analysis. PLIN5 expression was studied in kidney cortexes, and the effect of Ezetimibe on PLIN5 modulation, on LD-Mitochondrial contact and on podocyte injury was studied *in vitro* and *in vivo*.

**Results:** We demonstrate that PLIN5 is expressed in podocytes, and the expression of PLIN5 is significantly decreased in AS podocytes compared to WT podocytes ( $p < 0.01$ ). AS podocytes also showed significantly increased rates of TG lipolysis ( $p < 0.05$ ), intracellular free fatty acids ( $p < 0.05$ ) and apoptosis ( $p < 0.01$ ) when compared to WT podocytes. AS podocytes had reduced number of LD-mitochondrial contacts ( $p < 0.05$ ), implying that and apoptosis. Moreover, Ezetimibe, which restored LD-Mitochondrial contact *in vitro* ( $p < 0.05$ ) and improved kidney function *in vivo*, was found to restore PLIN5 expression *in vitro* and *in vivo* ( $p < 0.05$ ).

**Conclusions:** PLIN5 deficiency in AS podocytes causes excessive TG lipolysis and inefficient FA transfer from LD to Mitochondria, leading to mitochondrial dysfunction. Ezetimibe improves LD-mitochondria communication via restoring PLIN5 expression.

**Funding:** NIDDK Support

## FR-PO723

### Adriamycin-Induced Nephropathy Is Robust in N and Modest in J Substrain of C57BL/6 Mice

Claire Bryant,<sup>1</sup> Rachel Cianciolo,<sup>2</sup> Rajgopal Govindarajan,<sup>2</sup> Shipra Agrawal.<sup>1,2</sup> <sup>1</sup>Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>The Ohio State University, Columbus, OH.

**Background:** Adriamycin (ADR)-induced nephropathy remains the leading model to study human primary focal segmental glomerulosclerosis (FSGS), a common pathway for podocyte damage and glomerular loss of function that leads to chronic kidney disease. However, the use of this model for reverse genetics is limited by historical categorization of C57BL/6 mice as an ADR-resistant strain, which is also the most common genetically modified strain. Additionally, conflicting reports exist utilizing C57BL/6 for ADR-nephrosis due to lack of understanding of substrain differences (J/N) and variability in ADR dosage, timing, and frequency to induce damage. We have undertaken a systematic approach to elucidate the specifics of ADR-nephrosis in C57BL/6 N and J substrains.

**Methods:** We induced nephropathy with 2 doses of ADR, and measured albuminuria for 6 weeks. Additional serum chemistry was performed along with histological evaluations. Podocyte injury markers were evaluated to assess the damage of glomerular filtration barrier.

**Results:** Our findings revealed induction of robust and modest proteinuria in N and J substrains, respectively. The serum creatinine levels were elevated in N, but not J substrain. Both the substrains showed reduction in body weight with N greater than

J, although mortality remained at 0% in both substrains. Histological analysis showed worse renal lesions in the N than the J substrain. Podocyte markers synaptopodin, nephrin, podocin, and WT1 were reduced to a greater extent in the N than the J substrain.

**Conclusions:** In summary, we provide the nephrology community with a reproducible mouse model for FSGS, in a strain otherwise assumed to be ADR-resistant and highlight the differences between J and N substrains. This enables future studies, especially concerning genetically manipulated animal models in C57BL/6.

## FR-PO724

### Development of a Treatment Response Prediction Strategy for Sparsentan in Glomerular Disease

Sean Eddy,<sup>1</sup> Felix H. Eichinger,<sup>1</sup> Brad A. Godfrey,<sup>1</sup> Viji Nair,<sup>1</sup> Wenjun Ju,<sup>1</sup> Celia P. Jenkinson,<sup>2</sup> Patricia W. Bedard,<sup>2</sup> Radko Komers,<sup>2</sup> Laura H. Mariani,<sup>1</sup> Matthias Kretzler.<sup>1</sup> <sup>1</sup>University of Michigan, Ann Arbor, MI; <sup>2</sup>Travere Therapeutics Inc, San Diego, CA.

**Background:** Sparsentan is a dual endothelin receptor A inhibitor and angiotensin blocker that demonstrated reduced proteinuria in patients with FSGS in Phase II studies (DUET). Gene expression data from Adriamycin (ADR) treated rats treated with sparsentan were used to develop a response profile.

**Methods:** An interventional dose-response study was performed in rats challenged with Adriamycin (ADR) to induce an FSGS phenotype. UPCR randomization was performed at day 7 post-challenge, and daily dosing of sparsentan across a dose range was carried out for 35 days. Kidneys were harvested, stored in FFPE, and kidney cortex RNAseq profiles were generated. Differentially expressed gene (DEG) analysis followed by enrichment analysis was performed. A sparsentan response profile from the model was mapped onto human kidney RNAseq profiles from microdissected kidney biopsies from the NEPTUNE cohort and interrogated against demographic and clinical features of the cohort.

**Results:** DEG profiles were generated in ADR+vehicle vs. Sham animals (4271,  $q < 0.05$ ) and from ADR+sparsentan relative to ADR + vehicle. A high dose group (60mg/kg) generated the largest number of DEGs compared to ADR+vehicle (583,  $q < 0.05$ ); consistent with attenuation of proteinuria ( $p = 0.053$ ) and glomerulosclerosis ( $p < 0.05$ ) in this group at Day 33. Sparsentan reversed directionality 388 DEGs from the model. The 388 genes were enriched for genes in the endothelin pathway ( $p < 0.01$ ) and for genes consistent with active EDN1 ( $p < 0.01$ ). Based on gene expression profiles, activities of IL1B, IFN $\gamma$ , TNF, and TLR4 were predicted to be attenuated by sparsentan. Mapping the signature onto human data revealed elevated signaling in glomerular and tubule profiles of patients with FSGS ( $p < 0.05$ ). The signature was negatively correlated with eGFR ( $p < 0.01$ ) and positively correlated with UPCR ( $p < 0.05$ ). Changes in intrarenal transcriptional profiles were reflected in plasma and urine.

**Conclusions:** Sparsentan treatment attenuated gene expression and activity of disease-related networks in a rat model of FSGS. The sparsentan response signature from rats was elevated in human FSGS kidney tissue, associated with disease severity. Candidate non-invasive biomarkers were identified and are being developed for the NEPTUNE Match clinical trial (NCT04571658).

## FR-PO725

### Secreted Frizzled Related Protein 2: A New Therapeutic Target for Glomerular Disease?

Eugenia Papakrivopoulou,<sup>1,2</sup> Maja Lindenmeyer,<sup>3</sup> William J. Mason,<sup>1</sup> David A. Long.<sup>1</sup> <sup>1</sup>Developmental Biology Unit, UCL Institute of Child Health, London, United Kingdom; <sup>2</sup>Clinique Saint Jean Nephrology department, Brussels, Belgium; <sup>3</sup>Nephrological Center, Medical Clinic and Policlinic IV, University of Munich, Munich, Germany.

**Background:** Wnt/b-catenin signalling, critical during development but silenced in adult kidneys, is re-activated in podocytes following injury and plays a detrimental role in glomerular injury. Secreted frizzled-related proteins (sFRPs) modulate Wnt signalling and are involved in conditions such as myocardial infarction and cancer but their role in glomerular pathology is unknown. Here, we examined the role of sFRP2 in podocyte injury using *in vivo* and *in vitro* approaches.

**Methods:** Glomeruli from patients with minimal change disease, focal and segmental glomerulosclerosis, Type 2 Diabetes Mellitus and healthy donor kidneys were isolated from biopsy specimens and gene expression examined on Affymetrix gene chip arrays. Adriamycin (ADR) nephropathy was induced in Balb/c mice with 10mg/kg IV ADR. sFRP2 neutralising antibody or IgG was injected at day 0, and every 3 days, until day 14. Urine and serum samples were collected at 7 and 14 days. In a separate experiment, mRNA changes were examined in isolated glomeruli 2 days after ADR. An immortalised mouse podocyte cell line was used for *in vitro* experiments.

**Results:** sFRP2 mRNA levels were significantly upregulated (6 to 24-fold) versus live donor controls, in all patient cohorts. In mice, ADR injury increased glomerular sFRP2 mRNA expression (2-fold,  $p < 0.05$ ) 48hrs after induction, prior to the appearance of albuminuria and *in vitro*, ADR induced podocyte sFRP2 mRNA expression (10-fold,  $p < 0.01$ ). Increased sFRP2 staining was observed in podocytes following ADR injury. Exposure of podocytes *in vitro* to sFRP2 led to longer processes ( $53 \pm 4.6$  vs  $76 \pm 9.1$ , arbitrary units,  $p < 0.05$ ) and more processes/cell ( $8 \pm 0.96$  vs  $11 \pm 1.01$ ,  $p < 0.05$ ). Next, we examined the effect of sFRP2 blockade on ADR-induced glomerular injury. ADR significantly increased albuminuria compared to baseline ( $383.23$  vs  $0.04$ mg/24hr,  $p < 0.001$ ,  $n = 10$  mice/group) and blood urea nitrogen (BUN) levels ( $38.14$  vs  $21.57$ mg/dL,  $p < 0.05$ ,  $n = 10$ ) at 14 days. sFRP2 inhibition significantly attenuated both albuminuria

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

(40 vs 383 mg/24hr,  $p < 0.05$ ,  $n = 10$ ) and BUN levels (21.72 vs 38.14 mg/dL,  $n = 10$ ,  $p < 0.05$ ) compared to IgG control, at the same time point. No changes in body to kidney weight ratio were observed.

**Conclusions:** Glomerular *sFRP2* expression is upregulated in response to injury. This appears to be detrimental for podocytes as inhibition by antibody blockade attenuates the response to injury.

## FR-PO726

### Therapeutic Potential of Inducible Co-stimulator Ligand for Treating avb3-Mediated Glomerular Damage

Yan Xu,<sup>1</sup> Ryan Spear,<sup>1</sup> Yanxia Cao,<sup>1</sup> Kwi Hye Koh,<sup>1</sup> Steve Mangos,<sup>1</sup> Nicole Endlich,<sup>2</sup> Jochen Reiser,<sup>1</sup> Eunsil Hahm.<sup>1</sup> <sup>1</sup>Rush University Medical Center, Chicago, IL; <sup>2</sup>University Medicine Greifswald, Greifswald, Germany.

**Background:** Activation of avb3 integrin is an early pathological process in several podocytopathies leading to glomerular disease with no treatment options available. We recently identified inducible co-stimulator ligand (ICOSL) as a renoprotective agent that acts as an antagonist of avb3 integrin. We tested the precise mechanistic action of ICOSL in protecting the kidney from injury and evaluated *in vivo* efficacy of ICOSL and its small peptide in proteinuric animal models.

**Methods:** Expression dynamics of ICOSL during glomerular injury was established by performing quantitative PCR on 3 main glomerular cell types (human podocytes, glomerular endothelial cells, and mesangial cells) after different injury stimuli. We generated double knockout (DKO) mice (ICOS/ICOSL<sup>-/-</sup>) to explore the importance of ICOSL's canonical receptor to renoprotection. ACR and BUN measurements were used to evaluate renal function in DKO and control mice that were subjected to STZ-induced diabetic nephropathy. ICOSL's binding specificity and affinity toward RGD-binding Integrins was tested using surface plasmon resonance (SPR). A 19 amino acid portion of ICOSL was tested for its ability to target podocyte avb3 integrin using an *in vitro* podocyte adhesion assay, and for its ability to mitigate LPS-induced proteinuria in ICOSL KO mice.

**Results:** Glomerular ICOSL expression is regulated by immunological insults, not by conditions that cause oxidative stress. Among the cell types tested, podocytes are the predominant producers of ICOSL and could be stimulated to express ICOSL under immunological stress. Conversely, mechanical stress resulted in reduced ICOSL expression. KO mouse models treated with STZ demonstrate that the renoprotective function of ICOSL is independent of ICOS. Among the 7 different RGD-binding integrins tested, only  $\alpha v\beta 3$  integrin shows strong and preferential binding to ICOSL. Both full-length and a 19-mer portion of ICOSL protein could bind podocytes through avb3 integrin and reverse LPS-induced proteinuria in ICOSL KO mice.

**Conclusions:** Our data suggest that the glomerular expression of ICOSL mainly occurs in podocytes and can be triggered by immunological insults. Given the highly selective binding characteristics to avb3 integrin, ICOSL and ICOSL-based small peptides may offer novel and safe therapeutic options for treating avb3-mediated glomerular diseases.

**Integrin Activation as a Novel Therapeutic Strategy for Podocytopathies**  
Richard Helmuth,<sup>1</sup> Xiaobo Li,<sup>1</sup> Santiago Balza Pineda,<sup>2</sup> Darlah M. Lopez-Rodriguez,<sup>2</sup> Carl J. Abrahams,<sup>2</sup> Adithya Subramanian Sahasranamam,<sup>2</sup> Antonio Barbosa,<sup>2</sup> Vineet Gupta.<sup>1,2</sup> <sup>1</sup>Drug Discovery Center, Department of Internal Medicine, Rush University Medical School, Chicago, IL; <sup>2</sup>149 Bio, LLC, Miami, FL.

**Background:** Podocyte damage and loss is a key determinant of proteinuria and glomerular injury. Therefore, maintaining podocyte viability and preventing their urinary loss is a validated therapeutic strategy against glomerular diseases. Podocytes selectively utilize integrin  $\alpha 3\beta 1$  to adhere to the glomerular basement membrane (GBM) and such attachment is essential for maintaining their viability. Using a novel high-content imaging-based assay, we previously identified small molecule integrin  $\beta 1$  agonists as podocyte-protective. We have recently discovered integrin  $\alpha 3$  agonists as novel podocyte-protective agents.

**Methods:** K562 cells stably expressing  $\alpha 3\beta 1$  and differentiated podocytes (mouse and human) were used in *in vitro* assays. K562 cells were used in flow-cytometry based assays to characterize  $\alpha 3$  agonists. Podocytes were utilized in cell adhesion based functional assays. Furthermore, podocyte damage was induced using puromycin aminonucleoside (PAN) and treatment in the absence or presence of various agonists, for up to 48 hours, was used to determine efficacy of  $\alpha 3$  agonists. Podocytes were fixed and stained for detection using the confocal imaging based High-Content Screening (HCS) assays. Columbus software was used to quantify morphology properties such as roundness, as well as the overall F-actin and focal adhesion signal. Currently, the agonists are being tested for efficacy in *in vivo* assays.

**Results:** PAN damage resulted in quantitative reduction in F-actin fiber numbers and intensity, and increased roundness in podocytes. It also reduced binding of active  $\beta 1$  integrin probe antibody 9EG7. Newly discovered integrin  $\alpha 3$  agonists increased  $\alpha 3\beta 1$ -dependent cell adhesion and ameliorated PAN-mediated podocyte damage.

**Conclusions:** We have previously shown that integrin agonists are a novel therapeutic strategy for targeting integrins in various diseases. Activation of expressed integrin  $\alpha 3\beta 1$  in podocytes shows that it increases cellular adhesion to matrix proteins and protects cells from damage. Ongoing *in vivo* studies will demonstrate efficacy of this approach and will highlight integrin activation as a novel therapeutic strategy against various glomerulopathies.

## FR-PO728

### Plaque-induced Focal Segmental Glomerulosclerosis

Jack Luo,<sup>1,2</sup> Warda Zaman.<sup>3,1</sup> <sup>1</sup>Alameda Health System, Oakland, CA; <sup>2</sup>Highland Hospital Internal Medicine, Oakland, CA; <sup>3</sup>East Bay Nephrology Medical Group, Oakland, CA.

**Introduction:** Drugs and toxins that are typically associated with focal segmental glomerulosclerosis (FSGS) include interferons, bisphosphates, anthracyclines, lithium, and calcineurin inhibitors, but hydroxychloroquine is not. We present a case of FSGS in a patient on hydroxychloroquine (HCQ) for treatment of scleroderma.

**Case Description:** A 66-year-old female with a history of CREST syndrome with scleroderma was referred to clinic for nephrotic range proteinuria in 2021. She was last seen by rheumatology in the early 2000s. She is originally from Nicaragua, lives in Vallejo, California, and travels back and forth. Since 2020, she has purchased HCQ in Nicaragua which provided relief of joint pain. Physical exam was notable for PIP joint swelling of both hands and bilateral lower extremity edema. Labs showed Cr 0.8-0.9 mg/dL, eGFR 70-75 ml/min/1.73 m<sup>2</sup>, albumin 3.9 g/dL, urinalysis with 2+ protein and no sediment, albumin to creatinine ratio of 1750 mcg/mg in 8/2020. Further work up showed UPCR 4.6, HCV positive but RNA negative, Hep B, RPR, and HIV were negative. SPEP negative, K:L 0.9, dsDNA negative, normal complement, RF negative, Normal CRP. PLA2R antibody was also negative. Kidney biopsy showed myelin figures with widespread foot process effacement in the setting of HCQ use, without any immune complex, paraproteinemic disease, or membranous nephropathy. Patient was diagnosed with secondary FSGS from hydroxychloroquine use. HCQ was stopped, with decrease in proteinuria to 1.2g, almost 4 months since HCQ was held. Irbesartan was continued for medical management of proteinuria.

**Discussion:** Zebra bodies, or myelin figures, are intralysosomal inclusion bodies that suggest kidney phospholipidosis, which is a widely accepted feature of hereditary disorders such as Fabry disease, but it has also been seen in patients on drugs such as HCQ. The majority of cases that have demonstrated this have been in patients on HCQ for management of systemic lupus erythematosus. To our knowledge, there are no previous reports of zebra bodies seen on renal biopsies taken from patients on HCQ for treatment of scleroderma or any previous cases of FSGS occurring in the setting of HCQ use. Our case demonstrates the need to consider HCQ as a cause of FSGS in patients evaluated for proteinuria, with negative work up for the usual causes such as viral infections, drugs, or system conditions, but may be on HCQ for another disorder.

## FR-PO729

### Analysis of GR and miRs Expression in Renal Tissues of Patients With Renal Diseases Compared to Controls

Anna Angelousi, Georgios Liapis, Maria Gazouli, Ioannis Kofotolios, Ioannis Boletis, Smaragdi Marinaki. *Ethniko kai Kapodistriako Panepistimio Athenon Iatrike Schole, Athens, Greece.*

**Background:** Glucocorticoid Receptor (GR) is expressed in normal renal podocytes however, its expression differs among renal diseases. In this study, we analysed GR expression in renal tissues of patients with systemic lupus nephritis (LN), minimal changes disease (MCD) and pauci-immune glomerulonephritis (PIN) as well as the expression of its epigenetic regulators miR30a, miR24 and miR370.

**Methods:** Fifty-one patients ( $n = 20$  with LN,  $n = 14$  with MCD and  $n = 17$  with PIN) underwent renal biopsy and 22 controls with no history of parenchymal renal disease were recruited from the Clinic of Nephrology and Renal Transplantation of General Laikon hospital through November 2016 to March 2019. All patients were recently diagnosed and were naïve of any treatment. mRNA and protein expression was analysed through real time -polymerase chain reaction (rt-PCR) and immunohistochemistry respectively. Data were collected after obtaining written consents forms from all participants.

**Results:** GR mRNA expression was underexpressed in all pathological specimens of patients compared to "normal" renal tissues of controls ( $p = 0.023$  for LN,  $p = 0.05$  for MCD and  $p = 0.004$  for PIN). Similarly, GR protein expression was lower in all pathological specimens ( $> 6$  GR positive podocytes/glomerulus in 42% of patients with LN, 55% with MCD and 16.68% with PIN) compared with controls ( $> 6$  positive podocytes/glomerulus in all the controls). PIN specimens presented also significantly lower GR mRNA and protein expression comparing with LN and MCD specimens among patients. No significant differences were found in the miR30a expression comparing pathological renal specimens of patients with "normal" renal tissues of controls. miR24 and miR370 expression demonstrated statistically significant difference in all pathological compared to "normal" tissues. miRs expression didn't differ among the 3 studied groups. GR expression was not also associated neither with LN disease activity score nor with eGFR.

**Conclusions:** GR and miR24 expression was significantly underexpressed whereas miR370 significantly overexpressed in all pathological compared with adjacent "normal" renal tissues implying their potential role in nephritis pathogenesis and treatment.

FR-PO730

Study on the Pathogenesis of the Leu754Val Mutation of the ARHGAP32 Gene Inducing Focal Segmental Glomerulosclerosis

Pei S. Chen, Guisen Li. Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China.

**Background:** Focal segmental glomerulosclerosis (FSGS) is one of the most common causes of refractory nephrotic syndrome and end-stage renal disease. Previous studies indicated that genetic factors play an important role in the pathogenesis of FSGS. A new candidate pathogenic gene, *ARHGAP32* gene (c.1213C>G, p.Leu405Val), was found in FSGS family, which may be the cause of FSGS. This project is based on the previous studies, through in vitro and in vivo studies, to preliminarily explore the mechanism of *ARHGAP32* expression changes and mutations leading to podocyte damage, and to provide new ideas for the pathogenesis of FSGS and new treatment measures.

**Methods:** The function of *ARHGAP32* gene mutation was studied by in vivo and in vitro experiments, and the protein expression level was studied. After the construction of *Arhgap32* gene mutation mice, adriamycin was injected into tail vein to establish the kidney injury model of *Arhgap32* mutant mice. Urine, blood and kidney tissue samples were collected to detect the related biochemical indexes and pathological analysis; the markers of podocyte, nephrin and synaptopodin, were detected to study the effect of *ARHGAP32* gene mutation on podocytes and the mechanism of podocyte injury induced by *ARHGAP32* gene mutation.

**Results:** Immunohistochemical staining showed that there were protein expressions in the kidney of *Arhgap32* mutant mice. After adriamycin induced *Arhgap32* gene mutation mice, weight gain slowed down, proteinuria appeared, serum creatinine and urea nitrogen levels increased, renal tissue showed glomerular mesangial cell proliferation and other renal pathological damage, the podocyte markers Nephrin and Synaptopodin expression decreased, podocyte injury occurred. The expression of Rac1, RhoA and CDC42, which may be affected by Rho GTPase family members, was detected, and the expression of Rac1, RhoA and CDC42 in the mutant mice was increased.

**Conclusions:** This study showed that *ARHGAP32* gene was highly expressed in renal tissue. In addition, the mutations of *ARHGAP32* gene down regulates Rac1, RhoA and CDC42, which cause podocyte damage, affect glomerular filtration barrier, cause proteinuria, and even cause kidney damage, even develop into FSGS. The mechanism of podocyte damage caused by mutations of *ARHGAP32* gene was preliminarily discussed.

FR-PO731

Vincristine Treatment Produces a Milieu Which Reverses Podocyte Damage in Focal Segmental Glomerulosclerosis

William J. Mason,<sup>1</sup> Jennifer C. Chandler,<sup>1</sup> Marilina Antonelou,<sup>2</sup> Scott R. Henderson,<sup>2</sup> David A. Long,<sup>1</sup> Ruth Pepper.<sup>2</sup> <sup>1</sup>University College London Institute of Child Health, London, United Kingdom; <sup>2</sup>Royal Free Hospital, Dept of Nephrology, London, United Kingdom.

**Background:** Focal segmental glomerulosclerosis (FSGS) is a disease that causes damage to podocytes, which form a key component of the glomerular filtration barrier. Mutations in multiple podocyte genes are associated with FSGS, but there is evidence that circulating factors can also induce podocyte damage, manifested as foot process effacement and disorganisation of the F-actin cytoskeleton. Treating FSGS patients with the experimental drug, Vincristine, has been effective in some cases, however, the biological effects in human podocytes are not well understood. The aim of this study is to investigate the effects of Vincristine treatment on podocytes using serum taken from a patient presenting with FSGS who showed full remission of disease with Vincristine treatment.

**Methods:** Human immortalised podocytes were treated with 10% patient serum at different time points of Vincristine treatment (disease presentation, on treatment and remission). Fetal bovine serum (FBS) and serum from a non-renal patient were used as controls. To determine a role for IgG in causing podocyte damage, some experiments were performed with IgG depleted from the presentation serum. Podocytes were stained with Phalloidin after 24 hours of serum treatment to examine the F-actin cytoskeleton.

**Results:** Podocytes treated with the presentation serum showed an increase in cell area, and a reorganisation of cortical F-actin fibres to cytoplasmic stress fibres, compared with podocytes treated with serum from the non-renal patient. This effect was still observed when IgG was depleted from the presentation serum. Podocytes treated with serum from when the patient was responding to Vincristine treatment showed no change in podocyte cell area or F-actin organisation compared with cells treated with serum from the non-renal patient. There was also no change to podocyte cell area or F-actin when podocytes were treated with the remission serum, when compared with the non-renal patient serum, suggesting Vincristine prevented podocyte damage.

**Conclusions:** Serum, but not IgG, from a patient with FSGS directly affects podocyte cell area and F-actin cytoskeleton *in vitro*. Vincristine prevents F-actin related podocyte damage, ultimately leading to a remission of FSGS.

FR-PO732

Urinary CD80 and Serum suPAR as Biomarkers of Glomerular Disease Among Adults in Brazil

Renata D. Zen, Luis Yu, Leticia Jorge, Viktoria Woronik, Cristiane B. Dias. Universidade de Sao Paulo, Sao Paulo, Brazil.

**Background:** The objective of this study was to determine whether urinary CD80 and serum suPAR can be used for the diagnosis of MCD and FSGS, respectively, in the adult population of Brazil. We also attempted to determine whether these biomarkers assess the response to immunosuppressive treatment.

**Methods:** This was a prospective study in which urine and blood samples were collected, for analysis of CD80 and suPAR, respectively, only in the moment of renal biopsy, from patients undergoing to diagnostic renal biopsy. At and six months after biopsy, we analyzed serum creatinine, serum albumin, and proteinuria in order to evaluate the use of the CD80 and suPAR collected in diagnosis as markers of response to immunosuppressive treatment. In healthy controls were collected urinary CD80 and proteinuria, serum suPAR and creatinine.

**Results:** The results of 70 renal biopsies were grouped, by diagnosis, as follows: FSGS (n = 18); membranous nephropathy (n = 14); MCD (n = 5); and other glomerulopathies (n = 33). There was no significant difference among the groups in terms of the urinary CD80 levels, and serum suPAR was not significantly higher in the FSGS group, as would have been expected [Table 1]. Urinary CD80 correlated positively with nephrotic syndrome, regardless of the type of glomerular disease (r = -0.5 p < 0.0001). Neither biomarker correlated with proteinuria at six months after biopsy.

**Conclusions:** In adults, urinary CD80 can serve as a marker of nephrotic syndrome but is not specific for MCD, whereas serum suPAR does not appear to be useful as a diagnostic or treatment response marker.

Demographic characteristics and biomarker data at diagnosis in patients with glomerulopathies and in healthy controls

Characteristic	MCD (n = 5)	FSGS (n = 18)	Membranous nephropathy (n = 14)	Control (n = 10)	P value
Age (years), mean ± SD	37.60 ± 15	33.67 ± 13.60	42.15 ± 19.64	33.60 ± 6.63	0.003
Male sex, n (%)	1 (20.0)	10 (55.6)	6 (42.9)	3 (30.0)	0.40
Serum creatinine (mg/dL), median (IQR)	0.90 (0.76–1.95)	2 (0.92–2.62)	0.65 (0.50–1.17)	1.11 (0.98–1.18)	0.086
Protein-to-creatinine ratio (g/g), median (IQR)	3.10 (1.04–3.46)	4.05 (1.87–5.44)	4.42 (2.38–7.14)	0.003 (0–0.22)	< 0.0001
Serum albumin (g/dL), mean ± SD	2.08 ± 0.99	2.06 ± 0.87	2.25 ± 0.54	-	0.10
CD80 (ng/g creatinine), median (IQR)	104 (19.70–369.60)	63.15 (30.50–244.60)	76.80 (31.22–402.20)	24.70 (15.10–41.40)	0.15
suPAR (pg/mL), median (IQR)	3266 (2887–4225)	3887 (2359–4620)	3091 (2018–3711)	1336 (1033–1586)	0.0001+

FR-PO733

B-Cell Lymphoproliferative Disorder With NELL-1 Membranous Nephropathy

Neha Patel, Timothy P. Mccann, Amit K. Rajput. TriHealth, Cincinnati, OH.

**Introduction:** The predominant target antigen for primary membranous nephropathy (MN) has been Phospholipase A2 receptor (PLA2R), present in approximately 70% of cases. Neural epidermal growth factor like 1 protein (NELL-1) was recently identified as a new antigen in a distinct type of primary MN. NELL-1 was found to be the first candidate antigen highly prevalent in malignancy associated MN, seen in 33% of all cases. We will review a case of NELL-1 membranous nephropathy.

**Case Description:** A 54-year-old Caucasian female presented with shortness of breath, left flank/lower back pain, and bilateral lower extremity edema for four days. Physical exam exhibited BP 170/99 mmHg, nontender cervical lymphadenopathy (LAD), left CVA tenderness, and 2+ pitting edema. Initial labs were significant for elevated D-dimer, hypoalbuminemia (Alb 1.7g/dL), and nephrotic range proteinuria (UPCR 13.5g). Imaging revealed bilateral subsegmental pulmonary emboli, left renal vein thrombosis, and extensive bilateral LAD (axillary, supraclavicular, mediastinal, left periaortic retroperitoneal). Given concerns for podocytopathy due to a possible lymphoma, the patient underwent an unremarkable extensive serologic workup. Renal biopsy revealed NELL-1 MN, with diffuse (3+) fine granular staining along glomerular capillary loops for NELL-1 and subepithelial deposits with severe foot process effacement. Bone marrow biopsy, excisional axillary/cervical lymph node biopsies, PET scan, infectious workup, and age-appropriate malignancy screenings were nondiagnostic. Biopsies showed reactive lymphadenopathy concerning for evolving B-cell lymphoproliferative disorder with plasmacytic differentiation. Given the biopsy findings and NELL-1 MN, she was treated with rituximab. However, significant proteinuria persisted despite treatment. The patient refused cyclophosphamide and unfortunately, developed additional complications including a transient ischemic attack.

**Discussion:** NELL-1 is a rare emerging subtype of MN that has been identified in both primary MN and malignancy associated nephropathy. A thorough malignancy workup is warranted in all patients diagnosed with NELL-1 MN. More research is needed in the association between NELL-1 and specific cancers, in hopes of guiding future treatments for this disease.

FR-PO734

Nephrotic Syndrome During Pregnancy: Not Everything Is Preeclampsia

Rita B. Aguilar, Juan P. Gomez Villarreal, Michelle Morcos sandino, Elisa M. Guerrero Gonzalez, Lilia M. Rizo Topete. Hospital Universitario Dr Jose Eleuterio Gonzalez, Monterrey, Mexico.

**Introduction:** Nephrotic syndrome (NS) rarely presents during pregnancy, the incidence owing to primary glomerular disease is unknown due to difficulty in differentiating it from preeclampsia. NS increases maternal and fetal adverse outcomes and confers risk for many complications including AKI and thromboembolic events. We present a case of a

woman who developed progressive edema during second and third trimester of pregnancy, she underwent approach until a diagnosis of polyhydramnios was made.

**Case Description:** 30 year old female who was going through third trimester pregnancy, without history of chronic illness developed anasarca and polyhydramnios. On admission she underwent amniocentesis of 2L, hours later she started with uterine activity and went into labor. Laboratory results at admission revealed SCr 1.3mg/dl, BUN 18mg/dl, serum albumin 1g/dl, urinalysis with proteinuria +++++, RBC 12/field, WBC 10/field, 24hr protein quantification was performed with 11.4gr/1340ml; Nephrology department was consulted. Patient was stable, no hypertension developed during hospitalization and a diagnosis of NS was made. We started IV furosemide, atorvastatin and enoxaparin. At day 12 of puerperium kidney biopsy was performed and included 24 glomeruli (2 glomeruli with global sclerosis and 4 with segmental sclerosis) immunofluorescence staining showed glomerular deposition of albumin; IgG, IgA, C3 and fibrinogen were negative. Based on findings she was diagnosed with Tip Lesion variant Focal and Segmental Glomerulosclerosis, steroid therapy was initiated with oral prednisone at dose of 50mg/day, four weeks after initiation of steroid therapy patient had a 24h protein quantification of 450mg, SCr 0.7mg/dl, serum albumin increased to 4.2g/dl and edema disappeared.

**Discussion:** In this case we faced to a pregnant patient with anasarca, heavy proteinuria and hyponatremia in the absence of hypertension. We started treatment based on steroid as the primary regimen with close monitoring due to increased risk for thrombosis. AKI developed during hospitalization but patient had rapid recovery of renal function and went into complete remission.

FR-PO735

**Screening for Primary Hyperaldosteronism in Patients With Resistant Hypertension in an Outpatient Clinic**  
Nidharshan S. Anandasivam, Jaya Vasudevan, Douglas Benson, Annika L. Medhus, Paul Sarkaria, Sonal Gagrani, Brandon Herrera-Doerre, Ava Karimi, David J. Ben-Nun, Nisha Soneji, Arjun Aggarwal, Steven Taylor, Holli Sadler, Michelle L. Lubetzky, Christopher Moriates. *The University of Texas at Austin Dell Medical School, Austin, TX.*

**Background:** Clinical practice guidelines recommend screening for primary hyperaldosteronism (PH) in patients with resistant hypertension (HTN). However, screening rates are low in the outpatient setting. We aimed to increase screening rates for PH in patients with resistant HTN in our VA outpatient clinic from 24% to 80%.

**Methods:** Patients with resistant HTN were identified through a VA Primary Care Almanac Metric query with subsequent medical record review for resistant HTN criteria. Medication adherence was reviewed to rule out pseudo-resistant HTN. Three sequential patient-directed interventions were implemented. In the first intervention, patients with resistant HTN had preclinic screening (plasma aldosterone concentration and plasma renin activity) labs added on and were scheduled in clinic for hypertension follow-up. In the second intervention, patients without screening labs were called to confirm adherence to medications and counseled on the need for labs to screen for PH. In the final intervention, patients with positive screening labs (plasma aldosterone concentration>5-15ng/dL and plasma renin activity<1ng/ml/hr) were called to discuss mineralocorticoid receptor antagonist (MRA) initiation and Endocrinology referral.

**Results:** Of 97 patients with resistant HTN, 58 were found to have true resistant HTN, while 39 had pseudo-resistant HTN from medication non-adherence. Of the 58 with resistant HTN, 44 were not previously screened for PH, while 14 (24%) had already been screened or were already taking an MRA. Our screening rate for PH in resistant HTN patients increased from 24% at the start of the study to 84% (37/44 unscreened patients were ultimately screened). A total of 9 patients were found to have a positive screen for PH, and 5 were started on MRAs. None of these 5 patients developed hyperkalemia.

**Conclusions:** This quality improvement project demonstrated that a focused intervention process improved PH screening rates. Over 20% of screened patients had labs positive for PH.

FR-PO736

**Primary Aldosteronism in CKD Increases CV Risk and Death Independent of Adrenalectomy vs. Medical Management**  
Debbie L. Cohen,<sup>1</sup> Heather Wachtel,<sup>1</sup> Anand Vaidya,<sup>3</sup> Gregory L. Hundemer,<sup>2</sup> Yuta Tezuka,<sup>4</sup> Adina Turcu,<sup>4</sup> Jordana B. Cohen.<sup>1</sup> <sup>1</sup>*University of Pennsylvania Perelman School of Medicine, Philadelphia, PA;* <sup>2</sup>*Ottawa Hospital, Ottawa, ON, Canada;* <sup>3</sup>*Brigham and Women's Hospital Department of Medicine, Boston, MA;* <sup>4</sup>*University of Michigan Michigan Medicine, Ann Arbor, MI.*

**Background:** Primary aldosteronism (PA) is common and is associated with increased cardiovascular (CV) risk. Diagnosis and treatment of PA in CKD is often deferred for safety and efficacy concerns. Aim was to assess clinical outcomes in patients with confirmed PA and underlying CKD.

**Methods:** We conducted a retrospective cohort study of patients with biochemical PA and eGFR < 60 cc/min/1.73m<sup>2</sup> from 3 academic medical centers, who underwent adrenal vein sampling (AVS) between 2009-2019. Primary outcomes were BP control and number of antihypertensive medications (AHM). Secondary outcomes included CV and renal clinical events and all-cause mortality.

**Results:** Of 239 patients, 159 lateralized on AVS (67%); 158 (66 %) underwent adrenalectomy and 81 (34%) were treated medically. Mean (SD) age was 57 (10) years, 33% were female with mean BMI of 33 (6) kg/m<sup>2</sup>. At baseline 1/3 had DM and CVD with mean serum values: K 3.9 (0.6) mmol/L, creatinine 1.9 (4.5) mg/dL and eGFR (2021 CKD-EPI without race) 54 (21) mL/min; 49% of subjects were on K supplements with 47% receiving K sparing diuretics. Subjects were followed for a median of 4.5 years.

At 5 years mean BP decreased from 149/85 to 131/78 mm Hg and serum K increased from 3.9 to 4.2 mmol/L. Subjects who underwent adrenalectomy vs. medical management (MM) had 3.5 mm Hg lower SBP (p = 0.022) and required 1.8 fewer AHM at 5 years (p < 0.001). Every SD higher baseline eGFR (~20 mL/min/1.73m<sup>2</sup>) was associated with a 2 mm Hg lower SBP and reduced AHM requirement. Clinical event rates were high: MI 12(5%), TIA 11(5%), CHF 14(6%), Afib 21 (9%), dialysis 15(6%), death 23(10%). Using Cox models baseline non race-based eGFR was significantly associated with an increase in RRT and death even after adjustment for age, sex, CKD and DM (Table). No difference in clinical outcomes was detected if patients had adrenalectomy vs MM.

**Conclusions:** PA patient with CKD have a high risk for incident CV events, progression to RRT and death. PA patients with higher baseline eGFR had greater reductions in BP and AHM and are more likely to respond favorably to PA therapy, regardless if treated with adrenalectomy or MM.

Table. Association of Baseline eGFR and Surgical Adrenalectomy with Longitudinal Clinical Parameters and Risk of Clinical Outcomes								
Longitudinal Change in Parameter (mixed effects models with random intercept by patient and site)	Baseline eGFR (SD increase, using 2021 CKD-EPI equation without race)				Surgical Adrenalectomy			
	Unadjusted		Adjusted for age, sex, CVD, DM		Unadjusted		Adjusted for age, sex, CVD, DM

**Influence of Baseline Diastolic Blood Pressure (DBP) on the Effects of BP Lowering on All-Cause Mortality: A Meta-Analysis of NIH BP Trials**  
Amara Sarwal,<sup>1</sup> Robert E. Boucher,<sup>1</sup> Sydney E. Hartsell,<sup>1</sup> Guo Wei,<sup>1</sup> Xiangyang Ye,<sup>1</sup> Jincheng Shen,<sup>1</sup> Glenn Chertow,<sup>2</sup> Paul K. Whelton,<sup>3</sup> Alfred K. Cheung,<sup>1</sup> Tom Greene,<sup>1</sup> Srinivasan Beddhu.<sup>1</sup> <sup>1</sup>*University of Utah Health, Salt Lake City, UT;* <sup>2</sup>*Stanford University School of Medicine, Stanford, CA;* <sup>3</sup>*Tulane University School of Public Health and Tropical Medicine, New Orleans, LA.*

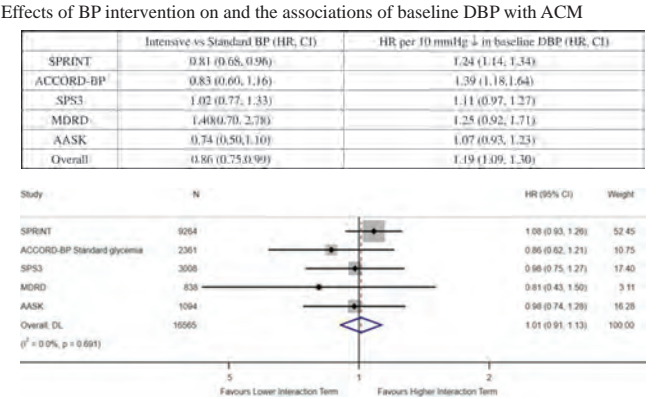

**Background:** Lowering systolic BP (SBP) in persons with low DBP might affect tissue perfusion and thereby, increase risk for mortality.

**Methods:** We conducted a meta-analysis of 5 large NIH BP trials that examined the effects of BP goals on ACM outcomes; SPRINT (N = 9264, SBP goal < 120 vs. < 140 mmHg), ACCORD BP standard glycemia arm (N = 2361, SBP goal < 120 vs. < 140 mmHg), SSPS3 (N= 3008, SBP goal < 130 vs. < 140 mmHg), MDRD (N=838, SBP goal ≤125 with MAP ≤92 vs SBP ≤ 140 with MAP≤ 107 mmHg) and AASK (N=1094, goal MAP < 92 mmHg vs. 102-107 mmHg). We used DerSimonian-Laird random-effects model in Stata 15.1 version to conduct meta-analyses of the interaction between baseline DBP and the BP intervention on mortality outcomes.

**Results:** Mean baseline DBP in SPRINT, ACCORD BP, SPS-3, MDRD and AASK were 78 ± 12, 76 ± 10, 78 ± 11, 82 ± 11, and 96 ± 14 mmHg, respectively with evidence of heterogeneity. In the 16,565 participants included in the analysis, there were a total of 989 mortality events over 65,656 total years of follow-up. Intensive BP control resulted in overall lower hazard ratio of ACM events, (HR 0.86, CI 0.75, 0.99) (Table). Lower baseline DBP was associated with increased risk of mortality events (HR 1.19, CI 1.09, 1.30) (Table). The interaction term of baseline DBP and the BP intervention on ACM was non-significant in each of the studies and overall (Figure).

**Conclusions:** In this meta-analysis of large, multicenter NIH funded trials, BP intervention was beneficial for improving ACM rates, but there was no evidence that these beneficial effects were modified by baseline DBP.

**Passive Heat Therapy Lowers Blood Pressure and Improves Vascular Function in Older Adults With Reduced Kidney Function**  
Vienna E. Brunt,<sup>1,2</sup> Amy Bazzoni,<sup>1</sup> Kathy H. Nguyen,<sup>1</sup> Michel Chonchol,<sup>2</sup> Christopher T. Minson,<sup>3</sup> Douglas R. Seals.<sup>1</sup> <sup>1</sup>University of Colorado Boulder, Boulder, CO; <sup>2</sup>University of Colorado - Anschutz Medical Campus, Aurora, CO; <sup>3</sup>University of Oregon, Eugene, OR.

**Background:** Passive heat therapy—chronic use of hot tubs or saunas—lowers blood pressure (BP) and reduces risk of cardiovascular-related mortality and hypertension in healthy populations but has not been studied in the context of kidney disease. We investigated if heat therapy could lower BP and improve vascular function in middle-aged and older adults (57-79 yrs) with reduced kidney function (MDRD eGFR at baseline <90 mL/min/1.73 m<sup>2</sup>).

**Methods:** As part of a randomized, parallel-design, clinical trial (NCT05300971), subjects underwent 30 x 60-min sessions over 8-10 weeks (~3x/week) of hot water immersion (n=9; 40°C water) or thermoneutral water immersion (n=8; “sham”; 36°C water; no change in body temperature). BP and vascular function were assessed before and after the intervention (24-72 h after the last session).

**Results:** Data are mean±SE. Baseline eGFR was comparable across groups: heat therapy, 74±3 vs. sham, 73±4 mL/min/1.73 m<sup>2</sup> (P=0.75). Remarkably, heat therapy reduced casual seated systolic BP in every subject. On average, systolic BP changed from 124±4 to 114±4 mmHg in the overall group (P<0.001), and from 119±4 to 109±4 mmHg in the subgroup of subjects with baseline eGFR <75 mL/min/1.73 m<sup>2</sup> (n=5; P=0.01). Casual diastolic BP was also reduced (overall group: 80±3 to 75±3 mmHg; lower eGFR subgroup: 76±4 to 70±3 mmHg; both P<0.01). In the overall group, heat therapy improved vascular endothelial function (brachial artery flow-mediated dilation: 4.7±0.6 to 6.3±1.1%Δ units, P<0.01) and reduced aortic stiffness (carotid-femoral pulse wave velocity: 8.8±0.6 to 8.1±0.8 m/sec, P=0.06). The magnitude of improvements in these vascular outcomes were similar in the subgroup of subjects with baseline eGFR <75 mL/min/1.73 m<sup>2</sup> vs. the overall group. Serum C-reactive protein tended to be reduced in the overall group, with the largest reductions observed in subjects with eGFR <75 mL/min/1.73 m<sup>2</sup> (5.5±2.8 to 2.1±0.7 mg/L, P=0.19). There were no changes in any outcomes in sham subjects.

**Conclusions:** Passive heat therapy substantially lowers BP in older adults with mildly reduced kidney function, accompanied by improved vascular function. Heat therapy may be a novel lifestyle intervention for treating hypertension and lowering cardiovascular risk and should be further studied in patients with more advance kidney disease.

FR-PO739

**The Impact of Repeated SBP Measurements in a Single Visit on Cardiovascular Prediction**  
Louis-Charles Desbiens,<sup>1,2</sup> Annie-Claire Nadeau-Fredette,<sup>1,2</sup> Francois Madore,<sup>1,3</sup> Mohsen Agharazi,<sup>4,5</sup> Remi Goupil.<sup>1,3</sup> <sup>1</sup>Universite de Montreal Faculte de Medecine, Montreal, QC, Canada; <sup>2</sup>Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; <sup>3</sup>Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; <sup>4</sup>Universite Laval Faculte de medecine, Quebec, QC, Canada; <sup>5</sup>CHU de Quebec-Universite Laval, Quebec, QC, Canada.

**Background:** Blood pressure (BP) is known for its intra-individual variability, even during a single clinic visit. Several guidelines recommend averaging BP measurements during a single office visit to monitor hypertension as it correlates more closely with ambulatory BP. However, whether these averages improve cardiovascular prediction has never been evaluated yet.

**Methods:** We studied individuals aged between 40 and 69 from the CARTaGENE cohort (Canada). Three SBP measurements (SBP<sub>1</sub>, SBP<sub>2</sub>, SBP<sub>3</sub>) at two-minute intervals were taken with an Omron 907L device. These values were averaged to generate SBP<sub>1,2</sub> (mean of SBP<sub>1</sub> and SBP<sub>2</sub>), SBP<sub>1,3</sub> (SBP<sub>1</sub> and SBP<sub>3</sub>), and SBP<sub>1,2,3</sub> (SBP<sub>1</sub>, SBP<sub>2</sub> and SBP<sub>3</sub>). Major adverse atherosclerotic events (MACE: cardiovascular death, stroke, myocardial infarction) during a 10-year follow-up were obtained using medico-administrative databases. Associations of each SBP parameter with MACE were obtained using fully adjusted Cox models. Attributable risks were derived for each SBP parameter. Predictive performance was assessed with 10-year atherosclerotic cardiovascular disease scores (ASCVD; using pooled cohort equations) for each SBP parameter and associated C-statistics.

**Results:** From 17,966 included individuals, 2,378 had a MACE during the follow-up. SBP values at baseline were 126.5 mmHg (SBP<sub>1</sub>), 123.2 (SBP<sub>2</sub>) and 122.5 (SBP<sub>3</sub>). After adjustment, SBP<sub>3</sub> had the strongest association with MACE incidence. This association was significantly greater than that observed for SBP<sub>1</sub>, SBP<sub>1,2</sub>, or SBP<sub>1,2,3</sub>. In comparison to SBP<sub>1</sub>, SBP<sub>3</sub> and SBP<sub>1,2,3</sub> increased the absolute risk attributable to SBP by up to two times. When included in ASCVD scores, SBP<sub>3</sub> yielded the highest C-statistic, which was significantly higher than all other SBP parameters except SBP<sub>1,2,3</sub>.

**Conclusions:** Averaging repeated SBP measurements during a single office visit improves cardiovascular risk prediction compared to a single measurement. The first SBP value should nevertheless be discarded in order to maximize predictive performance.

**Funding:** Government Support - Non-U.S.

Parameter	Hazard ratio		C-Statistic		Attributable risk ratio (compared to SBP <sub>1</sub> )	
	Fully adjusted value (95% CI)	Comparison with SBP <sub>1</sub> (p-value)	Value	Difference with SBP <sub>1</sub> (95% CI)	Men	Women
<b>Crude values</b>						
SBP <sub>1</sub>	1.06 (1.01, 1.10)	0.042	67.56	-0.35 (-0.19, -0.52)	Ref	Ref
SBP <sub>2</sub>	1.08 (1.03, 1.12)	0.065	67.75	-0.17 (-0.30, -0.03)	1.74	1.29
SBP <sub>3</sub>	1.10 (1.05, 1.15)	Ref	67.92	Ref	2.06	1.82
<b>Mean values</b>						
SBP <sub>1,2</sub>	1.07 (1.03, 1.12)	0.033	67.69	-0.23 (-0.36, -0.10)	1.43	1.21
SBP <sub>1,3</sub>	1.09 (1.05, 1.14)	0.064	67.86	-0.05 (-0.12, 0.02)	2.01	1.63
SBP <sub>1,2,3</sub>	1.08 (1.04, 1.13)	0.025	67.79	-0.13 (-0.22, -0.04)	1.71	1.46

*Hazard ratios (95% confidence interval) are displayed for one standard deviation increase. P-values for the comparison with the SBP<sub>1</sub> hazard ratio were computed using non-nested likelihood ratio tests.*  
*Fully adjusted models include age, sex, self-reported race, BMI, active smoking, total cholesterol, HDL cholesterol, eGFR, statin use, antihypertensive use, prior cardiovascular disease, and mean heart rate.*  
*C-Statistics were computed using predicted 10-year MACE risk from the ASCVD score (revised pooled cohort equations). Each C-Statistic was computed to the maximal one (SBP<sub>1</sub>) to generate C-Statistic differences (95% confidence interval).*  
*Attributable risk ratios were obtained by dividing the excess risk for a given SBP value (defined as the difference between the predicted risk at the SBP value minus the predicted risk at a reference SBP of 120 mmHg) by the excess risk for the corresponding SBP value for SBP<sub>1</sub> and averaging these ratios over all SBP values. Fully adjusted Cox models were used to generate predicted risks.*

**Routine Office Blood Pressure and All-Cause Mortality Among US Veterans**  
Masaaki Yamada,<sup>1,2</sup> Meenakshi Sambharia,<sup>2</sup> Benjamin R. Griffin,<sup>2,1</sup> Melissa L. Swee,<sup>2,1</sup> Heather Reisinger,<sup>1,2</sup> Brian C. Lund,<sup>1</sup> Diana I. Jalal.<sup>1,2</sup> <sup>1</sup>Iowa City VA Medical Center, Iowa City, IA; <sup>2</sup>University of Iowa Carver College of Medicine, Iowa City, IA.

**Background:** Randomized controlled trials have provided accumulating evidence of benefits from intensive blood pressure lowering utilizing standardized blood pressure measurement in individuals at high risk of cardiovascular disease (CVD). However, it remains unclear whether intensive blood pressure control, based on routine office BP, is associated with improved outcomes. Here, we examined the association of routine office blood pressure categories and all-cause mortality in US Veterans.

**Methods:** We identified Veterans with prevalent hypertension defined as International Classification of Disease-10 codes related to hypertension, prescribed antihypertensive drugs, or ≥2 office BP of ≥130/90 mmHg who had ≥2 systolic blood pressure (SBP) readings from 2016-2017 and follow-up through March 2021. We examined the association of mean SBP control (3 groups: <120, 120-129, and ≥130 mmHg) with all-cause mortality by using time-dependent Cox regression models adjusted for demographics, body mass index, and comorbid conditions defined by diagnostic codes after excluding individuals with mean SBP <100 mmHg. In these models, we analyzed effects in the high-risk individuals with CVD as sensitivity analysis.

**Results:** Of the 1,284,131 hypertensive Veterans, 10% (n=128,493) had mean SBP <120 mmHg at baseline; 20% (n=262,887) had 120-129 mmHg; and 70% (n=892,870) had ≥130 mmHg. 28% had previous CVD. Mean SBP <120 and 120-129 mmHg categories were associated with improved mortality compared to ≥130 mmHg (Table 1). Of note, SBP category 120-129 mmHg had the lowest mortality. Sensitivity analysis revealed similar findings among Veterans with prior history of CVD (Table 1).

**Conclusions:** Routine office SBP categories <130 mmHg (vs ≥130 mmHg) were associated significantly with reduced mortality among Veterans with prevalent hypertension independent of pre-existing CVD status.

**Funding:** Veterans Affairs Support

FR-PO741

**Routine Office Blood Pressure and All-Cause Mortality Among US Veterans With CKD**  
Masaaki Yamada,<sup>1,2</sup> Meenakshi Sambharia,<sup>1</sup> Benjamin R. Griffin,<sup>1,2</sup> Melissa L. Swee,<sup>2,1</sup> Heather Reisinger,<sup>2</sup> Brian C. Lund,<sup>2</sup> Diana I. Jalal.<sup>2,1</sup> <sup>1</sup>University of Iowa Carver College of Medicine, Iowa City, IA; <sup>2</sup>Iowa City VA Medical Center, Iowa City, IA.

**Background:** Intensive blood pressure control has been shown to reduce the risk of death in individuals at high risk of cardiovascular disease. Data regarding blood pressure control are limited in chronic kidney disease (CKD). Here, we examined the association of different office blood pressure categories with all-cause mortality in a national sample of US Veterans stratified by kidney function

**Methods:** Veterans with prevalent hypertension (as defined by i. International Classification of Disease-10 codes related to hypertension, ii. prescription of antihypertensive drugs, or iii. ≥2 office BP of ≥130/90 mmHg) who had ≥2 systolic blood pressure (SBP) readings between 2016-2017 with a follow-up through March 2021 were included. Those with mean SBP <100 mmHg were excluded. CKD categories were defined based on estimated glomerular filtration rate (eGFR): <30, 30-60, and >60 mL/min/1.73m<sup>2</sup>. We examined the association of mean SBP control (3 groups: <120, 120-129,

and  $\geq 130$  mmHg) with all-cause mortality by using time-dependent Cox regression models adjusted for demographics, body mass index, and comorbid conditions. SBP was modeled as a time-dependent variable

**Results:** Total 30,782,873 hypertensive Veterans had eGFR available were included in our analyses. Of those, 1.3% (n=394,132) had eGFR  $<30$  mL/min/1.73m<sup>2</sup> at baseline; 18.4% (n=5,649,379) had 30-60 mL/min/1.73m<sup>2</sup>; and 80.4% (n=24,739,362) had  $>60$  mL/min/1.73m<sup>2</sup>. Mean SBP  $<120$  and 120-129 mmHg categories were associated with reduced mortality compared to  $\geq 130$  mmHg (Table 1), although SBP category 120-129 mmHg was associated with the least risk of all-cause mortality (Table 1). These findings were notable in Veterans across all eGFR categories including those with stage 4 CKD

**Conclusions:** Mean SBP of 120-129 mmHg was indeed associated with lower mortality than  $<120$  mmHg, and both 120-129 and  $<120$  were superior to SBP  $\geq 130$  mmHg among all Veterans including advanced CKD

**Funding:** Veterans Affairs Support

Table 1. Mortality risk

Kidney function, eGFR (mL/min/1.73m <sup>2</sup> )	Mean systolic blood pressure (mmHg)	Hazard ratio	95% confidence interval
eGFR $<30$ , n=394,132 (1.3%)	$<120$	0.86	0.84-0.89
	120-129	0.63	0.61-0.66
	$\geq 130$	1 (reference)

	$\geq 130$	1 (reference)	

## FR-PO742

### Diagnosis of Hypertension in Children Using Ambulatory Blood Pressure Monitoring

Priyanka Chati, Rasheda Amin. Inova Fairfax Hospital, Falls Church, VA.

**Background:** 24-hour ambulatory blood pressure monitoring (ABPM) is becoming standard practice for diagnosis of hypertension (HTN) in pediatrics. ABPM is used to confirm HTN or white coat hypertension (WCH) in patients with office-based elevated BP readings, masked hypertension (MH) in high-risk populations and to assess treatment efficacy in patients with HTN. We describe the experience of a pediatric subspecialty clinic in improving utilization of ABPM by 2000% in 4 years, using limited resources and staff, and breakdown of diagnoses based on the procedure.

**Methods:** In April 2017, a formal ABPM program was set up by the pediatric nephrology division, comprising 2.0 FTE physicians and 1.5 FTE nurses, at a pediatric specialty practice. Outdated ABPM monitors were replaced by 3 new Spacelabs OnTrak devices. Nephrologists and nurses were trained to use new equipment. ABPM was promoted amongst community pediatricians and cardiologists through grand rounds, fliers and talks. New and established patients underwent ABPM with nurses or physicians performing procedures. Standard parameters of mean BP, BP load and nocturnal dipping were compared with normative pediatric data to determine normal or elevated BP by physicians. Those with no definitive diagnosis were labeled as concerns.

**Results:** The number of ABPM procedures increased from 6 procedures/year in 2017 to 125 procedures/year in 2021 – an increase of 2000%. During the years 2018-2021, a total of 315 ABPM procedures were performed (Figure 1). HTN was diagnosed in 96, WCH in 91 and MH in 7 patients. Poorly controlled HTN was found in 21 of 53 patients with known HTN. 71 patients who had concerning or indeterminate studies were asked to repeat the study.

**Conclusions:** We successfully set up an ABPM program and increased its utilization with limited resources and staff. We increased the number of patients undergoing ABPM and improved diagnosis of patients with HTN, WCH, MH and those with poorly controlled HTN with a goal to better identify and manage HTN.

Figure 1: ABPM Based Diagnosis over 4 years

## FR-PO743

### Reversal of ESKD After 4 Years of Peritoneal Dialysis (PD) With Improved Cardiorenal Pathophysiology

Akash Sharma, Rahul Patel, Shweta Bansal. The University of Texas Health Science Center at San Antonio, San Antonio, TX.

**Introduction:** Inadequate treatment of malignant hypertension (MHTN) results in multi-organ failure and sets up a pathophysiologic disequilibrium between heart and kidney where impairment of one causes malfunction of the other. We present a case of MHTN related ESKD who improved his kidney and diastolic dysfunction after 4 years on PD from improved cardiorenal interactions.

**Case Description:** A 39-year male with 10-year history of smoking and HTN on sporadic medications presented with fatigue and vomiting, BP was 230/150 mmHg, and serum creatinine (SCr) was 7.5mg/dl. Exam showed papilledema and 1+ peripheral edema. Pertinent blood work included anemia, normal platelets, high troponin, and potassium 3.2 mEq/L. Urine without blood but 1.7 gm 24H protein. Acute coronary syndrome and secondary hypertension were ruled out. Echo showed severe concentric left ventricular hypertrophy (LVH), moderate diastolic dysfunction (DD) and pulmonary arterial systolic pressure of 48 mmHg. Renal biopsy showed tubular atrophy and interstitial fibrosis in 80% cortex and severe hyperplastic obliterative arterial and arteriolar sclerosis with no acute damage. After initial BP control, he was discharged on oral carvedilol, nifedipine, hydralazine, and furosemide and plan to start PD as outpatient. Training and education let him change his lifestyle mainly by dietary sodium reduction, and he followed best PD practices. BP improved to  $<115/80$  mmHg with no edema over next few months. He was kept on low dose carvedilol and lisinopril for cardiorenal protection and furosemide. His SCr settled at 10 mg/dl and stayed there for 2 years, when echo showed no LVH and mild DD. He had no PD related infections and maintained 1-1.5L/d urine output. Over the 3<sup>rd</sup> year SCr lowered to 6-7mg/dl and 4<sup>th</sup> year to 4-5mg/dl when PD was stopped. SCr was 3.2mg/dl 6 months later (eGFR 24ml/min) with urine protein-Cr ratio 1.6g/g. BP remained at goal with same medications. Echo had normalization of DD.

**Discussion:** This is a rare case of reversal of ESKD after 4 years due to maintenance of euolemia and BP control from significant lifestyle changes and daily PD, resulting in resolution of DD and likely improved renal perfusion and healing of remanent nephrons. It highlights the important cardiorenal interactions and need for aggressive BP/volume control to achieve best outcomes.

## FR-PO744

### Impact of Blood Pressure on Mortality in Patients Undergoing Peritoneal Dialysis

Jwa-kyung Kim, Dong Hee Lee, Sungmin Kim, Sung Gyun Kim. Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.

**Background:** A recent KDIGO guideline recommends intensive blood pressure (BP) control in chronic kidney disease. However, no consensus on the optimal BP has been made in the dialysis population. With a well-characterized peritoneal dialysis (PD) cohort, we evaluated the impact of BP on long-term mortality.

**Methods:** With the incident PD patients who had more than 6 months' follow-up between 2000 to 2019 (n=490), the relationship between BP and mortality rate adjusting for age, sex, BMI, and comorbidities was analyzed. Mean BP levels at 3-6 months after PD initiation were studied for predicting all-cause mortality as well as fatal and non-fatal cardiovascular (CV) events.

**Results:** During the median PD duration of 40 months (IQR, 22 to 66), the mortality rate was 50.3 per 1000 patient-year (102 cases). Overall, the survival rates were much better than previously known; the 3-, 5- and 10-year patient survival rate was 87.6%, 79.1%, and 55.4%. It markedly differed according to the presence of diabetes; the 3, 5, and 10-year mortality were 84%, 71.4%, and 40.7% in diabetes and 92%, 89.0 %, and 74% in non-diabetes, respectively (p<0.001). In multivariate Cox proportional hazard modeling, the risk of death had a U-curved association with systolic BP (SBP) with a nadir between 120 and 140 mmHg. Based on this, the hazard ratios (HR, 95% confidence interval [CI]) for all-cause mortality with SBP  $<120$  mmHg, 140-160 mmHg, and  $\geq 160$  mmHg were 3.3 (1.7-6.4), 1.68 (0.83-3.4), and 2.3 (1.1-4.9) after adjusting age, sex, diabetes, body mass index, and previous coronary artery diseases. Similarly, fatal and non-fatal CV risks were significantly increased when SBP  $<120$  mmHg or  $\geq 160$  mmHg.

**Conclusions:** Patients who started PD in the 2000s showed improved survival rates than before. Low SBP  $< 120$  mmHg showed the highest mortality risk. And high SBP  $> 160$  mmHg was also associated with increased mortality even after adjusting for well-known risk factors.

## FR-PO745

### Triglyceride-Glucose (TyG) Index Is an Independent Predictor of the Coronary Artery Calcification Progression in CKD Patients

Ye Eun Ko,<sup>1</sup> Hee Byung Koh,<sup>1</sup> Jong Hyun Jhee,<sup>2</sup> Tae-Hyun Yoo.<sup>1</sup> <sup>1</sup>Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea; <sup>2</sup>Division of Nephrology, Department of Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea.

**Background:** There have been few studies about the relationship between triglyceride-glucose (TyG) index, which is known to be related to insulin resistance, coronary artery calcification (CAC) progression, and increase in cardiovascular events in general population. The aim of this study is to investigate the association between TyG index and CAC progression in CKD patients.

**Methods:** A total of 1,154 CKD (stage 1 to 5) patients were enrolled from the nationwide multicenter prospective observational cohort of KNOW-CKD (Korean Cohort Study for Outcomes in Patients With Chronic Kidney Disease). TyG index was calculated as follows:  $\ln(\text{fasting triglycerides} \times \text{fasting glucose}/2)$ . The patients were classified into tertile (low, intermediate, high) based on TyG index. The CAC density score was calculated by dividing the Agatston score by the total area score. Primary outcome was annualized percentage change in CAC score:  $(\text{percent change in CAC score} + 1) \geq (12/\text{follow-up months}) - 1$ , of  $\geq 15\%$ , which was defined as CAC progression.

**Results:** The mean age of study subjects was  $52.8 \pm 11.9$  years and  $688 (59.6\%)$  were male. During 4 year follow-up, annualized percentage change in CAC score was  $16.7 \pm 34.7$ ,  $20.8 \pm 39.4$ ,  $24.9 \pm 38.5$  in low, intermediate, high TyG index respectively. Percentage of patient with CAC progression showed stepwise increasing pattern across TyG index group (28.6%, 37.5%, 46.2% in low, intermediate, high TyG index group in order;  $P < 0.001$ ). In multivariate logistic regression analysis, the high TyG index group was associated with increased risk of CAC progression (OR, 1.48; 95% CI, 1.01-2.16;  $P = 0.04$ ) compared to low TyG index group. Moreover, 1 increase in TyG index was related to increased risk of CAC progression (OR, 1.34; 95% CI, 1.06-1.76;  $P = 0.02$ ) after adjusting confounding factors.

**Conclusions:** High TyG index may be useful predictor of CAC progression in CKD patients.

## FR-PO746

### High Hepcidin Is Associated With the Progression of Coronary Artery Calcification in Patients With CKD

Ye Eun Ko,<sup>1</sup> Hee Byung Koh,<sup>1</sup> Jong Hyun Jhee,<sup>2</sup> Tae-Hyun Yoo.<sup>1</sup> <sup>1</sup>Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea; <sup>2</sup>Division of Nephrology, Department of Internal Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea.

**Background:** Hepcidin is well known for its role in iron metabolism, but, its relationship with calcium metabolism had also been studied. In addition, a recent report showed a positive correlation between hepcidin level and the incidence of atherosclerotic disease. In hemodialysis population, elevated hepcidin level was related to increased cardiovascular outcome. The aim of this study is to investigate the association between hepcidin and coronary artery calcification progression in non-dialysis chronic kidney disease.

**Methods:** A total of 1,153 CKD (stage 1 to 5) patients were enrolled from the nationwide multicenter prospective observational cohort of KNOW-CKD (Korean Cohort Study for Outcomes in Patients With Chronic Kidney Disease). Primary outcome was CAC progression, which was defined as annualized percentage change in CAC score:  $(\text{percent change in CAC score} + 1) \geq (12/\text{follow-up months}) - 1$ , of  $> 15\%$ .

**Results:** The mean age of study subjects was  $52.8 \pm 12.0$  years and  $673 (59.8\%)$  were male. During 4 year follow up, annualized percentage change in CAC score was

$20.0 \pm 36.8$  in study patients,  $15.2 \pm 41.7$  in group without CAC,  $26.9 \pm 31.7$  in patients with CAC score above 0. There were statistically significant differences in age ( $50.5 \pm 12.3$ ,  $56.7 \pm 9.9$ ;  $P < 0.001$ ), gender (male 55.6%, 66.4%;  $P = 0.001$ ), DM status (19.6%, 38.4%;  $P < 0.001$ ), and hepcidin level at baseline ( $14.5 \pm 12.9$ ,  $16.3 \pm 15.4$ ;  $P = 0.04$ ) between CAC non-progression and progression group. In multivariate logistic regression analysis, all patients and patients with baseline CAC score above 0 showed the association between elevation in log (hepcidin+1) and increased risk of CAC progression (OR, 1.74; 95% CI, 1.02-2.96;  $P = 0.04$ , OR, 2.41; 95% CI, 1.08-5.37;  $P = 0.03$ ).

**Conclusions:** Hepcidin level may be an independent predictor of CAC progression in CKD patients.

## FR-PO747

### Does Post-Randomization Diuretics Use Account for the Cardiovascular Benefits of Intensive Systolic Blood Pressure Lowering in the Systolic Blood Pressure Intervention Trial (SPRINT)?

Shweta Bansal,<sup>1,6</sup> Robert E. Boucher,<sup>4</sup> Guo Wei,<sup>4</sup> Glenn Chertow,<sup>2</sup> Paul K. Whelton,<sup>3</sup> Alfred K. Cheung,<sup>4</sup> Jincheng Shen,<sup>4</sup> Srinivasan Beddhu.<sup>4,5</sup> <sup>1</sup>The University of Texas Health Science Center at San Antonio, San Antonio, TX; <sup>2</sup>Stanford University School of Medicine, Stanford, CA; <sup>3</sup>Tulane University Health Sciences Center, New Orleans, LA; <sup>4</sup>University of Utah Health, Salt Lake City, UT; <sup>5</sup>VA Salt Lake City Health Care System, Salt Lake City, UT; <sup>6</sup>South Texas Veterans Health Care System, San Antonio, TX.

**Background:** We examined whether the beneficial effects of intensive systolic blood pressure (SBP)-lowering on major cardiovascular (CV) events in the Systolic Blood Pressure Intervention Trial (SPRINT) could be explained, in part, by increased use of diuretics in the intensive arm.

**Methods:** The SPRINT evaluated the effects of intensive ( $< 120$  mmHg) vs. standard SBP ( $< 140$  mmHg) goal on primary outcome (CV composite) and all-cause mortality (ACM) in 9361 participants. In a post-hoc analysis, we examined whether adjustment for post-randomization time-varying diuretic use in Cox regression models attenuated the effects of BP intervention on the primary outcome and ACM. We also performed mediation analyses of post-randomization diuretic use at 6 months to separate the overall effects of the randomized SBP intervention into indirect effects (mediated by diuretic use) and direct effects (mediated through pathways other than diuretic used) on the primary outcome and ACM.

**Results:** The participants age was  $67.9 \pm 9.4$  years, 36% were women. During the trial, diuretics were used in 46% and 74% of participants in the standard and intensive groups, respectively. There were 726 CV events and 502 deaths over 3.8 years of follow-up. As shown in Fig 1A, intensive SBP goal lowered the risk of primary outcome (HR0.76, 95%CI0.65-0.88) and adjustment for post-randomization time-varying diuretics use did not attenuate the effect (HR0.73, 95%CI0.63-0.85). Formal mediation analyses suggested that the beneficial effects of the SBP intervention on primary outcome were mediated through direct effects and were independent of post-randomization diuretic use (Fig 1B). ACM results were similar.

**Conclusions:** In this post-hoc analysis of the SPRINT, post-randomization diuretics use did not appear to mediate the beneficial effects of intensive SBP treatment on the CV events and ACM.

### Depression and CKD as Risk Factors of Heart Failure: Post Hoc Analysis of SPRINT

Nikita Abraham, Sydney E. Hartsell, Ravinder Singh, Guo Wei, Alfred K. Cheung, Tom Greene, Robert E. Boucher, Srinivasan Beddhu. *The University of Utah School of Medicine, Salt Lake City, UT.*

**Background:** Depression and HF are common in CKD. We examined whether the presence of depression augments the risk of HF in CKD.

**Methods:** We used data from SPRINT, a RCT that tested the effects of SBP goal  $< 120$  vs.  $< 140$  mmHg on CV outcomes. CKD was defined as eGFR  $< 60$ . Based on the Patient Health Questionnaire (PHQ)-9, we defined 3 groups: no (score 0), minimal/mild (scores 1-9) and moderate/severe (scores 10-27) depressive symptoms. We related baseline PHQ9 groups and CKD status with adjudicated HF events during follow-up in Cox regression models.

**Results:** In 9,111 included participants, the mean age was  $68 \pm 9$  yrs., 36% were female, 31% were Black and 28% had CKD at baseline. Baseline characteristics by depression groups defined by PHQ9 scores are summarized (Table). There were 211 HF events over 34,340 years of follow-up. In a multivariable Cox regression model, higher PHQ9 scores (minimal/mild HR 1.43 (1.05, 1.96), moderate/severe HR 1.84 (1.09, 3.10)) and CKD (HR 3.33 (2.53, 4.37)) were each associated with HF. Highest HF risk was noted when both were present (Fig).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** Both depression and CKD are risk factors for HF with the highest risk of HF seen when both are present. Interventions targeting depression might reduce the risk of HF in CKD.

**Funding:** NIDDK Support, Other NIH Support - NIA, Veterans Affairs Support

Baseline characteristics by PHQ9 score (N = 9111)

**Impact of SGLT2 Inhibitors on Cardiovascular and Renal Outcomes According to Baseline Renal Function: A Systematic Review and Meta-Analysis**  
*Thomas Mavranakas,<sup>1</sup> Michael A. Tsoukas,<sup>1</sup> Abhinav Sharma,<sup>1</sup> Karim Gariani.<sup>2</sup>*  
<sup>1</sup>McGill University Health Centre, Montreal, QC, Canada; <sup>2</sup>Hopitaux Universitaires Geneve, Geneve, Switzerland.

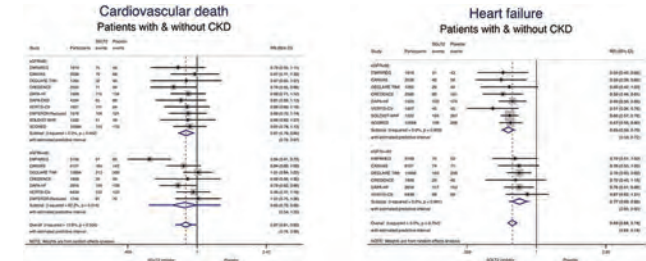

**Background:** The effect of sodium-glucose co-transporter-2 (SGLT-2) inhibitors on cardiovascular and renal outcomes has not been specifically examined across baseline kidney function groups in a meta-analysis including the most recent trials. We conducted a systematic review and meta-analysis of randomized control trials (RCTs) with SGLT-2 inhibitors in patients with and without CKD.

**Methods:** We performed a PubMed/Medline search of randomized, placebo-controlled, event-driven outcome trials of SGLT-2 inhibitors versus active or placebo control in patients with and without diabetes from inception to February 1, 2022. CKD was defined as an estimated glomerular filtration rate <60 ml/min/1.73m<sup>2</sup>. The primary outcome was cardiovascular death. Secondary outcomes included hospitalization for heart failure, major adverse cardiovascular events (MACE), progression to kidney failure, and all-cause mortality. The relative risk (RR) was estimated using a random-effects model.

**Results:** Eleven RCTs were identified and included in this meta-analysis (77541 patients, including 28515 patients with CKD). Use of an SGLT-2 inhibitor was associated with a lower incidence of cardiovascular death in patients with CKD, compared with placebo: RR 0.87 (95% CI 0.79-0.95). Use of an SGLT-2 inhibitor was associated with a lower incidence of heart failure in patients with CKD, compared with placebo: RR 0.65 (95% CI 0.59-0.70). Risk reduction with SGLT-2 inhibitors was more important among patients with CKD compared with patients without CKD (p for interaction 0.03). SGLT-2 inhibitors were associated with a lower incidence of CKD progression among patients with pre-existing CKD, compared with placebo: RR 0.74 (95% CI 0.63-0.88). SGLT-2 inhibitors were also associated with a lower incidence of MACE and death from any cause among patients with CKD, compared with placebo.

**Conclusions:** SGLT-2 inhibitors offer strong protection against cardiovascular and renal outcomes in patients with CKD. These results strongly advocate in favor of using these agents in patients with CKD.

**Efficacy of Sacubitril/Valsartan in Patients With Cardiorenal Syndrome**  
*Yue Zhang, Daqing Hong, Guisen Li. Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China.*

**Background:** To retrospectively study the efficacy of Sacubitril/Valsartan in patients with cardiorenal syndrome (CRS).

**Methods:** In-hospital patients with CRS who admitted in heart failure(HF) center of our hospital from October 2021 to December 2021, meeting inclusion criteria were involved: age>18y, diagnosed as cardiorenal syndrome and receiving maximum tolerated doses of sacubitril/valsartan therapy(400mg/d) for 3 months. Clinical data were collected at the baseline and 3-month endpoint to assess cardiac and renal function.

**Results:** 69 patients with CRS were observed and participated. After 3-month's therapy, mean sitting systolic pressure(msSBP), mean sitting diastolic pressure(msDBP), heart-rate, type-B natriuretic peptide (BNP) and serum uric acid (sUA) were improved significantly, *p*-value was 0.000, 0.001,0.011,0.004,0.000 respectively. All the patients were divided into 2 subgroups based on the left ventricular ejection fraction(LVEF) value: group A (EF more than 50%) and group B (EF less than 50%). LVEF and left ventricular (LV) diameter were significantly improved in group B (*p*=0.008). Kidney function assessed by estimated glomerular filtration rate (eGFR) and serum creatinine (sCr) were improved but not significantly in all patients (*p*=0.696, 0.514 respectively) and group B (*p*=0.297, 0.534 respectively).

**Conclusions:** Sacubitril/valsartan might effectively decrease blood pressure and improve cardiac function in patients with CRS. And it seems like be effective to preserving kidney function, especially in CRS patients with lower EF value. It need to be verified in large scale controlled prospective trials.

FR-PO751

**Results From a Phase 1 Study Demonstrating the Safety and Pharmacokinetics of the Aldosterone Synthase Inhibitor CIN-107 in Subjects With Varying Degrees of Renal Function**  
*Mason W. Freeman,<sup>1</sup> Yuan-Di Halvorsen,<sup>1</sup> Mary Bond,<sup>2</sup> Brian Murphy,<sup>2</sup> Jonathan Isaacsohn.<sup>2</sup>*  
<sup>1</sup>CinCor Pharma, Inc., Waltham, MA; <sup>2</sup>CinRx Pharma, LLC, Cincinnati, OH.

**Background:** Hypertension and chronic kidney disease are common comorbidities exacerbated by elevated aldosterone. CIN-107 is a selective inhibitor of aldosterone synthase with the potential to lower blood pressure and slow the progression of kidney disease. This phase 1 open-label study assessed the safety and pharmacokinetics (PK) of a single oral dose of CIN-107 in subjects with varying degrees of renal function.

**Methods:** Subjects enrolled into renal function groups based on estimated glomerular filtration rate (eGFR). The groups were control (eGFR ≥60mL/min), moderate to severe renal impairment (eGFR 15 to 59 mL/min), and kidney failure (eGFR <15mL/min, including subjects on dialysis). A single 10 mg CIN-107 dose was given, followed by 7 days of PK sampling (blood and urine). Safety was assessed based on adverse events, clinical laboratory evaluations, vital signs, ECGs, physical examinations, and weight measurements.

**Results:** 32 subjects completed the study. There were no deaths, and only one mild drug-related adverse event (diarrhea) occurred. There were no clinically meaningful changes in laboratory values, vital signs, physical examinations, or ECGs. The plasma concentration-time curves of CIN-107 in all groups were qualitatively similar (Figure 1). The urine PK parameters in the moderate to severe renal impairment group were similar to control (12% excreted); however, inadequate urine production in the kidney failure group resulted in negligible excretion of CIN-107.

**Conclusions:** A single dose of CIN-107 was well tolerated in all subjects, including those with kidney failure. Renal impairment did not significantly impact systemic exposure or clearance of CIN-107, suggesting that dose adjustment due to PK differences in these patients is unnecessary, even in cases of advanced kidney disease.

Plasma 107 Concentr vs Time

FR-PO752

Antihypertensive Treatment and Clinical Outcomes Among Patients Who Develop Severe Hypertension During Hospitalization

Lama Ghazi, James Nugent, Jason H. Greenberg, Christine Y. Bakhom, Francis P. Wilson. *Yale University, New Haven, CT.*

**Background:** Treatment of severe hypertension (HTN) that develops during hospitalization is not guideline dependent. Compared to oral antihypertensives, treatment with IV antihypertensives could lead to more acute blood pressure (BP) reductions and worse outcomes. Our goal was to assess the effect of treatment, overall and by treatment route, on clinical outcomes in patients who develop severe HTN.

**Methods:** This is a multi-hospital, retrospective study of adults admitted for reasons other than HTN who develop severe HTN. We defined severe HTN as blood pressure (BP) elevation of systolic>180 or diastolic>110 mmHg. Treatment was defined as receiving antihypertensives (intravenous (IV) or oral) within 6 hours of BP elevation. We used overlap propensity score weighted Cox models to study the association between treatment and clinical outcomes.

**Results:** We identified 224,265 patient hospitalizations, 9% developed severe HTN and 40% were treated. Of those treated, 21% and 72% received IV and oral antihypertensives respectively. Patients who received IV compared to oral only antihypertensives were more likely female (60 vs. 54%), less likely to be Hispanic or Latino (9 vs. 12%), less likely to have comorbidities such as hypertension (79 vs. 88%) and diabetes (42% vs. 52%), less likely to be admitted to medical ward (71% vs. 87%), have higher eGFR (63 [40, 86] vs. 55 [30,82]) on admission, have higher BP on admission (168/68 vs. 153/79) and higher BP at time of severe HTN development (188/92 vs. 185/88). Patients who received IV treatment compared to no treatment had higher risk of myocardial injury, acute kidney injury, and death. However, patients who received oral antihypertensives compared to no treatment had lower risk of death (Table 1).

**Conclusions:** IV antihypertensive treatment was associated with worse clinical outcomes and therefore oral antihypertensives should be considered as the more preferable alternative for treatment of severe HTN without acute end organ damage.

**Funding:** Other U.S. Government Support

Table 1. Inpatient Outcomes for Treated vs. Untreated Patients by Treatment Route

	Treated	Untreated	HR (95% CI)
<b>Treatment vs. no treatment</b>			
Myocardial Injury	3.1%	2.1%	1.07 [0.91, 1.26]
Stroke	0.7%	0.5%	1.26 [0.86, 1.84]
Acute Kidney Injury	19%	17%	1.12 [1.05, 1.20]
Death	1.4%	1.3%	0.94 [0.73, 1.21]
<b>IV treatment vs. no treatment</b>			
Myocardial Injury	4.7%	2.8%	1.68 [1.28, 2.19]
Stroke	0.5%	0.5%	0.98 [0.45, 2.15]
Acute Kidney Injury	23%	16%	1.45 [1.29, 1.63]
Death	2.6%	1.3%	1.96 [1.36, 2.81]
<b>Oral treatment vs. no treatment</b>			
Myocardial Injury	2.3%	2.8%	0.83 [0.67, 1.03]
Stroke	0.7%	0.5%	1.41 [0.91, 2.18]
Acute Kidney Injury	17%	17%	0.99 [0.92, 1.08]
Death	0.8%	1.4%	0.58 [0.41, 0.85]

HR: Hazard Ratio from overlap propensity Cox model accounting for demographics, comorbidities, admission vitals, admission labs, vitals at time of severe hypertension.

FR-PO753

Comparison of Beta Blocker Outcomes Among CKD Patients With Cardiorenal Syndrome

Albert Yu, Hui Zhou, Katherine J. Pak, Sally F. Shaw, Jiaxiao Shi, Benjamin Broder, Cheng-Wei Huang, John J. Sim. *Kaiser Permanente Southern California, Los Angeles, CA.*

**Background:** Beta blockers reduce mortality and hospitalization in patients with heart failure with reduced ejection fraction (HFrEF). The three guideline directed medical therapy (GDMT) beta blockers are bisoprolol, carvedilol, and metoprolol succinate,

however, their effects in chronic kidney disease (CKD) patients are not well studied. We compared one year outcomes among these three GDMT beta blockers in the patients with both HFrEF and CKD.

**Methods:** A retrospective study was performed within Kaiser Permanente Southern California (KPSC) during 2007-2017 among patients with incident advanced CKD (eGFR<45) who had prevalent HFrEF. We limited the study population to the patients who were taking GDMT beta blockers at baseline and followed them for one year to assess outcomes including major adverse cardiac events (MACE), renal events, all-cause death, and all-cause hospitalization. Multiple models were performed to estimate hazard ratio (HR) or rate ratio (RR) of these outcomes after adjustment for potential confounders or potential competing risk, respectively.

**Results:** A total of 2,355 (16.9%) among incident CKD patients had HFrEF and were treated with GDMT beta blockers. Within one year, 30.3% patients had encountered MACE, 52.2% had ≥ 1 hospitalization and 22.8% died with cardiovascular death accounting for 19.7% (Figure). Compared to carvedilol, bisoprolol had a lower one year MACE with adjusted HR 0.73 (0.58-0.93). There was no statistical difference in renal events and all-cause mortality or all-cause hospitalization.

**Conclusions:** The three GDMT beta blockers were associated with similar one year mortality and hospitalizations in patients with CKD and HFrEF. However, bisoprolol was associated with lower MACE outcomes.

FR-PO754

Dihydropyridine Calcium Channel Blockers and Incident Albuminuria

Matthew F. Blum,<sup>1,5</sup> Aditya L. Surapaneni,<sup>2</sup> Alex R. Chang,<sup>3</sup> Lesley A. Inker,<sup>4</sup> Jung-Im Shin,<sup>5</sup> Morgan Grams.<sup>2,5</sup> <sup>1</sup>*Johns Hopkins University School of Medicine, Baltimore, MD;* <sup>2</sup>*New York University Grossman School of Medicine, New York, NY;* <sup>3</sup>*Geisinger Health, Danville, PA;* <sup>4</sup>*Tufts Medical Center, Boston, MA;* <sup>5</sup>*Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

**Background:** Dihydropyridine calcium channel blockers (DHP-CCB) are first-line blood pressure agents that promote systemic vasodilation. In the kidney, they disproportionality vasodilate the afferent arteriole relative to the efferent arteriole, which poses a risk of glomerular hypertension and consequent albuminuria. For this reason, the amlodipine arm was halted early in the African American Study of Kidney Disease and Hypertension. However, DHP-CCBs remain commonly used, and few real-world studies have examined the development albuminuria with DHP-CCB use. Therefore, we sought to measure the association of DHP-CCBs with incident albuminuria compared to beta blockers, an active comparator not known to affect albuminuria.

**Methods:** We included 61,380 patients without known albuminuria who initiated either a DHP-CCB or beta blocker in a cohort from the Geisinger Health System from 2004-2019. We performed 1:1 propensity matching on age, sex, race, systolic and diastolic blood pressure, eGFR, smoking, body mass index, heart failure, diabetes, stroke, and coronary heart disease. We estimated risk of incident albuminuria (albumin to creatinine ratio [ACR] > 300 mg/g, protein to creatinine ratio converted to ACR, or urinalysis with > 2+ protein) using Cox proportional hazards regression.

**Results:** After matching, there were 28,716 patients (14,358 per group). Mean age was 60.5 years, mean systolic blood pressure was 142 mmHg, mean eGFR was 84 ml/min/1.73 m<sup>2</sup>, and 1.8% had heart failure. 2244 (7.8%) patients developed albuminuria over an average 4.8 years of follow up. DHP-CCB initiation was associated with a significantly higher risk of albuminuria compared to beta blocker initiation (hazard ratio 1.37 [95% confidence interval, 1.26-1.50]; Figure).

**Conclusions:** Compared to beta blockers, DHP-CCB use was associated with increased risk of incident albuminuria in a community cohort.

**Funding:** Other NIH Support - NHLBI

Cumulative incidence of albuminuria in DHP-CCB vs beta blocker use

FR-PO755

**Kidney Tubule Injury and Dysfunction Biomarkers and Risk of Incident Hypertension in Community-Living Individuals: Results From the Multi-Ethnic Study of Atherosclerosis**  
Rakesh Malhotra,<sup>1</sup> Ronit Katz,<sup>2</sup> Paul L. Kimmel,<sup>3</sup> Vasan S. Ramachandran,<sup>4</sup> Tala Al-Rousan,<sup>1</sup> Jason H. Greenberg,<sup>5</sup> Chirag R. Parikh,<sup>6</sup> Joseph V. Bonventre,<sup>7</sup> Jeffrey R. Schelling,<sup>11</sup> Mark J. Sarnak,<sup>8</sup> Orlando M. Gutierrez,<sup>9</sup> Michael Shlipak,<sup>10</sup> Joachim H. Ix.<sup>1</sup> <sup>1</sup>University of California San Diego, La Jolla, CA; <sup>2</sup>University of Washington, Seattle, WA; <sup>3</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>4</sup>Boston University School of Medicine, Boston, MA; <sup>5</sup>Yale University, New Haven, CT; <sup>6</sup>Johns Hopkins University, Baltimore, MD; <sup>7</sup>Brigham and Women's Hospital, Boston, MA; <sup>8</sup>Tufts Medical Center, Boston, MA; <sup>9</sup>UAB Health System, Birmingham, AL; <sup>10</sup>UCSF Medical Center, San Francisco, CA; <sup>11</sup>University Hospitals, Cleveland, OH.

**Background:** Hypertension (HTN) is a major risk factor for the onset and progression of chronic kidney disease (CKD) and cardiovascular disease (CVD). However, the mechanisms leading to essential HTN remain elusive. Here, we evaluated the association between tubule biomarkers and risk of developing HTN.

**Methods:** We randomly sampled 463 MESA participants who did not have prevalent CKD or diabetes, but excluded 166 participants who had prevalent HTN. We measured six plasma tubule biomarkers (KIM-1, MCP-1, suPAR, TNFR1, TNFR2 and YKL-40) and five urinary tubule biomarkers (EGF, KIM-1, MCP-1, YKL-40 and urine albumin) at baseline. The primary outcome was the development of incident HTN, defined as either a systolic BP $\geq$  140 mmHg, a diastolic BP  $\geq$  90 mmHg, or the use of any antihypertensive medication during a follow-up period. Multivariable Poisson regression was used to examine associations between baseline kidney tubule markers and urine albumin with incident HTN.

**Results:** Among the 297 participants, the mean age was 58 $\pm$ 10 years, 53% were women, 47% were White, and 20% were Black. The median number of BP measurements per participant was 6 (IQR 2 to 10). Nearly half (N=142) developed incident HTN event over 15 years of follow-up. In unadjusted models, higher urinary KIM-1, MCP-1 and urine albumin, as well as higher plasma MCP-1 and YKL-40 were individually associated with risk of incident HTN (**Figure 1**). However, in the fully adjusted model, only urine albumin remained associated with incident HTN (IRR 1.25 (1.1 to 1.5); P < .005).

**Conclusions:** In this study of community-living individuals without CKD, diabetes, or CVD, in an adjusted model there was no association of selected kidney tubule injury or dysfunction biomarkers with incident HTN. In comparison, urine albumin was independently associated with incident HTN.

**Funding:** NIDDK Support

**In SPRINT Participants With Creatinine Elevations During Follow-Up, Trajectories of Tubule Injury Markers Associate With eGFR Decline**  
Joachim H. Ix,<sup>1,2</sup> Ronit Katz,<sup>3</sup> Judy Shigenaga,<sup>4,5</sup> Alfred K. Cheung,<sup>6</sup> Kalani L. Raphael,<sup>7,8</sup> Stein I. Hallan,<sup>9</sup> Jesse C. Seegmiller,<sup>10</sup> Rakesh Malhotra,<sup>1</sup> Vasantha Jotwani,<sup>4,5</sup> Pranav S. Garimella,<sup>1</sup> Michael Shlipak.<sup>4,5</sup> <sup>1</sup>University of California San Diego, La Jolla, CA; <sup>2</sup>Veterans Medical Research Foundation, San Diego, CA; <sup>3</sup>University of Washington, Seattle, WA; <sup>4</sup>University of California San Francisco, San Francisco, CA; <sup>5</sup>San Francisco VA Health Care System, San Francisco, CA; <sup>6</sup>University of Utah Health, Salt Lake City, UT; <sup>7</sup>Oregon Health & Science University, Portland, OR; <sup>8</sup>Portland VA Medical Center, Portland, OR; <sup>9</sup>St. Olav University Medical Center, Trondheim, Norway; <sup>10</sup>University of Minnesota Twin Cities, Minneapolis, MN.

**Background:** Elevations in serum creatinine (SCr) often prompt clinicians to halt therapies. We hypothesized that biomarkers of tubule cell damage could prognosticate eGFR trajectories in this setting.

**Methods:** The SPRINT trial randomized 9361 hypertensive patients to an intensive (<120mmHg) vs. standard (<140mmHg) systolic blood pressure target. Of these, 652 (7.0%) had SCr elevations ( $\Delta$ SCr  $\geq$  0.3 mg/dL from baseline) during follow-up. We measured four urine biomarkers indexed to urine Cr (IL-18, KIM-1, MCP-1 & YKL-40) & 1 plasma (UMOD) biomarker at baseline and annual visits concurrent with SCr elevations. Intra-individual changes were calculated; those in the highest quartile were considered “abnormal”. The outcome was  $\Delta$ eGFR from SCr elevation through the end of follow-up. Models adjusted for clinical risk factors and stratified by randomization.

**Results:** The median  $\Delta$ SCr was 0.42 (IQR 0.34, 0.56) mg/dL. At baseline, mean age was 70 years, 33% were female, mean eGFR was 62 $\pm$ 25 ml/min/1.73m<sup>2</sup>, & 72% were randomized to the intensive arm. Over 23.5 months mean follow-up after SCr elevation, mean (SD)  $\Delta$ eGFR was 1.46  $\pm$  2.60% annually. In the standard arm, longitudinal increases of urine IL-18 and KIM-1 or decreases in plasma UMOD associated with faster declines in eGFR, independent of clinical risk factors and albuminuria. In the intensive arm, only increasing uMCP-1 associated with subsequent eGFR trajectory, and the direction was toward eGFR improvement.

**Conclusions:** Among hypertensive patients with SCr elevations, worsening kidney tubule damage associates with faster subsequent eGFR decline. These relationships were not observed in the intensive arm, where SCr elevations more likely result from hemodynamic causes.

**Funding:** NIDDK Support

Associations of Worsening Kidney Tubule Damage with Subsequent Annualized % Change in eGFR among SPRINT Participants whose SCr Increased $\geq$ 0.3 mg/dL During Follow-up in the SPRINT Trial*		
Biomarker	% Annual Change in eGFR (95% CI)	
	Standard Arm (N=180)	Intensive Arm (N=472)
u-IL-18/Cr	-3.55 (-6.74, -0.35)	-1.65 (-3.58, 0.28)
u-KIM-1/Cr	-3.95 (-7.06, -0.85)	0.24 (-1.68, 2.16)
u-MCP-1/Cr	1.13 (-1.84, 4.11)	2.60 (0.58, 4.62)
u-YKL-40/Cr	-2.09 (-5.24, 1.05)	-0.13 (-2.17, 1.90)
p-UMOD*	-3.58 (-6.71, -0.44)	-0.43 (-2.22, 1.37)
u-ACR	0.40 (-2.25, 3.05)	2.39 (0.10, 4.68)

Adjusted for baseline age, sex, race, CVD, smoking, BMI, SBP, BP meds, ACE/ARB use, uACR, and eGFR.  
\* pUMOD compares Q1 vs. Q2-4, whereas all others are Q4 vs. Q1-3.

**Protective Effect of AT1R Antibodies in Patients With ESKD on Hemodialysis**  
Maria Lourdes Gonzalez Suarez,<sup>1,2</sup> Neal S. Fedarko,<sup>3</sup> Seungyoung Hwang,<sup>4</sup> Adrienne Tin,<sup>2</sup> Tariq Shafi.<sup>2,3</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>The University of Mississippi Medical Center, Jackson, MS; <sup>3</sup>Johns Hopkins University, Baltimore, MD; <sup>4</sup>Boston Strategic Partners Inc, Boston, MA.

**Background:** The renin-angiotensin system (RAS) is one of the major contributors to accelerated CVD. Angiotensin II binds to its type 1 receptor (AT1R) contributing to the clinical phenotype characterized by hypertension, and CVD outcomes. Autoantibodies to AT1R (ATIRAb) mimic angiotensin II effects by binding to its receptor active site. ATIRAb have been described in severe preeclampsia, malignant hypertension, and kidney allograft failure. We assessed the association of ATIRAb with mortality in patients with ESKD on hemodialysis (HD).

**Methods:** Using serum samples from a national prospective cohort study of ESKD patients on HD, we measured ATIRAb by quantitative ELISA using two methods: a) a novel purified antigen sequence AFHYESQ (active site) assay; b) a commercial full length ATIR assay. We assessed the association of ATIRAb with mortality using Cox models adjusting for demographic and clinical factors.

**Results:** A total of 443 samples were measured by both ELISAs. Mean age was 61 (SD $\pm$ 13.9), 45% were women and 39% were Black. Charlson score was 5.7 $\pm$ 1.9. Mean number of years on dialysis was 6 (SD $\pm$ 4.3). 211 patients died during follow-up. Compared to the lowest tertile of ATIRAb, the highest tertile was associated with a 42% lower risk of death using the novel assay (HR 0.58; 95% CI, 0.41-0.82; p=0.002). Comparison of both assays is presented in the Table 1.

**Conclusions:** Our findings of a protective effect by ATIRAb that activate AT1 receptor are intriguing. The use of angiotensin receptor blockers, which can elevate circulating levels of ATIRAb may be a possible explanation. Larger population studies are needed to determine ARBs association with ATIRAb.

## Fasting Plasma Glucose and Glycated Hemoglobin Are Associated With Posterior Wall Thickness and Left Atrial Diameter in Patients With CKD

Marta Borges Canha,<sup>1</sup> Mariana F. Marques,<sup>1</sup> João Sérgio Neves,<sup>1</sup> Katherine S. Ravi,<sup>2</sup> Finnian R. McCausland,<sup>2</sup> <sup>1</sup>Centro Hospitalar Universitario de Sao Joao, Porto, Portugal; <sup>2</sup>Brigham and Women's Hospital, Boston, MA.

**Background:** Cardiovascular (CV) disease is the major cause of death in patients with chronic kidney disease (CKD), particularly among patients with diabetes. Several echocardiographic parameters are known to predict CV events and death in patients with CKD, but data on the association of glycemic metabolism with echocardiographic parameters in CKD is scarce.

**Methods:** Using the Chronic Renal Insufficiency Cohort (CRIC) Study, we excluded patients with baseline heart failure, missing fasting plasma glucose (FPG) or glycated hemoglobin (A1c) measurements, or echocardiography data at year 1 (2557 included patients). We used restricted cubic splines to assess the association of FPG and A1c with: left ventricular mass (LVM); posterior wall thickness (PWT); interventricular septal thickness in diastole (IVSTD); LV internal diameter in diastole and systole (LVIDD and LVIDS); left atrial diameter (LAD); LV ejection fraction (LVEF); A wave duration; E wave velocity and E/A wave ratio. Models were adjusted for age, sex, race, body mass index, systolic blood pressure, heart rate, history of peripheral vascular disease, stroke, myocardial infarction or prior revascularization, antiplatelet, lipid lowering or inhibition of renin-angiotensin-aldosterone axis therapy, hematocrit, serum albumin, baseline estimated glomerular filtration rate (CKD-EPI formula) and 24-hour urine protein excretion (log-transformed).

**Results:** Patients within higher FPG or A1c quartiles are more likely to be males, older, black, and to have medical history of coronary artery disease, stroke, and peripheral vascular disease. These patients have higher PWT, IVSTD, LV mass and LAD, and lower E/A ratio. The spline analyses show that higher FPG and A1c are associated with higher PWT, and that higher FPG is associated to higher LAD (Figure 1).

**Conclusions:** Among patients with CKD, higher FPG and A1c are independently associated with higher PWT, and higher FPG is positively associated to LAD. Whether interventions that improve glycaemic control can result in regression of these parameters is not clear.

## FR-PO759

## Exercise Induced Hypertension (EIH) in Healthy Young Individual

Parker Lehmann,<sup>1</sup> Ernest L. Mazzaferri,<sup>2</sup> Salem Almaani,<sup>2</sup> Udayan Y. Bhatt,<sup>2</sup> Asish Thakkar,<sup>3</sup> <sup>1</sup>Idaho College of Osteopathic Medicine, Meridian, ID; <sup>2</sup>The Ohio State University Wexner Medical Center, Columbus, OH; <sup>3</sup>VA Central Ohio Healthcare System, Columbus, OH.

**Introduction:** Exercise induced hypertension (EIH) is a phenomenon that is diagnosed with SBPs of >210mmHg in males and 190mmHg in females while exercising. Untreated, it can lead to increased risk of developing hypertension (HTN) along with an increase in cardiovascular morbidity and mortality. The proposed mechanisms associated with EIH include RAAS changes, arterial stiffness, and endothelial dysfunction. Generally, individuals with pre-exercise stage 1 HTN (SBP 130-139; DBP 80-89) or stage 2 HTN (SBP at least 140 or DBP 90) are evaluated for this condition.

**Case Description:** A 19yo male college lacrosse player was noted to have a pre-participation blood pressure of 125/79 and mild chest discomfort with training. He has no past medical history and denies any medications or drugs. A cardiology consult was obtained. Baseline EKG, echocardiogram and metabolic panel all were unremarkable. He was found to have a BP of 230/110 at stage IV of the Bruce Protocol during stress testing but EKG was negative for ischemia. He was referred to Nephrology for further evaluation. He had relatively normal ambulatory BPs while not exercising and hormonal evaluation unremarkable. The patient was felt to have EIH and was started on an ACE with improvement in his BP with exercise.

**Discussion:** Demographically, EIH is more often reported in middle-age, distance runners than in young healthy athletes with a normal pre-participation exam. This patient is a healthy young individual who had accelerated HTN during exercise. In addition, given his pre-participation exam, he did not meet criteria for any further testing based on current recommendations. Also, his level of general fitness may not have prompted an evaluation of blood pressure during exercise. This case does support the contention that screening for EIH could be expanded to encompass those individuals with elevated blood pressure but not meeting the criteria for Stage 1 HTN or beyond.

## FR-PO760

## Impact of Kidney Function on the Association Between Selected Proteomic Biomarkers and Cardiovascular Events and Mortality

Barbara Salzinger,<sup>1</sup> Kristina Lundwall,<sup>1</sup> Marie Evans,<sup>1</sup> Josefin L. Mortberg,<sup>2</sup> Hakan Wallen,<sup>1</sup> Tomas Jernberg,<sup>1</sup> Thomas Kahan,<sup>1</sup> Pia Lundman,<sup>1</sup> Bertil Lindahl,<sup>2</sup> Jonas Spaak,<sup>1</sup> Stefan H. Jacobson.<sup>1</sup> <sup>1</sup>Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Uppsala Universitet, Uppsala, Sweden.

**Background:** The link between chronic kidney disease (CKD) and the high burden of cardiovascular disease remains unclear. We aimed to explore whether CKD G3+ (eGFR<60 ml/min/1.73m<sup>2</sup>) modified the association between selected biomarkers reflecting systemic inflammation, endothelial activation, angiogenesis, and vascular calcification, and major adverse cardiovascular events (MACE) and mortality in patients admitted to hospital with an acute coronary syndrome.

**Methods:** In all, 1293 patients 2008-2015 hospitalized with an acute coronary syndrome registered in the SWEDEHEART registry were followed until Dec 31, 2017. Thirteen biomarkers were *a priori* identified and analyzed with two proteomic methods, the proximity extension assay technology and multiple reaction monitoring mass spectrometry. The primary outcome (MACE+) was a composite of the first event of readmission for myocardial infarction, heart failure, ischemic stroke or death from any cause. Adjusted Cox proportional hazard models with an interaction term for CKD G3+ was used.

**Results:** Six of the biomarkers (ESM-1 (endocan), IL-1Ra, FGF-23, PIGF, TIM1 and VEGF-A) showed a significant association with MACE+ in the Cox regression models adjusted for age, gender, diabetes, smoking and CKD. Of these biomarkers, only FGF-23 remained independently associated after additional adjustment for the other biomarkers (Figure). None of the 13 selected biomarkers showed significant interaction with CKD G3+.

**Conclusions:** In patients with acute coronary syndrome, FGF-23, ESM-1, IL-1ra, PIGF, TIM1 and VEGF-A were associated with cardiovascular events and mortality. FGF-23 was independently associated with MACE and death regardless of presence of CKD or not.

**Funding:** Commercial Support - fund from astra zeneca, Clinical Revenue Support, Government Support - Non-U.S.

## Genome-Wide Association Study of Apparent Treatment Resistant Hypertension in the Million Veteran Program

Adriana Hung,<sup>1,2</sup> Jacklyn N. Hellwege,<sup>2,1</sup> Hua-Chang Chen,<sup>2,1</sup> Peter W. Wilson,<sup>8,7</sup> Yan Sun,<sup>7,8</sup> Elvis A. Akwo,<sup>2</sup> Philip S. Tsao,<sup>5,6</sup> Ran Tao,<sup>2,1</sup> Csaba P. Kovacs,<sup>3,4</sup> Todd L. Edwards,<sup>2,1</sup> Million Veteran Program <sup>1</sup>VA Tennessee Valley Healthcare System, Nashville, TN; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>3</sup>Memphis VA Medical Center, Memphis, TN; <sup>4</sup>The University of Tennessee Health Science Center College of Medicine, Memphis, TN; <sup>5</sup>VA Palo Alto Health Care System, Palo Alto, CA; <sup>6</sup>Stanford University, Stanford, CA; <sup>7</sup>Emory University, Atlanta, GA; <sup>8</sup>Atlanta VA Medical Center, Atlanta, GA.

**Background:** Apparent treatment resistant hypertension (ATRH) is common. 9-16% of individuals in different populations are affected, and it is associated with poor outcomes compared with controlled hypertension, including increased risk of ESRD, cardiovascular morbidity and mortality.

**Methods:** We performed a large GWAS of ATRH in US veterans enrolled in the Million Veteran Program. ATRH was defined as treated with 3 different antihypertensive drugs including a thiazide with BP above goal (SBP  $\geq$  140 mm Hg and/or diastolic BP  $\geq$  90 mm Hg) or the use of 4 or more antihypertensive drugs regardless of BP control. Controls were patients with controlled hypertension. All participants had eGFR  $\geq$  60 ml/min/1.73m<sup>2</sup>. The analysis included 26,902 cases (27% AA, 73% EA) and 81,187 controls (18% AA, 82% EA). Association analyses were performed with logistic regression with an additive model adjusting for age, sex, body mass index, and 10 principal components of ancestry in GWAS data imputed using 1000 genomes project haplotypes. Analyses were stratified by ancestry (EA and AA) and inverse variance-weighted fixed-effects meta-analyses were carried out using METAL.

**Results:** Twenty-one loci reached genome wide significance in the transethnic meta-analysis: CASZ1 (2.46E-11), WNT2B(2.84E-09), KCNK3 (2.78E-15) CACNA1D (2.14E-11), ENPEP (6.38E-10), FBN2(1.05E-11), HTR4(3.88E-09), TRIM36 (1.89E-09), RSP03(3.17E-10), SLC22A7 (1.25E-09), HOTTIP (8.50E-17), HOXA10-HOXA9 (8.40E-11), CYP11B2-GML (4.84E-09), GATA4 (1.03E-11), MAPKAP1(2.10E-08) LSP1 (3.09E-10), TBX3(1.39E-09), RXFP2 (4.27E-24) and KLF5 (1.33E-11). CASZ1 was previously reported associated with ATRH in REGARDS and CACNA1D has also been reported in candidate gene studies. The remaining associated loci are novel for ATRH. All these loci have been previously associated with BP or hypertension. We also performed a phenome-wide association analysis for each sentinel variant and three loci were associated with hyperaldosteronism and hypopotassemia.

**Conclusions:** These results indicate that RH genetic susceptibility likely arises at known BP loci. Also our study results suggests an underlying physiology related to mineralocorticoid physiology.

**Funding:** Veterans Affairs Support

## FR-PO763

## Impact of ABO-Incompatibility and Early Antibody-Mediated Rejection on Kidney Allograft Outcomes

Ga Young Heo, Hyo Jeong Kim, Kyung Won Kim, Hee Byung Koh, Jaeseok Yang. Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.

**Background:** Early active antibody-mediated rejection (ABMR) has been reported to increase the risk of chronic ABMR and decrease long-term graft survival. Although desensitization has improved the long-term outcome of ABO blood type-incompatible (ABOi) kidney transplantation (KT), ABMR is still an important problem after ABOi KT. However, the impact of early ABMR on long-term outcomes in ABOi KT is not well-known.

**Methods:** We analyzed patients undergoing living-donor KT from Severance Hospital and Seoul National University Hospital between 2010 and 2019. Patients were categorized into 4 groups based on ABO incompatibility and early ABMR during the first year post-transplant. The primary outcome was a composite kidney outcome, defined as a  $\geq$ 30% decline in the eGFR from baseline or graft loss. Secondary outcomes were the diagnosis of chronic ABMR and *de novo* donor specific antigen (DSA) production after 1 year.

**Results:** There were 1,335 ABOc and 367 ABOi KT patients, with a median follow-up of 6.37 years. In multivariate Cox model, both ABOc with ABMR (HR 1.71, 95% CI 1.14-2.56) and ABOi with ABMR (HR 1.61, 95% CI 1.01-2.55) showed increased risk of composite kidney outcome compared to ABOc without ABMR group. However, ABOi without ABMR group did not show significant difference on risk of composite kidney outcome. In parallel, ABOi without ABMR group had a lower risk for the *de novo* DSA (HR 0.52, 95% CI 0.34-0.79) and chronic ABMR (HR 0.35, 95% CI 0.12-0.98) than ABOc without ABMR.

**Conclusions:** Our findings suggest that desensitization in ABOi KT might reduce *de novo* DSA production and chronic ABMR, as well as mitigate the adverse impact of anti-ABO antibody on long-term graft outcome. However, early ABMR in ABOi abrogates these beneficial effects and contributes to poor graft outcome.

Multivariate analyses for composite kidney outcome, *de novo* DSA, and late chronic ABMR according to categories based on ABO incompatibility and the early ABMR.

	Composite kidney outcome		<i>de novo</i> DSA		Late chronic ABMR	
	HRs (95% CI)	P	HRs (95% CI)	P	HRs (95% CI)	P
ABOc without ABMR	Ref		Ref		Ref	
ABOc with ABMR	1.71 (1.14-2.56)	<0.001	2.66 (1.74-4.07)	<0.001	6.70 (3.71-12.0)	<0.001
ABOi without ABMR	1.12 (0.89-1.41)	0.30	0.52 (0.34-0.79)	0.002	0.35 (0.12-0.98)	0.04
ABOi with ABMR	1.61 (1.01-2.55)	0.04	1.38 (0.68-2.82)	0.36	2.58 (0.92-7.20)	0.07

Adjusted for age, sex, donor age, HLA mismatches, induction drugs, calcineurin inhibitors and hospital.

## FR-PO765

## Donor-Derived Cell-Free DNA (dd-cfDNA) for Assessment of Response After Treatment of Allograft Rejection

Reginald Y. Gohh,<sup>1</sup> Enver Akalin,<sup>3</sup> Jeffrey A. Klein,<sup>2</sup> Nikhil Agrawal,<sup>4</sup> Grigoriy Shekhtman,<sup>4</sup> Yi Fu,<sup>4</sup> Matthew R. Weir,<sup>5</sup> <sup>1</sup>Rhode Island Hospital, Providence, RI; <sup>2</sup>University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS; <sup>3</sup>Montefiore Medical Center, Bronx, NY; <sup>4</sup>CareDx Inc, Brisbane, CA; <sup>5</sup>University of Maryland Baltimore, Baltimore, MD.

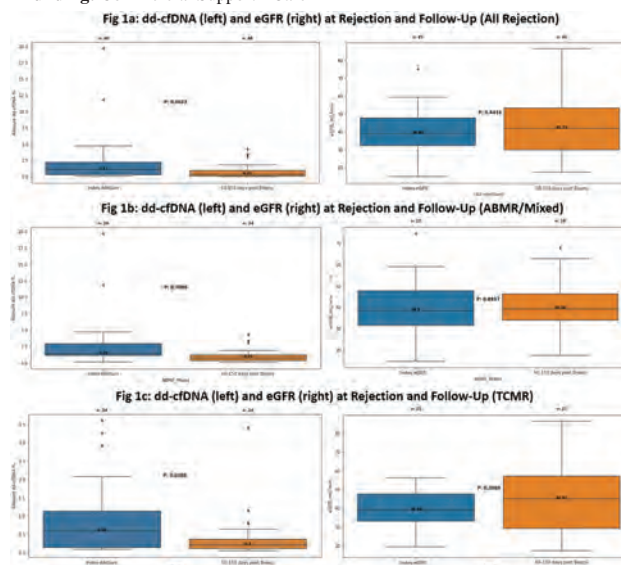

**Background:** Surveillance of dd-cfDNA after therapy for rejection represents a promising strategy for monitoring post-treatment response. We assessed post-rejection kinetics of dd-cfDNA among kidney transplant recipients in the Kidney allograft Outcomes AlloSure Registry (KOAR, NCT03326076).

**Methods:** We identified patients with biopsy-proven allograft rejection (BPAR), defined as ABMR, TCMR, or Mixed (Banff 2019), biopsy-paired dd-cfDNA measurements (within  $\leq$ 30d of biopsy), and follow-up results 60-150 days after BPAR. When available, treatment and follow-up histology data was also analyzed.

**Results:** 48 episodes of BPAR (24 TCMR, 19 ABMR, 5 Mixed) and paired dd-cfDNA results were identified in 42 patients. Overall, a significant reduction was seen between the median index (1.36%, IQR: 0.29-2.25) and follow-up dd-cfDNA results (0.35%, IQR: 0.13-0.95; p < 0.01) [Figure 1a]. For patients with concurrent eGFR measurements, no statistically significant improvement was seen. These patterns held when analysis was limited to TCMR and ABMR/Mixed rejections [Figure 1b, 1c]. 7 patients (2 ABMR, 4 TCMR, and 1 Mixed; median index dd-cfDNA 1.15%, IQR: 0.31-2.46) had repeat biopsies within 30days of their follow-up testing; 1 patient with acute ABMR had chronic active ABMR on repeat biopsy, with a dd-cfDNA of 1.86%, while the remainder had either no rejection or borderline findings (median dd-cfDNA 0.74%, IQR: 0.30-2.59).

**Conclusions:** Our findings highlight that reduction in dd-cfDNA is commonly seen following BPAR, suggesting that most patients experience a "molecular response" to therapy. Studies are needed to better understand the prognostic significance of a molecular response and how persistent elevations in dd-cfDNA after treatment should guide subsequent management.

**Funding:** Commercial Support - CareDx

## FR-PO766

# Kidney Endothelial Injury and Mononuclear Interstitial Inflammation in Hematopoietic Cell Transplant (HCT) Recipients: An Analysis of 81 Consecutive Kidney Biopsies

Shab E Gul Rahim,<sup>1</sup> Supriya Gerardine,<sup>2</sup> Steven Salvatore,<sup>1</sup> Victoria Gutgarts,<sup>2</sup> Sangeeta R. Hingorani,<sup>3</sup> Edgar A. Jaimes,<sup>2</sup> Surya V. Seshan,<sup>1</sup> Thangamani Muthukumar.<sup>1</sup> <sup>1</sup>Weill Cornell Medicine, New York, NY; <sup>2</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>3</sup>University of Washington, Seattle, WA.

**Background:** Graft versus host disease (GvHD) of the kidney in HCT recipients has not been well described. Kidney endothelial injury and interstitial inflammation frequently observed in kidney biopsies could be a manifestation of GvHD. We sought to characterize the spectrum of kidney endothelial injury and interstitial inflammation in HCT recipients.

**Methods:** We reviewed 81 consecutive kidney biopsies done between July 2009 and February 2022 at our institution. Biopsies were evaluated by light, immunofluorescence, and electron microscopy.

**Results:** The 81 biopsies were obtained from 76 HCT recipients (age 58 years, median); 67 (88%) were allogeneic transplants; 28 (37%) were women; 48% received total body irradiation (TBI) as part of conditioning regimen. Time from transplant to biopsy was 18.8 (9.8-40.9) months. Thrombotic microangiopathy (19 [23%] biopsies, 15 chronic and 4 acute) was the most common primary diagnosis (Fig. 1 left). Membranous nephropathy was present in only 7 (9%) biopsies. Endothelial injury was found in 70% of biopsies; 35 (43%) had glomerular endothelial basement double contouring. By logistic regression, TBI was not associated with biopsy findings of endothelial injury (P=0.18). Moderate to severe mononuclear interstitial inflammation (inflammation in >25% of unscarred cortical parenchyma) was observed in 57% of biopsies (Fig. 1 right). Moderate to severe interstitial fibrosis and tubular atrophy (involving >25% of the cortical area) was present in 70% of the biopsies.

**Conclusions:** In this large kidney biopsy study of HCT recipients, thrombotic microangiopathy was the most common primary diagnosis and the majority of biopsies had an endothelial injury and mononuclear cell interstitial inflammation, raising the possibility of GVHD involving the kidneys. Further studies are ongoing in our laboratory to characterize kidney injury at a molecular level and to develop noninvasive biomarkers.

## FR-PO767

# Natural Killer Cell Activity Is Increased in Chronic Active Antibody-Mediated Rejection (caABMR) of Human Kidney Allografts

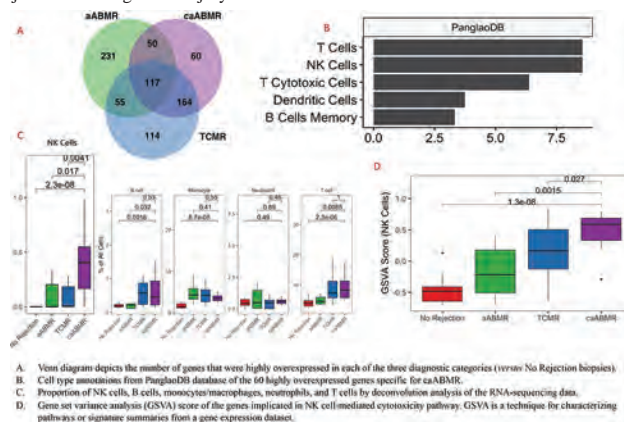

Shab E Gul Rahim, Elly Varma, Thalia Salinas, Carol Y. Li, Catherine Snopkowski, Steven Salvatore, Surya V. Seshan, Darshana M. Dadhania, Manikkam Suthanthiran, Thangamani Muthukumar. Weill Cornell Medicine, New York, NY.

**Background:** caABMR of the kidney allograft has several unique clinicopathological features that are distinct from acute ABMR. Using RNA sequencing of kidney allograft biopsies, we tested the hypothesis that caABMR is characterized by heightened natural killer (NK) cell activity.

**Methods:** We studied 57 biopsies from 57 adult kidney transplant recipients; 18 surveillance biopsies reported as No Rejection (normal) and 39 for-cause biopsies reported as caABMR (N=15), acute ABMR (N=7), and TCMR (N=17). Biopsies were independently assessed by two transplant pathologists using immunofluorescence, light, and electron microscopy. Individual cDNA libraries were prepared from each RNA sample, pooled, and sequenced on an Illumina sequencer. All quality measures were met. Standard tools were used for bioinformatic analysis.

**Results:** There were 1425 upregulated and 29 downregulated genes that were different (two-fold difference and P-FDR<0.05) between caABMR and No Rejection biopsies. Among the 391 highly overexpressed genes (four-fold difference and P-FDR<0.05) between caABMR and No rejection, 60 were specific for caABMR (Fig 1A). Cell-type annotation of these 60 genes revealed an increase in NK cells (Fig 1B). Several genes involved in the NK cell-mediated cytotoxicity pathway were upregulated in caABMR. Deconvolution analysis revealed an increased proportion of NK cells in caABMR (Fig 1C). Gene set variation analysis score for the NK cell cytotoxicity pathway set of 133 genes was highest for caABMR (Figure 1D). In addition, tissue expression of the terminal complement protein C9 was increased in acute ABMR but not in caABMR compared to No Rejection.

**Conclusions:** Our findings of heightened NK cell activity in caABMR suggest that the antibody-dependent cellular cytotoxicity pathway mediated by NK cells likely plays a major in mediating tissue injury in caABMR.

## FR-PO768

# Genetic Polymorphism and Serum Levels of Toll-Like Receptors (TLR-2 and TLR-4) in Renal Transplant Recipients With and Without Cytomegalovirus (CMV) Infection

Sandeep Mahajan, Arshi Rizwan. All India Institute of Medical Sciences, New Delhi, India.

**Background:** Viral infections like CMV are important cause of morbidity, mortality & limited graft survival in RTRs. TLR-2 & TLR-4 play important role in innate immune response & regulating production of antiviral peptides & inflammatory cytokines. Reduced TLR expression & polymorphisms (TLR2: Arg677Trp & Arg753Gln, TLR4: Asp299Gly & Thr399Ile) are associated with blunted immunological response & higher infectious complications. No study has looked at TLR expression & polymorphisms in RTRs & their association with infectious complications like CMV. Identifying this population at higher risk of infections can help in individualizing immunosuppressive therapy

**Methods:** 85 consenting RTRs (35 with CMV & 50 without CMV infection) & 50 healthy controls were studied. All RTRs were on standard triple drug immunosuppression of Tacrolimus, MMF & steroids. Patients given ganciclovir prophylaxis, rATG induction and with recent infection & anti-rejection therapy were excluded. Diagnosis of CMV infection was based on blood quantitative CMV DNA PCR testing (>500 copies/ml), done as per protocol at 45 days, 3, 6, 9 & 12 months post-RT and/or as per clinical need. Allele-specific polymorphisms were studied on extracted DNA samples by using PCR-based genotyping assay and serum levels of TLR-2 & TLR-4 were determined by using commercially available ELISA kits

**Results:** Mean age and gender distribution were similar in three groups. CMV infection was symptomatic in 23 (60 %) patients & all presented with history of fever & diarrhea. As shown in table: RTRs having CMV infection had lower serum TLR2 and TLR4 values as compared to other groups. While, RTRs without CMV infection only had lower TLR4 levels as compared to controls. None of studied subject showed polymorphism in either TLR-2 or TLR-4 genes

**Conclusions:** We found that RTRs with CMV disease had lower serum TLR-2 & TLR-4 levels as compared to RTRs without CMV infection & healthy controls. However, we did not document any polymorphism in studied genes. These results require further validation in larger studies

**Funding:** Government Support - Non-U.S.

Serum Concentration (pg/ml.) (mean ± SD)	RTRs with CMV infection	RTRs without CMV infection	Healthy Control	P-Value Group 1 vs Group 2	P-value Group 1 vs Group 3	P-value Group 2 vs Group 3
TLR-2	11.5±3.1	22.7±8.1	28.1±9.6	<0.001	<0.001	>.05
TLR-4	6.1±1.3	8.2±2.2	12.4±4.1	<0.001	<0.001	<0.02

## FR-PO769

# Clinical and Native Histological Predictors of Recurrent IgA Nephropathy After Kidney Transplantation

Chukwuma A. Chukwu,<sup>1,2</sup> Christopher Holmberg,<sup>3</sup> Rachel Middleton,<sup>1</sup> Philip A. Kalra,<sup>1,2</sup> Howida Shawki,<sup>3</sup> Anirudh Rao.<sup>3</sup> <sup>1</sup>Salford Royal Hospital, Salford, United Kingdom; <sup>2</sup>The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; <sup>3</sup>Royal Liverpool University Hospital, Liverpool, United Kingdom.

**Background:** Although recurrent IgA Nephropathy (rIgAN) in kidney transplant recipients (KTR) has been regarded as benign, there is increasing evidence that rIgAN may lead to late allograft loss in a significant proportion of KTR. Data on the risk predictors and outcomes of rIgAN is limited. We investigated the incidence, clinical and histologic predictors, and outcomes of rIgAN in KTR.

**Methods:** KTR with biopsy-proven IgA nephropathy between 2005 and 2020 at 2 tertiary nephrology centers in North-west England were evaluated. Demographic,

clinical, and native kidney histological data were analysed. Risk factors and allograft outcomes were assessed using Cox proportional hazard method.

**Results:** rIgAN was diagnosed in 35 of 203KTR (17%). mean age was 45±13yr, and median follow-up was 7yr. Time to recurrence and from recurrence to graft loss was 4.8yr(IQR 2.7-6.7) and 2.9yr(IQR 1.3-4.3) respectively. Factors associated with rIgAN include younger age(Hazard ratio[HR] 0.68, 95%CI 0.51-0.9; p=0.009); higher pre-transplant proteinuria(HR 1.21, 95% CI 1.09-1.35; p<0.001); living donor graft(HR 2.32, 95%CI 1.1 - 4.6;p=0.016), Cyclosporin use(HR 2.82, 95%CI 1.07-7.41;p=0.035); history of acute rejection(HR 2.33, 95%CI 1.14-4.77;p=0.020); higher proportion of native glomeruli with segmental sclerosis (HR 1.05, 95%CI 1.01-1.09; p=0.014). Death censored graft loss was 11 times higher in recipients with rIgAN (HR 11.0, 95%CI 4.35-27.7; p<0.001).

**Conclusions:** KTR with rIgAN were 11 times more likely to lose their graft than those without recurrence. Younger age, higher pre-transplant proteinuria, living donor allograft, history of acute rejection, cyclosporin use and a higher degree of segmental sclerosis in the original disease are associated with rIgAN.

**Table 1: Factors associated with recurrent IgA Nephropathy**

Variables	Hazard ratio	95% CI	P-value

### Clinical and Histologic Predictors of Recurrent Focal Segmental Glomerulosclerosis After Kidney Transplantation

Chukwuma A. Chukwu,<sup>1,2</sup> Christopher Holmberg,<sup>3</sup> Rachel Middleton,<sup>1</sup> Philip A. Kalra,<sup>1,2</sup> Anirudh Rao,<sup>3</sup> Howida Shawki,<sup>3</sup> <sup>1</sup>Salford Royal Hospital, Salford, United Kingdom; <sup>2</sup>The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; <sup>3</sup>Royal Liverpool University Hospital, Liverpool, United Kingdom.

**Background:** Recurrent FSGS (rFSGS) after transplantation is a major cause of allograft loss. Data on the clinical and native kidney histological predictors of rFSGS is limited. We investigated the clinical and histological predictors of rFSGS and its impact on allograft outcome

**Methods:** 71 KTR with biopsy-proven FSGS transplanted between 2005 and 2020 at two tertiary nephrology centres in North-west England were evaluated. Demographic, clinical, and native kidney histological data were analysed. Risk factors of rFSGS and their impact on allograft outcomes were evaluated using Cox proportional hazard methods

**Results:** FSGS recurrence was diagnosed in 14 of 71 KTR (20%). Mean age at transplantation was 43.8±17yr, and median follow-up was 7yr. The median duration to rFSGS was 0.6yr(IQR 0.2-2.9) and the time from rFSGS to graft loss was 4.9yr(IQR

3-10). rFSGS was associated with higher pre-transplant proteinuria (HR 1.115, p=0.002); alemtuzumab induction(HR 3.38, p=0.035); younger donor age(HR 0.95, p=0.020); proteinuria at 12months post-transplant(HR 1.16, p<0.001); history of acute rejection(HR 3.17, p<0.039), lower baseline eGFR(HR 0.30, p<0.037), mesangial proliferation(HR 5.38, p=0.043); glomerular IgG(HR 20.5, p<0.033) and IgA(HR 12.1, p<0.001) deposits in the native disease. Death-censored graft loss adjusted for donor type, history of acute rejection and baseline eGFR was 6 times higher in KTR with rFSGS(HR 6.1, 95% CI 1.5-24.7;p=0.012)

**Conclusions:** rFSGS occurred early post-transplantation and was associated with a 6 fold increase in graft loss. Higher pre-and post-transplant proteinuria, alemtuzumab induction, acute rejection, low baseline eGFR, as well as mesangial proliferation, IgG and IgA deposits in native disease are factors associated with rFSGS

Factors associated with rFSGS

### The Role of Gut Microbiome in Dose Selection of Envarsus Among High Tacrolimus Metabolizers

Joseph K. Melancon,<sup>1</sup> Mehdi Nayeypour,<sup>2</sup> Obi D. Ekwenna,<sup>3</sup> Hanaa Ibrahim,<sup>1</sup> Naoru Koizumi,<sup>1</sup> <sup>1</sup>The George Washington University, Washington, DC; <sup>2</sup>Virginia BioAnalytics, Washington, DC; <sup>3</sup>The University of Toledo, Toledo, OH.

**Background:** The role of gut microbiome in kidney transplant outcomes has been of great interest among researchers and physicians. Yet the number of studies to investigate the effect of microbiome on kidney transplant has been limited, particularly in regard to personalized medicine. Preliminary studies show significant associations between the relative abundance of certain bacterial species such as *Faecalibacterium prausnitzii* and tacrolimus (Tac) dosing. No study has translated the findings into application. This study develops a dose selection algorithm based on gut microbiome and gene marker profile of kidney transplant patients.

**Methods:** 30 kidney transplant patients from the George Washington University Hospital and the University of Toledo Medical Center were recruited. From each subject 3 ml of blood was collected for gene marker sequencing of CYP3A5. 2 stool samples were collected per subject for gut microbiome sequencing using shotgun metagenomics. The first stool sample was collected 1 week pre-transplant and the second sample was collected 1-2 months post-transplant. Administered dose of Envarsus and Tac trough concentrations were recorded from day of transplant till 90 days post-surgery. Relative abundance of all bacterial genera was analyzed for detection of association with Envarsus dosage and potential inclusion in a dose selection model.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Results:** All patients were high metabolizers of Tac by expressing either the homozygote or heterozygote CYP3A5\*1 allele. Building upon the gene-guided dose selection model of Jacobson et al., we added the relative abundance of two bacterial genera as predictors of optimum Envarsus dose. Using a linear OLS regression model, the pre-transplant relative abundance of *Phocaeicola* in days<10 and the change in relative abundance of *Bacteroides* in 10<days<90 were predictors of optimum Envarsus dose with  $p<0.01$ . Our gene/microbiome-guided dose selection model is a better predictor for optimum dose of Envarsus compared to the gene-only dose selection model.

**Conclusions:** Personalized dose selection for high Tac metabolizers has been proven to improve transplant outcomes. For this purpose we recommend using gut microbiome profile matched with gene marker information. In the next phase we will conduct a clinical trial to investigate the effectiveness of our dose selection model on transplant outcomes.

## FR-PO772

### Outcomes of ABO-Incompatible Living Donor Kidney Transplantation Compared to Waiting or Deceased Donor Kidney Transplantation

Tai yeon Koo,<sup>1</sup> Ga Young Heo,<sup>2</sup> Hyo Jeong Kim,<sup>2</sup> Beom Seok Kim,<sup>2</sup> Jaeseok Yang,<sup>2</sup> <sup>1</sup>Korea University Anam Hospital, Seoul, Republic of Korea; <sup>2</sup>Yonsei University College of Medicine Department of Internal Medicine, Seoul, Republic of Korea.

**Background:** ABO-incompatible (ABOi) living donor kidney transplantation (LDKT) is one of efforts to overcome organ shortage for end stage kidney disease (ESRD) patients. However, it is unclear whether ABOi LDKT has better outcomes compared to remaining on dialysis while waiting for ABO-compatible (ABOc) deceased donor kidney transplantation (DDKT).

**Methods:** We performed a retrospective study with propensity matching. Four hundred twenty-six patients underwent ABOi LDKT between 2010 and 2020 in Seoul National University Hospital and Severance Hospital in Korea. We compared outcomes between ABOi LDKT group and the matched control groups (ABOc LDKT group,  $n = 426$ ; waiting-list-only group,  $n = 1278$ ; waiting-list-or-ABOc-DDKT group,  $n = 1278$ ). The matched controls were derived from 3,053 adult waiting lists for first-time KT, 426 ABOc DDKT and 1366 ABOc LDKT patients.

**Results:** Patient survival rates of the ABOi LDKT group were significantly lower than those of the ABOc LDKT group at 1 year (97.9% vs. 99.8%, respectively) and 8 years (95.2% vs. 97.2%), respectively ( $P = 0.032$ ). Furthermore, ABOi LDKT group showed significantly lower death-censored graft survival rate compared to ABOc LDKT group ( $P=0.032$ ). Interestingly, ABOi LDKT with a low baseline anti-ABO titer ( $\leq 1:32$ ) also showed lower patient and death-censored graft survival rate compared to ABOc LDKT group ( $P=0.011$ ,  $P=0.005$ , respectively). Next, we compared outcomes of ABOi LDKT compared to those of waiting-list-only group and waiting-list-or-ABOc-DDKT group. Patient survival rates at 1- and 8-years in the waiting-list-only group were 97.8%, and 89.1%, respectively, and those in the waiting-list-or-ABOc-DDKT group were 97.7% and 89.3%, respectively. ABOi LDKT group showed significantly better patient survival rate compared to waiting-list-only group ( $P=0.015$ ) and waiting-list-or-ABOc-DDKT group ( $P=0.018$ ).

**Conclusions:** ABOi LDKT is a better choice for end stage kidney disease patients without potential ABOc living donors, especially in Asian countries with a long waiting time for DDKT.

## FR-PO773

### PRO-C6-Rec: Investigating Circulating Endotrophin as a Biomarker in Kidney Transplantation

Federica Genovese,<sup>1</sup> Daan Kremer,<sup>2</sup> Firas F. Alkaff,<sup>2</sup> Stephan J. Bakker,<sup>2</sup> Martin Tepel,<sup>3</sup> Olivier Thauan,<sup>4</sup> Jacob van den Born,<sup>2</sup> Morten A. Karsdal,<sup>1</sup> Daniel Guldager Kring Rasmussen,<sup>1</sup> <sup>1</sup>Nordic Bioscience, Herlev, Denmark; <sup>2</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>3</sup>Syddansk Universitet, Odense, Denmark; <sup>4</sup>Hospices Civils de Lyon, Lyon, France.

**Background:** Novel biomarkers are needed to improve management of kidney transplant recipients. During kidney injury, collagen type VI formation increases. The C-terminal fragment from the alpha3 chain (endotrophin) is released during formation and promotes inflammation and fibrosis. In the Eurostars (Eureka) funded consortium, PRO-C6-Rec, we investigated endotrophin in nine transplant cohorts from three European countries to obtain a comprehensive insight on the ability of this fragment to predict disease progression.

**Methods:** We analyzed plasma endotrophin with the PRO-C6 ELISA in nine transplant cohorts from three European countries. In incident kidney transplant recipients (KTR), levels were investigated both before and after transplantation, and the association with both acute (delayed graft function and rejection) and long-term outcomes (graft failure and mortality) was investigated. Relevant clinical variables were used to adjust the associations of endotrophin with the investigated outcomes.

**Results:** Levels of endotrophin in donors of kidney grafts were the same as observed in healthy individuals [7.1 [6.2-8.2] vs 7.8 [7.1-8.3]]. Pretransplant endotrophin levels were independently associated with delayed graft function in three independent cohorts (OR [95% CI] per increase in one SD of 1.56 [1.13-2.17], 2.09 [1.30-3.36], and 2.06 [1.43-2.97]). Levels of endotrophin were markedly reduced after transplantation (Figure,  $p<0.001$ ). KTRs who experienced rejection had significantly higher endotrophin ( $p<0.001$ ). In prevalent KTRs  $\geq 1$  year after transplantation, levels of endotrophin independently predicted both graft failure and all-cause mortality (HR [95% CI] per doubling; 1.87 [1.07-3.28] and 2.59 [1.73-3.87], respectively).

**Conclusions:** We show that the pro-fibrotic and pro-inflammatory molecule endotrophin is markedly increased in plasma of patients known to have increased risk of outcome, and that endotrophin is an independent predictor of clinically relevant outcomes, likely related to kidney fibrosis and inflammation.

**Funding:** Government Support - Non-U.S.

## FR-PO774

### Donor-Derived Cell-Free DNA (dd-cfDNA) in Kidney Transplant Recipients With Indication Biopsy: Results of a Prospective Single-Center Trial

Louise Benning,<sup>1</sup> Annette Fink,<sup>2</sup> Florian Kälble,<sup>1</sup> Claudius Speer,<sup>1</sup> Christian Nussbag,<sup>1</sup> Martin G. Zeier,<sup>1</sup> Caner Süsal,<sup>3</sup> Christian Morath,<sup>1</sup> Thuong H. Tran,<sup>2</sup> <sup>1</sup>Department of Nephrology, University Hospital Heidelberg, Heidelberg, Germany, Heidelberg, Germany; <sup>2</sup>Transplantation Immunology, Heidelberg Institute of Immunology, University Hospital Heidelberg, Heidelberg, Germany, Heidelberg, Germany; <sup>3</sup>Transplant Immunology Research Center of Excellence, Koç University Hospital, Istanbul, Turkey, Istanbul, Turkey.

**Background:** Donor-derived cell-free DNA (dd-cfDNA) is a marker of allograft injury in kidney transplant recipients (KTR). Little is known about the possible use of dd-cfDNA in evaluating response to anti-rejection treatment.

**Methods:** This far, we enrolled 84 KTR with indication biopsy between November 2020 and May 2022. Besides routine transplant laboratory, AlloSeq dd-cfDNA was quantified at time of biopsy and on days 7, 30, and 90 following biopsy.

**Results:** 27/84 (32%) biopsies were graded as different types of rejection, whereof 19/27 (70%) showed borderline changes, 5/27 (19%) antibody-mediated rejections (ABMR) and 3/27 (11%) T-cellular mediated rejections (TCMR). Patients with signs of active rejection, including borderline changes, had significantly higher levels of dd-cfDNA at time of biopsy than patients without any signs for rejection, whereas estimated glomerular filtration rate did not differ significantly between the two groups ( $P<0.001$  and  $P>0.99$ , respectively, Figure 1A). Patients with ABMR or TCMR showed highest dd-cfDNA levels with a median (IQR) of 2.6% (0.57–9.13) compared to 0.44% (0.20–1.10) in patients with borderline changes and 0.18% (0.11–0.50) in patients with no signs of rejection. dd-cfDNA levels decreased in most of these patients with ABMR or TCMR following initiation of anti-rejection therapy (pooled slope -0.02, Figure 1B). In patients with borderline changes and low levels of dd-cfDNA ( $<1\%$ ) at time of biopsy we see an increase in eGFR after initiation of corticosteroid pulse therapy, whereas patients with high levels of dd-cfDNA ( $\geq 1\%$ ) show subsequent eGFR decline (Figure 1C).

**Conclusions:** dd-cfDNA significantly discriminates active rejection at time of biopsy in KTR. Decreasing levels of dd-cfDNA may indicate treatment response in patients with ABMR and TCMR. dd-cfDNA may further help to identify borderline changes with favorable outcome from changes where additional therapy and closer monitoring is needed.

**Funding:** Commercial Support - CareDX

### The Gut Microbiome Links to Metabolic Syndrome Following Kidney Transplantation

Peter J. Mannon, Roslyn B. Mannon. University of Nebraska Medical Center, Omaha, NE.

**Background:** The metabolic syndrome (MBS) contributes to cardiovascular morbidity and mortality following kidney transplantation. Gut microbiome dysbiosis impacts lipid metabolism, insulin resistance, atherosclerotic factors, and in kidney transplant recipients (KTRs), may be linked to alloimmunity. We hypothesized that changes in gut microbiome pre- and post-transplant are linked to the outcome of MBS in KTRs.

**Methods:** Stool specimens (pre and 6-12 months post) from 14 serial KRTs from living donors and 8 healthy controls had 16S rRNA gene sequencing, microbial metagenome analysis, and targeted (69 gut metabolites in serum and 104 fecal

metabolites) and untargeted metabolomics. Clinical data were extracted from the EMR. The primary outcomes were differences in microbiome and metabolome pre-Tx vs control and vs post-Tx. Secondary outcomes were differences in microbiome and metabolome between pre-Tx vs post-Tx stratified by MBS status and if a microbiome or metabolome "signature" predicted MBS outcome in KTRs.

**Results:** 11 KTRs met criteria for MBS pre-Tx, of which 8 were stable or worsened and 3 improved MBS post-Tx; 1 developed MBS *de novo*. Versus controls, pre-Tx gut microbiome were less diverse, with significantly ↑ *E coli* and *Fusobacterium*, ↑ CKD metabolites, and ↑ glutathione (oxidative stress) & proteolytic metabolic pathways with ↓ *Coprococcus* and *Roseburia* and ↓ short chain fatty acids. Post-Tx microbiome showed significantly ↑ *Roseburia* with ↓ *Akkermansia*, ↓ uremic toxins, and ↓ proteolytic pathways. Untargeted metabolomics aligned with improvement in MBS post-Tx (Fig 1) and independently discriminated between MBS outcomes (Fig 2). Improved MBS post-Tx was associated with ↑ *Ruminococcus*, ↓ *Akkermansia*, and dominant saccharolytic, butyrogenic, and methanogenic pathways.

**Conclusions:** We found that the gut microbiome discriminates pre- and post-KTR MBS states and provides a signature of MBS post-Tx. These data support using targeted prebiotics and probiotics to confer a beneficial metabolic state pre-Tx and post-Tx to improve long term patient and graft survival.

**Funding:** Private Foundation Support

Figure 1. Heat map of untargeted stool metabolites (vertical axis) with pre-Tx (green) or post-Tx (red) transplant samples. Post-Tx samples separated in two distinct groups, which correlate with clinical MBS status.

Figure 2. Principle component analysis showing separation of post-transplant stool metabolites based on patients with same/worse (red) or better (green) MBS after transplantation.

## FR-PO776

### FGF23 Is Associated With Cardiovascular Functional Capacity Before and After Kidney Transplantation

Arvin Halim,<sup>1</sup> Heather Burney,<sup>1</sup> Xiaochun Li,<sup>1</sup> Yang Li,<sup>1</sup> Tzongshi Lu,<sup>5,4</sup> Thomas Hiemstra,<sup>2</sup> Daniel Zehnder,<sup>3</sup> Kenneth Lim.<sup>1</sup> <sup>1</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>2</sup>University of Cambridge, Cambridge, United Kingdom; <sup>3</sup>North Cumbria Integrated Care NHS Foundation Trust, Whitehaven, United Kingdom; <sup>4</sup>Harvard Medical School, Boston, MA; <sup>5</sup>Brigham and Women's Hospital, Boston, MA.

**Background:** Impaired cardiovascular functional capacity is a major complication in CKD and associated with mortality. Fibroblast Growth Factor 23 (FGF23) is a bone-derived phosphaturic hormone that is involved in cardiac remodelling in CKD. To-date, it is unknown whether FGF23 has a role in regulating cardiovascular functional capacity in CKD. Herein, we sought to examine the relationship between FGF23 and exercise ventilatory response variables of cardiovascular functional capacity.

**Methods:** We analyzed a total of 235 patients from the Cardiopulmonary Exercise Testing in Renal Failure and After Kidney Transplantation (CAPER) cohort: 87 advanced chronic kidney disease (CKD) stage 5 patients who underwent kidney transplantation, 65 non-transplanted waitlisted CKD patients, and 83 hypertensive controls. 186 patients were followed longitudinally for 1-year. All patients underwent cardiopulmonary exercise testing (CPET).

**Results:** Patients in higher FGF23 quartiles had significantly lower mean arterial pressure ( $p < 0.001$ ) and lower BMI ( $p = 0.004$ ) compared to patients with lower levels of FGF23. There was no significant difference in sex ( $p = 0.5$ ) or age ( $p = 0.08$ ) across quartiles. Patients with high FGF23 levels exhibited impaired  $\dot{V}O_{2\max}$  ( $p < 0.001$ ) as well as  $\dot{V}O_{2\text{AT}}$  ( $p < 0.001$ ), peak exercise heart rate ( $p < 0.001$ ), max workload ( $p < 0.001$ ), and endurance time ( $p < 0.001$ ) compared to patients with low FGF23 levels. There was no significant difference in oxygen pulse ( $p = 0.2$ ). Patients in all quartiles achieved a mean respiratory exchange ratio  $\geq 1.0$ . Among patients who underwent kidney transplantation, FGF23 significantly decreased at 2 months post-transplant ( $p < 0.001$ ), followed by significant improvement in  $\dot{V}O_{2\max}$  ( $p < 0.001$ ) and max workload ( $p < 0.001$ ) at 1-year. Multivariable regression modelling revealed significant association between FGF23 and  $\dot{V}O_{2\max}$  before and after kidney transplantation after adjusting for age, sex, systolic blood pressure, smoking status, dyslipidemia, and albumin and hemoglobin levels.

**Conclusions:** FGF23 levels are inversely associated with cardiovascular functional capacity before and after kidney transplantation. Our study suggests that FGF23 may be a regulator of alterations in cardiovascular functional capacity in CKD.

### 25(OH)D- but Not 1,25(OH)2D- Is an Independent Risk Factor Predicting Graft Loss in Stable Renal Transplant Recipients

Shufei Zeng,<sup>1</sup> Yide Yang,<sup>4</sup> Shuping Li,<sup>2</sup> Chang Chu,<sup>3</sup> Zhihua Zheng,<sup>2</sup> Bernhard K. Krämer,<sup>3</sup> Berthold Hoher.<sup>3</sup> <sup>1</sup>Southern Medical University Nanfang Hospital, Guangzhou, China; <sup>2</sup>The Seventh Affiliated Hospital Sun Yat-sen University, Shenzhen, China; <sup>3</sup>Universitätsklinikum Mannheim, Mannheim, Germany; <sup>4</sup>Hunan Normal University, Changsha, China.

**Background:** Vitamin D deficiency (VDD) or vitamin D insufficiency is common in kidney transplant recipients (KTRs). The impact of VDD on clinical outcomes in KTRs remain poorly defined and the most suitable marker for assessing vitamin D nutritional status in KTRs is unknown so far.

**Methods:** We conducted a prospective study including 600 stable KTRs (367 men, 233 women) and a meta-analysis to pool existing evidence to determine whether 25(OH)D or 1,25(OH)<sub>2</sub>D predicted graft failure and all-cause mortality in stable KTRs.

**Results:** Compared with a higher 25(OH)D concentration, a low concentration of 25(OH)D was a risk factor for graft failure (HR 0.946, 95%CI 0.912-0.981,  $p = 0.003$ ), whereas 1,25(OH)<sub>2</sub>D was not associated with the study end-point graft loss (HR 0.993, 95%CI 0.977-1.009,  $p = 0.402$ ). No correlation was found between either 25(OH)D or 1,25(OH)<sub>2</sub>D and all-cause mortality. We furthermore conducted a meta-analysis including 8 studies regarding the association between 25(OH)D or 1,25(OH)<sub>2</sub>D and graft failure or mortality, including our study. The meta-analysis results were consistent with our study in finding that lower 25(OH)D levels were significantly associated with the risk of graft failure (OR=1.04, 95%CI: 1.01-1.07), but not associated with mortality (OR=1.00, 95%CI: 0.98-1.03). Lower 1,25(OH)<sub>2</sub>D levels were not associated with the risk of graft failure (OR=1.01, 95%CI: 0.99-1.02) and mortality (OR=1.01, 95%CI: 0.99-1.02).

**Conclusions:** Baseline 25(OH)D concentrations but not 1,25(OH)<sub>2</sub>D concentrations were independently and inversely associated with graft loss in adult KTRs.

## FR-PO778

### Association Between the Distribution of Regulatory T Cell Populations and Immunosuppressant

Yanghyeon Kim,<sup>1,2</sup> Sujung Heo,<sup>1,2</sup> Nagyem Lee,<sup>1,2</sup> Ye na Kim,<sup>1,2</sup> Ho Sik Shin,<sup>1,2</sup> Yeonsoon Jung,<sup>1,2</sup> Hark Rim.<sup>1,2</sup> <sup>1</sup>Renal Division, Department of Internal Medicine, Gospel Hospital, Kosin University College of Medicine, Busan, Republic of Korea; <sup>2</sup>Transplantation Research Institute, Kosin University College of Medicine, Busan, Republic of Korea.

**Background:** Current immunosuppressants cannot achieve induction of immune tolerance and their nonspecific immunosuppressive effects result in many adverse effects. Regulatory T cells (Tregs) play crucial roles in controlling allospecific immune responses. This study evaluated the distribution of Tregs and their effects on kidney allograft function in Korean KT recipients.

**Methods:** We enrolled 113 KT recipients with stable graft function between 1995 and 2018. Differentiation and expansion of Tregs were studied by flowcytometry to compare the Tregs subpopulations. Tregs were defined as CD4+CD25 high CD 127 low/- Fox P3+ cells.

**Results:** Among the 113 patients, 73 patients (64.6%) were males and mean follow-up period was  $147.5 \pm 111.3$  months. All patients received calcineurin-inhibitors as maintenance immunosuppressants. Patients with follow-up period more than 144.3 months tended to have more gating Tregs numbers than that in shorter follow-up period ( $92.3 \pm 142.4$  vs.  $50.1 \pm 76.4$ ,  $p = 0.061$ , respectively). There were no significant differences in Tregs subpopulations between patients with serum creatinine more than 1.5 mg/dL and patients with serum creatinine less than 1.5 mg/dL. In terms of the number of Tregs, when the trough level of tacrolimus was at an appropriate level, the number of Tregs tended to be higher than that of Tregs when the trough level of tacrolimus was low or high, and the organ function of the transplant was also stable.

**Conclusions:** In the present study, there was significant association between the distribution of Tregs and immunosuppressant's type and dose. However, there was no significant relationship between Tregs and kidney allograft function.

Table 1-1. Demographics of patients		
Variables	All patients (n = 113)	
Age (years)	54.5 ± 9.7	
Sex (Male)	73 (64.6)	
Height (cm)	163.7 ± 13.5	
Body weight (kg)	63.9 ± 11.7

FR-PO779

**Wide Spectrum of Molecular Injury Highlights Heterogeneity of Banff Tubulitis and Interstitial Inflammation Lesions**  
Sridhar Reddy Allam,<sup>1</sup> Daniel C. Brennan,<sup>2</sup> Thin Thin Maw,<sup>3</sup> Erik Stites,<sup>4</sup> Nikhil Agrawal,<sup>5</sup> Grigoriy Shekhtman,<sup>5</sup> Fuad S. Shihab,<sup>6</sup> <sup>1</sup>Medical City Fort Worth, Fort Worth, TX; <sup>2</sup>Johns Hopkins University, Baltimore, MD; <sup>3</sup>University of Southern California, Los Angeles, CA; <sup>4</sup>University of Colorado, Denver, CO; <sup>5</sup>CareDx Inc, Brisbane, CA; <sup>6</sup>University of Utah Health, Salt Lake City, UT.

**Background:** The pathological definition and clinical significance of borderline T cell-mediated rejection (BL-TCMR) remains active debate, leading to inconsistencies in therapeutic strategy. Previously published data suggests that donor-derived cell-free DNA (dd-cfDNA) levels at the time of BL-TCMR diagnosis may identify patients at risk of adverse long-term outcomes. We characterized dd-cfDNA levels associated with BL-TCMR among patients in the Kidney allograft Outcomes AlloSure Registry (KOAR, NCT03326076).

**Methods:** Patients with BL-TCMR findings (Banff 2019) on either for-cause or surveillance biopsy and a dd-cfDNA result within 30 days were included in the analysis. Patients with biopsies showing isolated tubulitis or interstitial inflammation without tubulitis were also analyzed.

**Results:** We identified 56 cases of BL-TCMR with paired dd-cfDNA results; median dd-cfDNA among these patients was 0.34% (IQR:0.17 - 1.00) [Figure 1a]. The differences in dd-cfDNA among individual BL-TCMR combinations (t1/i1, t2/i1, t3/i1, t1/i2, t1/i3) were not significant, though the number of t3/i1 (n = 3, dd-cfDNA = 0.04%, 4.85%, 9.06%) and t1/i3 (n = 1, dd-cfDNA = 3.03%) cases was small. No differences were observed between biopsies with BL-TCMR and those with isolated tubulitis (t1/i0, t2/i0) or isolated inflammation without tubulitis (t0/i1) [Figure 1b]. 31 of 56 BL-TCMR cases had prior dd-cfDNA measurement, with median result of 0.24% (IQR: 0.20 - 0.37) obtained 63 (IQR: 53.5 - 100) days before the index biopsy. The median percent increase between these sequential results was 55% (IQR: -9 - 235%).

**Conclusions:** Substantial heterogeneity is observed with regards to dd-cfDNA levels at the time of BL-TCMR and the trajectory of dd-cfDNA preceding index biopsy. No differences in dd-cfDNA are observed between BL-TCMR and t/i lesions not presently included in Banff criteria for BL-TCMR. BL-TCMR, isolated tubulitis, and isolated inflammation without tubulitis represent a spectrum of molecular injury that may be further characterized via assessment of dd-cfDNA.

FR-PO780

**Non-Invasive Monitoring With Torque Teno Virus for the Prediction of Antibody-Mediated Rejection in Kidney Transplant Patients**  
Paul Van Hummelen,<sup>1</sup> Jessica Tang,<sup>1</sup> Dhiren Kumar,<sup>2</sup> Felecia McDougan,<sup>2</sup> Kannagi Yashroy,<sup>1</sup> Ebad Ahmed,<sup>1</sup> Adam Prewett,<sup>1</sup> Gabrielle Heilek,<sup>1</sup> Hossein Tabriziani,<sup>1</sup> Phil Gauthier,<sup>1</sup> Gaurav Gupta,<sup>2</sup> <sup>1</sup>Natera, Inc., Austin, TX; <sup>2</sup>Virginia Commonwealth University, Richmond, VA.

**Background:** Kidney transplant (KT) patients require immunosuppressive (IS) treatment to prevent allograft rejection. The final net state of IS is a result of preexisting comorbidities, induction therapy and maintenance regimens. Torque Teno Virus (TTV) has been reported to be a marker of immune function and transplant-related complications in immunocompromised patients. TTV is a prevalent, non-pathogenic single-strand DNA virus that is easily detected in blood. Evidence for the clinical benefit of quantitative TTV monitoring in KT recipients is still emerging.

**Methods:** We selected 245 longitudinal serum samples from 66 KT patients with: a) stable without rejection in 1st year of transplant [N=26]; b) BK Polyoma viremia/nephropathy [N=10]; c) T-cell mediated Rejection (TCMR) [N=7]; and d) Antibody-mediated Rejection (AMR) [N=23]. Samples were obtained within days of transplantation surgery (Tx), pre-diagnosis, at biopsy diagnosis and several weeks after diagnosis. TTV levels were quantified by real-time quantitative PCR.

**Results:** At Tx, TTV levels were between 103-105 cps/ml and increased to 1010 in the first three months, followed by a gradual decrease to around 106 cps/ml. TTV levels varied by 2 logs between patients within each diagnosis group, confirming earlier published results, while the kinetics within each patient was more consistent. A delayed TTV increase in the first 3 months was observed in AMR patients, with overall lower TTV levels, while TCMR patients had higher and steady TTV levels. Patients with BK viremia/nephropathy generally had the highest titers, suggesting more robust IS.

**Conclusions:** Lower TTV titers in patients who were diagnosed with AMR may indicate an active immune state, possibly due to poor IS response. In contrast, BK viremia may be associated with high immune suppression and high TTV titers. More studies and patients are needed to confirm these results.

## FR-PO781

**Delta Changes in Donor-Derived Cell-Free DNA (dd-cfDNA) Complement the Donor Fraction in Kidney Transplant Surveillance**

Alexander C. Wiseman,<sup>1</sup> Mohanram Narayanan,<sup>2</sup> Nikhil Agrawal,<sup>3</sup> Grigoriy Shekhtman,<sup>3</sup> Yi Fu,<sup>3</sup> Kevin Pinney,<sup>3</sup> Gaurav Gupta.<sup>4</sup> <sup>1</sup>Centura Health, Englewood, CO; <sup>2</sup>Baylor Scott & White Health, Dallas, TX; <sup>3</sup>CareDx Inc, Brisbane, CA; <sup>4</sup>Virginia Commonwealth University, Richmond, VA.

**Background:** We explored dd-cfDNA trajectories preceding biopsy-proven rejection (BPAR) events among kidney transplant recipients in the Kidney Allograft Outcomes AlloSure Registry (KOAR, NCT03326076) and undergoing surveillance with dd-cfDNA.

**Methods:** We compared the change in dd-cfDNA from baseline to the time of BPAR (for-cause or surveillance biopsies). We identified patients with first-time rejection events and at least 3 prior dd-cfDNA results; selected the lowest of two preceding results as the baseline and compared this with the index result. We then analyzed patients with rejection (first or subsequent, at least 90 days apart) and  $\geq 2$  dd-cfDNA results. The reference change value (RCV) was calculated using a reference population of patients with stable allograft function, at least 3 dd-cfDNA measurements, and no significant clinical events.

**Results:** A total of 28 patients with BPAR met criteria for the primary analysis; among these, median baseline dd-cfDNA was 0.22% (IQR: 0.19 - 0.35) and median dd-cfDNA at the time of rejection was 1.35% (IQR: 0.75 - 2.75), representing a 491% (IQR: 177 - 1133) increase between these results, obtained 71.5 (IQR: 46 - 113) days apart [Table 1a]. 51 events met criteria for the second analysis where a median increase of 253% (IQR: 72 - 821%) between sequential dd-cfDNA values obtained 69 days (IQR: 45 - 108) apart preceded biopsy-proven rejection events [Table 1b]. The calculated RCV for the stable reference population within KOAR was 56.3%. 39 of these 51 events (76%) demonstrated increases greater than this RCV.

**Conclusions:** Longitudinal surveillance with dd-cfDNA allows the integration of delta changes and trajectories over time, allowing earlier identification of evolving allograft injury.

**Funding:** Commercial Support - CareDx

	All Rejection (excl. borderline)	ABMR	TCMR (excl. borderline)

## FR-PO782

**Interactive Impact of Tacrolimus Inter-Patient Variability and Intra-Patient Variability in Allograft Outcomes in Kidney Transplantation**

Yohan Park,<sup>1</sup> Hanbi Lee,<sup>2</sup> Sang Hun Eum,<sup>2</sup> Se-Hee Yoon,<sup>1</sup> Won Min Hwang,<sup>1</sup> Sung-Ro Yun,<sup>1</sup> Chul Woo Yang,<sup>2</sup> Byung ha Chung.<sup>2</sup> <sup>1</sup>Konyang University Hospital, Daejeon, Republic of Korea; <sup>2</sup>Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea.

**Background:** Concentration to dose ratio (CDR) of tacrolimus (TAC) is an index of inter-patient variability that reflects tacrolimus metabolism, and whether it influences allograft outcomes is controversial in kidney transplantation (KT). This study analyzed the effect of TAC inter-patient variability combined with TAC intra-patient variability (IPV) on allograft outcomes.

**Methods:** In total, 1,080 patients with immunologic low risk were enrolled. Inter-patient variability was calculated as the mean value of CDRs up to 3 months after KT, and was defined as rapid metabolizer (RM) if it was lower than 1.05. IPV was calculated as the time-weighted coefficient variability (TWCV) of the TAC-trough level (C<sub>0</sub>) up to 1 year after KT, and was defined as high IPV group if it was higher than 30%. According to CDR and TWCV, patients were divided into 4 groups: Low IPV/Non-rapid metabolizer (NRM), High IPV/NRM, Low IPV/RM, and High IPV/RM.

**Results:** Death-censored graft loss (DCGL) rates were 5.5% (25/452) in the Low IPV/NRM group, 10.5% (38/375) in the High IPV/NRM group, 5.7% (6/106) in the Low IPV/RM group, and 19.1% (28/147) in the High IPV/RM group, which was the significantly highest in the High IPV/RM group (P < 0.001). In Cox regression analysis, the odds ratio (OR) of High IPV/RM was 3.06 (1.78-5.25), which was observed as a significant risk factor. In the analysis in which the TAC time weighted average value was adjusted, High IPV/RM was remained as a significant risk factor with OR 2.60 (1.41-4.79).

**Conclusions:** High TAC-IPV in patients with low CDRs in the early post-transplantation period is thought to have a significant adverse effect on the allograft outcomes. Stratification is required for patients with RM characteristics (low CDRs) in the clinical field, and more careful tacrolimus dose adjustment efforts are needed in these patients.

## FR-PO783

**Plasma Cell Rich Rejection (PCRR) of Kidney Allografts: A Review of 94 Patients**

Hameeda T. Khan, Jonathan T. Lin, Thalia Salinas, Steven Salvatore, Darshana M. Dadhania, Choli Hartono, Surya V. Seshan, Thangamani Muthukumar. Weill Cornell Medicine, New York, NY.

**Background:** PCRR, defined as an acute rejection in which plasma cells constitute >20% of the cells infiltrating the kidney interstitium, occurs in the context of mixed AMR/TCMR or TCMR. Allograft outcome after PCRR is poor and risk factors have not been well defined.

**Methods:** We did a chart review of 94 consecutive transplant kidney biopsies (7/2007-12/2021) at our center reported as PCRR. Patients with functioning grafts were censored at 60 months after biopsy diagnosis. Allograft outcome and risk factors were assessed by Kaplan-Meier and Cox regression analysis.

**Results:** Mean (SD) age of patients was 40 (17) years; 43% were women; 36% were Black. Mean (SD) age of donors was 35 (17) years; 45% were deceased donors; 63% were women; 29% were Black. 83% received Thymoglobulin induction and all were on calcineurin-based immunosuppression. Time (median, IQR) from transplantation to biopsy was 48 (16-75) months. Medication nonadherence was observed in 37%. 75 (80%) patients had mixed acute rejection. Besides methylprednisolone pulse, treatment included combinations of thymoglobulin, intravenous immunoglobulin, plasmapheresis, and bortezomib. During a median follow of 49.8 months, 58 patients lost their grafts. The median allograft survival was 27.5 months (Fig 1). Variables associated with the outcome are shown in Fig 2. Bortezomib-based antirejection therapy did not improve outcome (HR 0.75 [0.39-1.44], P=0.38).

**Conclusions:** PCRR, irrespective of whether it occurs in the context of mixed AMR/TCMR or TCMR, is associated with poor allograft outcomes. Molecular characterization of PCRR biopsies may provide clues to better understand the pathogenesis and develop targeted therapeutics.

Fig 1

Variables (at the time of allograft biopsy)	N (%)	Reference	Hazard Ratio (95%CI)	P value
Age of the transplant recipient	94 (100)	per year	0.98 (0.96-1.00)	0.199

## Selectively Increased Urinary Endotrophin Levels in T-Cell Mediated Kidney Transplant Rejection

Firas E. Alkaff,<sup>1,2</sup> Daan Kremer,<sup>1</sup> Daniel Guldager Kring Rasmussen,<sup>3</sup> Martin Tepel,<sup>4</sup> Olivier Thauinat,<sup>5</sup> Marius C. van den Heuvel,<sup>1</sup> Stefan P. Berger,<sup>1</sup> Federica Genovese,<sup>3</sup> Morten A. Karsdal,<sup>3</sup> Jacob van den Born,<sup>1</sup> Stephan J. Bakker,<sup>1</sup> <sup>1</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>2</sup>Universitas Airlangga Fakultas Kedokteran, Surabaya, Indonesia; <sup>3</sup>Nordic Bioscience, Herlev, Denmark; <sup>4</sup>Odense Universitetshospital, Odense, Denmark; <sup>5</sup>Hospices Civils de Lyon, Lyon, France.

**Background:** Endotrophin (ETP) is a proteolytic fragment of collagen VI  $\alpha 3$  chain and involved in adipose tissue homeostasis. However, upon renal tissue remodeling, collagen VI is increased and ETP is released. In this study we evaluated whether plasma and/or urinary ETP is associated with graft rejection in kidney transplant recipients (KTR).

**Methods:** This is a cross-sectional study among KTR who are enrolled in TransplantLines Biobank and Cohort Study. Blood and urine were collected on the same day as the biopsy procedure. Plasma and urinary ETP were measured using Enzyme-Linked Immunosorbent Assay. Diagnosis of graft rejection was according to the BANFF classification at the time the biopsies were taken.

**Results:** See Table for results. KTR with indication biopsy showed increased plasma ETP and urinary ETP/Creatinine ratio (ECR). Among patients who underwent indication biopsy, both plasma ETP and ECR were significantly correlated with C-reactive protein, serum creatinine, and eGFR but not with urinary protein excretion. Further, those with T-cell mediated rejection (TCMR) had higher ECR but similar plasma ETP level. In the logistic regression analysis, ECR was significantly associated with TCMR, even after adjustment for age, sex, eGFR, and 24-hour protein excretion (OR per doubling 1.39, 95%CI = 1.08-1.78,  $p = 0.011$ ).

**Conclusions:** Our findings show that in urine, but not in plasma, ETP is selectively increased in TCMR independent of kidney function and proteinuria, suggesting increased renal ETP release upon TCMR. Further studies focusing on T-cell specific cytokines in collagen VI synthesis needs to be done.

**Funding:** Commercial Support - Astellas BV, and Chiesi Pharmaceuticals BV, Government Support - Non-U.S.

## FR-PO785

## Torque Teno Virus Might Be a Better Predictor of Immunosuppressive Burden in BK Viremia Post Renal Transplant

Ramyangshu Chakraborty, Jon Bible, Michelle E. Allan, Tasnuva S. Kashem, Stanley Fan, Kieran McCafferty, Teresa M. Cutino Moguel, Muhammad Magdi Yaqoob. The Royal London Hospital, London, United Kingdom.

**Background:** The ubiquitous Torque Teno DNA virus (TTV) promises increased accuracy in IS burden prediction. We examined the presence and change in TTV titres in patients with BK viremia in preparation for a prospective observational study evaluating TTV as a measure of IS burden.

**Methods:** Stored blood samples and electronic records from 20 renal transplant recipients from 2017-19 at a tertiary care centre were included in the analysis. All received standardised tacrolimus based IS and experienced a clinically significant episode of BK viremia which responded to standard of care cessation of mycophenolate (MMF). BK & TTV titres, 30-day average tacrolimus concentration, antiproliferative & prednisolone doses were collected at four-time points: the last negative BK PCR; the onset of viremia; the peak BK titre & BK titre <500 copies. TTV PCR was performed on DNA extracted from frozen plasma. Multivariable linear regression analysis was performed in R to assess the relationship between TTV and other variables.

**Results:** TTV DNA was detectable at 78 out of 80 time points. The mean TTV titre at the 4 time points were 5.0 (2.07), 5.5 (1.74), 6.2 (2.14) & 4.6 (1.27) log copies respectively. In the linear model, log-transformed BK virus titre was strongly associated with TTV titres once adjusted for tacrolimus concentration: every 1 log rise in TTV titre led to 0.6 (0.17) log copies increase in BKV titre ( $p < 0.001$ ). The tight relationship between BKV and tacrolimus concentration ( $p < 0.001$ ) disappeared when TTV titre was added as a predictor variable, implying the superiority of TTV to tacrolimus concentration as a predictor for BK viral load. Changes in MMF or prednisolone dose did not predict linear changes in BKV titres. Five patients had graft loss within the follow-up period (mean 2.8 years). All had low ( $p < 0.05$ ) TTV titres indicating suboptimal IS burden. There was no relationship between rejection ( $n = 5$ ) or de novo DSA ( $n = 3$ ) with TTV titre in this cohort.

**Conclusions:** This pilot study suggests that TTV is detectable in most instances post-transplant. TTV titres indicate the effect of IS changes on BK titre independently. An ongoing adequately powered prospective study will further assess the relationship between TTV titres & post-transplant immunological events.

## FR-PO786

## Serial Testing of Blood Gene Expression and Donor-Derived Cell-Free DNA for Predicting Future Kidney Allograft Failure

Kexin Guo,<sup>1</sup> Alexis J. Kushner,<sup>1</sup> Christabel Rebello,<sup>1</sup> Bradley M. Kinsella,<sup>1</sup> Rohita Sinha,<sup>2</sup> Lihui Zhao,<sup>1</sup> John J. Friedewald,<sup>1</sup> Sookhyeon Park.<sup>1</sup> <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>Eurofin Viracor, Lee Summit, MO.

**Background:** Both gene expression profiles (GEP) and donor-derived cell-free DNA (dd-cfDNA) have been established as non-invasive biomarkers to detect subclinical and clinical acute rejection in a kidney allograft. However, the clinical impact of combined serial testing of GEP and dd-cfDNA on kidney allograft survival has not been well studied. We hypothesized that we could predict future kidney allograft survival using serial testing of combined GEP and dd-cfDNA.

**Methods:** We analyzed 261 subjects from a previously reported multicenter, prospective observational study. Multiple serial samples of GEP and dd-cfDNA were collected throughout the study period. Graft failure was defined as returning to dialysis or re-transplant. We used a joint model to predict future allograft survival using serial GEP and dd-cfDNA and allograft failure. The study cohort was randomly divided into 70 and 30%, training and testing sets, respectively. We assessed the model performance with the area under the receiver operating characteristic (AUROC).

**Results:** Of 261 subjects, 182 (70%) were used for training the model. A total of 16 cases of allograft failure were observed in the training set. In the training set, the AUROC to predict graft failure at 4-year post kidney transplant (KT) was 0.83 using GEP and dd-cfDNA until 1 year KT (Fig 1A). When we used GEP and dd-cfDNA data from up to 2 years post KT, the AUROC improved to 0.88 (Figure 1B). For the validation set, 7 graft failures were observed from 79 subjects. The performance remains stable in the validation set. The AUROCs were 0.67 and 0.83, using up to 1-year and 2-year serial GEP and dd-cfDNA data, respectively.

**Conclusions:** The combination of GEP and dd-cfDNA tests can be used to predict future graft failure.

**Funding:** Private Foundation Support

### Molecular and Cellular Landscape of Peripheral Blood Mononuclear Cells (PBMCs) Associated With Kidney Transplantation Operational Tolerance

Shafquat Azim,<sup>1</sup> Haseeb Zubair,<sup>1</sup> Amol C. Shetty,<sup>2</sup> Jennifer M. McDaniels,<sup>1</sup> Thomas Rousselle,<sup>1</sup> Cem Kuscus,<sup>3</sup> Canan Kuscus,<sup>3</sup> Manish Talwar,<sup>3</sup> James D. Eason,<sup>3</sup> Daniel G. Maluf,<sup>4</sup> Valeria R. Mas,<sup>1</sup> Mas Lab <sup>1</sup>University of Maryland School of Medicine, Baltimore, MD; <sup>2</sup>University of Maryland Baltimore, Baltimore, MD; <sup>3</sup>The University of Tennessee Health Science Center College of Medicine, Memphis, TN; <sup>4</sup>University of Maryland Medical Center, Baltimore, MD.

**Background:** Under rare event kidney transplant recipient (KTR) establish long-term allograft acceptance without the need of immunosuppressive drugs (ISD), usually due to medical nonadherence. Understanding the immune landscape in patients of spontaneous tolerance can define novel mechanisms of tolerance induction and provide biomarkers for clinical testing to reduce or withdraw ISD.

**Methods:** PBMCs isolated from non-transplant healthy control (Nor, n=2), KTR on ISD (NwIS, n=3), and KTR with operational tolerance (OT, n=1) were processed for single-cell RNA-seq according to the 10X Genomics Chromium platform and analyzed on Cell Ranger and Seurat.

**Results:** Subclusters of T-cell included Treg (FOXP3). Treg was present in higher fraction in NwIS (Fig 1A). Pathway analysis on Treg differentially expressed genes (FDR≤0.05, log2FC≥±1.5) was done using Metascape (Fig 1B). *LGALS1* an important effector of Treg-mediated regulation was upregulated specifically in OT. Interestingly, perforin (*PRF1*), also a mediator of Treg-induced tolerance, was >5-fold less in NwIS compared to N and OT. B cell population was also dissimilar between the three. OT had the highest proportion, while NwIS the lowest. Subclustering B cell identified the presence of a single activated B cell subpopulation in NwIS, which were very low in OT and Nor (Fig 2). However, most of the activated B cells in NwIS were in the G1 phase with decreased CD27 and CD24 expression indicating B cell exhaustion.

**Conclusions:** Increased *LGALS1* and *PRF1* in OT indicates a role in achieving tolerance via Tregs. Moreover, abundance in B cell subtypes and associated transcriptome found in OT also indicate tolerance maintenance.

**Funding:** NIDDK Support

## FR-PO788

### Development of a Tissue-Based Classifier of Allograft Inflammation Using Imaging Mass Cytometry

Mariam P. Alexander,<sup>1</sup> Mark Zaidi,<sup>2</sup> Mark D. Stegall,<sup>1</sup> Andrew J. Bentall,<sup>1</sup> Trevor D. McKee,<sup>3</sup> Timucin Taner.<sup>1</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>University of Toronto, Toronto, ON, Canada; <sup>3</sup>Decipher Ltd, Dublin, Ireland.

**Background:** Molecular phenotyping of allograft inflammation has improved both diagnostic accuracy & our understanding of the heterogeneity of rejection. Current molecular techniques lack histological correlation & spatial dimensionality. Our goal was to use Imaging Mass Cytometry (IMC) to develop a tool to accurately predict the cause of allograft inflammation.

**Methods:** Our cohort included biopsies of rejection, BK nephropathy, pyelonephritis & normal kidneys. Using a panel of 28 markers, IMC images were processed by the Hyperion imaging system. Details of analysis are in Fig 1A. Cell segmentation was performed using Universal StarDist for Qupath. Cell classification was performed based on mean intensity threshold.

**Results:** 139 regions of interest (ROI) were processed. Violin plots ensured there were measurable differences in known markers associated with each allograft inflammation category. Distribution of percent positive scoring of immune cells are seen in the heatmap (1B) [e.g.: cellular & mixed rejection cases enriched in CD45<sup>+</sup>, HLA-DR<sup>+</sup> cells and CD4<sup>+</sup> memory T cells]. The trained regularized gradient boosting classifier model XGBoost was used to predict the allograft inflammation category for all cells, ROIs and each original histological diagnosis. (Fig 1C & D). The trained model accurately predicted the allograft inflammation category for each cell with an accuracy of 64.3%. When using the mean intensity parameter of each cell, the classifier accuracy improved to 87.8% in predicting the type of renal allograft inflammation, independent of ROI. The accuracy improved to 90.9% when dimension of intracellular spatial features (proximity metrics) were added to the algorithm. Granzyme, CD68 and Vista were the three most important markers in achieving this high accuracy.

**Conclusions:** Using highly multiplexed imaging of renal allograft biopsies with subcellular resolution by IMC we have developed a novel classifier of allograft inflammation, which demonstrates high diagnostic accuracy.

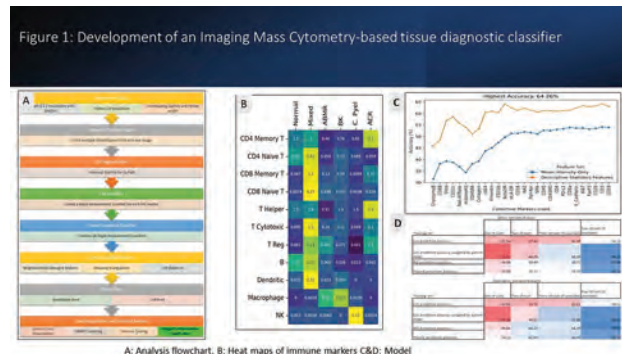

Figure 1

## FR-PO789

### Non-human Leukocyte Antigen (Non-HLA) Antibodies Against GSTT1 Are Associated With Homozygote Status for the Null Allele and With Histological Changes of Antibody Mediated Rejection

Bogdan Obriscu,<sup>1</sup> Nicolae Leca,<sup>2</sup> Elaine Chou-Wu,<sup>3</sup> Gener Ismail,<sup>1</sup> Idoia Gimferrer.<sup>3</sup> <sup>1</sup>Fundeni Clinical Institute, Bucharest, Romania; <sup>2</sup>University of Washington, Seattle, WA; <sup>3</sup>Bloodworks Northwest, Seattle, WA.

**Background:** The presence of anti-GSTT1 Abs have been detected in patients with Antibody Mediated Rejection (AMR) after liver and kidney transplantation (KTx). We aimed to evaluate the relation between anti-GSTT1 Abs and AMR in a cohort of KTx patients.

**Methods:** Pre and Post-transplant samples from 87 KTx recipients were analyzed by Immunocor's non-HLA Luminex assay. We included 29 patients with AMR due to HLA-DSA (AMR/DSA+), 28 patients with non-HLA mediated AMR (AMR/DSA-) and 30 patients without rejection with stable allograft function (control).

**Results:** At an MFI cut-off of 3,000, the overall prevalence of anti-GSTT1 Abs was 14%. The prevalence was higher among AMR/DSA- patients (25%), compared to the control group (13.3%) and AMR/DSA+ group (3.4%) (p=0.06). 81/87 patients underwent GSTT1 genotyping, 16 (19.75%) were negative: 9 AMR/DSA- patients (33.3%), 6 controls (22.2%) and 1 AMR/DSA+ (3.7%) (p=0.02). In the ABMR/DSA- group, the anti-GSTT1 ab MFI was significantly higher in patients negative compared to patients positive for GSTT1 gene (Figure 1). In two multivariate logistic regression models, negativity for GSTT1 gene (OR 43.2; 95%CI, 2.6-716) and anti-GSTT1 Ab positivity (OR 11.9; 95%CI, 1.1-129) were strongly associated with AMR. 14/57 patients with AMR (24.5%) lost their allograft at a median 6.1 years (IQR: 3.7-7.7). Patient with anti-GSTT1 Abs had AMR earlier (17 vs 35 months) than patients without GSTT1 Abs (p=0.02). Despite this, there were no differences in graft loss. When taking into consideration the GSTT1 gene status, among subjects displaying homozygote null status those without allograft failure had an overall higher MFI levels of anti-GSTT1 ab compared to those that lost their allograft (Figure 1).

**Conclusions:** Presence of GSTT1 Abs and GSST1 gene negative status are associated with AMR, but do not appear to lead to increased graft loss, possibly being a marker of favorable response to rejection treatment.

Figure 1

## FR-PO790

### The Number of Episodes of Subtherapeutic Tacrolimus Levels During the First Year Post Transplant Is Independently Associated With Reduced Graft Survival

Benaya Rozen-zvi,<sup>1</sup> Dana Bielopolski, Ruth Rahamimov. *Rabin Medical Center, Petah Tikva, Israel.*

**Background:** Multiple studies have shown that tacrolimus (TAC) trough level variability is associated with reduced graft survival. However, specific patterns of TAC level that are associated with adverse outcome were not identified. In this study we sought to evaluate the association between the number of episodes of sub therapeutic TAC level during the first year after transplantation and graft outcome.

**Methods:** a single center retrospective cohort study including all kidney transplanted patients between 2001 and 2017 inclusion criteria were immunosuppression with with TAC and graft survival of more than one year. An Episode of sub therapeutic TAC level was defined as any value below 6 ng/ml during the first year, following a value above 6 ng/ml. exposure variable was the number of episodes of Tac sub therapeutic levels with cap of six (all patients with six or more episodes were categorized as having six episodes). Univariate and multivariate Cox model were used to evaluate the primary outcome of death censored graft loss. Tac level variability during the first year was included in the multivariate model.

**Results:** the study included 1305 patients, the mean age was 49.5±14.8 years and 884(67.7%) of them were men. The median number of sub therapeutic Tac level episodes was 1 (IQR 0-3) and 327 (25.1%) patients had no sub therapeutic Tac levels during the first year. Increased number of sub therapeutic Tac level episodes was associated with reduced graft survival (Hazard Ratio (HR), 1.41 per episode, 95% Confidence Interval (CI) 1.27-1.55, p<0.001). the results were not significantly changed after multivariate adjustment (HR, 1.23 per episode, 95% CI 1.09-1.37, p=0.001). when the composite outcome of graft loss and mortality was evaluated the results were comparable (HR, 1.23 per episode, 95% CI 1.15-1.32, p<0.001) and (HR, 1.16 per episode, 95% CI 1.07-1.26, p<0.001) for univariate and multivariate analysis respectively.

**Conclusions:** Episodes of sub therapeutic Tac level are associated with reduced graft survival independent of Tac level variability. Studies evaluating the effect of strategies to reduce the number of sub therapeutic Tac levels on graft outcomes might be helpful.

## FR-PO791

### Association Between Tacrolimus Level and Graft Outcome According to Bisphosphonate Use in Kidney Transplantation Patients

Hee Byung Koh,<sup>1</sup> Ga Young Heo,<sup>1</sup> Hyo Jeong Kim,<sup>1</sup> Chan-Young Jung,<sup>1</sup> Hyung Woo Kim,<sup>1</sup> Seung Hwan Song,<sup>3</sup> Hoon Young Choi,<sup>2</sup> Jaeseok Yang,<sup>1</sup> Kyu ha Huh,<sup>1</sup> Beom Seok Kim.<sup>1</sup> *<sup>1</sup>Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; <sup>2</sup>Gangnam Severance Hospital, Seoul, Republic of Korea; <sup>3</sup>Ewha Womans University Seoul Hospital, Seoul, Republic of Korea.*

**Background:** Although the introduction of tacrolimus significantly improved the prognosis of kidney transplantation (KT), an immunosuppressive drug that further improves the current prognosis has not yet been developed. Several recent studies have shown that bisphosphonate (BPP) use was associated with a favorable graft outcome in patients with KT. Therefore, we investigated whether the association between tacrolimus and graft outcome was different according to the use of BPP in patients with KT.

**Methods:** This retrospective study was conducted by analyzing 1,657 patients who underwent KT at Severance Hospital in South Korea between January 2006 and December 2020. Patients with preoperative BPP use, cyclosporine use, rapamycin use, re-transplantation, and missing information were excluded. Primary exposure was time-dependent cross-product term of tacrolimus trough level (low TAC vs. normal-high TAC with reference of 4ng/mL) and BPP use. Primary outcome was graft failure defined as patient's death or conversion to kidney replacement therapy. Sensitivity analysis was performed with outcome of eGFR <30 ml/min/1.73 m<sup>2</sup>.

**Results:** Among 1,657 patients, 362 (21.8%) patients were BPP user. During the 11211.8 person-year, graft outcomes occurred in 183 (11.0%) patients. In multivariable Cox regression analysis, normal-high TAC without BPP was associated with a lower risk of graft outcome (HR, 0.40 [95% CI, 0.29-0.54]) compared to low TAC without BPP. Normal-high TAC with BPP was associated with a further lower risk of graft outcome

(HR, 0.17 [95% CI, 0.09-0.31]) compared to low TAC without BPP. Low TAC with BPP was also associated with a lower risk of graft outcome (HR, 0.15 [95% CI, 0.06-0.36]) compared to low TAC without BPP. This association was maintained in analyses using tacrolimus trough level of 5 or 6 ng/mL as reference. In addition, similar results were observed with outcome of eGFR <30 ml/min/1.73 m<sup>2</sup>.

**Conclusions:** The use of BPP was associated with favorable graft outcomes even in lower tacrolimus trough level. The addition of BPP to the conventional immunosuppressant regimen may reduce tacrolimus requirement.

## FR-PO792

### High Pretransplant FGF-23 Level Is Associated With Poor Graft Survival and Persistent Vitamin D Insufficiency in Kidney Transplant Patients

Jung-hwa Ryu,<sup>1</sup> Tai yeon Koo,<sup>3</sup> Hyo Jeong Kim,<sup>2</sup> Ga Young Heo,<sup>2</sup> Jaeseok Yang,<sup>2</sup> KNOW-KT Study group *<sup>1</sup>Ewha Womans University Seoul Hospital, Seoul, Republic of Korea; <sup>2</sup>Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; <sup>3</sup>Korea University, Seongbuk-gu, Seoul, Republic of Korea.*

**Background:** Vitamin D [25(OH)D] insufficiency and FGF-23 elevation in chronic kidney disease (CKD) is usually ameliorated after kidney transplantation (KT). However, post-transplant vitamin D insufficiency are still associated with poor graft outcome. This study aimed to investigate the effect of pretransplant FGF-23 level on post-transplant vitamin D status and clinical outcomes.

**Methods:** The KoreaN cohort study for Outcome in patients With Kidney Transplantation (KNOW-KT) is a multicenter, observational cohort study. Four hundred subjects for whom serum FGF-23 measurement was available, were included in this study. Annual serum 25(OH)D and clinical outcomes; all-cause mortality, cardiovascular event, graft survival, and fracture were assessed according to baseline FGF-23 levels.

**Results:** Median follow-up duration was 6.5 years. Serum 25(OH)D<sub>3</sub> levels were increased after KT (before KT, 12.6±7.4; 1 year after KT, 22.6±6.4; 3 years after KT, 24.3±5.8 ng/mL). However, they were declined to 20.9±9.2 ng/mL at 7 years after KT. Vitamin D deficiency was present in 79.1% just before KT, then it was decreased to 30.8% at 3 years after KT, whereas it was increased 37.8% at 6 years after KT. Serum FGF-23 level was decreased after KT [2140.6 (391-9277) pg/ml before KT vs. 50.0 (23.6-94.6) pg/ml at 3 years after KT, P=0.001]. The FGF-23 showed negative correlation with serum vitamin D levels. When we categorized subjects into tertile according to baseline FGF-23 level (low, middle, high FGF-23 groups), the 25(OH)D<sub>3</sub> in the low baseline FGF-23 group was lowest at any point during follow-up. High baseline FGF-23 level was a risk factor for poor graft survival (HR 5.882, 95% C.I.; 1.443-23.976, P=0.022).

**Conclusions:** Increased FGF-23 could interfere vitamin D activation even after KT and is a risk factor for poor graft survival.

## FR-PO793

### Postoperative Neutrophil to Lymphocyte and Platelet Ratio as a Predictor of Delayed Graft Function

João M. Oliveira, Joana Gameiro, Marta R. Neves, Alice Santana, Jose A. Lopes. *Centro Hospitalar Universitario Lisboa Norte EPE, Lisboa, Portugal.*

**Background:** Development of delayed graft function (DGF) has been associated with worse short and long-term outcomes after kidney transplantation (KT). Inflammation plays a key role in the development of DGF. The neutrophil to lymphocyte and platelet (NLP) ratio is an affordable biomarker of systemic inflammation easily determined from a complete blood cell count. We aimed to assess whether postoperative NLP ratio may be used as an early predictor of DGF in KT patients.

**Methods:** We conducted a retrospective cohort of adult patients submitted to KT at our unit, between 1 January 2010 and 31 December 2020. NLP was calculated at 24h post-KT. Primary outcome was development of DGF. Logistic regression was calculated to determine significant factors which may have contributed to DGF.

**Results:** We included 527 patients with a mean age of 49.9 ± 12.8 years and the majority were male (n=308, 58.4%). Patients had been under renal replacement therapy for 5.9±4 years. In 47.8% of patients expanded criteria donors were used, and in 3.6% non-heart-beating donors. DGF occurred in 17.8% of patients. Use of rabbit anti-thymocyte immunoglobulin for induction therapy was similar between groups (DGF vs. early graft function, p=0.078). Mean post-KT NLP was 26.4±3.5 and, as expected, was higher in patients submitted to induction therapy with lymphocyte depleting antibodies (50.2±40.3 vs. 11.9±7.4 in patients treated with basiliximab, p<0.001), but it was found to be higher even before KT (and thereby before induction therapy) (5.2±1.8 in patients treated with rabbit anti-thymocyte immunoglobulin vs. 1.9±1.2 with basiliximab, p=0.001) and not predictive of DGF. Grafts from non-heart-beating donors (OR 13.989, 95% CI 4.741, 41.274, p=0.000), longer warm ischemia time (OR 1.035, 95% CI 1.007, 1.064, p=0.014) and higher NLP ratio 24 hours after transplantation (OR 1.009, 95% CI 1.002, 1.016, p=0.015) were independent predictors of DGF. Creatinine at discharge (3.3±2.2 versus 1.4±0.5, p=0.000) was higher in patients with DGF.

**Conclusions:** In our cohort, a higher NLP ratio at 24 hours after KT was an independent predictor of DGF. This reflects the impact of inflammation on KT outcomes and highlights the role of the NLP ratio as a sensitive marker of systemic inflammatory response after KT.

## FR-PO794

## Longitudinal Analysis of Donor-Derived Cell-Free DNA (dd-cfDNA) in En Bloc Kidney Transplantation

Sanjeev Akkina,<sup>1</sup> Neeraj Singh,<sup>2</sup> Jeffrey A. Klein,<sup>3</sup> Nikhil Agrawal,<sup>4</sup> Mingwei Fei,<sup>4</sup> Amishi S. Desai.<sup>1</sup> <sup>1</sup>Loyola University Chicago, Chicago, IL; <sup>2</sup>Willis-Knighton Health System, Shreveport, LA; <sup>3</sup>University of Kansas School of Medicine, Kansas City, KS; <sup>4</sup>CareDx Inc, Brisbane, CA.

**Background:** The longitudinal dd-cfDNA patterns in en-bloc kidney transplant recipients have not been studied. It is unknown how the initial smaller mass of the two pediatric organs impacts dd-cfDNA early post-transplant or if the dd-cfDNA rises over time as the organs enlarge. We analyzed dd-cfDNA scores over the first 12 months in recipients of pediatric en-bloc kidneys enrolled in the Kidney allograft Outcomes AlloSure Registry (KOAR, NCT03326076).

**Methods:** 16 recipients of pediatric en-bloc kidneys with donors aged  $\leq 7$  years old were identified and compared with 931 single, non en-bloc deceased donor recipients. Patients with rejection were excluded.

**Results:** Of the 16 en-bloc recipients, 56.2% were male with median donor age of 1.4 years and median cold ischemia time (CIT) of 20 hours. None of the en-bloc transplants had delayed graft function. Aside from KDPI, donor age, and recipient age, no other differences were observed between groups. Higher median dd-cfDNA values were seen in the en-bloc cohort compared to not en-bloc at month 1 (M1, 1.4% vs 0.4%) and month 2 (0.58% vs 0.23%) after transplant ( $p < 0.001$ ) [Figure 1a]. Median dd-cfDNA values were comparable for month 3 (0.21% vs 0.16%,  $p = 0.07$ ) and all subsequent time points. [Figure 1a, 1b]. Among 8 patients with M1 dd-cfDNA results, there was no significant association between M1 dd-cfDNA and either CIT ( $r = 0.33$ ,  $p = 0.419$ ) or KDPI ( $r = 0.23$ ,  $p = 0.589$ ).

**Conclusions:** Our results demonstrate higher early post-transplant dd-cfDNA values among en-bloc kidney compared to single kidney recipients however, no difference or upward trend is observed beyond month 2 and out to 12 months.

**Funding:** Commercial Support - CareDx

## FR-PO795

## Tegoprubart Reduced Inflammation in Patients With Amyotrophic Lateral Sclerosis (ALS): Potential Implications for Its Use in the Prevention of Rejection in Kidney Transplant

Steven Perrin,<sup>1</sup> Alan Gill,<sup>2</sup> Jeffrey D. Bornstein,<sup>1</sup> Joachim Theilhaber.<sup>1</sup> <sup>1</sup>Eledon Pharmaceuticals, Irvine, CA; <sup>2</sup>ALS Therapeutic Discovery Institute, Boston, MA.

**Background:** Tegoprubart (AT-1501) is a monoclonal antibody that inhibits CD40 ligand (CD40L); it is expected to downregulate both cell mediated and antibody mediated immunity while also creating a more tolerogenic environment, and preventing antibody class switching, reducing high affinity IgG antibodies. Tegoprubart is currently being evaluated in an ongoing trial in kidney transplant (KT).

**Methods:** Tegoprubart was studied in an open-label, dose-escalating trial in patients with ALS. 54 participants received tegoprubart at doses of 1mg/kg (N=9), 2mg/kg (N=9), 4mg/kg (N=18) or 8mg/kg (N=18) IV every 2 weeks for 6 infusions. Safety and the effect of tegoprubart on inflammatory biomarkers were assessed. Target engagement was measured directly via reduction in CD40L and indirectly using CXCL13, a marker of B cell activation. Pro-inflammatory chemokines and cytokines previously shown to be elevated in ALS patients were assessed, and several of these biomarkers may be relevant to the ongoing studies in KT, notably CXCL9 and CXCL10.

**Results:** Tegoprubart appeared safe and well tolerated at the doses administered. Target engagement was achieved in a dose dependent fashion. In this population of ALS patients, tegoprubart reduced inflammatory biomarkers with the same dose dependent pattern as target engagement. Importantly for KT, tegoprubart reduced CXCL9 and CXCL10, chemokines reported to be associated with acute allograft rejection.

**Conclusions:** In a study of patients with ALS, tegoprubart at doses of 4mg/kg and 8mg/kg IV every 2 weeks demonstrated target engagement with an associated reduction in inflammation. Among the inflammatory biomarkers reduced were CXCL9 and CXCL10, positive signals for tegoprubart's ongoing program in KT.

**Funding:** Commercial Support - Eledon Pharmaceuticals

Figure 1. Effect of Tegoprubart on CD40L, CXCL13, CXCL9 and CXCL10

## FR-PO797

## Donor Derived Cell-Free DNA in Stable Dual Kidney Transplant Recipients

Kunal Yadav,<sup>1</sup> Navchetan Kaur,<sup>2</sup> David C. Barnes,<sup>2</sup> Ebad Ahmed,<sup>2</sup> Phil Gauthier.<sup>2</sup> <sup>1</sup>The University of Toledo, Toledo, OH; <sup>2</sup>Natera, Inc., Austin, TX.

**Background:** Dual kidney transplants from deceased donors with limited renal function expand the donor pool to help circumvent the organ shortage. It is unclear whether the donor derived cell-free DNA (dd-cfDNA) fraction, a validated biomarker for the detection of allograft injury, has a different baseline in individuals with dual kidney transplants, compared to those with single kidney transplants. Here we evaluate the baseline dd-cfDNA in a cohort of stable dual kidney transplant recipients (DKTR).

**Methods:** dd-cfDNA testing was performed clinically with the Prospera™ test (Natera, Inc.) on 117 plasma samples from 13 DKTR. dd-cfDNA fractions  $\geq 1\%$  were considered at high risk for rejection. Of these patients, 11/13 had functioning grafts, 2/13 patients had interstitial fibrosis and glomerulosclerosis on biopsy and 1/13 patient died during the study. A randomly selected clinical cohort consisting primarily of stable single kidney transplant recipients was chosen for comparison.

**Results:** The median time from transplant to sample collection was 6.4 months (IQR: 2.8-10.6 months). The median dd-cfDNA fraction in DKTR was 0.25% (IQR: 0.14%-0.39%) as compared to 0.23% (IQR: 0.12%-0.45%) from a clinical cohort of 5067 samples. However, in the initial three months post transplant median dd-cfDNA fraction was significantly higher in the DKTR cohort 0.46% (IQR: 0.28%-0.89%) compared to clinical samples 0.30% (IQR: 0.16%-0.54%) ( $p = 0.002$ ). The median dd-cfDNA was similar in organs with kidney donor profile index  $\geq 85\%$  vs.  $< 85\%$ . Locally weighted scatterplot smoothing shows similar DKTR and clinical sample dd-cfDNA fraction trends, plotted against time since transplant, in Figure 1.

**Conclusions:** This preliminary analysis demonstrated that the baseline dd-cfDNA fractions in dual kidney transplants is comparable to that of single kidney transplants from standard criteria donors. Furthermore, the quality of the donor kidneys (KDPI) does not appear to affect baseline dd-cfDNA fractions. This study is limited due to the small cohort size. Future studies will be needed to validate these findings.

## FR-PO798

## Obinutuzumab-Containing Multimodality Induction in Kidney Transplantation

Evaldo Favi,<sup>1,2</sup> Maria Teresa Gandolfo,<sup>1</sup> Mariarosaria Campise,<sup>1</sup> Samuele Iesari,<sup>1</sup> Carlo Alfieri,<sup>1,2</sup> Marta Perego,<sup>1,2</sup> Giuseppe Castellano,<sup>1,2</sup> Mariano Ferraresso,<sup>1,2</sup> <sup>1</sup>Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; <sup>2</sup>Universita degli Studi di Milano, Milano, Italy.

**Background:** Hard-to-match deceased donor kidney transplant (KT) candidates can rarely benefit from desensitization programs and often arrive at transplant with elevated donor-specific antibodies (DSA) levels. In this particular setting, current

immunosuppressive strategies have been associated with exceedingly high antibody-mediated rejection (AMR) rates and poor graft survivals. We report our experience with a novel induction protocol.

**Methods:** We analysed data from 7 high-risk (PRA 95%, DSA >3000 MFI) deceased donor KT recipients who had been treated with the following scheme. One session of plasma exchange (PEX) was carried out before surgery and 3 sessions between post-op day 5 and 14. Patients received eculizumab 900 mg prior graft reperfusion. Post-op, they were given thymoglobulin 5 mg/kg total dose from day 0 to day 4, IV immunoglobulin 2 gr/kg total dose (after PEX), methylprednisolone, and obinutuzumab 1000 mg within 2 weeks of the last PEX. As maintenance, we used LCP-tacrolimus (C0, 10-15 ng/mL), mycophenolate mofetil (MMF, 2000 mg/day), and prednisone.

**Results:** After a median follow-up of 13 (3-16) months, all patients were alive with a functioning allograft and a median serum creatinine of 1.6 (1.1-2.5) mg/dL. DGF was recorded in 5 recipients. Overall, we observed one episode of cell-mediated rejection and 2 episodes of AMR rejection in 2 patients. Notably, both cases of AMR were recorded before obinutuzumab could be administered (day 7 and day 13). By week 2 after obinutuzumab infusion, all subjects showed full CD19+ cell depletion with no signs of repopulation up to the last visit. Changes in anti-HLA antibodies were extremely variable, but no de novo DSA were identified. Obinutuzumab was not associated with infusion-related adverse events. One of the patients developed severe leukopenia requiring MMF withdrawal. Asymptomatic CMV, EBV, or BKV viraemia were detected in 57%, 14%, and 0% of the recipients, respectively. No features of AMR could be detected in protocol biopsies obtained 6 months after KT.

**Conclusions:** Our experience shows that obinutuzumab induction is safe and effective in high-immunological risk KT recipients. Also, obinutuzumab-induced B-cell depletion appears to be unaffected by concomitant complement inhibition. Such encouraging findings should prompt further investigation.

## FR-PO799

### Association Between Fecal MicroRNAs and B-Glucuronidase Activity in Kidney Transplant Recipients

Guillaume C. Onyeaghala,<sup>1,2</sup> Sarah Elmer,<sup>1,2</sup> Mohammad H. Khan,<sup>2</sup> Pa Chia Yang,<sup>1</sup> Matilda Wagner,<sup>2</sup> Levi Teigen,<sup>2</sup> Baolin Wu,<sup>2</sup> Weihua Guan,<sup>2</sup> Christopher Staley,<sup>2</sup> Arthur J. Matas,<sup>2</sup> Samy M. Riad,<sup>2</sup> Casey R. Dorr,<sup>1,2</sup> Rory P. Remmel,<sup>2</sup> William S. Oetting,<sup>2</sup> Pamela A. Jacobson,<sup>2</sup> Ajay K. Israni.<sup>1,2</sup> <sup>1</sup>Hennepin Healthcare Research Institute, Minneapolis, MN; <sup>2</sup>University of Minnesota Twin Cities, Minneapolis, MN.

**Background:** The inactivated metabolite of Mycophenolate mofetil is de-glucuronidated by gut bacterial beta-glucuronidase and the active metabolite MPA is reabsorbed back into the blood. This enterohepatic recirculation likely enhances immunosuppression and toxicity in kidney transplant recipients. Further, host microRNA (miRNA) can influence the microbiome, leading to changes in b-glucuronidase levels. We hypothesized that host miRNA levels would be associated with b-glucuronidase levels in kidney transplant recipients.

**Methods:** In this analysis, 30 stool samples were collected from participants of the Microbiome and Immunosuppression in Kidney Transplantation (MISSION) study within 60 days post-transplant. Fecal miRNA was profiled using the nCounter human v3 miRNA codeset. b-glucuronidase activity levels were measured using the ab234625 Assay Kit. After QC and data normalization, we examined the association of 798 miRNA probes with b-glucuronidase activity. In a secondary analysis, we conducted focused analyses of 17 microbiome associated fecal miRNAs and their association with b-glucuronidase activity.

**Results:** At the Bonferroni corrected 0.05 significance level, we found 20 fecal miRNAs associated with b-glucuronidase activity, with miR-2116-5p, miR-4888 and miR-600 being the most abundant. In our focused analyses, we found that miR-1253, miR-1224-5p, miR-194-5p and miR-200a-3p were associated with b-glucuronidase activity (p-value < 0.05). Interestingly, miR-1224-5p was shown to align with *E. coli* DNA, while miR-1253 was shown to align with *F. nucleatum* DNA (Figure 1), which are known producers of b-glucuronidase enzymes.

**Conclusions:** Our preliminary findings show that fecal miRNAs are associated with b-glucuronidase. Further mechanistic studies are needed to validate these findings. Fecal miRNAs may enter bacteria, such as *E. coli* and *F. nucleatum* and potentially regulate bacterial growth or gene transcripts such as b-glucuronidase.

\*miRbase alignment data was adapted from Liu et al. (PMID:26764595)  
Figure 1: Alignment of microbiota-associated host miRNA-1253 and miRNA-12245p with *E. coli* and *F. nucleatum* targets.

### A Novel, Sensitive Assay for Rapid Point of Care Monitoring of Tacrolimus Level in Capillary Blood of Kidney Transplant Recipients

Kamyar Kalantar-Zadeh,<sup>1</sup> Trong Nguyen,<sup>2</sup> Maria Ortega,<sup>2</sup> Yalcin Kulahci,<sup>3</sup> Fatih Zor,<sup>3</sup> Vijay S. Gorantla,<sup>3</sup> Andrea C. Daza Aguilar,<sup>1</sup> Ekamol Tantisattamo,<sup>1</sup> Uttam G. Reddy,<sup>1</sup> Connie Rhee,<sup>1</sup> Rahul Ganguli,<sup>2</sup> <sup>1</sup>University of California, Irvine, Irvine, CA; <sup>2</sup>Intelligent Optical Systems, Inc., Torrance, CA; <sup>3</sup>Wake Forest for Regenerative Medicine, Winston-Salem, NC.

**Background:** Frequent monitoring of immunosuppression in kidney transplant recipients (KTRs) is needed to prevent allograft rejection and toxicity. This is due to the short therapeutic window and the differences in pharmacokinetics/-dynamics across KTRs. Intelligent Optical Systems (IOS) has partnered with the University of California Irvine (UCI) Nephrology and Wake Forest Institute for Regenerative Medicine to develop a novel enhanced lateral flow assay (ELFA) platform, with a point-of-care (POC) assay, to determine tacrolimus (TAC) levels from fingerstick capillary blood.

**Methods:** We performed assay validations for ELFA using spiked whole blood, and then clinical validation using whole blood from 16 KTRs. For technical validation we assessed intra-/inter-assay repeatability based on CV% across measurements of samples spiked at different TAC levels. Each sample was measured with five replicates (n=5) to obtain CV% values. We also built a standard calibration curve (SCC) with n=3 for each level of the relevant ranges to determine the TAC levels from ELFA readouts from KTR samples. ELFA TAC measurements, n=3, of capillary blood from fingerstick were compared to LC-MS measurements of venous blood collected from the same patient immediately before the KTR's next dose of TAC. Pearson correlation was used to estimate ELFA and LC-MS correlations.

**Results:** Inter-/intra-assay assessment with spiked human whole blood demonstrated good repeatability, with CV ≤ 10%. SCCs indicated the assay has good performance in the range from 0-30 ng/ml, with limit of detection of 1 ng/ml. ELFA and LCMS measurements showed strong correlation (r = 0.89) for blood samples from KTRs (figure).

**Conclusions:** The ELFA platform is a minimally invasive, convenient sampling POC device using capillary fingerstick blood, and provides accurate, rapid measurements of TAC, which demonstrate good repeatability and strong correlation against LC-MS standard reference measurements.

**Funding:** Other U.S. Government Support

## FR-PO801

### Metagenomic Detection of Clinical and Potentially Undiagnosed Infections in Kidney Transplant Recipients

Steven Kleiboeker,<sup>1</sup> Mikaela A. Miller,<sup>1</sup> Rohita Sinha,<sup>1</sup> Sookhyeon Park,<sup>2</sup> Christabel Rebello,<sup>2</sup> Bradley M. Kinsella,<sup>2</sup> John J. Friedewald.<sup>2</sup> <sup>1</sup>Eurofins Viracor Inc, Lee's Summit, MO; <sup>2</sup>Northwestern University Feinberg School of Medicine, Chicago, IL.

**Background:** Kidney transplant recipients are immunosuppressed and predisposed to infections. Current diagnostics detect single pathogens, often by qPCR. Unbiased detection of common viruses with sensitivity and specificity comparable to qPCR allows more comprehensive diagnosis or surveillance. Quantification of donor-derived cell-free DNA (dd cfDNA) is an established method for diagnosis of allograft rejection. Combining dd cfDNA and pathogen detection by sequencing (mNGS) into one test represents an opportunity to screen for both infection and rejection.

**Methods:** A total of 1,980 plasma samples from 256 CTOT-08 study subjects were tested by whole genome sequencing, with dd cfDNA analyzed as described (CJASN 16:1539). Non-human reads underwent reference-assisted assembly and taxonomic annotation using KrakenUniq (K-mers of 16, 21, and 31) trained on ~12,000 viral genomes. Final predictions were made with a majority-wins rule.

**Results:** For transplant viruses, BK virus (BKV) was most often detected (11.5% of samples), followed by cytomegalovirus (CMV, 8.3%), adenovirus (ADV, 2.6%), Epstein Barr virus (EBV, 2.6%) and JC virus (JCV, 2.0%). Concordance with qPCR results was 97.7%. Clinical infections of BKV, CMV and EBV were reported, and a total of 62 samples collected up to 60 days prior to the onset of infection were tested by mNGS (Table 1). The pathogen diagnosed clinically was detected by mNGS for 32 of 33 samples collected at infection onset to 10 days prior to onset. From 11 to 60 days prior to onset, detection ranged from 31% to 50% of samples. Additionally, 19 BKV infections >10,000 copies/mL and 10 CMV infections >1,000 IU/mL, all from different subjects, were detected by mNGS but not reported as clinical infections, suggesting under-diagnosis or lack of reporting for these viruses.

**Conclusions:** Viral detection by sequencing demonstrated sensitive and specific detection of key viral pathogens which correlated with clinical diagnoses, as well as suggested an unrecognized pathogen burden. Prospective studies will assess the clinical utility of combined metagenomic and dd cDNA analysis.

**Funding:** Commercial Support - Eurofins Viracor

Table 1. Metagenomic NGS detection of viral pathogens prior to reported clinical infection

Clinical Infection	Days prior to onset of clinical infection							
	0	1 - 10	11 - 20	21 - 30	31 - 40	41 - 50	51 - 60

Serum and Urine Uromodulin, Kidney Volume, and Function in Living Kidney Donors

Arda Erdut,<sup>1</sup> Jabrayil Jabrayilov,<sup>1</sup> Ceren Önal,<sup>1</sup> Muge Uzerk Kibar,<sup>1</sup> Tuncay Hazirolan,<sup>2</sup> Ali C. Bozaci,<sup>3</sup> Tolga Yildirim,<sup>1</sup> Bulent Altun,<sup>1</sup> Fazil T. Aki,<sup>3</sup> Mustafa Arici.<sup>1</sup> <sup>1</sup>Hacettepe University Faculty of Medicine, Department of Nephrology, Ankara, Turkey; <sup>2</sup>Hacettepe University Faculty of Medicine, Department of Radiology, Ankara, Turkey; <sup>3</sup>Hacettepe University Faculty of Medicine, Department of Urology, Ankara, Turkey.

**Background:** Uromodulin is an indicator of nephron mass and tubular function. This study has investigated the relationship between serum uromodulin (Sumod), urine uromodulin (Uumod) and remaining kidney volume and function in living kidney donors (LKD).

**Methods:** One hundred LKD (Mean age 52.46 ± 10.38, 65 women, average follow-up 63.23±56.82 months) were included in the study. Kidney volumes were assessed by preoperative abdominal computed tomography and by magnetic resonance imaging at the last clinic visit. Uromodulin levels were measured in blood and urine by uromodulin human ELISA kit.

**Results:** There was a correlation between Sumod and glomerular filtration rate (GFR) (r=0.29, P=0.006), creatinine (r=-0.25, P=0.02) and age (r=-0.36, P<0.001) (Table 1). 16 donors had chronic kidney disease (CKD) during the follow up. Sumod levels of 16 patients with CKD was lower than those without CKD (78.12±34.19 vs. 94.03±32.55 ng/ml, P=0.047). A strong correlation between Uumod and GFR was found in patients with CKD (r=0.64, P=0.007). Uumod level changed in parallel with the follow-up period (r=0.28, P=0.006). A negative correlation between Uumod and proteinuria difference was demonstrated (r=-0.32, P=0.002). The remaining kidney was found to be enlarged by 22% (Table 2). The increase in volume correlated with GFR (r=0.34, P=0.001) and follow-up time (r=0.37, P<0.001). There was no relationship among Sumod, Uumod and remaining kidney volume.

**Conclusions:** Kidney function in LKD were associated with Sumod, Uumod and remaining kidney volume. Uumod was a better indicator of kidney function in donors who developed CKD.

**Funding:** Government Support - Non-U.S.

FR-PO803

Enhanced Histological Yield and Actionable Findings When Biopsy Is Guided by Donor-Derived Cell-Free DNA (dd-cfDNA)

Matthew R. Weir,<sup>1</sup> Didier A. Mandelbrot,<sup>2</sup> Emilio D. Poggio,<sup>3</sup> Jonathan Bromberg,<sup>1</sup> Shikha Mehta,<sup>4</sup> Wenlan Tian,<sup>5</sup> Nikhil Agrawal,<sup>5</sup> Matthew Cooper.<sup>6</sup> <sup>1</sup>University of Maryland Baltimore, Baltimore, MD; <sup>2</sup>University of Wisconsin System, Madison, WI; <sup>3</sup>Cleveland Clinic, Cleveland, OH; <sup>4</sup>University of Alabama, Birmingham, AL; <sup>5</sup>CareDx Inc, Brisbane, CA; <sup>6</sup>MedStar Georgetown University Hospital, Washington, DC.

**Background:** Implementation of molecular biomarkers in kidney transplantation has expanded the amount of information available to clinicians before deciding to pursue biopsy. We evaluated how use of donor-derived cell-free DNA testing (dd-cfDNA) impacts histologic biopsy yield.

**Methods:** 1663 kidney transplant (KTx) recipients enrolled in the Kidney allograft Outcomes AlloSure Registry (KOAR, NCT03326076) were followed with dd-cfDNA post-transplant; testing was obtained either as part of a surveillance strategy or for-cause; indications for biopsy and histologic diagnoses were captured. This analysis included only for-cause biopsies.

**Results:** 65 biopsies (from 59 pts) driven by elevated dd-cfDNA levels were compared to 540 biopsies (392 pts) obtained for causes other than elevated dd-cfDNA. Patient age (55 vs 56 years), percent deceased donor (84.75% vs 78.83%), and biopsy timing post-transplant (123 vs 105.5 days) did not differ between groups. Among dd-cfDNA-guided biopsies, yield was enriched for rejection (48% vs 29%) and included fewer cases of ATN/ATN (12% vs 22%) compared to biopsies obtained for other causes (p<0.05) [Figure 1]. Among dd-cfDNA-guided biopsies with rejection (ABMR, TCMR, or Mixed), median dd-cfDNA was 1.46% (IQR: 1.15 - 2.87). Among biopsies not performed due to elevated dd-cfDNA but with paired results available (n = 267), median dd-cfDNA was 0.24%. Within this group, patients with rejection had median dd-cfDNA of 0.82% and demonstrated an increase of 133% from the preceding result.

**Conclusions:** Dd-cfDNA surveillance enhances the histologic yield for actionable results in for-cause allograft biopsies. A low dd-cfDNA result can obviate the need for biopsy even in the presence of other clinical factors that are routinely used to guide the biopsy decision.

**Funding:** Commercial Support - CareDx

FR-PO804

Elevated Donor-Derived Cell-Free DNA (dd-cfDNA) in the Early Post-Transplant Period Is Associated With an Increased Incidence of Adverse Clinical Outcomes in Kidney Transplant Recipients

David Wojciechowski,<sup>1</sup> Daniel C. Brennan,<sup>2</sup> Anil S. Paramesh,<sup>3</sup> Jeffrey A. Klein,<sup>4</sup> Nikhil Agrawal,<sup>5</sup> Mingwei Fei,<sup>5</sup> Kunbin Qu,<sup>5</sup> Puneet Sood.<sup>6</sup> <sup>1</sup>The University of Texas Southwestern Medical Center, Dallas, TX; <sup>2</sup>Johns Hopkins University School of Medicine, Baltimore, MD; <sup>3</sup>Tulane University School of Medicine, New Orleans, LA; <sup>4</sup>University of Missouri Kansas City, Kansas City, MO; <sup>5</sup>CareDx Inc, Brisbane, CA; <sup>6</sup>UPMC, Pittsburgh, PA.

**Background:** Early post-transplant elevations in dd-cfDNA, even in the absence of histologic rejection or other overt pathology, have been suggested to carry a risk of adverse outcomes among solid organ transplant recipients. We investigated this association among kidney transplant recipients enrolled in the Kidney allograft Outcomes AlloSure Registry (KOAR, NCT03326076).

**Methods:** To assess the impact of early post-transplant dd-cfDNA elevations, we evaluated the incidence of a clinical composite that included biopsy-proven rejection (BPAR), detection of de novo donor specific antibodies (dnDSA) and return to dialysis in patients with and without median dd-cfDNA >1% over the first 100 days post-transplant. Patients with events before day 100 were excluded. Univariate and multivariate analyses were performed.

**Results:** 51 of 1296 patients (3.9%) had a median dd-cfDNA  $\geq 1.0\%$  during the first 100 days post-transplant. In a univariate model, these patients had a significantly higher risk of experiencing both the composite outcome and each individual component during the first post-transplant year [Figure 1]. In a multivariate Cox proportional hazards model that included recipient age, delayed graft function, donor type (living vs deceased), and recipient sensitization, only 100-day median dd-cfDNA elevation  $\geq 1.0\%$  was a statistically significant predictor of the composite outcome, with a hazard ratio of 2.99 (95% CI: 1.59-5.61,  $p < 0.005$ ).

**Conclusions:** Our findings suggest that early post-transplant elevations in dd-cfDNA among kidney transplant recipients, even in the absence of clear immunologic or histologic correlates, identify a population of patients at risk for adverse clinical outcomes during the first post-transplant year. Molecular risk-stratification using dd-cfDNA may have implications for clinical surveillance and therapeutic management of these patients.

**Funding:** Commercial Support - CareDx

**Figure 1: Rejection, dnDSA, and Death-Censored Graft Loss after Day 100**

## FR-PO805

### Correlation of Donor-Derived Cell-Free DNA With Histology and Molecular Diagnoses of T-Cell Mediated Rejection in Kidney Transplant Biopsies

**Dhiren Kumar,**<sup>1</sup> Irfan A. Moinuddin,<sup>1</sup> Layla Kamal,<sup>1</sup> Johanna L. Christensen,<sup>1</sup> Meagan Shinbashi,<sup>1</sup> Nihar G. Raju,<sup>1</sup> Robert J. Minniti,<sup>1</sup> Philip F. Halloran,<sup>2</sup> Gaurav Gupta,<sup>1</sup> <sup>1</sup>Virginia Commonwealth University Health System, Richmond, VA; <sup>2</sup>University of Alberta, Edmonton, AB, Canada.

**Background:** We reported correlation of donor-derived cell-free DNA (dd-cfDNA) with histologic and molecular diagnosis (MMDx) of kidney transplant biopsies (Gupta et al, Transplantation 2021). Here we build on that initial cohort with a larger TCMR sample size and provide data on therapy and outcomes.

**Methods:** We identified biopsies classified as TCMR by histology and/or MMDx. Those with viral/bacterial nephritis/mixed rejection were excluded. Prior to therapy fractional dd-cfDNA (%; Allosure) was measured. 37 such biopsies were divided into two groups, H+M+ (concomitant TCMR; N=18) and H+M- (discordant TCMR; N=19).

**Results:** Median dd-cfDNA was lower ( $p=0.02$ ) in H+M- (0.32%; IQR: 0.15-0.43) compared to H+M+ group (1.03%; IQR: 0.38-1.8). In histologic findings interstitial and tubular inflammation (i+t) ( $4.8 \pm 1.5$  vs  $3.3 \pm 1.2$ ,  $p=0.002$ ) was worse for H+M+ vs H+M-. A graded dose-response was seen between i+t and dd-cfDNA for H+M+ and not seen in H+M- (Figure 1a). Borderline/1A TCMR was seen frequently in the H+M- (16/19, 84%) while TCMR  $\geq 1B$  was seen in the H+M+ group (12/18, 67%). MMDx scores for TCMR ( $0.50 \pm 0.29$  vs  $0.02 \pm 0.02$ ,  $p<0.0001$ ) and inflammation ( $4.6 \pm 2.1$  vs  $-0.55 \pm 1.5$ ,  $p<0.0001$ ) were higher in the H+M+ vs H+M- group. eGFR at biopsy was worse in the H+M+ group ( $27 \pm 19$ ml/min) compared to the H+M- ( $40 \pm 23$ ml/min;  $p=0.06$ ). A majority of H+M+ were treated (16/18; 89%; 14 rATG and 2 steroids only) and a minority of H+M- received steroids only (7/19; 37%). Despite this discrepancy, there was improvement in eGFR in both groups. At median follow-up of 14.7 months eGFR improved to  $34 \pm 24$ ml/min in the H+M+ and  $49.2 \pm 26$ ml/min in the H+M- group (Figure 1b). All 4 graft losses and one patient death was in the H+M+ group ( $p=0.02$ ).

**Conclusions:** We confirm our findings in patients with histologic TCMR absent on molecular gene expression is associated with low dd-cfDNA. Majority of patients had improvement in kidney function without targeted therapy. This may indicate low-grade TCMR is a 'response to wounding', rather than cognate allo-recognition.

## FR-PO806

### Predictors of Kidney Delayed Graft Function and Its Prognostic Impact Following Combined Liver-Kidney Transplantation

**Paolo Vincenzi,**<sup>1,2</sup> Jeffrey J. Gaynor,<sup>1</sup> Gaetano Ciancio,<sup>1</sup> Miami Transplant Institute <sup>1</sup>Miami Transplant Institute, Miami, FL; <sup>2</sup>ASUR Area Vasta 1 Pesaro Fano Urbino, Pesaro, Italy.

**Background:** Combined liver-kidney transplantation (CLKT) improves patient survival among liver transplant recipients with renal dysfunction. However, kidney delayed graft function (KDGF) still represents a common and challenging complication that can negatively impact clinical outcomes. This retrospective study analyzed the incidence, potential risk factors, and prognostic impact of KDGF development following CLKT in a recently transplanted cohort.

**Methods:** 115 consecutive CLKT recipients who were transplanted at our center between January 2015 and February 2021 were studied. All transplanted kidneys received hypothermic pulsatile machine perfusion (HPMP) prior to transplant. The primary outcome was KDGF development. Secondary outcomes included the combined incidence and severity of developing postoperative complications, development of postoperative infections, biopsy-proven acute rejection (BPAR), renal function at 1, 3, 6, and 12 months post-transplant, and death-censored graft and patient survival.

**Results:** KDGF was observed in 37.4% (43/115) of patients. Multivariable analysis of KDGF revealed the following independent predictors: preoperative dialysis ( $P=0.0003$ ), lower recipient BMI ( $P=0.006$ ), older donor age ( $P=.003$ ), utilization of DCD donors ( $P=0.007$ ), and longer delay of kidney transplantation after liver transplantation ( $P=0.0003$ ). With a median follow-up of 36.7 months post-transplant, KDGF was associated with a significantly increased risk of developing more severe postoperative complication(s) ( $P<0.000001$ ), poorer renal function ( $P<0.000001$ ), and worse death-censored graft ( $P=.00004$ ) and patient survival ( $P=.0002$ ).

**Conclusions:** KDGF may be responsible for remarkable negative effects on immediate and potentially longer-term clinical outcomes after CLKT. Understanding the important risk factors for KDGF development in CLKT may better guide recipient and donor selection(s) and improve clinical decisions in this increasing group of transplant recipients.

## FR-PO807

### Safety of Sodium-Glucose Cotransporter 2 Inhibitors and Glucagon-Like Peptide-1 Receptor Agonists in Diabetic Kidney Transplant Recipients

**Tarek S. Mahmoud,**<sup>1,2</sup> Jude A. Yagan,<sup>1,2</sup> Amal Hasan,<sup>3</sup> Osama Gheith,<sup>1</sup> Mohamed M. Mostafa,<sup>1</sup> Suzann Rida,<sup>1</sup> Mohamed Shaker,<sup>1</sup> Mahmoud M. Abdrabou,<sup>1</sup> <sup>1</sup>Hamed Al-Essa Transplant Center, Kuwait City, Kuwait; <sup>2</sup>Jaber Al Ahmed Armed Forces Hospital, Kuwait, Kuwait; <sup>3</sup>Dasman Diabetes Institute, Kuwait City, Kuwait.

**Background:** Kidney transplant recipients (KTRs) with type 2 diabetes (T2D) have poorer cardiovascular and renal outcomes. The favorable impact of the new glucose lowering therapies like sodium-glucose cotransporter 2 inhibitors (SGLT2i) and Glucagon-like peptide-1 receptor agonists (GLP-1RA) on patients with T2D is clearly evident now based on the recent outcome trials. However, there is inertia in using these drugs for KTRs due to the fear of their side effects and the absence of clear guidelines. We retrospectively assessed the efficacy, safety and short-term outcomes of these drugs.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Methods:** We collected one year follow up data from records of 98 diabetic KTRs who received SGLT2i and 41 who received GLP-1RA in addition to standard of care therapy (SOC) for at least 3 months. We compared them to 70 diabetic KTRs who were on only SOC. Patients were over 3 months post-transplant with minimum estimated glomerular filtration rate (eGFR) of 25 ml/min/1.73m<sup>2</sup>. No significant difference in the demographics between the groups except for a lowish HbA1c in the control group (8.0% versus 7.2%)

**Results:** HbA1c dropped by 0.4% in SGLT2i (p=0.0001) and GLP-1RA (p=0.0003) compared to only 0.05% in the control group. BMI decreased by 0.32 (p=0.0450) in SGLT2i and 0.34 (p=0.0105) in GLP-1RA compared to an increase by 0.015 in control group. There was a tendency for better eGFR by the end of the year in both study groups (figure 1) though it was not statistically significant except for KTRs on SGLT2i with eGFR more than 90 ml/min (p=0.0135). A dip in eGFR was observed in SGLT2i group at 1 and 3 months. Albuminuria was significantly reduced at 12 months in SGLT2i by a median of 28 mg/mmol (p=0.0095) and by 20 mg/mmol in GLP-1RA (p=0.0072) compared to increase by 3.4 mg/mmol in control group (figure 2). Adverse events were minimal.

**Conclusions:** Use of SGLT2i and GLP-1RA appears to be safe in diabetic KTRs with good outcome. Randomized control trials are required to confirm these findings and establish guidelines.

FR-PO808

**Measured Glomerular Filtration Rate Compared to Creatinine and Cystatin C Estimating Equations in Predicting Graft Failure, Cardiovascular Events, and Death in Kidney Transplant (KTx) Recipients**  
Mira T. Keddis, Matthew Howard, Nan Zhang, Richard J. Butterfield, Andrew D. Rule. Mayo Foundation for Medical Education and Research, Scottsdale, AZ.

**Background:** We compared CysC eGFR, Cr eGFR, Cr-CysC eGFR and measured GFR in predicting graft failure, cardiovascular (CV) events, and death in a cohort of KTx recipients.

**Methods:** Consecutive adults that received a KTx between 2011-2013 at a single center were evaluated. CysC eGFR, Cr eGFR, Cr-CysC eGFR, and mGFR by urinary iothalamate clearance were obtained at the same time at least 1 year after KTx. The risk of graft failure or of CV events or death with eGFR was assessed after adjusting for mGFR, and for risk factors (recipient age, diabetes, serum albumin, hemoglobin, deceased donor transplant, 24-hour urine protein, and history of CV events).

**Results:** There were 1148 recipients: mean age 56.0 years, 56% male, 35% with diabetes, 94% with hypertension, 11% with prior history of CV events, 53% required dialysis, and 76% received living donor KTx. After a median follow-up of 74 months, there were 203(18%) graft failures, 229(20%) deaths, and 290(25%) CV events. Graft failure and CV events or death were predicted by lower GFR by any method (Figure 1). After adjusting for mGFR, CysC eGFR and Cr-CysC eGFR but not Cr eGFR were predictive of graft failure. After adjusting for risk factors, CysC eGFR and Cr-CysC eGFR remained predictive of graft failure. After adjusting for mGFR, CysC eGFR and Cr-CysC eGFR but not Cr eGFR were predictive of CV events or death. After further adjusting for risk factors, CysC and Cr-CysC eGFR no longer predicted CV events or death.

**Conclusions:** In KTx recipients, Cr eGFR predicts clinical outcomes via the same pathway as mGFR, whereas CysC eGFR and Cr-CysC eGFR predict these same outcomes via both GFR and non-GFR pathways. The risk of CV events or death via the non-GFR biology of CysC appears to be via the same pathway as risk factors for CV disease. These findings do not support the routine use of CysC based eGFR in KTx recipients due to its non-GFR biology that distorts the prediction outcomes.

GFR method and prediction of graft failure (per-10ml/min/1.73m <sup>2</sup> )	Unadjusted HR (95% CI), p-value	Adjusted for mGFR alone	Adjusted for mGFR and risk factors *
mGFR	1.53 (1.46, 1.60), p<0.001	-	-
Cr eGFR	1.49 (1.37, 1.62), p<0.001	1.37 (0.98, 1.90), p=0.035	1.11 (0.90, 1.33), p=0.260
CysC eGFR	1.76 (1.63, 1.90), p<0.001	1.50 (1.32, 1.72), p<0.001	1.33 (1.13, 1.57), p<0.001

FR-PO809

**Malignancy Risk in Kidney Transplant Recipients Exposed to Immunosuppression Pre-Transplant for the Treatment of Glomerulonephritis**  
David Massicotte-Azarniouch,<sup>1,2</sup> Randal K. Detwiler,<sup>2</sup> Yichun Hu,<sup>2</sup> Ronald Falk,<sup>2</sup> Manish K. Saha,<sup>2</sup> Susan L. Hogan,<sup>2</sup> Vimal K. Derebail.<sup>2</sup>  
<sup>1</sup>University of Ottawa, Ottawa, ON, Canada; <sup>2</sup>University of North Carolina System, Chapel Hill, NC.

**Background:** Kidney transplant patients with glomerulonephritis (GN) as their native disease may be exposed to significant amounts of pre-transplant immunosuppression (PTI), which could increase the risk for the development of malignancy post-transplant.

**Methods:** We conducted a single-center, retrospective study of adult and pediatric kidney transplant recipients at University of North Carolina Hospitals from January 2005 until May 2020. Patients with GN as their native kidney disease who received PTI for the treatment of GN (n=184) were compared to a control cohort (n=579) of non-diabetic, non-PTI receiving kidney transplant patients. We calculated hazard ratios (HR) with 95% confidence intervals (95%CI) for the outcomes of the first occurrence of solid or hematologic malignancy, non-melanoma skin cancer (NMSC) and post-transplant lymphoproliferative disorder (PTLD).

**Results:** Over a median follow-up of 5.7 years, PTI for GN was associated with significantly increased risk for malignancy compared to controls (13.0% vs 9.7% respectively, adjusted HR 1.82 [95%CI 1.10-3.00]), but not for NMSC (10.3% vs 11.4% respectively, adjusted HR 1.09 [95%CI 0.64-1.83]) nor PTLD (3.3% vs 3.1% respectively, adjusted HR 1.02 [95%CI 0.40-2.61]). The risk for malignancy was significantly increased in those who received cyclophosphamide (HR 2.59 [95%CI 1.48-4.55]) or rituximab (HR 3.82 [95%CI 1.69-8.65]) pre-transplant, and particularly in those who received both cyclophosphamide and rituximab, but not for calcineurin inhibitors nor mycophenolate.

**Conclusions:** The use of PTI for treatment of GN, in particular cyclophosphamide or rituximab, is associated with increased risk for development of solid or hematologic malignancy post-transplant.

FR-PO810

**Urinary Copper Excretion Is Associated With Graft Failure in Kidney Transplant Recipients**  
Manuela Yepes Calderon,<sup>1</sup> Daan Kremer,<sup>1</sup> Tim J. Knobbe,<sup>1</sup> Kai Luersen,<sup>2</sup> Michele F. Eisenga,<sup>1</sup> Martin H. De Borst,<sup>1</sup> Gerjan Navis,<sup>1</sup> Gerald Rimbach,<sup>2</sup> Stephan J. Bakker.<sup>1</sup> TransplantLines Investigators <sup>1</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>2</sup>Christian-Albrechts-Universität zu Kiel Institut für Humanernährung und Lebensmittelkunde, Kiel, Germany.

**Background:** Urinary copper (Cu) excretion increases with the development of proteinuria due to an increase in excretion of Cu carries. This Cu overload is proposed to enhance nephropathy through tubular damage. We aimed to assess whether in kidney transplant recipients (KTR) proteinuria is associated with urinary Cu excretion. Furthermore, if urinary Cu excretion is associated with the biomarker of tubular damage urinary liver-type fatty acid-binding protein (u-LFABP) and with graft failure development.

**Methods:** In this prospective cohort study, KTR with a functioning allograft ≥1 year were recruited. Urinary Cu was measured in 24-hours urine samples by coupled plasma mass spectrometry. Multivariable linear regression and Cox regression analyses were performed.

**Results:** In 693 KTR (57% men, 53 ± 13 years old), baseline Cu excretion was 23.57 [Interquartile range (IQR) 11.32–15.87] µg. Cu was directly associated with proteinuria (Std β 0.45, P<0.001) independent of graft function and with u-LFABP (Std β 0.34, P<0.001) independent of proteinuria. During a median follow-up of 5.3 years, 83 (12%) KTR developed GF. Being on the third tertile of urinary Cu excretion was associated with an increased risk of GF (HR 2.94 [95% CI 1.34–6.45]; P < 0.001) independent of adjustment by multiple potential confounders. u-LFABP significantly mediated this association accounting for 46% of the total effect.

**Conclusions:** We concluded that in KTR proteinuria is associated with increased Cu excretion and this is further associated with the risk of graft failure apparently by enhancing tubular damage. Further studies seem warranted to elucidate whether Cu-targeted interventions may decrease the burden of GF in KTR.

**Funding:** Government Support - Non-U.S.

	Tertile 1	Tertile 2	Tertile 3	
Number of events	10	26	47	
Cox Regression	Reference	Hazard ratio (95%CI)	P	Hazard ratio (95%CI) P
Crude	Reference	2.62 (1.26-5.43)	0.01	5.07 (2.56-10.04) <0.001
Model 1	Reference	1.89 (0.86-4.14)	0.11	2.94 (1.34-6.45) 0.007
Model 2	Reference	1.85 (0.83-4.11)	0.13	3.19 (1.44-7.06) 0.004
Model 3	Reference	2.18 (0.99-4.80)	0.05	3.45 (1.57-7.58) 0.002

**Urinary Copper excretion and graft failure.** Model 1: adjustment for age, sex, eGFR, proteinuria, 24-hours urinary volume, and u-LFABP. Model 2: Model 1 + pre-emptive transplantation, transplant vintage, donor type, donor age, donor sex, and HLA mismatch. Model 3: Model 1 + prednisolone cumulative dose, use of calcineurin inhibitors and proliferation inhibitors, and acute rejection treatment.

## FR-PO811

**One Year Outcome of SGLT2 Inhibitors Amongst Diabetic Kidney Transplant Recipients**

Chelsey Song, Andrew Brown, Ryan Winstead, Sara Sterling, Johanna L. Christensen, Idris Yakubu, Gaurav Gupta. *Virginia Commonwealth University, Richmond, VA.*

**Background:** The use of Sodium Glucose Linked Transporter Inhibitors (SGLT-2i) among non-transplant diabetic patients with chronic kidney disease (CKD) have demonstrated reduced cardiovascular mortality and delayed CKD progression. As more published data has validated the early safety outcomes of SGLT-2i, there is currently a lack of evidence on the long term renal benefits amongst kidney transplant (KT) recipients and its impact on kidney function, and metabolic outcomes. We aimed to bridge this knowledge gap and report our 12 months experience with SGLT-2i at our center.

**Methods:** This was a single center, retrospective study conducted in adult KT recipients who met SGLT-2i initiation criteria at our center. Patients were eligible if they had type II diabetes (pre-existing or new onset post-transplant); no AKI  $\leq 30$  days prior to drug initiation; and an estimated glomerular filtration rate (eGFR)  $> 25$  mL/min. Primary outcomes were changes in weight, hemoglobin A1C (HbA1C), and eGFR. Secondary outcomes included rates of treated urinary tract infections (UTIs), diabetic ketoacidosis (DKA), amputations, and sever. Choice of the specific SGLT-2i agent was based upon insurance preference.

**Results:** 123 patients met enrollment criteria. The median time to initiation from transplant was 250 days (IQR 88-887). The mean change in eGFR from the time of initiation to 6 and 12 months of therapy was 2.95 mL/min [(SD:14.8,  $p=0.04$ (CI:0.19,5.72)] and 4.09 mL/min [(SD:17.7,  $p=0.02$ (CI: 0.60,7.57))]. There were also significant improvement in weight by -1.35 kg [(SD 3.27,  $p=0.001$ (CI:-0.75, -1.96))] over the course of 12 months. Mean change in HbA1c was 0.05 [(SD 1.72,  $p=0.759$ (CI: -0.28, 0.39))]. Of those, 112 (91%) received empagliflozin, 2 (2%) canagliflozin, and 9 (7%) dapagliflozin. Overall 1 patient had euglycemic DKA, and 18 (15%) experienced UTI, none of the patients experienced amputations or hospitalizations due drug induced AKI.

**Conclusions:** Amongst diabetic KT patients, we found that patients who were treated SGLT-2i had statistically significant improvement in eGFR at 6 and 12 months. The risk of adverse events with SGLT-2i initiation post-kidney transplant were comparable with previously published data and confer a trend towards both improvement in renal function and metabolic profile.

## FR-PO812

**Clinical Significance of Incident Osteoporotic Fractures After Kidney Transplantation: A Nationwide Matched Comparative Cohort Study**

Yunyoung Jang,<sup>1</sup> Ji Eun Kim,<sup>2</sup> Jina Park,<sup>3</sup> Sehoon Park,<sup>4</sup> Yong Chul Kim,<sup>1</sup> Kwon Wook Joo,<sup>1</sup> Hajeong Lee.<sup>1</sup> <sup>1</sup>*Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea;* <sup>2</sup>*Korea University Guro Hospital, Seoul, Republic of Korea;* <sup>3</sup>*Biomedical Research Institute of Seoul National University Hospital, Seoul, Republic of Korea;* <sup>4</sup>*Seoul National University College of Medicine, Seoul, Republic of Korea.*

**Background:** Osteoporotic fracture is one of the main concerns of kidney transplantation recipients (KTR) due to mineral bone disorders and the use of immunosuppressive agents including glucocorticoid, although its incidence and clinical significance remains unclear.

**Methods:** We constructed a nationwide cohort consisting of 141,674 end-stage kidney disease patients from 2008 to 2020 using the National Health Insurance System database of Korea. We excluded patients experiencing parathyroidectomy and previous osteoporotic fracture or taking osteoporosis-treating medication. Then, we compared osteoporotic fracture incidence between KTRs and 1:1-matched dialysis patients. Osteoporotic fractures are defined as fractures associated with low bone mineral density including hip, spine, forearm, and humerus. After the comparison, we explored the effect of incident osteoporotic fracture after kidney transplantation on death and death-censored graft failure using fracture status as a time-varying covariate in an extended Cox model.

**Results:** After exclusion, 53964 dialysis patients and 12297 KTRs were included and their new-onset osteoporotic fracture was 8.0% of dialysis patients and 5.0% of KTRs, respectively. After matching, both groups showed similar incidence of osteoporotic fracture with 5.2% of dialysis patients and 5.6% of KTRs, respectively. During overall 5.7  $\pm$  3.0 years of follow up, KTRs showed a lower risk for the incident osteoporotic fracture than matched dialysis controls (adjusted hazard ratio [aHR] 0.83, 95% CI 0.73-0.94,  $p = 0.04$ ). Among osteoporotic fracture sites, the hip was significantly lower (aHR 0.43, 95% CI 0.33-0.57,  $p < 0.001$ ) in KTRs, although the other sites were not. Among KTRs, the incident osteoporotic fracture was associated with an elevated risk of mortality (aHR 2.07, 95% CI: 1.54-2.78,  $p < 0.001$ ), but not with death censored graft failure (aHR 1.29, 95% CI: 0.96-1.72,  $p = 0.087$ )

**Conclusions:** Incident osteoporotic fracture risk was significantly lower in KTRs than in patients remaining in dialysis. However, once it occurred in KTRs, it was associated with a higher mortality risk than in KTRs without experience of it.

## FR-PO813

**The Application of Artificial Intelligence in IgA Nephropathy After Kidney Transplantation**

Xumeng Liu,<sup>1,2</sup> Qunjuan Lei,<sup>3,2</sup> Xiaoshuai Hou,<sup>4</sup> Dongmei Liang,<sup>1,2</sup> Feng Xu,<sup>2</sup> Shaoshan Liang,<sup>2</sup> Dandan Liang,<sup>2</sup> Fan Yang,<sup>2</sup> Yuan Ni,<sup>4</sup> Guotong Xie,<sup>4</sup> Cai-hong Zeng,<sup>2</sup> <sup>1</sup>*Nanjing University, Nanjing, China;* <sup>2</sup>*Nanjing General Hospital of Nanjing Military Command Research Institute of Nephrology, Nanjing, China;* <sup>3</sup>*Southern Medical University, Guangzhou, China;* <sup>4</sup>*Ping An Healthcare Technology, Shanghai, China.*

**Background:** A convolutional neural network named Analytic Renal Pathology System (ARPS) was trained to identify glomerular lesions in immunoglobulin A nephropathy (IgAN). However, whether ARPS can be applied to renal graft biopsy is still unknown. This study aimed to analyze the application of ARPS in transplant patients with IgAN.

**Methods:** From January 2016 to April 2020, patients diagnosed as IgAN by renal graft biopsy in our center were collected. The performance of ARPS in transplant patients with IgAN was evaluated. The correlation of clinicopathologic data were further analyzed.

**Results:** A total of 57 patients were enrolled. The median (interquartile range: IQR) age at renal biopsy was 32 (28, 40) years. ARPS could identify the types of glomerular lesions and intrinsic cells in transplant patients with IgAN, achieving F1-scores for different lesions ranged between 72.40% and 96.05%. The ratio of mesangial cells (M), endothelial cells (E), and podocytes (P) was 0.37:0.39:0.25. Compared with autologous IgAN patients (0.41:0.36:0.23), the percentage of E was higher in transplant patients with IgAN. Urine protein level was negatively correlated with the number of P ( $p < 0.05$ ), but positively correlated with mesangial area ( $p < 0.05$ ). Serum creatinine level was negatively correlated with the number of E ( $p < 0.05$ ). The course of disease after transplantation was positively correlated with the glomerular and mesangial area ( $p < 0.05$ ). According to the results of receiver operating characteristic curve, the lower number of E or P, and higher percent segmental sclerosis (SS) or glomerular sclerosis (GS) could indicate poorer prognosis, with all the area under curve of them greater than 0.7 ( $p < 0.05$ ).

**Conclusions:** ARPS can automatically identify and quantify the types of glomerular lesions and intrinsic cells in transplant patients with IgAN. The ARPS quantified glomerular lesions and intrinsic cells correlated well with key clinical indicators and the prognosis of transplant patients with IgAN.

**Funding:** Government Support - Non-U.S.

## FR-PO814

**Associations of Social Determinants of Health With SGLT2 Inhibitor Use in Kidney Transplant Recipients: A National Study**

Krista L. Lentine,<sup>1</sup> Kana N. Miyata,<sup>1</sup> Yasar Caliskan,<sup>1</sup> Nagaraju Sarabu,<sup>2</sup> Sandeep Singh Dhindsa Dhindsa,<sup>1</sup> David Axelrod,<sup>3</sup> Huiling Xiao,<sup>1</sup> Mara McAdams-DeMarco,<sup>4</sup> Sunjae Bae,<sup>4</sup> Gregory Hess,<sup>5</sup> Corey Joseph,<sup>6</sup> Daniel C. Brennan,<sup>6</sup> Mark Schnitzler.<sup>1</sup> <sup>1</sup>*Saint Louis University School of Medicine, Saint Louis, MO;* <sup>2</sup>*University Hospitals, Cleveland, OH;* <sup>3</sup>*University of Iowa, Iowa City, IA;* <sup>4</sup>*New York University, New York, NY;* <sup>5</sup>*Thomas Jefferson University, Philadelphia, PA;* <sup>6</sup>*Johns Hopkins University, Baltimore, MD.*

**Background:** Recent clinical trials demonstrate benefits of SGLT2 inhibitors (SGLT2i) in patients with chronic kidney disease, but data on SGLT2i use in kidney transplant (KTx) recipients are limited.

**Methods:** We examined a novel database linking SRTR registry data for KTx recipients (2000-2021) with outpatient fill records from a large pharmaceutical claims warehouse (2015-2021). Adult (age  $\geq 18$ ) KTx recipients treated with SGLT2i were compared to those who received other non-insulin diabetes medications without SGLT2i. Characteristics associated with SGLT2i use were quantified by multivariable logistic regression (adjusted odds ratio, aOR).

**Results:** Among 18,988 KTx recipient treated with non-insulin diabetes agents in the study period, 2,224 filled an SGLT2i. Mean time from KTx to SGLT2i prescription was 6.7 yrs. vs.4.7 yrs. to first captured non-SGLT2i fill. SGLT2i use was more common in adults who were age  $> 30$  (compared to age 18-30 yrs.), Asian (aOR, 1.3), or had BMI  $\geq 30$  (aOR, 1.24), and trended higher with self-pay status (aOR, 1.52). SGLT2i use was lower in patients who were women (aOR, 0.88), Black (aOR, 0.88), other race (aOR, 0.75), publicly insured (aOR, 0.92), or had less than college education (aOR, 0.87). SGLT2i use in KTx patients increased dramatically in 2019-2021 (aOR, 5.64 vs prior yrs). [Figure]

**Conclusions:** SGLT2i use is increasing in KTx recipients, but varies with factors including race, education and insurance. While ongoing study is needed to define risks and benefits of SGLT2i use in KTx patients, attention should also focus on reducing treatment disparities related to social determinants of health rather than clinical indications.

## FR-PO815

## Deep Learning-Based Instance Medullary Pyramid Segmentation in Routine CT Examinations

Adriana Gregory, Amr Moustafa, Bhavya Poudyal, Aleksandar Denic, Andrew D. Rule, Timothy L. Kline. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

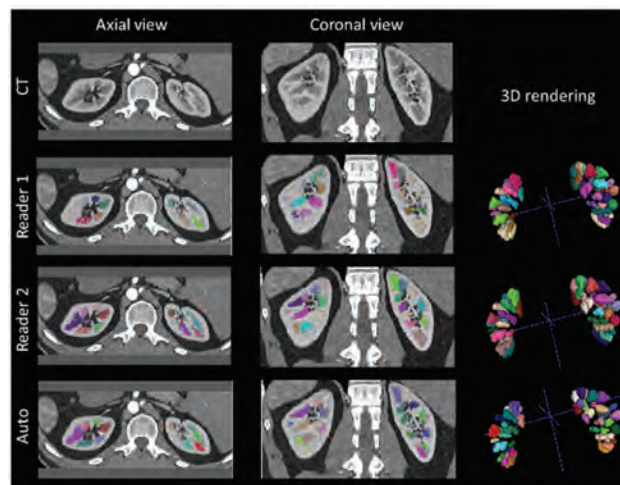

**Background:** The kidney accounted for ~60% of the total transplanted organs in the U.S. in 2021. We recently demonstrated that smaller medullary volume predicted allograft loss independent of donor's and recipient's characteristics. In addition, the number of medullary pyramids has been suggested as a surrogate for nephron endowment, but manual quantification of pyramids is time consuming. Therefore, we developed the first fully automated approach for segmenting and differentiating individual medullary pyramids from angiogram-phase CTs.

**Methods:** Contrast-enhanced axial abdominal CTs were collected from 178 predonation living kidney donors. CTs from 158 subjects were used to train and validate a deep learning model that could automatically segment medullary pyramid edges and cores. 20 CT images were held out for testing. The nnU-Net framework was used to train a 5-fold cross validation ensemble model. Manual segmentations from two independent readers were used to establish interobserver variability. We used the Dice score to evaluate the segmentation similarity and Bland-Altman analysis to estimate the bias in pyramid count and volume with the reference.

**Results:** The test set interobserver Dice score was 0.93. The automated method had a Dice score of 0.82 compared to the first reader and 0.81 compared to the second reader. The predicted medullary pyramid count and average pyramid volume bias±sd with the reference standard was 2±5 pyramids and -0.02±0.3 ml, respectively.

**Conclusions:** A fully automated instance medullary pyramid segmentation method was developed and tested for healthy kidney CT scans. This approach unlocks the potential of medullary size and count as a kidney biomarker. Further work needs to determine whether size and number of medullary pyramids relates to nephron size and number and associates with kidney disease risk factors and outcomes.

**Funding:** NIDDK Support

**Figure.** Example case. The colors show the difference between adjacent pyramids and are assigned arbitrarily.

## FR-PO817

## Effectiveness of Metformin in Kidney Transplant Recipients With Post-Transplantation Diabetes Mellitus

Dongyeon Lee,<sup>1</sup> Jiyun Jung,<sup>2,3</sup> Jangwook Lee,<sup>3,4</sup> Sung Joon Shin,<sup>3,4</sup> Sichan Kim,<sup>1</sup> Chung Hee Baek,<sup>1</sup> Su-Kil Park,<sup>1</sup> Jae Yoon Park,<sup>3,4</sup> Hyosang Kim.<sup>1</sup>  
<sup>1</sup>Asan Medical Center, Songpa-gu, Seoul, Republic of Korea; <sup>2</sup>Data management and Statistics Institute, Dongguk University Ilsan Hospital, Goyang, Gyeonggi, Republic of Korea; <sup>3</sup>Research Center for Chronic Disease and Environmental Medicine, Dongguk University College of Medicine, Goyang, Gyeonggi, Republic of Korea; <sup>4</sup>Dongguk University Medical Center, Goyang, Gyeonggi, Republic of Korea.

**Background:** Post-transplantation diabetes mellitus (PTDM) is an important risk factor for cardiovascular disease and mortality. We aimed to determine the influence of metformin on cardiovascular and graft outcome in PTDM.

**Methods:** We included 618 kidney transplant recipients with new-onset PTDM in Asan Medical Center and Dongguk University Ilsan Hospital between 2000 and 2018. PTDM was defined as maintained hypoglycemic treatment, three months or more after transplantation. We conducted the propensity score matching (PSM) in metformin and non-metformin group by estimated Glomerular Filtration Rate (eGFR), sex, age, body mass index, and immunosuppressive agents. Cox proportional hazard models were also conducted to estimate the effects of the metformin usage compared to non-metformin on percutaneous coronary intervention (PCI), major adverse cardiovascular events (MACE), acute rejection (AR), and graft failure (GF).

**Results:** Before matching, 406 patients (66%) prescribed metformin, and the average eGFR (59.8 mL/min/1.73m<sup>2</sup>) and HbA1c (7.5%) in metformin group was higher than non-metformin group (53.3 mL/min/1.73m<sup>2</sup> for eGFR; 7.2 % for HbA1c). After 1:1 matching in PSM, no group differences in eGFR and HbA1c were observed. In Kaplan-Meier plot, metformin usage was associated with higher survival probability on PCI (p=0.01) and GF (p=0.03). In Cox proportional hazard model, metformin usage was associated with lower risk of PCI (hazard ratio [HR]: 0.31; 95% confidence interval [CI]: 0.11–0.86; p=0.02). In addition, compared with the non-metformin group, the HR of the long-term use of metformin (≥1664 days, median value) was 0.21 (95% CI 0.06–0.70; p=0.01).

**Conclusions:** This study demonstrates that the use of metformin was associated with a decreased risk of coronary artery disease in kidney transplant recipients with PTDM. Metformin would be considered as one of feasible treatment options for PTDM.

## FR-PO818

# Transition of Metabolic Dysfunction After Kidney Transplantation and Its Association With Transplant Outcomes: A Nationwide Prospective Cohort Study

Yu ho Lee,<sup>1</sup> So-young Lee,<sup>1</sup> Jin sug Kim,<sup>2</sup> Kyung hwan Jeong,<sup>2</sup> Hyeon Seok Hwang,<sup>2</sup> <sup>1</sup>CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; <sup>2</sup>Kyung Hee University Medical Center, Dongdaemun-gu, Seoul, Republic of Korea.

**Background:** Metabolic dysfunction (MD) is prevalent disorder in patients with end-stage kidney disease and kidney transplantation is expected to modify the metabolic status. However, it remains unclear whether the transition of metabolic status before and after transplantation affects the transplant outcomes.

**Methods:** We analyzed 4187 kidney transplant recipients registered in a nationwide prospective cohort from 2014 to 2020. MD was considered, if  $\geq 3$  conditions are met (body mass index, blood pressure, fasting blood glucose, triglyceride, and high-density lipoprotein cholesterol level). Patients were categorized into four groups based on the presence of MD at pre-transplant and one-year post-transplant. The primary outcome was the occurrence of death-censored graft failure and patient death.

**Results:** Prevalence of pre- and post-transplant MD was 49.0% and 40.1%, respectively. Among recipients without pre-transplant MD, 19.6% (419/2135) developed MD at one-year post-transplantation. By contrast, MD disappeared in 38.7% (794/2052) of the recipients with pre-transplant MD. The cumulative event rate of composite of graft failure and patient death was significantly higher in both recipients with newly developed post-transplant MD and recipients with persistent MD ( $p < 0.001$ ). Compared to recipients without pre- and post-transplant MD, those with newly developed post-transplant MD showed an increased risk of graft failure (adjusted hazard ratio [HR] 2.41, 95% confidence interval [CI] 1.17-4.98) and those with persistent MD had higher risk of patient death (adjusted HR = 2.51, 95% CI 1.12-5.63). The risk of composite event was increased as more metabolic components was converted to be dysfunctional after transplantation. An analysis of each component of MD showed that a normalization of blood pressure after transplantation led to a decrease in the risk of composite event.

**Conclusions:** Kidney transplantation significantly affects the metabolic status in patients with end-stage kidney disease. Newly developed post-transplant MD increases the risk of graft loss and persistent post-transplant MD adversely affects patient survival, suggesting that transition of metabolic status was significantly associated with kidney transplant outcomes.

**Funding:** Government Support - Non-U.S.

## FR-PO819

# Effect of Delayed Graft Function on Early Pancreatic Graft Failure in Simultaneous Pancreas-Kidney Transplant Recipients

Ahmed Daoud,<sup>1,2</sup> Zemin Su,<sup>1</sup> Genta Uehara,<sup>1</sup> Karim M. Soliman,<sup>1</sup> Maria Aurora C. Posadas,<sup>1</sup> David J. Taber,<sup>1</sup> Derek Dubay,<sup>1</sup> Michael Casey,<sup>1</sup> <sup>1</sup>Medical University of South Carolina, Charleston, SC; <sup>2</sup>Cairo University Medical School, Cairo, Egypt.

**Background:** A recent single center study suggests kidney DGF may be a risk factor for early pancreas graft failure in simultaneous pancreas-kidney transplants (SPK). We explore whether kidney DGF continues to be a risk factor for early pancreas graft failure in a national database study.

**Methods:** We analyzed the SRTT database for all adult SPK recipients from 2000-2018. Our primary outcome was pancreas graft failure  $\leq 90$  days. We determined the association between kidney DGF and pancreatic graft failure. We adjusted for recipient age, gender, race, PRA, HLA mismatch, transplant era, and pretransplant dialysis, as well as donor age, gender, race & donation after cardiac death.

**Results:** 15512 adult SPK recipients were identified with 1258 (8.1%) with kidney DGF. 90-day pancreas transplant survival with and without kidney DGF was 81.8% and 92.4% (Figure 1). After adjusting for covariates, kidney DGF was associated with a higher risk of early pancreas loss versus non-DGF (HR 2.457, 95% CI 2.121-2.846,  $p < 0.0001$ ). Other risk factors for early pancreas loss include female recipient, obesity, peak PRA 80-100%, & donor age. Pretransplant dialysis and transplants after 2009 were associated with a lower risk of early pancreas failure (Table 1).

**Conclusions:** Our study suggests that kidney DGF may be a major risk factor for early pancreas graft failure in SPK recipients. Future studies are still needed.

Cox regression for time to Pancreas Graft Loss within 90 days after transplant

Variable	HR	95%CI	P-value
Kidney DGF	2.457	2.121-2.846	<0.0001

# Differences in Outcomes Between High Dose and Low Dose Belatacept Conversion on Allograft Function in Kidney Transplant Patients

Hay Me Me, Pooja Budhiraja, Lavanya Kodali, Sumi Sukumaran Nair. Mayo Clinic Arizona, Scottsdale, AZ.

**Background:** Belatacept, a selective costimulation T cell blocker is used to avoid unwanted side effects from calcineurin inhibitors. Improved allograft function despite increased risk of early rejection and viral infection have been reported.

**Methods:** This is a single center retrospective study conducted at Mayo Clinic Arizona. We converted patients to the high dose belatacept (10mg/kg) if transplanted within 1 month and to the low dose (5mg/kg) after 1 month if they had significant side effects with calcineurin inhibitors or suboptimal allograft function with chronicity changes on biopsy findings. Tacrolimus dose was discontinued immediately in high dose conversion group but was overlapped and tapered down within 4 weeks in low dose conversion group. We included both deceased donor and living donor transplant recipients from 2013 to 2021. We compared the effect of high dose and low dose on the occurrence of rejection and infection at 1 year.

**Results:** Total of 75 patients were switched to belatacept and 56 (74%) was converted to low dose and 17 (26%) were converted to high dose. No statistical difference found in recipient and donor characteristics between 2 groups (Fig 1). There was no statistical significance in allograft function, rejection rate and infection rate at 1 year (Fig 2). However, the occurrence of COVID 19 infection was statistically significant in high dose conversion group.

**Conclusions:** Allograft function was comparable at 12 months between 2 groups for those transplanted within 1 year. It is important to recognize the potential for over-immunosuppression when transitioning to belatacept.

## Comparison of Recipient and Donor Characteristics

	High dose Conversion (N=17)	Low dose Conversion (N=56)	P value
<b>Recipient Characteristics</b>			
Gender (Female)	9 (53%)	19 (34%)	0.4
Diabetes	6 (35%)	19 (34%)	0.2
Hypertension	16 (94%)	49 (88%)	0.7
Pretransplant dialysis	1 (5.9%)	12(21%)	0.3
DDRT	12 (71%)	42 (75%)	0.7
<b>Donor Characteristics</b>			
Age	41 (SD 12.1)	45.8 (SD 13.6)	0.2
KDPI	48.4 (SD 18)	60 (SD 24.9)	0.13
DDRT	83 (28.1%)	95 (26.5%)	0.63
Induction (Campath)	10 (59%)	34 (61%)	0.9
Induction (Simulect)	6 (35%)	20 (36%)	0.9
Induction (Thymoglobulin)	1 (6%)	2 (3.5%)	0.9

Comparison of Allograft function and infection rate based on Belatacept conversion cohort			
	High dose Conversion (N=17)	Low dose Conversion (N=56)	P value
Allograft Function			
Creatinine before switch	3.7 (SD 1.7)	3.4 (SD 2.7)	0.7
Creatinine after 6 <sup>th</sup> month	1.7 (SD 0.7)	2.1 (SD 1)	0.2
GFR at the time of switch	16.5 (13.2)	27 (21)	0.03
GFR at 6 <sup>th</sup> month	51 (18.7)	39.7 (19.5)	0.04

FR-PO821

**The Impact of Mycophenolate Dosing on BK Viremia in Low-Risk Kidney Transplant (KT) Recipients**  
Dylan Thomas,<sup>1</sup> Shuangcheng Hua,<sup>2</sup> Jon R. Von Visger,<sup>3</sup> Vaqar H. Shah,<sup>3</sup> Samer Kareem,<sup>3</sup> Michael C. Ott,<sup>1</sup> Kabir Jalal,<sup>2</sup> Shirley S. Chang.<sup>3</sup> <sup>1</sup>Erie County Medical Center, Buffalo, NY; <sup>2</sup>University at Buffalo, Buffalo, NY; <sup>3</sup>University at Buffalo Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY.

**Background:** BK polyomavirus infection affects 10-60% of KT recipients. Risk factors include degree of immunosuppression, and allograft rejection. Management of BK viremia includes reduction of immunosuppression with close monitoring for rejection. The data is limited in MMF dosing at time of KT & effect on BK.

**Methods:** This is a single-center, retrospective study examining effect of MMF dosing in low-risk (CPRA <20%, non-Black) KT recipients on BK viremia at Erie County Medical Center between 8/2019-8/2021. Per protocol, MMF dosing was reduced from 750 mg BID (Higher MMF group) to 500 mg BID (Lower MMF group) for low-risk KT recipients on 8/2020. We performed chart review one-year prior & one-year post 8/2020. Exclusion criteria: multiorgan transplants, CPRA ≥20%, Black race, not on MMF. All had serum BK PCR at 2 weeks, monthly x 1-year, then 6 months x 2-years post-transplant. For those with BK viremia, MMF reduction was per clinician discretion, dosing was recorded with time. Primary outcome: BK viremia rate; Secondary outcome: biopsy-confirmed acute rejection rate.

**Results:** There were 75 in the Higher MMF group, and 62 in the Lower MMF group. Clinical characteristics were similar (age, gender, race, BMI, cPRA, KDPI, EPTS, type of KT). All received thymoglobulin induction (3 mg/kg) and steroid. MMF dosing in the Higher MMF group was 1527 mg/day after transplant, 1510 at month 1, 1389 at month 3 post-transplant; MMF dose in the Lower MMF group was 1082 mg/day after transplant, 1103 at month 1, 1123 at month 3 post-transplant (p<0.01, p<0.01, p=0.005 respectively). Other immunosuppressions, eGFR, allograft loss, and death were not different. BK viremia rate was 32% in the Higher MMF group vs. 16% in the Lower MMF group (p=0.052). Of those with BK viremia, BK duration was not different, however, time from transplant to BK onset was shorter in the Lower MMF group (91 days vs. 190 days, p=0.019). Biopsy confirmed acute rejection rate was not different. There were 16 patients (21%) who develop ACR in the Higher MMF group; 10 patients (14.5%) developed ACR and 1 patient (1.6%) with AMR in the Lower MMF group (p=NS).

**Conclusions:** Lower MMF at time of KT in low-risk KT recipients tend to have lower BK viremia rate and has no effect in acute rejection rate. More and larger studies are needed to confirm above findings.

FR-PO822

**Outcomes of Kidney Transplantation in Cystic Fibrosis**  
Mirjana Stevanovic,<sup>1</sup> Asha Zimmerman,<sup>2</sup> Martha L. Graber.<sup>2</sup> <sup>1</sup>Dartmouth Guarini School of Graduate and Advanced Studies, Hanover, NH; <sup>2</sup>Dartmouth College Geisel School of Medicine, Hanover, NH.

**Background:** There is a paucity of published data on the outcomes following kidney transplantation in patients with cystic fibrosis (CF).

**Methods:** The USRDS database was used to locate all patients with CF who were diagnosed with ESRD prior to 12/31/2018 undergoing a first kidney transplant. CF patients were compared to non-CF patients undergoing first kidney transplant for the same period. Demographic data was compared using linear and logistic regression. Survival curves for death-censored graft survival and death were compared between groups using cox regression.

**Results:** A total of 192 patients with CF and 248,820 patients without CF underwent kidney transplantation. Compared to the non-CF population, CF patients were more likely to be female (52.1% vs 40.2%, p < 0.001), have a lower BMI (21.8 vs 27.7, p < 0.001), be white (91.7% vs 67.2%, p < 0.001), have a transplant as first ESRD treatment (22.9% vs 14.1%, p < 0.001), be on dialysis for less time (1.95 yr vs 3.29 yr, p < 0.001), have a living donor transplant (60.4% vs 32.9%, p < 0.001) and less likely to have transplant failure (22.9% vs 30.6%, p = 0.021). Death censored graft survival was no different between the groups (p = 0.28). Five-year death-censored graft survival was 90% vs 85% for patients

with CF and non-CF patients, respectively. Patients with CF had worse survival when compared to patients without CF (p < 0.001). Five year and median survival was 92% vs 95% and 17.7 yrs vs 26.8 yrs for CF and non-CF patients, respectively.

**Conclusions:** There is no difference in death-censored graft survival for patients with CF. Patients with CF have shorter survival after transplantation when compared to a non-CF cohort.

FR-PO823

**Thrombotic Microangiopathy (TMA) After Kidney Transplant: A 10-Year Experience**  
Gaurav Rajashekar, Nyein Chann Wai Lynn, Karen Flores, Massini Merzkani, Rowena B. Delos Santos, Anuja Java. Washington University in St Louis, St Louis, MO.

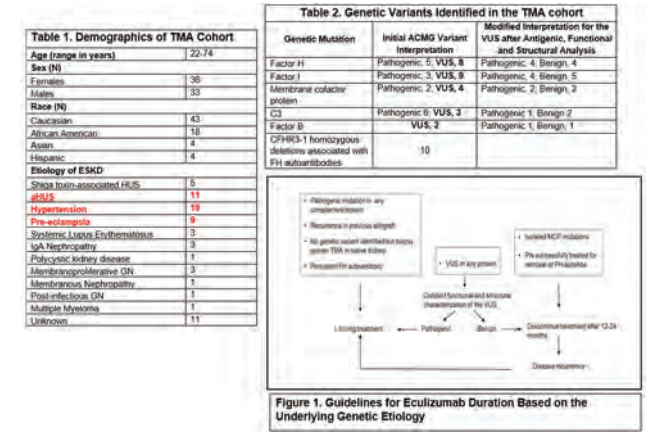

**Background:** TMA is primary when a genetic or acquired defect is identified [e.g. complement genetic variants in atypical hemolytic uremic syndrome (aHUS)] or secondary when occurring in the setting of infection, malignancy, or drugs. Kidney transplant is associated with multiple triggers such as drugs, rejection, or infections, making it challenging to distinguish aHUS from secondary TMAs. This distinction is critical since aHUS is non-responsive to conservative measures. We report our approach to TMA evaluation and demonstrate how comprehensive analyses can facilitate clinical decision-making regarding treatment and recurrence risk.

**Methods:** Between 2011 and 2020, pre-transplant patients with TMA in the native kidney and post-transplant patients with recurrent or *de novo* TMA were evaluated. Genetic testing was conducted using the clinically validated aHUS panel. Variants were classified based on the American College of Medical Genetics (ACMG) guidelines.

**Results:** 69 patients (41 post-transplant and 28 pre-transplant) underwent genetic testing (Table 1). 11 of 69 had a known aHUS diagnosis; 19 patients (27.5%) were (mis)diagnosed as hypertensive nephrosclerosis and nine (13%) developed ESKD after preeclampsia. 42 patients (60.8%) carried a complement genetic variant and 10 patients (14.4%) harbored a Factor H autoantibody (Table 2). 26 of 42 (61.9%) were classified as variants of unclear significance (VUS). A systematic antigenic and structure-function analysis of the VUS determined their clinical significance, re-categorized them as pathogenic or benign and guided treatment decisions (Fig 1).

**Conclusions:** 1) Patients with ESKD due to HTN/preeclampsia or another TMA whose evolution is aggressive should be evaluated for complement defects. 2) Functional assessment of VUS defines their clinical significance, aids in diagnosis, informs disease etiology, facilitates assessment of recurrence risk and helps to determine treatment.

## A Propensity-Score Matched Analysis of Long-Term Outcomes for Living Kidney Donation in Alternative Complement Pathway Diseases

Yasar Caliskan,<sup>1</sup> Seda Safak,<sup>2</sup> Ozgur A. Oto,<sup>2</sup> Arzu Velioglu,<sup>3</sup> Berna Yelken,<sup>4</sup> Ahmet B. Dirim,<sup>2</sup> Abdulmecit Yildiz,<sup>5</sup> Safak Mirioglu,<sup>2</sup> Nurana Guller,<sup>2</sup> Halil Yazici,<sup>2</sup> Alparslan Ersoy,<sup>5</sup> Aydin Turkmen,<sup>2</sup> Krista L. Lentine.<sup>1</sup> <sup>1</sup>Saint Louis University School of Medicine, Saint Louis, MO; <sup>2</sup>Istanbul Universitesi Istanbul Tıp Fakultesi, Istanbul, Turkey; <sup>3</sup>Marmara Universitesi, Istanbul, Turkey; <sup>4</sup>Koc Universitesi, Istanbul, Turkey; <sup>5</sup>Bursa Uludag Universitesi, Bursa, Turkey.

**Background:** We examined the clinical course of living donors (LDs) to recipients with atypical hemolytic-uremic syndrome (aHUS) and C3 glomerulopathy (C3G) and compared their outcomes with a control group to improve understanding of the clinical course and outcomes of living donation in this context.

**Methods:** The cohort of LDs of aHUS/C3G recipients (Complement-LD group) and propensity score-matched control LDs without any family history of aHUS/C3G (Control-LD group) were retrospectively identified from data at 4 transplant centers (2003-2021). LD were followed for major cardiac events (MACE), *de novo* hypertension, cancer, death, post-donation eGFR and proteinuria.

**Results:** The cohort comprised 24 LD to recipients with aHUS (46%) and C3G (54%) including 18 related LDs. Long-term outcomes were compared with propensity score-matched control group over 5 years (IQR,3-11.8) follow-up. During follow-up, none of the LDs in complement-LD group developed MACE whereas two LDs in control-LD group developed MACE (18.5%) after 8 (IQR,2.6-12.8) years (p=0.15). New-onset hypertension was similar between groups (20.8% vs 25%, p=0.73) (Table 1). There were no differences between study groups regarding last eGFR and proteinuria levels (p=0.11 and p=0.40, respectively). None of the donors developed kidney failure (eGFR<15ml/min/1.73m<sup>2</sup> or dialysis). In complement-LD group a related donor developed gastric cancer and another related donor developed a brain tumor and died at 4<sup>th</sup> year after donation (Table 1).

**Conclusions:** The risks of kidney failure, cardiovascular disease, *de novo* aHUS and C3G in carefully selected LD to recipients with aHUS and C3G appear to be low. Cancer development in related LDs of recipients with complement mediated disease may need further investigation.

Table 1. Demographic and follow up characteristics of living donors of recipients with complement related kidney diseases and propensity score matched control donor group.

Characteristics	Complement-LD Group (n=24)	Control-LD Group (n=24)	P value
Age at donation (years), mean±SD	45.5±11	49.1±8.4	0.21
Sex, male/female, n (%)	15 (62.5) / 9 (37.5)	12 (50.0) / 12 (50.0)	0.38
HLA mismatch, mean±SD	3.5±1.3	3.2±1.4	0.52
Donor's relationship to recipients, n (%)

## FR-PO825

## Sodium Glucose Cotransporter2 Inhibitors in Kidney Transplant Recipients

Kristin Progar, Massini Merzkani, Haris F. Murad, Andrew F. Malone, Rowena B. Delos Santos, Anuja Java. Washington University in St Louis, St Louis, MO.

**Background:** Sodium glucose cotransporter2 inhibitors (SGLT2i) demonstrate a cardioprotective effect and are associated with slowing or preventing CKD progression in the native kidney. However, there is limited data in the literature about their use after a kidney transplantation.

**Methods:** This is an observational retrospective study in a cohort of kidney transplant recipients at Washington University in St. Louis, treated with SGLT2i for diabetes mellitus type 2. Data collection was conducted by chart review. Our primary endpoint was to assess the safety and adverse reactions in this cohort. Our secondary endpoints included assessments of change in weight/BMI, blood pressure, serum creatinine and eGFR, LDL,

HDL and hemoglobin A1C every 6 months with a follow up to 2 years. Analysis for change of these parameters from baseline (at the time of start of the medication) was conducted using matched paired t test.

**Results:** A total of 36 of kidney transplant recipients were included. The average age of patients was 55.5 ± 10.4 years. 23 of 36 patients (63.9%) were males. The adverse events reported were congestive heart failure 2/36 (5.6%), AKI 2/36 (5.6%), candidiasis 1/36 (2.8%), and urinary tract infection 1/36 (2.8%). Our results also revealed that two patients died unrelated to medication use (1 patient died after COVID infection and 1 patient died due to septic shock from a foot infection). As shown in table 1 there was no significant change from baseline in weight/BMI, blood pressure, serum creatinine and eGFR, LDL, HDL or hemoglobin A1C at 6, 12, 18 and 24 months.

**Conclusions:** Our preliminary data shows that SGLT2i are relatively safe in the kidney transplant population. Larger multicenter studies are needed to determine the efficacy of these drugs in improving renal function, decreasing cardiovascular events and survival post-transplant, as seen in non-transplant recipients.

## Domain Specific Changes in Cognitive Function After Kidney Transplantation

Aditi Gupta,<sup>1</sup> Rebecca J. Lepping,<sup>2</sup> Neal Montgomery,<sup>2</sup> Mark J. Sarnak,<sup>3</sup> Jeffrey M. Burns,<sup>2</sup> William M. Brooks.<sup>2</sup> <sup>1</sup>University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS; <sup>2</sup>University of Kansas Medical Center, Kansas City, KS; <sup>3</sup>Tufts University, Medford, MA.

**Background:** In this largest study assessing cognitive function pre-to post-kidney transplantation (KT) with multiple cognitive tests, we assessed changes in distinct cognitive domains to determine reversibility in cognitive impairment in ESKD.

**Methods:** We measured cognitive function pre-KT (n=97), 3-months post-KT (n=68), and 1-year post-KT (n=50) and compared changes using linear mixed model analysis.

**Results:** Logical Memory IA (fig) and IIA (episodic memory) and Digit symbol substitution (psychomotor speed, visuospatial function) scores were low pre-KT (pre-KT vs. norm: p<0.001 for all) and improved post-KT (pre- vs. post-KT: p<0.001 for Logical Memory IA and IIA, p=0.01 for Digit symbol substitution). Category Fluency (animals) (p<0.001) and Category Fluency (vegetables) (p=0.05) (semantic memory) also improved post-KT. Other cognitive domains did not change with KT (Table).

**Conclusions:** ESKD is associated with impairments in episodic memory, semantic memory, psychomotor speed, working memory, attention, and visuospatial function. Episodic and semantic memory improve post-KT while cognitive deficits persist in other domains. The differential improvement in cognitive function may reflect differences in underlying mechanisms affecting distinct cognitive domains in ESKD.

**Funding:** Other NIH Support - NIA

**Post-Simultaneous Kidney and Pancreas Transplant Outcomes in Type 2 Diabetics Compared to Type 1 Diabetics**  
Luz E. Liriano-Ward, Yorg Al Azzi, Sanjana Kapoor, Maria Ajaimy, Cindy T. Pynadath, Enver Akalin. *Montefiore Medical Center, Bronx, NY.*

**Background:** The aim is to evaluate and compare short term and long-term outcomes in simultaneous kidney and pancreas transplant (SPK) recipients with a history of type 2 diabetes compared to those with type 1 diabetes

**Methods:** This is a retrospective review of all kidney and pancreas transplant recipients over 18 years of age transplanted at our center from June 2014 to December 2021

**Results:** 107 SPK were performed at our center during the study period. 46.7% were type 2 diabetics and 53.3% were type 1. 80% were black or Hispanics (80%), but there was no racial difference between the two groups. The type 2 diabetics were older (median 49.5 (IQR 43-53.8) vs 35 (IQR 33-44), p<0.001), had lower pre-transplant HbA1c (7.6 ± 1.6 vs 8.4 ± 1.6 p= 0.04), and had higher c-peptide (5.1±2.6 vs 1.1± 2.4, p<0.001). There was no difference in BMI (25.6 ±3.9 in type 1 vs 27 ± 3.7 in type 2, p=0.096), pre-transplant insulin requirements, history of HTN, HLD, ESRD, and dialysis vintage. Type 1 diabetics developed more acute rejection (22.8% vs 2%, p 0.002) and CMV viremia (31.4% vs 10%, p 0.01). There was no difference in length of hospital stay, 30 days re-admissions, incidence of DGF in both kidney and pancreas allografts, hypoglycemia (BS<55), and need for oral antiglycemic drugs post-transplant. Mean serum creatinine levels were similar at 3 months (1.2 ± 0.45mg/dl vs 1.0 +/- 0.31mg/dl), p=1.6), and 6 months (1.3± 0.4mg dl vs 1.1 ± 0.33mg/dl, p=0.1). Type 2 diabetics had better kidney function at 1 year with mean eGFR 71 ± 27.3 vs 61 ± 22.7, p=0.06), but there was no difference in renal function at last follow up. There was no difference HbA1c levels at 6 months (median 5.2 (IQR 5-5.6) in type 1 vs 5.2 (IQR 5-5.6) in type 2, p=0.97) and 1 year (5.4 (IQR 5.3-5.7) vs 5.7 (IQR 5.2-5.7), p=0.3). During a median follow-up of 22 months (IQR 16-34.5), patient's survival was 98% and kidney and pancreas graft survival was, 100% and 92%, respectively in type 2 diabetics. Meanwhile, patients' survival was 88% and kidney and pancreas graft survival was 90% for both at a median follow up of 42months (17.5-60.5)

**Conclusions:** Type 1 diabetics were more likely to develop acute rejection and CMV viremia as compared to type 2 diabetics. Both patient's and allografts' survival are comparable between the two groups

FR-PO828

**Treatment Outcome of Patients With Chronic Active Antibody-Mediated Rejection After Kidney Transplantation: Follow-Up Report of a Single Center Retrospective Study**  
Hsien-Fu Chiu, Cheng-Hsu Chen. *Taichung Veterans General Hospital, Taichung, Taiwan.*

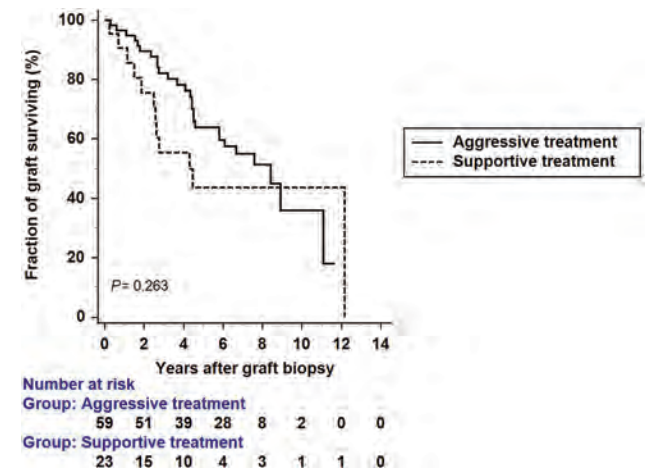

**Background:** Chronic active antibody-mediated rejection is a major etiology of graft loss in renal transplant recipients. Previously, we had reported that aggressive treatment was associated with better graft outcome at a median follow up duration of 32.5 months after the diagnosis of CAMR. Since chronic antibody mediated rejection is a chronic disease, this study aimed to prolong the follow up duration for 3 more years.

**Methods:** Adult kidney transplant recipients in Taichung Veterans General Hospital with CAMR were divided into two groups : Group 1 received aggressive treatment (double filtration plasmapheresis and one of the followings: rituximab, intravenous immunoglobulin, antithymocyte globulin, bortezomib, or methylprednisolone pulse therapy); and group 2 received supportive treatment.

**Results:** After 3 more years of follow up, 1 more patient in supportive treatment group and 15 more patients in aggressive treatment group lost their allograft. Median graft survival was 8.4 and 4.3 years for aggressive treatment group and supportive

treatment group, respectively. 27/59 (45.76%) patients in aggressive treatment group and 12/23 (52.17%) patients in supportive treatment group lost their allograft. Kaplan-Meier analysis of death-censored graft survival showed no significant difference between these two groups (p=0.263 by log-rank test).

**Conclusions:** Aggressive treatment is associated with better graft outcome in short term. However, there is still high risk of graft failure despite aggressive treatment in the long run. Risk and benefit of aggressive treatment should be evaluated before clinical decision.

Kaplan-Meier analysis of death-censored graft survival showed no significant difference between aggressive treatment and supportive treatment group (p=0.263 by log-rank test)

FR-PO829

**Healthcare Utilization and Costs Associated With Neutropenia in Kidney Transplant Recipients Receiving Valganciclovir Prophylaxis: An Administrative Claims Database Study**  
Vladimir Turzhitsky, Amit Raval, Pamela Moise, Sanjay Merchant. *Merck & Co., Inc., Rahway, NJ.*

**Background:** Kidney transplant recipients (KTRs) who have a D+/R- or R+ cytomegalovirus (CMV) IgG status receive valganciclovir (VGCV) as CMV prophylaxis. However, VGCV is myelosuppressive and may cause medically significant neutropenia. In this study, we evaluate healthcare resource use (HCRU) and cost in KTRs who develop neutropenia on VGCV.

**Methods:** KTRs between 1/1/2012 - 12/31/2018 from IBM MarketScan Commercial and Medicare Supplemental claims databases were included if they had 1 year of continuous enrollment before (baseline) and after (follow-up) their kidney transplant (KT). KTRs with VGCV prescription fills of 450mg or 900 mg/day within 30 days of KT were included in the cohort. Neutropenia was identified as either one inpatient or two outpatient claims separated by 14 or fewer days based on ICD-9/10 codes (288.0x/D70.x). HCRU and cost was evaluated for emergency department (ED), inpatient (IP), outpatient (OP), and pharmacy use.

**Results:** 3,258 (66%) of KTRs with requisite enrollment requirements met the VGCV inclusion criteria. Baseline demographics, HCRU, and cost between the neutropenic and non-neutropenic KTRs were similar. KTRs with neutropenia had significantly higher number of ED visits, other outpatient visits, and hospitalizations compared to those without neutropenia (Table 1). Healthcare costs were significantly higher among KTRs with neutropenia compared to those without neutropenia. Similar trends were observed for leukopenia.

**Conclusions:** Neutropenia in KTRs is associated with significantly higher HCRU and cost. We hypothesize that strategies aimed at mitigating the development of neutropenia in this immunosuppressed population may also decrease economic burden. These may include investigating less myelotoxic alternatives for CMV prophylaxis. Future studies are needed to further evaluate clinical outcome impacts of such practices.

**Funding:** Commercial Support - Merck & Co., Inc.

Impact of Iron Status on Kidney Outcomes in Kidney Transplantation Patients

Hyo Jeong Kim, Ga Young Heo, Kyung Won Kim, Hee Byung Koh, Jaeseok Yang, *Yonsei University Health System, Seodaemun-gu, Seoul, Republic of Korea.*

**Background:** Dynamic changes occur in iron storage after kidney transplantation (KT). Recently, iron has been reported to play a crucial role in hemodynamics of the heart, infections, and the immune system, independently of anemia. However, there are insufficient studies on the impact of iron status on kidney functions in KT patients. In this study, we investigated the association of iron status and kidney outcomes in KT patients.

**Methods:** We analyzed data from the KoreaN cohort study for Outcome in patients With KT(KNOW-KT). Patients were excluded who met the following criteria: 1) subjects who did not follow-up for at least 1 year after KT, 2) subjects without ferritin or transferrin saturation (TSAT) level at 1 year after KT. Iron status were classified based on ferritin and TSAT level. Ferritin and TSAT were categorized to 3 groups, where 20%, 35% as reference points for the TSAT, and 100ng/mL, 300ng/mL for the ferritin, respectively. Based on the quartiles of ferritin and transferrin saturation at 1 year after KT, iron status was classified as “Iron replete”, “Iron deficiency”, “Functional iron deficiency”, “High iron”, and “non-classified”. Primary outcome was the composite outcome of graft failure and eGFR decline≥50%. Cox regression analysis was used to analyze the association of iron status with the primary outcome.

**Results:** A total of 895 patients were included in the final analysis. During median follow-up of 5.8 years, primary outcome occurred in 94 patients, with an incidence rate of 19.8 per 1,000 person-years. The risk of composite outcome was higher in the high TSAT groups (> 35%) compared to the TSAT in range of 20-35% group (adjusted HR 1.68, 95% CI 1.01-2.79). The high ferritin groups also showed a trend of increased risk of the composite outcome despite statistical insignificance. Moreover, high iron groups showed a trend of increased risk of the composite outcomes compared to iron replete group (adjusted HR 2.05, 95% CI 0.97-4.34).

**Conclusions:** High iron status with high TSAT levels increased the risk of graft failure and renal progression in KT patients.

FR-PO831

Proton Pump Inhibitor Use in Kidney Transplant Recipients: A Population-Based Study

James A. Kiberd, Robert R. Quinn, Pietro Ravani, Rachel Jeong, Ngan Lam, Alix Clarke, *University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

**Background:** Kidney transplant recipients are commonly prescribed proton pump inhibitors (PPIs), but due to concerns of long-term adverse events, chronic use should be limited to those with specific indications.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only  
Underline represents presenting author.

**Methods:** We conducted a retrospective, population-based cohort study using linked healthcare databases in Alberta, Canada to study PPI use in prevalent adult kidney-only transplant recipients (2008-2017) who were at least 1-year post-transplant. We compared recipients with evidence of a PPI prescription in the 3 months prior to study entry to those with a histamine-2-receptor antagonist (H2Ra) fill and those with neither. The primary outcome was ongoing or new PPI use and patterns of use, including frequency and duration of therapy, and assessment of indication for PPI use.

**Results:** We identified 1,823 kidney transplant recipients, of whom 868 (48%) were on a PPI, 215 (12%) were on a H2Ra, and 740 (41%) were on neither at baseline. Over a median follow-up of 5.4 years (interquartile range [IQR] 2.6-9.3), there were almost 45,000 unique PPI prescriptions dispensed, the majority (80%) of which were filled by initial PPI users. Recipients who were on a PPI at baseline would spend 91% (IQR 70-98) of their graft survival time on a PPI in follow-up, of which Nephrologists were the main prescribers. We identified an indication for ongoing PPI use in 54% of the PPI group with the most common indication being concurrent antiplatelet use (26%).

**Conclusions:** Most kidney transplant recipients are on a PPI at or beyond the 1-year post-transplant date and are likely to stay on a PPI in follow-up. Almost half of the recipients in our study did not have an identifiable indication for ongoing PPI use. Nephrologists frequently prescribe PPIs to kidney transplant recipients and should be involved in deprescribing initiatives to reduce polypharmacy and its associated risks.

FR-PO832

Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitors for Treatment of Post Kidney Transplant Anemia

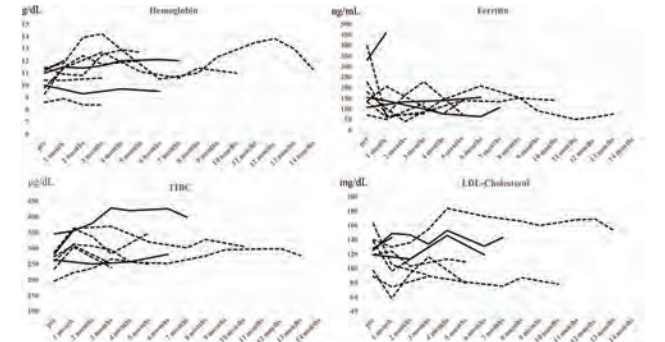

Masatomo Ogata, Takamasa Miyauchi, Marie Murata, Maho Terashita, Kiyomi Osako, Kazunobu Shinoda, Yugo Shibagaki, Masahiko Yazawa, *St. Marianna University School of Medicine, Kawasaki, Japan.*

**Background:** We previously reported the short-term efficacy of hypoxia-inducible factor prolyl hydroxylase inhibitors (HIF-PHI) for the treatment of post kidney transplant anemia (PTA). The present report re-analyzes our experience with HIF-PHI for PTA in the context of longer follow-ups and using a different class of HIF-PHI.

**Methods:** Nine kidney transplant recipients (KTRs) in our institute who were administered HIF-PHI for PTA were evaluated. The indication of HIF-PHI to erythropoiesis-stimulating agent (ESA) naive patients was an hemoglobin (Hb) level below 11.0 g/dL, and to ESA treated patients was an Hb level below 13.0 g/dL. Either roxadustat (Rox) or enarodustat (Ena) was employed as per the recommended dose adjustments to achieve target Hb levels between 11.0-13.0 g/dL. Anemia-related parameters, including Hb, total iron - binding capacity, and ferritin levels were evaluated along with LDL cholesterol up to 14 months. Adverse events of HIF-PHI were defined as thromboembolic events and malignancy.

**Results:** Rox and Ena were prescribed to 6 and 3 KTRs, respectively. The mean eGFR was 25.6 mL/min/1.73 m<sup>2</sup>. Hb levels and iron metabolism are shown in **Figure** (Solid line: Ena and dashed line: Rox). While most of the KTRs demonstrated an increase or maintain in their Hb levels from baseline, 2 of them kept their Hb level below the target ranges. Further, a few of the Rox-treated KTRs showed rapidly increase and decrease in their Hb and ferritin levels, respectively, despite being prescribed the recommended initial dose. Additionally, a drop in LDL cholesterol levels was only observed in the Rox-treated group. Adverse events were not recorded during the observation period.

**Conclusions:** Based on the recommended dose of HIF-PHI, treatment with Rox resulted in a more rapid increase in Hb levels along with a stronger improvement in iron utilization as compared to that seen in treatment with Ena. For PTA, HIF-PHI would be safe and useful in clinical use.

FR-PO833

Kidney Transplantation Is Significantly Associated With Severe Herpes Zoster Infection: A Nationwide Population-Based Cohort Study With Propensity Score Matching Analysis

Tung-Min Yu, *Taichung Veterans General Hospital, Taichung, Taiwan.*

**Background:** Kidney organ recipient has been considered to be on immunosuppression lifelong and that is suggested to be likely associated with various infection diseases including virus infection. We conducted a nationwide population-based cohort study to investigate the risk of herpes virus infection in this population.

**Methods:** From the Taiwan National Health Insurance Research Database (NHIRD) records, individuals hospitalized as solid organ recipients including kidney recipients

were defined as a case group of solid organ transplantation (SOT) patients and matched with a non-SOT cohort.

**Results:** A total of 18748 individuals, namely 9374 (50%) with (case) and 9374 (50%) without a medical SOT record (comparison) were enrolled. Because the patients were propensity score matched according to gender, age, index year, and comorbidities, no significant difference was observed between the case and comparison groups for these factors. We classified SOT as kidney, heart, lung, liver, bone, or pancreas transplantation. Compared with patients without SOT, patients with kidney (aHR = 9.07, 95% CI = 6.84–12.03), heart (aHR = 13.95, 95% CI = 8.63–22.57), lung (aHR = 48.47, 95% CI = 21.03–111.73), liver (aHR = 6.03, 95% CI = 4.15–8.75) transplantation had a significantly higher risk of HZ after adjustment for demographic factors and comorbidities.

**Conclusions:** In the present study, our findings disclose that renal transplant recipient was differentially associated with remarkably high risk of herpes alpha virus infection including herpes simplex virus which was neglected previously. For clinical practice, professionals should maintain high index of suspicion in patients with kidney transplantation.

FR-PO834

**Risk Factors for Heart Failure Hospitalization in Kidney Transplant Recipients: Results From FAVORIT**  
Martina M. McGrath,<sup>1,2</sup> Finnian R. McCausland,<sup>1,2</sup> Brian Claggett,<sup>1,2</sup> Andrew Bostom,<sup>5</sup> Andrew S. Levey,<sup>3</sup> Daniel E. Weiner,<sup>3</sup> Matthew R. Weir,<sup>4</sup> Marc A. Pfeffer.<sup>1,2</sup> <sup>1</sup>*Brigham and Women's Hospital, Boston, MA;* <sup>2</sup>*Harvard Medical School, Boston, MA;* <sup>3</sup>*Tufts Medical Center, Boston, MA;* <sup>4</sup>*University of Maryland School of Medicine, Baltimore, MD;* <sup>5</sup>*Rhode Island Hospital, Providence, RI.*

**Background:** The development of heart failure (HF) post kidney transplantation is associated with a higher risk of allograft failure and death. Using data from stable kidney transplant recipients (KTRs) enrolled in FAVORIT, we evaluated risk factors for HF hospitalization.

**Methods:** FAVORIT randomized 4,110 stable KTRs to either a high-dose or low-dose multivitamin (folate, B6, B12). HF hospitalizations were determined by review of discharge diagnoses. Stepwise Cox regression models with forwards selection ( $P < 0.05$  for entry) were fit to assess for independent risk factors of HF hospitalization events (candidate variables included age, sex, race, country, BMI, cardiovascular disease, diabetes, donor type, graft vintage, albuminuria, smoking, aspirin, statin, ACEi or ARB use; treatment assignment and eGFR were forced in the model).

**Results:** Of the 3,633 patients with complete data available, 115 patients (3.2%) experienced a HF hospitalization over a mean follow-up of four years (0.8 events per 100 patient years (95%CI 0.7-1.0)). The variables associated with a higher adjusted risk of HF events were albuminuria, older age, higher BMI, Black race (vs. non-Black), country (United States+Canada vs. Brazil), prior history of CV disease, and diabetes (Table 1).

**Conclusions:** In a post-hoc analysis of FAVORIT, we identified multiple independent risk factors for HF hospitalization. Some of these, such as BMI and albuminuria, may be modifiable by lifestyle modifications and newer drug therapies, which should be adequately tested in this high-risk population.

Risk factors for heart failure hospitalization among stable kidney transplant recipients

Baseline characteristics	Baseline measurement	Hazard Ratio per unit change	Hazard Ratio	95% Confidence Interval	P
Urine albumin/creatinine ratio, mg/g	53 [9, 101]	per 10-fold log-unit	1.76	1.40 to 2.22	<0.001
eGFR ml/min/1.73m2	49 ±16	per 10 ml/min/1.73m2	1.09	0.96 to 1.24	0.20
Age, years	52 ±9	per 10 years	1.40	1.14 to 1.72	0.01
Black, n(%)	630 (17%)	Black (vs non-Black)	1.67	1.09 to 2.55	0.02
USA+Canada participants, n(%)	3,021 (83%)	USA + Canada (vs Brazil)	6.01	1.47 to 24.6	0.01
BMI, kg/m2	29 ±6	Per 5 kg/m2	1.18	1.03 to 1.36	0.02
History of cardiovascular disease, n(%)	729 (20%)	History of cardiovascular disease (vs without)	2.35	1.60 to 3.47	<0.001
Diabetes, n(%)	1,455 (40%)	Diabetes (vs without)	1.54	1.04 to 2.26	0.01
Randomized Treatment (Higher dose), n(%)	1,825 (50%)	Higher vs. lower dose	0.86	0.60 to 1.24	0.35

**Importance of Dedicated Outreach Program to Facilitate COVID-19 Vaccination in Kidney Transplant Patients**  
Arezou Shahmoradi,<sup>1,2</sup> Wilma M. Hopman,<sup>2</sup> Margaret Lacey,<sup>2</sup> Jessy Donelle,<sup>2</sup> Natalie Witton,<sup>2</sup> Lori N. Van Manen,<sup>2</sup> Samuel A. Silver,<sup>1,2</sup> M. Khaled Shamseddin.<sup>1,2</sup> <sup>1</sup>*Queen's University, Kingston, ON, Canada;* <sup>2</sup>*Kingston Health Sciences Centre, Kingston, ON, Canada.*

**Background:** Transplant patients are at high risk of COVID-19 infection and its complications. Timely vaccination in this population is important. To achieve this, we launched an Outreach Program (OP) and a Vaccine Clinic (VC) for transplant patients in early April 2021, as part of Canadian phase II roll out policy.

**Methods:** We started an Outreach Program at our clinic in April 2021 that consisted of a clinical clerk, a nurse and a transplant nephrologist in conjunction with a VC, located separately from the Transplant Clinic, at either hospital site designated for transplant patients. Patients were assessed for vaccination eligibility by the transplant team, consented by phone by the nurse, and then booked in the VC and notified by the clerk prior to their vaccination appointment. Vaccination statuses were assessed on regular intervals up until April 15<sup>th</sup>, 2022. Time between doses in patients who received their vaccinations

at the OP versus those who got vaccinations elsewhere (External Vaccination–EV) were compared using the Mann-Whitney Test.

**Results:** 213 adults kidney transplant patients [Age 57±14 year, female (35.7%), Caucasian (89.7%)] were followed in our clinic. By April 15<sup>th</sup>, 2022, 207 (97.2%) patients received their 1<sup>st</sup> vaccination, 204 (95.8%) received 2<sup>nd</sup> dose, 179 (84%) received 3<sup>rd</sup> dose and 152 (71.4%) received 4<sup>th</sup> dose. Vaccination was facilitated through the OP for 145 (70%), 165 (80.9%), 171 (95.5%), and 152 (100%) of patients for 1<sup>st</sup>, 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> doses, respectively. The time interval between doses was shorter when vaccination was facilitated by the OP compared with EV [1<sup>st</sup> and 2<sup>nd</sup> doses: 23 (21-24) vs. 35 (26-67) days,  $P < 0.001$ ; 2<sup>nd</sup> and 3<sup>rd</sup> doses: 106 (98-126) vs. 134 (102-173) days,  $P = 0.046$ ]. The 4<sup>th</sup> dose was exclusively provided to our eligible patients through the OP with a median interval of 153 (140-158) days from the 3<sup>rd</sup> dose.

**Conclusions:** An Outreach Program for kidney transplant patients shortened the time between COVID-19 immunizations compared with external vaccination.

FR-PO836

**Outcomes of Thymoglobulin vs. Basiliximab Induction in Simultaneous Heart Kidney Transplant: A Single-Center Experience**  
Juhi Bhargava, Rita L. McGill, Sambhavi Krishnamoorthy, Michelle A. Josephson, Yousuf Kyeso. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

**Background:** Simultaneous heart kidney transplants (SHK) are less common than kidney-only transplants due to the complex medical and surgical factors involved. Optimal induction immunosuppressive therapy is not known. Ariyamuthu et al. showed no statistically significant difference in mortality or infection rates based on induction agent. Data are sparse on best induction therapy for SHK patients so we studied outcomes associated with different induction therapy approaches.

**Methods:** From 2008-2021, 55 SHK with either Thymoglobulin (r-ATG) or Basiliximab (IL2rAb) induction were performed at our center. We retrospectively reviewed those patient records and compared renal outcomes, infection rates, and mortality over a 12-month period post transplantation. Continuous variables and outcomes were compared using Student's t-test, and categorical variables and outcomes were compared using chi-squared tests.

**Results:** Baseline characteristics are summarized in figure 1. At 12 months, average GFR was 55.4 with r-ATG and 55.1 with IL2rAb ( $P = 0.96$ ). One year mortality was 9.4% with r-ATG and 21.7% with IL2rAb ( $P = 0.20$ ). Delayed graft function (DGF) was 18.8% with r-ATG and 34.8% with IL2rAb ( $P = 0.2$ ). One-year rejection rate was 25.0% with r-ATG and 17.4% with IL2rAb ( $P = 0.5$ ). BK viremia was 40.6% with r-ATG and 39.1% with IL2rAb ( $P = 0.9$ ). CMV viremia was 34.3% with r-ATG and 17.4% with IL2rAb ( $P = 0.2$ ). Infection related hospitalization rates in r-ATG and IL2rAb were 43.8% and 39.1% ( $P = 0.7$ ).

**Conclusions:** In this single-center cohort, we observed roughly 50% lower mortality and DGF in SHK recipients when r-ATG was used, compared to IL2rAb, but the rates of CMV viremia were nearly twice as high and rejection over the first year was 30% greater. These differences were not statistically significant but provide an early signal for differential effects of induction strategy. Further work is needed to clarify optimal approach to this increasingly performed, lifesaving multi-organ transplant

**Urinary Tract Infections in the First Year After Renal Transplantation in Current of Immunosuppression Setting: A 5-Year Retrospective Single-Centre Study**  
Jorge C. Andrade,<sup>1</sup> Jorge Andrade-Sierra,<sup>2,1</sup> Elsa A. Fuentes Lopez,<sup>1</sup> Enrique Rojas-Campos,<sup>1</sup> Manuel Martinez,<sup>1</sup> Jose Ignacio Cerrillos,<sup>1</sup> Luis Alberto Evangelista-Carrillo.<sup>1</sup> <sup>1</sup>*Instituto Mexicano del Seguro Social Delegacion Jalisco, Guadalajara, Mexico;* <sup>2</sup>*Universidad de Guadalajara Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico.*

**Background:** Urinary tract infection (UTI) is associated with development impaired allograft function. Our objective was assessing to UTI risk factors and its impact in the allograft function.

**Methods:** Retrospective Cohort from March-2014 to March-2019 included 1341 patients with kidney transplantation. All patients with development at least one UTI

event during first year after transplantation were registered. Prophylaxis with TMP-SMX (160/800mg) was used for 3-6 months and the main immunosuppression scheme was based on TAC/MMF/PDN.

**Results:** The accumulated incidence of UTI was 41% and ESBL-producing *Escherichia Coli* was the most frequent agent causing. In a Logistic Regression analysis; risks factors were Anti-thymocyte globulin (ATG) (RR 1.5; 1.18-1.91;  $p=0.001$ ), surgical complications (RR 2.4; 1.7-3.4;  $p=0.001$ ), duration of bladder catheterization (RR 1.43; 1.09-1.9;  $p=0.021$ ), transplant number (RR 1.8; 1.09-3.0;  $p=0.001$ ).

**Conclusions:** Despite the high incidence of UTI, there was no impact on graft function at 12 months post transplantation. Use of ATG and prolonged bladder catheterization are some of the risk factors.

## FR-PO839

### Comparison of Trends and Mortality Benefit to Preemptive Kidney Transplantation Over the Last Two Decades

Abhishek Kumar,<sup>1</sup> Patrick Ten Eyck,<sup>2</sup> Sarat C. Kuppachi.<sup>2</sup> <sup>1</sup>*Yale School of Medicine, New Haven, CT;* <sup>2</sup>*The University of Iowa Hospitals and Clinics, Iowa City, IA.*

**Background:** Pre-emptive kidney transplantation (PKT) is considered the optimal treatment option for advanced chronic kidney disease with improved patient and graft survival. We studied the trends in PKT over the last two decades -to determine whether kidney transplants are being performed at a higher eGFR as a consequence of greater push for preemptive transplant.

**Methods:** We analyzed adult, first time PKT alone recipients using United Network of Organ Sharing data. Baseline characteristics were compared using chi-square analysis for categorical variables and t test for continuous variables. Multivariable Cox regression was used to assess the difference in mortality.

**Results:** 49,675 patients have received preemptive kidney transplant since 2000 in our cohort. PKT rates have been stable at about 15% to 17% of all kidney transplant. Proportion of preemptive kidney transplants from living donors have slightly reduced from 67% to 62% over the last decade. Early PKT (egfr >15ml/min) account for 25% of preemptive transplants and has remained stable over the last decade. Living donors account for 70% of these transplants with some decline in the last five years to 65%. We did not find any mortality benefit in early PKT compared to being on dialysis for < 180 days (HR of 1.12, CI 0.994-1.27,  $p=0.063$ ).

**Conclusions:** Early preemptive kidney transplant in recipients with egfr >15ml/min is not an uncommon occurrence even among living recipients where the procedure timing can be controlled. Starting the proverbial transplant clock earlier does not confer a mortality benefit.

Distributions of eGFR at the time of transplantation in recipient of preemptive kidney transplant as illustrated by kernel density plots.

## FR-PO840

### Retrospective Evaluation of the Prevalence of Diabetes Mellitus in a Single Center Renal Transplant Cohort

Carlo Alfieri,<sup>1,2</sup> Elisa Cicero,<sup>1</sup> Paolo Molinari,<sup>1</sup> Donata C. Cresseri,<sup>1</sup> Anna Regalia,<sup>1</sup> Mariarosaria Campise,<sup>1</sup> Maria Teresa Gandolfo,<sup>1</sup> Evaldo Favi,<sup>1,2</sup> Giuseppe. Castellano.<sup>1,2</sup> <sup>1</sup>*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy;* <sup>2</sup>*Università degli Studi di Milano, Milano, Italy.*

**Background:** Novel onset of diabetes after transplantation (NODAT) might impact significantly in renal transplant (RTx) and RTx patients (RTxps) outcome. In this study we evaluated: 1) the prevalence of diabetic patients who access the RTx 2) the incidence of NODAT and 3) the most related factors for the development of diabetes after RTx.

**Methods:** We retrospectively studied 522 RTxps transplanted in our Unit between January 2004 and December 2014. Each patient underwent: 1) to a collection of remote and pathological anamnesis and complete physical examination and to routine and specific clinical and biochemical determinations at 1 (T1), 6 (T6) and 12 (T12) months after RTx. At six months of RTx, the Oral Glucose Tolerance Test (OGTT) was performed.

**Results:** The age of RTxps was 48±12 years. Patients with glucose metabolism abnormalities were significantly older, without differences in gender. In patients with NODAT (12.6%), cyclosporine was used more than tacrolimus, and higher doses of steroids at T1 and T6 were prescribed. They had a worse general metabolic and glucose (HOMA index, glycaemia and HbA1c) status than normoglycemic. Of note, no differences in 25-(OH)-D and in the other mineral metabolism parameters were found. In multivariate analysis, we found that age at transplant (OR 1.28 for 5 years older) ( $p=0.006$ ), BMI at T1 (OR 1.22 for 2 kg / m<sup>2</sup> more) ( $p=0.01$ ) and the dose of steroid prescribed during the first post RTx month (OR 2.7 per 100 mg additional drug) ( $p=0.03$ ) were independently correlated with NODAT.

**Conclusions:** In this study, we demonstrated that the prevalence of NODAT was relatively high in our cohort reflecting data present in the literature. Interestingly, age at RTx, BMI and cumulative dose of steroids resulted the variables that significantly and strongly influence its development. On the other hand, no relationship was observed between blood values of vitamin D, parathormone and the onset of NODAT. Future research, possibly involving a higher number of RTxps could also evaluate the effects of NODAT on graft and patients on long term outcome.

## FR-PO841

### Safety and Tolerability of Tixagevimab/Cilgavimab for Pre-Exposure Prophylaxis of COVID-19 in Kidney Transplant Recipients

Thalia Salinas, Gabriel J. Stryniak, John R. Lee, Deirdre L. Sawinski, Thangamani Muthukumar, Darshana M. Dadhania. *Weill Cornell Medicine, New York, NY.*

**Background:** Kidney transplant recipients (KTR) remain at risk for severe COVID-19 because of emerging SARS-CoV-2 variants and impaired antibody response to COVID-19 vaccines. There is an urgent need for effective vaccination and pre-exposure prophylaxis. In December 2021, the FDA issued an emergency use authorization of tixagevimab/cilgavimab for pre-exposure prophylaxis of COVID-19 in moderately-severely immunocompromised individuals. In PROVENT, tixagevimab/cilgavimab resulted in 83% relative risk reduction in incidence of symptomatic COVID-19, but only 3% of subjects received immunosuppressive medications and <1% had immunosuppressive disease. We report safety and tolerability of tixagevimab/cilgavimab in KTR at our center.

**Methods:** 40 doses initially allocated to KTR. We designed an online questionnaire to assess therapy tolerability. 28/38 KTR who received therapy responded.

**Results:** Patient characteristics of 38 KTR who received tixagevimab/cilgavimab are listed (Table 1a). Negative Anti-S antibody documented in 54.1% patients, with 17(85%) testing negative after three vaccines. 28 KTR completed the survey and authorized use of their deidentified data. Most patients, 81.5%, reported tolerating tixagevimab/cilgavimab "Very Well" (Table 1b). The most common symptom was fatigue, moderate in 25% and mild in 29%. Other symptoms were less frequent, <15%.

**Conclusions:** Tixagevimab/cilgavimab was generally "very well" tolerated. Additional data substantiating safety and tolerability of tixagevimab/cilgavimab over a longer observation period and with more study participants should help increase confidence in a pre-exposure prophylaxis strategy and offer a safety net for kidney transplant recipients and others at risk for severe COVID-19.

### Outcome of COVID-19 Infections After Vaccination in Kidney Transplant Patients

Mariarosaria Campise,<sup>1</sup> Carlo Alfieri,<sup>1,2</sup> Paolo Molinari,<sup>1</sup> Maria Teresa Gandolfo,<sup>1</sup> Anna Regalia,<sup>1</sup> Donata C. Cresseri,<sup>1</sup> Giuseppe. Castellano,<sup>1,2</sup>  
<sup>1</sup>Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy;  
<sup>2</sup>Università degli Studi di Milano, Milano, Italy.

**Background:** Kidney transplant recipients (KT) are a vulnerable population with a risk of death after COVID-19 infection (COV-I) four times higher than in the general population. mRNA COVID-19 vaccines changed the prognosis. Although KT have an impaired immunological response to mRNA vaccines, in March 2021 we started a vaccination campaign.

**Methods:** Among 1611 KT, 72 (4.2%) had COV-I (positive molecular nasopharyngeal swab) between 31 October 2021 and 15 January 2022 (3<sup>rd</sup> outbreak). Forty-one (57%) were male and 58 (80.5%) had a deceased donor transplant, median age was 52 (43-60) years, median transplant vintage 57 (27-159) months, median serum creatinine 1.37 (1.0-1.7) mg/dL. KT were on calcineurin inhibitors, prednisone, mycophenolate (MMF) and mTOR inhibitors in 93-87-79% and 5.6% respectively. At COV-I 43 KT had received 3 doses of Comirnaty (BNT162b2)®, 21 two and 4 one, 4 were not vaccinated. Δ variant was present in 36. Treatment included: increase of the daily steroid dosage (69%), MMF withdrawal (70%) or halving (5%) and monoclonal antibodies: Ronapreve® or Xevudy® (32%). Nine δ positive KT were hospitalized for severe respiratory distress: 2 died (6.6%).

**Results:** The variables associated with an increased risk for hospitalization were older age and dyspnea (p=0.023, p<0.0001 respectively). At multivariate analysis, dyspnea (p<0.0001) and MMF (p=0.003) were independently associated with the risk for hospitalization. Combination of the two variables increased the significance (p<0.0001). Comparing this series to the 82/1503 (5.4%) KT infected during the previous waves, hospitalization, mortality and cumulative mortality rates dropped from 45%, 29.3% and 13.4% to 30%, 6.6% and 2.7% respectively, main difference being the absence of vaccination in the first group.

**Conclusions:** Vaccinations did not reduce the incidence of COV-I among KT but provided certain protection associated with a significantly better outcome.

## FR-PO843

### Weight Gain in the First Year Post Kidney Transplantation

Ziad Arabi,<sup>1,2</sup> Jawaher N. Aljabri,<sup>1,2</sup> Mohammed H. Tawhari,<sup>1,2</sup> <sup>1</sup>Division of Nephrology, King Abdulaziz Medical City, Riyadh, Saudi Arabia; <sup>2</sup>King Abdullah International Medical Research Center; College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.

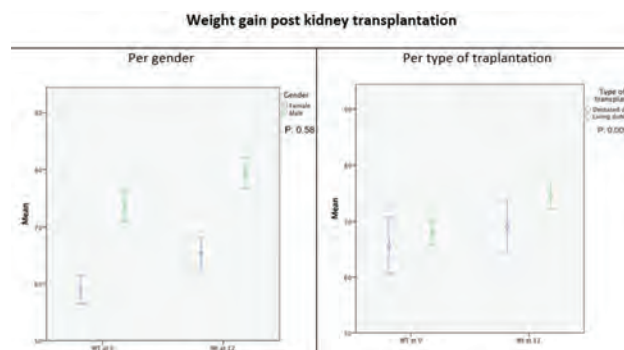

**Background:** Undesirable weight gain following kidney transplantation (KT) is relatively common. In this study we examined the incidence and risk factors for weight gain of >5% in the first post-transplantation year.

**Methods:** A single center retrospective study of the kidney transplant recipients (KTR) who underwent KT between 2017 to 2020 with 12 months follow up. We reviewed the patients' demographics, weight changes and A1C values. We also examined the factors associated with weight gain >5%.

**Results:** A total of 287 KTR were included. 74% were ≥ 30 years, 58% were men and 80% were living-donor KTR. Preemptive KT was 10.1%, PD: 11.5% and HD: 78.4%. At baseline, 20.2% of patients had obesity stage 1 (BMI: 30-34.9), while 4.2% had obesity stage 2 (BMI 35-39.9). Diabetes (DM) was present in 34.5% (n=99) of whom 25.3% had type-1 DM while 74.7% had type-2 DM. The average weight gain by one year of transplant was 6.0±8.3 (kg) and 59.6% patients had weight increase of ≥5%. Both males and females significantly gained weight and in a comparable degree (p: 0.588). Weight gain after living donor KT was much more than after deceased donor KT [6.63 Kg (5.58 to 7.69) versus 3.42 Kg (1.12 to 5.71), p: 0.009]. Multivariate analysis showed that the odd ratio of weight gain ≥ 5% after living donor KT (versus deceased donor) is OR: 2.86 (CI: 1.49 to 5.523, p: 0.002). Baseline BMI was negatively associated with weight gain post KT (OR: 0.9, CI: 0.854 to 0.949, p: <0.00). Age, gender, DM and hypertension were not associated with higher weight gain.

**Conclusions:** About two thirds of the renal transplant recipients gain at least ≥5% of their baseline weight by the first year after kidney transplantation. Recipients of living donor kidney transplant and those with lower BMI are at increased risk factor.

	BMI at baseline (pre-transplant)	BMI at 12 months (post-transplant)
Obese stage 2 (BMI 35-39.9)	12 (4.2%)	23 (11.4%)
Obese stage 1 (BMI: 30-34.9)	58 (20.2%)	59 (29.2%)
Overweight	84 (29.3%)	65 (32.2%)
Normal	103 (35.9%)	52 (25.7%)
Underweight	29 (10.1%)	3 (1.5%)

## FR-PO844

### The Impact of Kidney Transplantation on Systolic and Diastolic Blood Pressure and the Number of Blood Pressure Medications in the First Year Post Kidney Transplantation

Ziad Arabi,<sup>1,2</sup> Mohamad Y. Abdulgadir,<sup>1,2</sup> Talha M. Youssouf,<sup>1,2</sup> Abdullah S. Althani,<sup>1,2</sup> Hamzah A. Alhamzah,<sup>1,2</sup> Faye F. Alhejaili,<sup>1,2</sup> Elwaleed A. Elhassan,<sup>1,2</sup> <sup>1</sup>Division of Nephrology, Department of Medicine, King Abdulaziz Medical City, Riyadh, Saudi Arabia; <sup>2</sup>King Abdullah International Medical Research Center; College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.

**Background:** To examine the impact of kidney transplantation (KT) on systolic (SBP) and diastolic blood pressure (DBP) and the number of blood pressure (BP) medications in the first-year post-kidney transplantation at our center.

**Methods:** This is a single center retrospective study of renal transplant recipients who underwent KT between January 2017 and May 2020 with 12 months follow up. The BP target goal at the time of this retrospective study was <140/90 mm Hg. We reviewed

BP readings before and at one, 6, and 12 months after kidney transplantation. We also reviewed the number of BP medications at the same intervals post transplantation.

**Results:** A total of 278 renal transplant recipients were included. Of those, 74% were  $\geq 30$  years of age, 58% were men and 80% were living-donor kidney recipients. Preemptive transplantation was 10.1%, PD 11.5% and HD 78.4% respectively. At one year, 70.1% of patients attained the target BP goal. SBP was  $138.6 \pm 22.3$  at baseline and it improved by  $-6.51$  ( $-9.62$  to  $-3.4$ ) by 12 months ( $P < 0.001$ ). DBP was  $77.6 \pm 15.1$  at baseline and it improved by  $-5.25$  ( $-7.5$  to  $-3$ ) by 12 months ( $P < 0.001$ ). {Figure.1} These changes were observed in both genders and at a comparable difference ( $P = 0.579$  for SBP,  $P = 0.136$  for DBP). The number of blood pressure medications also significantly decreased. {Figure.2}

**Conclusions:** Our study demonstrated the positive effect of kidney transplantation on systolic and diastolic blood pressures in the first-year post transplantation in both genders. The number of BP medications also significantly decreased.

Number of medications	1 month	6 months	12 months	P (For 1 month vs. 12 months)
0	67 (23.3%)	82 (28.6%)	84 (29.3%)	0.001
1	91 (31.7%)	93 (32.4%)	89 (31%)	
2	85 (29.6%)	83 (28.9%)	81 (28.2%)	
3	27 (9.4%)	18 (6.3%)	18 (6.3%)	
4	6 (2.1%)	2 (0.7%)	6 (2.1%)	
5	2 (0.7%)			

## FR-PO845

### Do the Findings of Arterial Calcifications or Atherosclerosis on Pre-Transplant Cardiovascular Imaging Correlate With Persistent Hyperparathyroidism at 1 Year Post Kidney Transplantation?

Ziad Arabi,<sup>2,1</sup> Mohamad Y. Abdulgadir,<sup>2,1</sup> Talha M. Youssouf,<sup>2,1</sup> Aya K. Alkhudhairy,<sup>2,1</sup> Osama A. Mahmoud,<sup>2,1</sup> Elwaleed A. Elhassan,<sup>2,1</sup> Ahmad I. Alfaiw,<sup>2,1</sup> Hazim S. Alghamdi,<sup>2,1</sup> Hamzah A. Alhamzah,<sup>2,1</sup> Abdullah S. Althani,<sup>2,1</sup> <sup>1</sup>King Abdullah International Medical Research Center; College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia; <sup>2</sup>Division of Nephrology, Department of Medicine, King Abdulaziz Medical City, Riyadh, Saudi Arabia.

**Background:** Hyperparathyroidism is common in chronic kidney disease, and it can persist post kidney transplantation (KT). It is unknown whether the findings of arterial calcifications/ atherosclerosis on cardiovascular imaging pre- transplantation correlate with the persistence of hyperparathyroidism (persHPTH) at one-year post-renal transplantation.

**Methods:** A single center retrospective study of renal transplant candidates from January 2017 to May 2020. We collected patients' demographics, cardiovascular (CV) risk factors, the findings of pre- transplant CV imaging (echo, nuclear cardiac perfusion stress test, calcium scoring, cardiac catheterization results and the degree of calcification/ atherosclerosis of pelvic arteries on screening pelvic CT scan). We also collected iPTH values [at baseline (before transplant), 1- 6 months, 6-12 months, and 12-24 months post transplantation]. We defined persHPTH as iPTH  $\geq 25.5$  pmol/L after 12 months post kidney transplantation (normal= 12.73 pmol/L).

**Results:** A total of 287 kidney transplant recipients (KTR) were included. 74% were  $\geq 30$  years, 58% were men and 80% were living-donor KTR. Preemptive transplantation was performed in 10.1%. Dialysis modality used prior to KT was PD in 11.5% and HD in 78.4% (AVF: 42% versus Permcath: 58%). Dialysis vintage was  $4.8 \pm 3.3$  years for deceased donor kidney transplantation (DDKT) versus  $2.4 \pm 2.6$  years for living donor kidney transplantation (LKT). The prevalence of persHPTH was 16.4% ( $n=47$ ) There were no association between persHPTH and the findings of pre- transplant CV imaging including echo findings (EF, LVH and abnormal wall motion), cardiac nuclear perfusion stress test (cardiac PET), cardiac catheterization, calcification/atherosclerosis of pelvic arteries seen on screening pelvic CT scan. However, the presence of calcium scoring  $\geq 400$  on pre -transplant cardiac PET scan was associated with higher incidence of persHPTH at 12 months post renal transplantation (37% versus 13.1%;  $p: 0.013$ ).

**Conclusions:** Higher calcium scoring ( $> 400$ ) seen on cardiac PET scan during pre-transplant workup is associated with higher incidence of persHPTH at 12 months post KT.

## FR-PO846

### Do the Findings of Arterial Calcifications or Atherosclerosis on Pre-Transplant Cardiac Workup Correlate With Having Uncontrolled Hypertension Post Kidney Transplantation?

Ziad Arabi,<sup>1,2</sup> Mohamad Y. Abdulgadir,<sup>1,2</sup> Hamzah A. Alhamzah,<sup>1,2</sup> Nasser M. Alnazari,<sup>1,2</sup> Ahmad I. Alfaiw,<sup>1,2</sup> Mohammed H. Tawhari,<sup>1,2</sup> Elwaleed A. Elhassan,<sup>1,2</sup> Dr Junaid Iqbal,<sup>1,2</sup> Faye F. Alhejaili,<sup>1,2</sup> <sup>1</sup>Division of Nephrology, Department of Medicine, King Abdulaziz Medical City, Riyadh, Saudi Arabia; <sup>2</sup>King Abdullah International Medical Research Center; College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.

**Background:** ESKD is often associated with higher calcium scoring, calcification of the arteries or abnormal echocardiography findings. It is unknown if these anatomical changes contribute to uncontrolled hypertension (HTN) post KT.

**Methods:** A single center retrospective study of kidney transplant recipients (KTR) who underwent KT between January 2017 and May 2020 and followed up for 12 months. The BP target was  $<140/90$  mmHg as per published guidelines at the time of this study. We divided patients according to their blood pressure (BP) control at one-year post KT, into two groups: controlled ( $\leq 140/90$ ) and uncontrolled ( $>140/90$ ). We collected data about patients' demographics, baseline cardiovascular risk factors and their pretransplant imaging. Analyzed parameters included echocardiography (ejection fraction and wall motion abnormalities), nuclear stress test (calcium scoring, and cardiac perfusion), cardiac catheterization, and CT of pelvic arteries (assessing severity of calcifications/ atherosclerosis).

**Results:** A total of 254 KTR were included. Of those, 74% were  $\geq 30$  years, 58% were men and 80% were living-donor kidney recipients. Preemptive transplantation was 10.1%, PD 11.5% and HD 78.4%, respectively. At one year, 76 (29.9%) of the patients did not attain the target BP goal of  $<140/90$ . No pre-transplant cardiovascular imaging finding was associated with uncontrolled BP. Age (47 vs. 41 years,  $P=0.008$ ), and DM ( $P=0.012$ ) were significantly correlated with higher incidence of uncontrolled HTN. However, gender, dialysis vintage, preemptive transplantation, type of dialysis, and type of transplant (living vs. deceased-donor KT) were not different among the two groups. Multivariate analysis showed that an elevated creatinine ( $OR=1.016$ ,  $CI=1.004-1.028$ ,  $p=0.01$ ) and smoking ( $OR=3.58$ ,  $CI=1.001-12.8$ ,  $p=0.05$ ) were significantly associated with uncontrolled BP.

**Conclusions:** Arterial calcification/ atherosclerosis on pre-KT cardiac work up did not correlate with uncontrolled hypertension at 12 months post KT.

## FR-PO847

### Persistent Hyperparathyroidism Post Kidney Transplantation

Ziad Arabi,<sup>1,2</sup> Abdullah S. Althani,<sup>1,2</sup> Jawaher N. Aljabri,<sup>1,2</sup> Mohammed H. Tawhari,<sup>1,2</sup> Ahmad I. Alfaiw,<sup>1,2</sup> <sup>1</sup>Division of Nephrology, Department of Medicine, King Abdulaziz Medical City, Riyadh, Saudi Arabia; <sup>2</sup>King Abdullah International Medical Research Center; College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.

**Background:** Hyperparathyroidism (HPT) is a frequent complication in chronic kidney disease and may persist in 20 to 50% of cases one year after kidney transplantation; and may contribute to long term allograft dysfunction and increased risk of fractures. There is scant data on the prevalence of post-transplant HPT in kidney transplant patients in Saudi Arabia. The aim of this study is to evaluate the prevalence of this complication and to identify its risk factors in single center in Saudi Arabia.

**Methods:** In a retrospective study, data of 287 kidney transplant recipients, who underwent kidney transplant between January 2017 and May 2020 were collected. Data included demographic characteristic, history of hypertension, diabetes mellitus, coronary artery disease, duration of chronic kidney disease and dialysis therapy, dialysis modality, and type of vascular access. Serum iPTH measured prior to transplant then every 6 months post-transplant for 2 years.

**Results:** Of 287 kidney transplant recipients: 119 (41.5%) were diabetic and 38 (13.2%) had coronary artery disease. 231 (80.5%) had received living-donor kidneys and 56 (19.5%) were cadaveric recipients. iPTH was before transplant:  $82.2 \pm 84.2$  pmol/L, 1- 6 months:  $27.5 \pm 31.4$ , 6-12 months:  $28.8 \pm 35.9$ , and 12-24 months:  $30.1 \pm 43.3$ .  $p$  value  $< 0.001$ . Figure.1 Persistent hyperparathyroidism was found in 47 (16%) of patients at one year post renal transplant. The presence of diabetes mellitus as well as the duration of dialysis were predictors of persistent HPT. Type of transplant and allograft function did not seem to have any correlation.

**Conclusions:** In a single center experience, (16%) of kidney transplant patients had persistent HPT and the presence of diabetes mellitus and the duration of dialysis were important risk factors in its development.

iPTH post kidney transplantation

## FR-PO848

## Kidney Transplant Outcomes in Patients With Scleroderma: A Single Center Experience

Juan P. Portocarrero Caceres, Cybele Ghossein, Ibrahim Tawhari. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

**Background:** Scleroderma Renal Crisis (SRC) is a devastating complication of Scleroderma (SSc) affecting 5-20% of all SSc patients. End stage kidney disease (ESKD) develops in 25-40% of SRC patients. Kidney transplantation (KT) is a viable option for patients that progress to ESKD, but little data exists on outcomes in this population. Here we report on patient and graft outcomes in a case series of SSc patients undergoing KT.

**Methods:** This was a retrospective study of all patients with SSc who underwent KT at Northwestern Hospital between 2000 and 2020. The objective of this study were to determine graft and patient survival at year 1, 5 and 10 post-transplant.

**Results:** Nine patients (eight females and one male) with SSc underwent KT. All the patients had diffuse SSc. Six patients were on HD and three had preemptive transplantation. Five patients had a Living Donor KT (LDKT) while 4 had a deceased donor KT (DDKT). Only one patient had delayed graft function. Standard immunosuppression was used as induction and maintenance. All patients were maintained on ace inhibitors post-transplant. Graft survival at 1, 5 and 10 years was 100%, 100% and 78% respectively (Table 1). The survival rate in our cohort was similar to graft survival. Two patients had recurrence of SRC at 3 and 6 years respectively after transplant[GC1], leading to ESKD.

**Conclusions:** KT is a viable option for patients with ESKD due to SSc with acceptable graft and patient survival. Recurrence of SRC while rare can occur years after initial KT.

Table 1. Clinical characteristics and outcomes of KT in SSc patients

Female Gender	8 (88.9%)
Age in years	61 (+/-4)
Patients on HD	6 (66.6%)
Time on HD in years	2.5 (+/-1)
Living Donor Transplant	5 (55.5%)
Deceased Donor Transplant	4 (44.4%)
ACE-i Post-Transplant	9 (100%)
Graft Survival Rate (%)	
1 year	100%
5 years	100%
10 years	78%

## FR-PO849

## Healthcare Resource Utilization Associated With Post-Transplant Neutropenia and Leukopenia Among Kidney Transplant Recipients: A Real-World Evidence Study

Sanjay Merchant,<sup>1</sup> Amit Raval,<sup>1</sup> Vladimir Turzhitsky,<sup>1</sup> Elnara Fazio-Eynullayeva,<sup>2</sup> Harry Jin.<sup>2</sup> <sup>1</sup>Merck and Co Inc, Rahway, NJ; <sup>2</sup>TriNetX LLC, Cambridge, MA.

**Background:** Kidney transplant recipients (KTRs) are often prescribed medications to reduce the risk of cytomegalovirus (CMV) infection, including valganciclovir/ganciclovir (V/G), however, use of V/G increases the risk of developing post-transplant neutropenia (PTN) and post-transplant leukopenia (PTL). Real-world evidence describing health care resource utilization (HCRU) associated with PTN/PTL are limited.

**Methods:** This retrospective cohort study utilized the TriNetX Dataworks – USA Network, a federated network of de-identified electronic health record data for 82.5 million patients in the US. KTRs who were treated with V/G between January 1, 2012, and September 30, 2020, were included in this analysis. PTN was defined as absolute neutrophil count <1500/ $\mu$ L, and PTL was defined as white blood cell count <3,500/ $\mu$ L. We analyzed HCRU among KTRs and compared HCRU between those with and without PTN/PTL.

**Results:** Overall, 8,791 patients had a mean age of 52.8 years, 40.7% female, 41.6% White, and 32.6% Black. A total of 3,383 patients (38.5%) developed PTN and 6,127 patients (69.7%) developed PTL. The mean (SD) time from transplantation to the development of PTN or PTL were 5.6 (3.1) months and 6.4 (3.7) months, respectively. Among the 3,383 patients who developed PTN, 61.5% had inpatient admission(s), 16.5% had PTN-related hospitalization, 36.7% had emergency room visit(s), and 38.9% were treated with G-CSF. Similarly, among the 6,127 patients who developed PTL, 60.8% had inpatient admission(s), 24.5% had PTL-related hospitalization, 34.9% had emergency room visit(s), and 22.8% were treated with G-CSF.

**Conclusions:** The results of the study suggest that V/G treated KTRs are at elevated risk of developing PTN/PTL, both of which are associated with increased HCRU. Further research is needed to inform the development of interventions designed to decrease the risk of suboptimal health outcomes and HCRU among KTRs.

**Funding:** Commercial Support - Merck & Co., Inc

## Health care resource utilization among KTRs

	With PTN (n=3,383)	Without PTN (n=5,408)	P-value	With PTL (n=6,127)	Without PTL (n=2,664)	P-value
Inpatient admission post-transplant	2,080 (61.5%)	2,990 (55.3%)	<0.001	3,724 (60.8%)	1,346 (50.5%)	<0.001
Neutropenia/Leukopenia-related hospitalization	555 (16.5%)	58 (1.1%)	<0.001	1,502 (24.5%)	89 (3.3%)	<0.001
Emergency room visit	1,242 (36.7%)	1,689 (31.2%)	<0.001	2,138 (34.9%)	793 (29.8%)	<0.001
Granulocyte colony-stimulating factor (G-CSF) use	1,316 (38.9%)	195 (3.6%)	<0.001	1,398 (22.8%)	113 (4.2%)	<0.001

## Kidney Transplantation in Elderly Patients With ESKD: A Systematic Review and Meta-Analysis

Masahiko Yazawa,<sup>1</sup> Maho Terashita,<sup>1</sup> Takamasa Miyauchi,<sup>1</sup> Hideyo Oguchi,<sup>2</sup> Makoto Tsujita,<sup>3</sup> Tadashi Sofue,<sup>4</sup> Kosuke Masutani.<sup>5</sup> <sup>1</sup>St. Marianna University School of Medicine, Kawasaki, Japan; <sup>2</sup>Toho University Faculty of Medicine, Tokyo, Japan; <sup>3</sup>Masuko Memorial Hospital, Nagoya, Japan; <sup>4</sup>Kagawa University, Kagawa, Japan; <sup>5</sup>Faculty of Medicine, Fukuoka University, Fukuoka, Japan.

**Background:** Kidney transplantation (KT) provides considerably better survival than dialysis, although this reflects outcomes from young or middle-aged adults. With the increasing average age of patients receiving dialysis, it is expected that elderly patients will prefer KT. Although some studies have examined the prognosis of KT in elderly patients, the solid evidence on whether performing a kidney transplant is more effective than continued dialysis needs to be evaluated.

**Methods:** In this systematic review and meta-analysis, a literature search was performed in PubMed/MEDLINE until August 25, 2021, for studies with KT and dialysis therapy in elderly patients as key terms. Primary screenings of 3,116 articles were performed to include observational studies with patients age  $\geq 65$  years that compared KT and dialysis and with outcomes (mortality). A total of 17 articles were extracted for a full read as secondary screening. Statistical analysis was performed on mortality, which was the only parameter that could be integrated, and the adjusted hazard ratio (aHR) for each study was evaluated using RevMan (Reviewer Manager). This study was conducted according to the Japanese Society of Nephrology for Chronic Kidney Disease guideline 2023.

**Results:** On secondary screening, six observational studies were identified that evaluated mortality. The aHR was calculated for four of these studies. Among end-stage kidney disease (ESKD) patients aged  $\geq 65$  years, the aHR for mortality of the KT group was 0.52 (95% confidence interval [CI]: 0.47-0.56), which was significantly lower than that of the dialysis group (mainly patients on waiting list). A sub-analysis of three studies for only patients aged  $\geq 70$  years, showed that the mortality risk was significantly lower in the KT group (aHR: 0.61, 95% CI: 0.55-0.67).

**Conclusions:** This study showed that compared with dialysis therapy, KT was associated with lower mortality in elderly ESKD patients.

FR-PO851

Cardiovascular Outcomes in Kidney Transplant Recipients With Autosomal Dominant Polycystic Kidney Disease

Maroun Chedid<sup>1</sup>, Hasan-Daniel N. Kaidbay,<sup>2</sup> Stijn Wigerinck,<sup>1</sup> Dalia Zubidat,<sup>1</sup> Prajwal Reddy,<sup>1</sup> Parikshit Duriseti,<sup>1</sup> Naim S. Issa,<sup>1</sup> Ziad Zoghby,<sup>1</sup> Christian Hanna,<sup>1</sup> Sarah R. Senum,<sup>1</sup> Peter C. Harris,<sup>1</sup> Vicente E. Torres,<sup>1</sup> Vuyisile T. Nkomo,<sup>1</sup> Fouad T. Chebib.<sup>1</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Lebanese American University, Beirut, Lebanon.

**Background:** Cardiovascular disease leads to high morbidity and mortality in patients with kidney failure who undergo kidney transplantation. Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a systemic disease with various cardiac abnormalities. However, details on the cardiovascular profile in ADPKD patients undergoing kidney transplantation (KT) and its progression following transplantation are limited

**Methods:** Echocardiographic data within 2 years prior to kidney transplantation (1993-2020), and MACE (major adverse cardiovascular events) post transplantation were retrieved. The primary outcome was to assess cardiovascular abnormalities on echocardiography at time of transplant in ADPKD as compared to diabetic (DN) and nondiabetic non-ADPKD (NDNA) (n=217 each group) patients, matched by gender (male, 59.4%) and age at transplantation (57.2 ± 8.8 years) (Table 1)

**Results:** Compared with DN and NDNA patients at time of transplantation, patients with ADPKD had lower rates of left ventricular hypertrophy (39.4% vs 66.4% vs 48.6%), mitral (2.7% vs 6.3% vs 7.45) and tricuspid regurgitations (1.8% vs 6.6%, 7.2%) (Table 1). ADPKD patients had less diastolic (25.3%) and systolic (5.6%) dysfunction at time of transplantation. ADPKD patients had the most favorable post-KT survival (median survival 18.7 years vs 12.0 for DN and 13.8 years for NDNA; P<0.01) and the most favorable MACE-free survival rate (HR=0.51, P<0.001). Finally, ADPKD patients showed an improvement of systolic function post-KT compared to pre-transplantation (7.96 vs 6.20%, P=0.53); however, ADPKD patients had worsening of their valvular function and an increase in the sinus of Valsalva diameter (38.2 vs 39.9 mm, P<0.01).

**Conclusions:** ADPKD transplant recipients had the most favorable cardiac profile pre-transplantation with better patient survival and MACE-free survival rates but worsening valvular function and increasing sinus of Valsalva diameter, as compared to those with other kidney diseases.

Table 1: Baseline characteristics and echocardiographic findings among kidney failure patients at time of transplantation

	ADPKD	Diabetic High-risk group	Non-Diabetic, Non-ADPKD	p value
Hypertension at time of transplant, n (%)	252 (100.0)	316 (100.0)	216 (100.0)	p<0.001
Diabetes at time of transplant, n (%)	22 (8.3)	173 (100.0)	54 (25.0)	p<0.001
LV hypertrophy present by LVH/height <sup>2.7</sup> measurement, n (%)	87 (39.4)	142 (66.4)	105 (48.6)	p<0.001
Diastolic dysfunction present, n (%)	18 (25.3)	17 (53.3)	23 (42.6)	p=0.002
≥ Moderate mitral valve regurgitation, n (%)	6 (11.1)	13 (19.3)	17 (27.4)	p=0.06
≥ Moderate tricuspid valve regurgitation, n (%)	4 (11.8)	15 (44.1)	17 (27.4)	p<0.001
LVEF < 45%, n (%)	13 (5.6)	18 (54.6)	29 (52.8)	p<0.001

FR-PO852

Safety and Efficacy of Long-Term Use of GLP-1RA in Post-Transplant Diabetes Mellitus (PTDM): Analysis of Dulaglutide vs. Liraglutide

Ritwika Mallik, Dorcas Mukuba, Mahalia Casabar-Licayan, Stanley Fan, Kieran McCafferty, Omer Ali, Muhammad Magdi Yaqoob, Tahseen A. Chowdhury. *The Royal London Hospital, London, United Kingdom.*

**Background:** GLP-1RA are increasingly used in PTDM patients with limited long-term safety and efficacy data. We reviewed the real-world data of the use of Dulaglutide versus Liraglutide in our centre.

**Methods:** Retrospective analysis was performed in kidney transplant recipients with PTDM and T2D treated for a minimum of 6 months on GLP-1RA therapy. Changes in clinical and biochemical parameters, doses of insulin and immunosuppressive medications, rejection episodes and graft function were assessed.

**Results:** 17 patients were on Dulaglutide and 6 on Liraglutide. Mean age was 56 ± 8.5 years, 65% male, 61% South-Asian and 22% White. Between-group differences in change of weight, blood pressure (BP), HbA<sub>1c</sub>, alanine transaminase (ALT), creatinine, eGFR and urine protein: creatinine ratio (uPCR) was not statistically significant at 6, 12 and 24 months. Both treatments resulted in decreased weight (more marked with liraglutide at 24 months), HbA<sub>1c</sub> (more marked in Dulaglutide at 24 months) and insulin doses compared to baseline. There were no changes in immunosuppressive medication due to GLP-1RA despite universal use of mycophenolate. GLP-1RA were discontinued due to adverse effects in 3 patients.

**Conclusions:** Addition of GLP-1RA therapy in transplant patients with diabetes was well tolerated, with improvement in glucose control and weight. There was no between-group difference in the parameters. Further prospective randomized control studies are warranted.

	Dulaglutide	Liraglutide

Immunosuppression Practices in Failing Renal Allografts: A South Asian Perspective

Srikanth Bathini<sup>1</sup>, Vivekanand Jha,<sup>2,3</sup> <sup>1</sup>Asian Institute of Nephrology and Urology, Hyderabad, India; <sup>2</sup>The George Institute for Global Health, New Delhi, India; <sup>3</sup>Manipal Academy of Higher Education, Manipal, India.

**Background:** Immunosuppression practices in failed grafts vary across the world. While the available evidence is not robust, multiple factors complicate the decisions. We conducted a survey to understand these practices in South Asia.

**Methods:** We distributed a web-based survey to identify the patterns and factors influencing immunosuppression use through a mailing list of over 2000 transplant teams. We collected data on factors affecting their practices in failing renal allografts.

**Results:** We received 190 valid responses. 88.9% individualized the decision to wean immunosuppression (IS) while 11.1% used a standard protocol. 63.8% first withdrew antimetabolite whereas CNI was most likely to be withdrawn next at 58.9%. 90% continued steroids. 26.3% made a CNI to mTOR inhibitor switch. Factors considered in changing (IS) included ongoing rejection (77.8%), infections (72.6%), & re-transplant prospects (71.1%). Ongoing rejection/graft intolerance (45.3%) and steroid-resistant rejection (17.4%), were the major indications for nephrectomy.

**Conclusions:** Immunosuppression (IS) practices in failed grafts across South Asia are varied and are guided by individual choices but not a standardized protocol. Ongoing rejection, & re-transplant prospects prompt continuation of IS, and graft intolerance was the most common indication for graft nephrectomy.

Factors Considered in Continuing/Stopping Immunosuppression

Factors Considered in Continuing/Stopping Immunosuppression	Percentage of Respondents
Ongoing Features of Rejection	77.8
History of Infections	72.6
Plans to Re-Transplant	71.1
Urine Output	48.4
History of BK Nephropathy	46.3
History of Rejection	39.5
Panel Reactive Antibody Status	37.4
Refractory Anemia with Raised CRP	33.6
Kidney Disease Recurrence	31.1
Cost of Medication	24.2

Respondents were asked to choose as many factors as they would consider before deciding to stop/continue immunosuppression.

FR-PO854

Is It Calcineurin Inhibition That Abolishes Cardiovascular Sex Differences in Kidney Transplant Patients?

Zeynep Ural. *Gazi Universitesi Tıp Fakültesi, Ankara, Turkey.*

**Background:** Cardiovascular disease (CVD) is the leading cause of death after renal transplantation. Cardiac hypertrophy is a stronger risk factor for heart failure. Estrogen protects heart by counteracting pro-hypertrophy signaling pathways. Whereas androgen mostly plays an opposite role in cardiac hypertrophy. Cardiac hypertrophy is characterized by abnormality of intracellular calcium homeostasis and calcium related

activation of major hypertrophic signaling pathway (calcineurin-nuclear factor activation transcription pathway). Estrogen inhibits calcineurin expression. In this study we aimed to explore sex difference in cardiac hypertrophy and sex specific cardiac hypertrophy rates in renal transplant patients under CNI (Calcineurin inhibitors) or mTORi (mammalian target of rapamycin inhibitors) based regimes.

**Methods:** This study consist of one hundred and fifty two (152) renal allograft recipients with less than one year of dialysis and who are at least three years of follow-up. The exclusion criterias were, dialysis for more than one year before transplant, pre-transplant cardiac hypertrophy. Echocardiograms of the patients at the third year after transplantation were evaluated. Ejection fraction rate, left atrial diameter, presence of left ventricular hypertrophy were evaluated.

**Results:** Baseline characteristics and helath parameters were similar between CNI and mTORi based regimes. Ejection fraction, left atrial diameter, left ventricular hypertrophy were evaluated. There is important difference between man and women for echocardiography findings. Moreover, cardiac hypertrophy findings were significantly less observed in those using the CNI regimen (%5,7 to %29). In addition, cardiac hypertrophy was more common in males using mTORi regimen (Male/female; %35/%18), while there was no difference males and females using CNI regimen (Male/female; %6/%5,2).

**Conclusions:** The role of the calcineurin pathway in cardiac hypertrophy has been demonstrated in many studies. Cardiac hypertrophy and heart failure, which are one of the most important causes of death in kidney transplant patients, can be prevented by calcineurin inhibition. Further prospective studies with larger numbers of patients examining this effect are needed. This effect of estrogen on the calcineurin pathway may be the solution to one of our most important problems in kidney transplant patients.

## FR-PO855

### Expanded Experience With Ultra-Short Duration Pangenotypic Direct Acting Anti-Viral (DAA) to Prevent Virus Transmission From Hepatitis C Viremic Donors to Hepatitis C Negative Kidney Transplants

Idris Yakubu, Dhiren Kumar, Marlon F. Levy, Layla Kamal, Gaurav Gupta. *Virginia Commonwealth University Health System, Richmond, VA.*

**Background:** Studies have shown that HCV D+/R- kidney transplantation (KT) is feasible using 8-12 weeks of DAAs. The use of abbreviated regimens may obviate the need for insurance approval and delay in therapy. We previously showed low transmission with a prophylactic peri-operative 7-day DAA (Sofusobuvir/Velpatasvir; SOF/VEL) regimen for KT. Ezetimibe (EZ), has been shown to restrict HCV entry in hepatocytes in a humanized mouse model. Studies suggest that EZ may be synergistic in reduction of HCV transmission from donors to recipients. We report our experience on 115 D+/R- KT with or without EZ to the prophylactic regimen.

**Methods:** Data were collected via an Ethics Board approved prospective registry (REFORMHEPC). Inclusion criteria included: a) De-novo transplant; b) cPRA ≤50%; c) absence of synthetic liver dysfunction; and c) absence of active viral hepatitis. Primary outcome was donor HCV transmission at 90 days post-transplant. Patients were screened with HCV NAT at Day 7, 14, 28 and 90 post-transplant. All subjects received an initial dose of SOF/VEL +/- EZ on day 0 ≤6 hours prior to transplant and then daily for a total of 7 days. The protocol mandated initiation of full-course DAA therapy in case of 2 consecutive positive NAT tests.

**Results:** 115 D+/R- transplants (mean age=56 yrs) were included from May 2019-August 2021. The distribution of patients across the two groups was Group 1 (7 days prophylaxis with SOF/VEL alone; N=32) and Group 2 (7d prophylaxis with SOF/VEL plus EZ; N=83). Patients enrolled in the two groups were demographically similar. Five patients (5/115; 4.3%; 95%CI:2%-10%) developed HCV viremia [1/32 (3%) in group 1, and 4/83 (4.8%) in group 2]. The donor genotypes (GT) are as follows: 3/5 (60%) GT3; 1/5 (20%) GT1b; 1/5 (20%) GT2b. All 5 patients with HCV transmission achieved SVR with 12 weeks of Glecapravar/Pibrentasvir therapy.

**Conclusions:** Our data suggests that 7-days ultra-short duration pan-genotypic SOF/VEL prophylaxis was safe and largely effective in preventing donor-derived HCV transmission and has the potential of resulting in significant cost-savings by avoiding longer DAA therapy in a large majority of D+/R- KT. The addition of EZ did not appear to provide any additional benefit in preventing HCV viral transmission.

## FR-PO856

### Three Decades of Dialysis Initiation After Kidney Transplant (KT) Failure: Trends in Waitlisting, Retransplantation, and Survival (1988-2018)

Pascale Khairallah,<sup>1</sup> Jingbo Niu,<sup>1</sup> Elizabeth C. Lorenz,<sup>2</sup> Wolfgang C Winkelmayer.<sup>1</sup> <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>Mayo Foundation for Medical Education and Research, Rochester, MN.

**Background:** The number of persons returning to dialysis after KT failure has been increasing; they now constitute the 4th largest group of dialysis starts. Little is known about the trends in mortality, waitlisting, and retransplantation and after KT failure.

**Methods:** From the USRDS we identified patients age ≥18 yrs who received a first KT and experienced KT failure between 1/1/1988 and 12/31/2017. Recipients of other solid organ allografts were excluded. Patients were followed from the time of KT failure date to the outcomes of 1) death, 2) waitlisting, and 3) retransplantation. Patients were censored at end of dialysis record, end of Medicare coverage, or at 5 yrs from time of KT failure. We used multivariable Cox regression to estimate hazard ratios (HR) and 95% confidence intervals (CI) comparing death, and cause-specific hazard model to compare other outcomes across subsequent eras relative to 1988-92.

**Results:** We studied 100,373 patients with a failed first KT. Of all patients initiating dialysis de novo, the proportion of patients (re)initiating dialysis after allograft failure increased from 2.49% in 1988-92 to 3.94% in 2013-17. The median age at which allografts failed increased from 41 yrs in 1988-92 to 56 yrs in 2013-2017. After adjusting for age, sex, race and ethnicity, and relative to 1988-92: 1) mortality was 10%, 25%, and 34% significantly lower in 2003-07, 2008-12, and 2013-17, respectively; 2) the rates of waitlisting were similar across subsequent eras, but 24% lower in 2013-17 (3.2% of patients were waitlisted preemptively); and 3) the rates of retransplantation were between 13% and 20% lower in later eras (Figure).

**Conclusions:** While mortality rates of patients with failed allografts have improved over time, rates of waitlisting and retransplantation rates have decreased. Understanding the barriers to retransplantation will be crucial to inform potential future interventions designed to improve access to KT in this growing population.

**Funding:** NIDDK Support

Figure. Hazard ratios and 95% confidence intervals of mortality, waitlisting, and re-transplantation following kidney transplant failure in subsequent eras compared to 1988-1992.

## FR-PO857

### Nationwide Pregnancy Outcomes After Kidney Transplantation and Prediction of Adverse Pregnancy Outcomes: A Dutch Cohort Study

Margriet Gosselink,<sup>1</sup> Marleen V. Buren,<sup>2</sup> Judith Kooiman,<sup>1</sup> Henk Groen,<sup>3</sup> Wessel Ganzevoort,<sup>4</sup> Henk W. Van Hamersvelt,<sup>5</sup> Olivier W. van der Heijden,<sup>5</sup> Jacqueline Van De Wetering,<sup>2</sup> Titia Lely,<sup>1</sup> PARTOUT working group <sup>1</sup>Universitair Medisch Centrum Utrecht - Locatie Wilhelmina Kinderziekenhuis, Utrecht, Netherlands; <sup>2</sup>Erasmus MC, Rotterdam, Netherlands; <sup>3</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>4</sup>Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; <sup>5</sup>Radboudumc, Nijmegen, Netherlands.

**Background:** Although numbers of pregnancy after kidney transplantation (KT) are rising, high risks of adverse pregnancy outcomes (APO) remain. Though important for preconceptional counselling and pregnancy monitoring, analyses on APO after KT per pregnancy eGFR-CKD-categories have not been performed on a large scale before.

**Methods:** A Dutch nationwide cohort study investigated consecutive singleton pregnancies >20 weeks of gestation after KT between 1971-2017. Outcomes were analysed per pregnancy eGFR-CKD-category. A composite adverse pregnancy outcome (cAPO) was established including birthweight <2500 gram, preterm birth <37 weeks, 3<sup>rd</sup> trimester severe hypertension (SBP >160 and/or DBP >110 mmHg) and/or >15% increase in serum creatinine (SCR) during pregnancy. Risk factors for cAPO were analysed in a multilevel model after multiple imputation of missing predictor values.

**Results:** 288 pregnancies in 192 women were included. Total live birth was 93%, mean gestational age 35.6 weeks, mean birthweight 2383 gram. Independent risk factors for cAPO were pregnancy eGFR, midterm percentage SCR dip and midterm mean arterial pressure dip; ORs 0.98 (95% CI 0.96-0.99), 0.95 (0.93-0.98) and 0.94 (0.90-0.98). cAPO was a risk indicator for graft loss (HR 2.55, 1.09-5.96) but no significant risk factor on its own when considering pregnancy eGFR (HR 2.18, 0.92-5.13).

**Conclusions:** This was the largest and most comprehensive study of pregnancy outcomes after kidney transplantation. The novel analysis per eGFR-CKD-category, including pregnancies in women with poor kidney function, facilitates pregnancy counselling. Overall obstetric outcomes are good. The risk of adverse outcomes is mainly dependent on pre-pregnancy graft function and hemodynamic adaptation to pregnancy.

## FR-PO859

### Racial and Ethnic Disparities in the Anatomic Location of Arteriovenous Access (AVA) for Hemodialysis (HD) Initiation

Melandra L. Worsley, Wolfgang C. Winkelmayer, Kevin F. Erickson, Jingbo Niu, L Parker Gregg. *Baylor College of Medicine, Houston, TX.*

**Background:** Racial/ethnic disparities have been shown in the type of AVA (arteriovenous fistula [AVF] vs graft [AVG]) used at incident HD. We evaluated racial and ethnic disparities in the anatomic location of HD AVA in the U.S.

**Methods:** Using the clinical records of a large dialysis organization we evaluated patients ≥16 years old with incident end-stage kidney disease who initiated outpatient center HD via an AVF or AVG between 2006-2021. Individuals who initiated HD via a catheter, had multiple access types/locations reported at incident HD, were on peritoneal dialysis, or had a kidney transplant were excluded. Race/ethnicity was categorized as White, Black, Hispanic, or other. Access location was defined as forearm vs non-forearm.

Multivariable logistic regression estimated associations of race/ethnicity with AVA forearm location and trends over time in AVA location using race x year interaction terms.

**Results:** Of 42,373 participants, 22,596 were White, 10,729 were Black, 5,054 were Hispanic, and 3,994 were other races; 61% had diabetes and 6% had heart failure. There was a decrease in HD initiation via a forearm AVA over time in all race/ethnicity groups (**Figure 1A**). In 2006, 48% had a forearm AVA, compared to 28% in 2021. An omnibus test for interaction of race x calendar time was significant (p=.006). In 2021, Black patients were 24% (95% CI, 16%-31%) less likely and Hispanic patients were 19% (95% CI, 8%-28%) less likely than White patients to initiate HD with a forearm AVA; these findings were consistent within the AVF and AVG subgroups (**Figure 1B**). Other races were 23% (95% CI, 8%-41%) more likely than White patients to initiate HD with a forearm AVA.

**Conclusions:** Racial disparities exist in the anatomic location of AVA used for initiation of outpatient HD with Black and Hispanic patients being less likely than White patients to have a forearm location. Use of forearm AVA, generally the preferred anatomic location, has decreased over time across all racial/ethnic groups. Further investigation is needed into factors influencing these disparities and temporal trends.

FR-PO860

**Patient and Physician Perspectives on Treatment Burden in ESKD: a Nominal Group Technique Study**  
Sarah T. Thomas,<sup>1</sup> Adem Sav,<sup>2</sup> Rae Thomas,<sup>3</sup> Magnolia Cardona,<sup>3</sup> Zoe A. Michaleff,<sup>3,4</sup> Thomas T. Titus,<sup>1</sup> Claudia C. Dobler.<sup>3,5</sup> <sup>1</sup>Gold Coast Hospital and Health Service, Southport, QLD, Australia; <sup>2</sup>Queensland University of Technology Faculty of Health, Kelvin Grove, QLD, Australia; <sup>3</sup>Bond University Faculty of Health Sciences and Medicine, Gold Coast, QLD, Australia; <sup>4</sup>Northern NSW Local Health District, Lismore, NSW, Australia; <sup>5</sup>The George Institute for Global Health, Newtown, NSW, Australia.

**Background:** The treatment workload associated with end stage kidney disease (ESKD) is high. The treatment burdens experienced by ESKD patients are not well understood. We aimed to elucidate the most important areas of treatment burden for discussion in a clinical encounter from ESKD patients and nephrologists' perspectives, as well as possible solutions to these treatment burden challenges.

**Methods:** ESKD participants with diverse characteristics were purposively recruited from one tertiary treatment centre in Queensland, Australia. Nominal group technique (NGT), a mixed-methods consensus approach, was used to collect data. Treatment burden themes generated were ranked in order of importance. Three in-person NGT sessions were conducted with ESKD patients. One online NGT session was conducted with nephrologists from two Australian states.

**Results:** Nineteen dialysis-dependent ESKD patients (mean age 64 years; range 47-82) and six nephrologists participated. All patients were retired or on a disability pension; 74% perceived moderate or severe treatment burden; 90% spent more than 11 hours on treatment-related activities per week (range 11-30). Every patient group ranked *health system issues* as the most important treatment burden priority encompassing lack of continuity and coordination of care, dissatisfaction with frequent healthcare encounters and challenges around healthcare access. Physicians perceived *psychosocial burdens* of treatment to be most important to patients and families, which was ranked the second highest priority by patients.

**Conclusions:** Discussing treatment burden in a clinical encounter may lead to a better understanding of patients' capacity to cope with their treatment workload. This could facilitate tailored care, improve health outcomes, treatment sustainability, and patients' overall quality of life.

Figure 1. Comparison of treatment burden priorities in patients and physicians

FR-PO861

**Protecting the Vulnerable: The Challenges of Dialysis in the Mentally Ill**  
Julie Steinberg,<sup>1</sup> Lauren Sparber.<sup>2</sup> <sup>1</sup>Cohen Children's Medical Center, Queens, NY; <sup>2</sup>Northwell Health, New Hyde Park, NY.

**Introduction:** We present a case of a patient with mental illness who is refusing life-saving hemodialysis. The interdisciplinary moral distress experienced and the journey of managing chronic illness in the setting of psychiatric illness will be illustrated through the framework of ethical principles. This case brings to light several issues including the role of proportionality and social justice issues related to social determinants of health including potential social and/or moral health disparity.

**Case Description:** We report a case of a 58 year old female with PMH of ESRD on dialysis (often non-compliant with dialysis), hypertension, hyperlipidemia and morbid obesity who presented to the ED with complaint of "vomiting blood". It is noted that when questioned the patient stated "they told me I was vomiting blood" and when asked to elaborate she stated the person she lives with told her this. Patient was admitted for treatment and management of severe electrolyte derangements secondary to non-compliance with hemodialysis and medications. Patient initially evaluated by Psychiatry and diagnosed with major depressive disorder. Throughout this lengthy complex hospital course it was evident that patient was becoming more delusional as she no longer believed she had renal failure despite ten months of dialysis.

**Discussion:** The ethical analysis faces the substantial difficulty of balancing 3 bioethical principles in "managing" the patient's renal disease: Beneficence, which leads her physicians to recommend hemodialysis due to ESRD; Respect for Autonomy, the patient's own right to self-determination in matters related to the integrity of her body and self; and Non-Maleficence, the physician's duty to "do no harm" by an intervention that has distinct risks, but without hemodialysis, the patient would face certain mortality. Individuals with mental illness should be afforded the opportunity to make their own health care decisions if they have the capacity to do so. In this case, the patient continues to lack insight into her medical condition. The patient's genuine interest is served by continuing hemodialysis to prevent life threatening metabolic complications, attempting to restore capacity and intervening in her potentially treatable condition prior to her condition reaching life threatening urgency.

FR-PO862

**Reducing Stigma of Chronic Pain by Intervention Patient and Provider Co-Design in Dialysis**  
Kerri L. Cavanaugh,<sup>1</sup> Jane Liebschutz,<sup>2</sup> Megan E. Hamm,<sup>2</sup> Hailey W. Bulls,<sup>2</sup> Donna Olejniczak,<sup>2</sup> Nwamaka D. Eneanya,<sup>3</sup> Caroline M. Wilkie,<sup>4</sup> Manisha Jhamb.<sup>2</sup> <sup>1</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>2</sup>University of Pittsburgh, Pittsburgh, PA; <sup>3</sup>Fresenius Medical Care, Philadelphia, PA; <sup>4</sup>University of Pennsylvania, Philadelphia, PA.

**Background:** Stigma is frequently experienced by patients with end-stage kidney disease receiving dialysis due to perceptions of health condition etiology or self-care, identity or social context. This is particularly evident for chronic pain, and when considering buprenorphine for therapy.

**Methods:** Semi-structured interviews of patients, multidisciplinary healthcare providers (n=20), dialysis administrators (n=4) and insurers (n=3) informed the conduct and content of three interactive group design sprints with the objective of developing a multilevel intervention to eliminate stigma related to chronic pain care. Group video meeting facilitated sessions occurred twice in one week for two hours and occurred three times with (a) patients only (n=5), (b) providers only (n=5), and (c) both patients, providers and LDO representatives (n=11). Participants prepared by completing assignments and used a whiteboard in meeting to sketch, synthesize and select final strategies.

**Results:** A total of 27 qualitative interviews identified the lack of owning responsibility for pain management, lack of integration with dialysis and perception that pain was not related to ESKD as a key problems. Buprenorphine expertise is rare, perceived to be of low value and inconvenient to use. Design sprint sessions initially mapped and sketched intervention strategies. Patients promoted strategies to educate both patients and providers. Novel training approaches included modeling of how to evaluate, develop and implement a successful treatment plan. Providers identified organizational strategies employing automation/technology to facilitate care coordination and deliver treatment concurrent to dialysis on site. Incentivization was identified as a requirement for adoption and maintenance. Together a detailed step-by-step plan for how this would occur at the dialysis plan was created as a foundational framework for future testing.

**Conclusions:** Chronic pain management suffers from lack of ownership by any one discipline for patients receiving dialysis for ESKD. Patients in partnership with providers designing actions to address current gaps have high potential to be feasible and effective to elevate care and eliminate related stigma.

**Funding:** NIDDK Support

## FR-PO863

**“The Psychosocial Power Team”: A Multidisciplinary Approach to Mitigating Health Inequities for Pediatric Patients on Hemodialysis**

Kristin Whaley,<sup>1</sup> Megan G. Hermetz,<sup>1</sup> Beth A. Vogt,<sup>1,2</sup> Abby Grisham,<sup>1</sup> Tara J. Van Der Eems,<sup>1</sup> Orville Newton-Ray Bignall,<sup>1,2</sup> Anne E. Dawson.<sup>1,2</sup>  
<sup>1</sup>Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>The Ohio State University College of Medicine, Columbus, OH.

**Background:** Children with kidney failure from minoritized communities face structural inequities that preclude access to home dialysis and portend poor outcomes. In-center hemodialysis (HD) confers disadvantages, including missed school and exposure to traumatizing procedures leading to decreased quality of life (QoL). To improve QoL and mitigate inequities for children on HD, we developed a multidisciplinary collaboration called the “Psychosocial Power Team” (PSPT). This team - comprised of child life, therapeutic recreation, massage therapy, social work, music therapy, nutrition, education, psychology, and nursing - used a modified quality improvement framework to pilot research-based psychosocial interventions to support social development and mental health for children on HD.

**Methods:** The PSPT created patient-specific and unit-wide treatment goals and interventions to support patient coping and adjustment. We sought to measure the impact of our interventions (e.g., collaborative meetings, educational games, cross-unit camaraderie activities, milestone celebrations, and emotional supports) on psychosocial outcomes in 16 children treated with HD.

**Results:** The PSPT created an average of 11 psychosocial goals per patient, with patients meeting 70% of goals. Post-intervention, fewer patients required psychology follow-up for psychosocial concerns (from 80% to 15% of patients). Patients demonstrated improved QoL ratings, often exceeding the average QoL expectations for patients on dialysis (Figure). Physical health metrics (e.g. serum phosphorus) are being tracked at this time.

**Conclusions:** Pediatric patients with kidney failure are at risk for poor psychosocial outcomes, due in part to structural inequities related to HD versus home dialysis. Through intentional, multidisciplinary collaboration, the PSPT demonstrated improved psychosocial health metrics in our pediatric dialysis unit.

Demonstration of QoL improvement for 2 patients on HD after PSPT intervention.

## FR-PO864

**ESKD Amongst Irish Travellers**

Paul O'Hara,<sup>1</sup> Husam Alzayer,<sup>2,3</sup> David Gorey,<sup>1</sup> Edward P. Mc Monagle,<sup>4</sup> Michelle Madden,<sup>5</sup> Elhussein A. Elhassan,<sup>2</sup> Donal N. Reddan,<sup>1</sup> Liam F. Casserly,<sup>4</sup> Sean F. Leavey,<sup>5</sup> Peter J. Conlon.<sup>2</sup> <sup>1</sup>Galway University Hospitals, Galway, Ireland; <sup>2</sup>Beaumont Hospital, Dublin, Ireland; <sup>3</sup>Saudi Arabia Ministry of Health, Arar, Saudi Arabia; <sup>4</sup>University Hospital Limerick, Dooradoyle, Ireland; <sup>5</sup>University Hospital Waterford, Waterford, Ireland.

**Background:** The occurrence of end stage kidney disease (ESKD) amongst Irish travellers has not been well described. This study will determine the burden of ESKD among the Irish Traveller population and identify determinants of health among this cohort which may differ from the general population.

**Methods:** This was a retrospective cohort study design involving any self-identifying Irish Travellers with ESKD registered in the National Kidney Disease Clinical Patient Management System between (1995-2021). ESKD was defined as a patient; with an eGFR <15ml/min/1.73m<sup>2</sup>, dialysis or transplant. The primary outcome was the prevalence of ESKD in Irish Travellers. Secondary exploratory outcomes were the age of diagnosis, family history or biopsy diagnosis, kidney replacement modality, time to initiation of kidney replacement therapy and the primary vascular access used, and time to receive a kidney transplant.

**Results:** Four hospital groups among six in Ireland participated in the study. A total of 38 patients were identified as Irish Travellers with ESKD with a crude prevalence rate of ESKD of 0.12% or 1.19 per 1,000 Irish travellers. The mean age for diagnosis of kidney disease was 43 (SD, 20.8) and commencement of kidney replacement therapy was 45 (SD, 20.9) years. A biopsy-proven diagnosis was provided in 24% of cases identified. Slightly more than one in five cases (22%) had a diagnosis of PKD or CAKUT. The predominant modality for kidney replacement therapy was hemodialysis (89%) with central venous catheters being the most common initial vascular access (72%). Kidney transplant occurred in 45% of those studied with a mean waiting time of 1.96 (SD, 1.6) years. The main mode of kidney transplant was cadaveric donation at 76%.

**Conclusions:** Allowing for small numbers and ascertainment bias; Irish Travellers are younger, have a higher prevalence of ESKD, and less likely to have a biopsy diagnosis than the prevalent ESKD general population. They tend to have a short time interval from diagnosis until commencement of kidney replacement therapy and are less likely to benefit from home therapies but appear to be in line with the national waiting time to receive a kidney transplant. This data will help build a framework for policy development and practice enhancement in relation to kidney health in Irish Travellers.

## FR-PO865

**Nephrologist Preferences Exacerbate Disparities in Access to High Quality Dialysis Facilities**

Eugene Lin,<sup>1</sup> Khristina I. Lung,<sup>2</sup> Karen Van Nuys.<sup>2</sup> <sup>1</sup>University of Southern California Keck School of Medicine, Los Angeles, CA; <sup>2</sup>University of Southern California, Los Angeles, CA.

**Background:** Ideally, patients initiating outpatient dialysis for end-stage kidney disease are referred to higher quality facilities closer to their residence. However, nephrologists might refer patients to “preferred facilities,” even if lower quality or distant. We investigated whether patients were more likely referred to nephrologists’ preferred facilities and racial differences in referrals.

**Methods:** For adults with fee-for-service Medicare initiating dialysis from 2016-2018, we identified the nephrologist’s “preferred facility” or the facility with the plurality of the nephrologist’s patients. For the patient’s first facility and the nephrologist’s preferred facility, we determined the quality (using Medicare’s published Five-Star ratings, a score based on Medicare quality measures) and distance to the patient. Since quality differs by region, we define a high-quality facility as the top quartile of facilities within a referral area (i.e., the highest quality available to the patient).

**Results:** Unadjusted, patients had a 19% probability of dialyzing at their nephrologist’s preferred facility if it was distant but a 65% probability if low-quality/close and a 74% probability if high-quality/close. In multivariable analysis, patients were more likely to dialyze at preferred facilities if close. Relative to when the preferred facility was low-quality/distant, patients were more likely to dialyze at preferred facilities that were low-quality/close (OR: 8.1, 95% CI: 7.7, 8.4) and high-quality/close (OR: 11.6, 95% CI: 11.0, 12.3). When preferred facilities were low-quality/close, patients were more likely to dialyze at low-quality facilities (OR: 3.2, 95% CI: 3.0, 3.4), and when high-quality/close, patients were more likely to dialyze at high-quality facilities (OR: 3.8, 95% CI: 3.5, 4.1). Relative to White patients, Black patients were less likely to have nephrologists with high-quality preferred facilities (OR: 0.93, 95% CI: 0.88, 0.97) and were less likely to dialyze at high-quality facilities (OR: 0.88, 95% CI: 0.84, 0.92).

**Conclusions:** Patients more likely dialyzed at nephrologists’ preferred facilities when close. Patients thus opt for low-quality facilities if their nephrologist prefers a low-quality facility. Because Black patients more likely had nephrologists preferring low-quality facilities, they more likely dialyzed at the lowest-quality facilities available.

**Funding:** NIDDK Support, Private Foundation Support

## FR-PO866

**Optimising COVID-19 Vaccination and Reducing Health Inequalities in Patients on Renal Replacement Therapy**

Dimitrios J. Poulikakos, Rajkumar Chinnadurai, Edmond O’riordan, Rachel Middleton. Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom.

**Background:** COVID-19 vaccine hesitancy has been associated with social deprivation and selected minority ethnic groups who are over-represented in the Renal Replacement Therapy (RRT) population. We designed a COVID-19 vaccination programme for our RRT population with the aim to increase vaccination uptake and decrease health inequalities.

**Methods:** Key interventions included addressing vaccine hesitancy by deploying the respective clinical teams as trusted messengers, prompt eligible patient identification and notification, deployment of resources to optimise vaccine administration in a manner convenient to patients and timely collection and analysis of local safety and efficacy data. First COVID-19 vaccination uptake data in relation to ethnicity and social deprivation, measured by the multiple deprivation index, in our RRT population were analysed and compared with uptake data in the regional total adult clinically extremely vulnerable (CEV) population in Greater Manchester (GM). Univariate logistic regression analysis was used to explore the factors associated with not receiving a vaccine.

**Results:** Out of 1156 RRT patients included in this analysis (Table) 96.7% received the first dose vaccination compared to 93% in the cohort of CEV patients in the GM. Age, sex, ethnicity and index of multiple deprivation were not associated with first dose vaccine uptake. Vaccine uptake in Asian and Black RRT patients was 94.9% and 92.3% respectively compared to 93% and 76.2% for the same ethnic groups in the reference CEV GM. Vaccine uptake was 96.1% of RRT patients in lowest quartile of multiple deprivation index compared to 90.5% in the GM reference population.

**Conclusions:** Bespoke COVID-19 vaccination programme based on local clinical teams as trusted messengers can address vaccine hesitancy and reduce health inequalities.

### Sociodemographic Characteristics and Symptom Treatment Status of Hemodialysis Patients With Pain, Depression, and/or Fatigue

Susan M. Devaraj,<sup>1</sup> Maria-Eleni Roumelioti,<sup>2</sup> Jonathan Yates,<sup>1</sup> Mary M. Schopp,<sup>1</sup> Jennifer L. Steel,<sup>1</sup> Sarah J. Erickson,<sup>3</sup> Bruce L. Rollman,<sup>1</sup> Steven D. Weisbord,<sup>1</sup> Mark L. Unruh,<sup>2</sup> Manisha Jhamb.<sup>1</sup> <sup>1</sup>University of Pittsburgh Department of Medicine, Pittsburgh, PA; <sup>2</sup>University of New Mexico Health Sciences Center, Albuquerque, NM; <sup>3</sup>University of New Mexico Department of Psychology, Albuquerque, NM.

**Background:** End Stage Kidney Disease patients on hemodialysis (HD) often experience clinically significant pain, fatigue and depressive symptoms, and efforts to identify and manage symptom burden are essential to improve patient outcomes. We sought to identify sociodemographic differences by symptom burden and treatment among HD patients consented for a multi-center trial of collaborative care to reduce symptom burden (TACcare).

**Methods:** Protocol-eligible patients screened positive for clinical levels of pain (Likert scale  $\geq 4$ ), fatigue (Likert scale  $\geq 5$ ), and/or depression (Patient Health Questionnaire-9 score  $\geq 10$ ) and provided informed consent to participate in the trial (years 2018-2022). We used ANOVA or Fisher's exact tests to analyze the cross-sectional associations of age, race, ethnicity, gender, employment, education, marital status, home neighborhood walkability, and tobacco, alcohol, and illicit drug use with symptom experience and treatment status (receiving psychosocial/behavioral treatment vs. willing to receive treatment) at baseline.

**Results:** Of n=215 participants, 55% were male, 19% were Hispanic, 29% were Black/African American, 17% were American Indian/Alaskan Native, and 60% had an annual income  $< \$20k$ . Patients with depression were younger than those without [age: 56 (SD:13) vs. 60 (14) years;  $p=0.02$ ]. The percentage of patients experiencing pain was inversely proportional to annual household income ( $< \$20k$ : 75%,  $\$20-40k$ : 80%,  $\$40-60k$ : 69%,  $> \$60k$ : 36%;  $p=0.04$ ). There was a significant association between experiencing pain and history of illicit drug use, with pain most prevalent with use  $> 5$  years ago (never used: 70%, used  $< 5$  years ago: 57%, used  $> 5$  years ago: 92%;  $p=0.03$ ). No significant differences in symptom count were noted across any other sociodemographic subgroup. Women were more likely than men to be receiving treatment for symptoms (52% vs. 34%,  $p=0.01$ ).

**Conclusions:** Sociodemographic correlates with symptoms could help inform targets to improve pain, fatigue, and depression identification and treatment in HD patients. Being male may indicate less frequent symptom treatment, while income and history of illicit drug use may be important to consider in identifying and managing pain.

**Funding:** NIDDK Support

## FR-PO868

### Sex, Gender, and Quality of Life in Hemodialysis

Victoria J. Riehl-Tonn,<sup>1</sup> Sandi M. Dumanski,<sup>1</sup> Meghan J. Elliott,<sup>1</sup> Jennifer M. MacRae,<sup>1</sup> Neesh I. Pannu,<sup>2</sup> Kara Schick-Makaroff,<sup>3</sup> Kelsea Drall,<sup>2</sup> Taryn Gantar,<sup>4</sup> Colleen M. Norris,<sup>3</sup> Sofia B. Ahmed.<sup>1</sup> <sup>1</sup>University of Calgary Cumming School of Medicine, Calgary, AB, Canada; <sup>2</sup>University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; <sup>3</sup>University of Alberta Faculty of Nursing, Edmonton, AB, Canada; <sup>4</sup>University of Alberta, Edmonton, AB, Canada.

**Background:** Women on conventional hemodialysis (HD) have a lower reported quality of life (QoL) compared to men. Incremental HD, which gradually increases dialysis dose over time, is a potential strategy to improve QoL. Despite differences in QoL, current HD prescription remain sex (biology) and gender (sociocultural) blind.

We aimed to determine if sex and gender-related measures (gender roles, relations and identity) were associated with QoL when initiating incremental HD ( $< 3$  sessions/week) compared to conventional HD (3 sessions/week).

**Methods:** Patients initiating HD in Alberta, Canada, were invited to enrol (June-December 2021) in this prospective cohort study. Sex assigned at birth was obtained by self-report. Eligibility for incremental HD at initiation is determined by kidney care providers using standardized assessments. The Kidney Disease Quality of Life 36 (KDQOL-36) and the GENESIS-PRAXY Gender Questionnaires were administered at baseline and at 3-months. The physical component score (PCS) and mental component scores (MCS) of the KDQOL-36 determined QoL. The GENESIS-PRAXY creates a composite gender score that is measured on a spectrum, with lower scores consistent with behaviours ascribed to males and high scores consistent behaviours ascribed to females. Non-parametric tests analysed the association between sex and QoL by HD type. Multiple linear regressions explored the association between gender score and QoL by HD type.

**Results:** All 48 participants identified as cisgender. There were 22 participants on conventional HD (7 female, 15 male) and 26 on incremental (13 female, 13 male) ( $p=0.11$ ). There was no significant change in MCS (female  $p=0.68$ , male  $p=0.41$ ) or PCS (female  $p=0.84$ , male  $p=0.61$ ) after 3-months regardless of HD type. Linear regression analysis showed a significant negative association between gender score and PCS ( $p<0.01$ ,  $R^2=0.54$ ) but not with MCS ( $p=0.09$ ,  $R^2=0.43$ ).

**Conclusions:** Sex was not associated with QoL in this cisgender cohort. Behaviours traditionally ascribed to females as indicated by higher gender scores were associated with decreasing QoL with regards to physical health. Understanding sex and gender differences will allow care providers to better address the needs of patients receiving HD.

## FR-PO869

### Informal Advance Care Planning in Black Patients With Kidney Failure

Marlena Fisher,<sup>1</sup> Deidra C. Crews,<sup>1</sup> Nancy A. Perrin,<sup>1</sup> Justin J. Sanders,<sup>2</sup> Martha Abshire Saylor,<sup>1</sup> Marie T. Nolan.<sup>3</sup> <sup>1</sup>Johns Hopkins University, Baltimore, MD; <sup>2</sup>McGill University, Montreal, QC, Canada; <sup>3</sup>The Catholic University of America, Washington, DC.

**Background:** Research examining advance care planning (ACP) in kidney failure patients is primarily assessed in research by written advance directives. Black patients have limited representation in ACP research, and many prefer informal conversations. We examined the relationship of informal ACP conversations with personal, interpersonal, and structural level factors.

**Methods:** We conducted a concurrent mixed-methods study including a survey and semi-structured interviews to identify personal, interpersonal, and structural factors related to engagement in informal ACP conversation. We conducted a survey of 280 Black patients who are on dialysis or have a history of being on dialysis. We conducted twenty semi-structured interviews using maximum variation sampling among survey respondents focused on the content, context, barriers and facilitators of informal ACP conversations. Multivariable logistic regression, thematic analysis, and triangulation were used to analyze the data.

**Results:** Sixty-six percent engaged in an informal ACP conversation and 38% completed an advance directive. Of the 197 patients who engaged in informal ACP conversations, 51% also completed an advance directive. Mean age was 56 years, 52% were female, and 68% are currently treated with dialysis. In preliminary bivariate analyses of informal ACP, illness acceptance (OR 1.07,  $p=0.016$ ), social support (emotional OR 1.12,  $p=0.002$ ; Instrumental OR 1.09,  $p=0.005$ ; informational OR 1.13,  $p=0.00$ ), education (OR 1.32,  $p=0.18$ ), and previous experience as a surrogate decision maker (OR 1.89,  $p=0.017$ ) increased the likelihood of engaging in informal ACP. The interviews revealed that the content often includes financial, healthcare, and funeral planning wishes. These conversations often follow a health status change like a hospitalization or a worsening in their condition. Key facilitators were having a strong trusted social support system and past experience with ACP or a loved one dying. Barriers included distrust of family to carry out their wishes as outlined and a discomfort/avoidance of having informal ACP conversations.

**Conclusions:** Informal ACP conversations with family occur more frequently than written directives in Black dialysis patients. Future efforts should assess the patient's social support system and target interventions to engage patients with limited support networks.

## FR-PO870

### The Status of Provision of Kidney Replacement Therapy for Undocumented Immigrants in the United States

Katherine M. Rizzolo, Manisha Dubey, Katherine E. Feldman, Lilia Cervantes. University of Colorado, Denver, CO.

**Background:** There are 6000-8000 undocumented immigrants with kidney failure living in the US. As undocumented immigrants are barred from receiving federal insurance, access to kidney replacement therapies (KRT) is decided at the state, city, or institutional level. In states where maintenance hemodialysis is not available, undocumented immigrants with kidney failure are resigned to emergency hemodialysis, or dialysis when critically ill. In 2019, 12 states were found to cover maintenance hemodialysis for undocumented immigrants at the state level. Since 2019, a wave of advocacy for improved access to kidney care for undocumented immigrants has received greater traction. We investigate the current status of kidney replacement therapies (including maintenance dialysis, home dialysis, and transplantation) available to undocumented immigrants throughout the US.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Methods:** Identifying state by state policy was conducted via interviews with nephrology providers caring for undocumented immigrants and reviewing state Medicaid policy handbooks.

**Results:** At the time of this submission, 27 states have been reviewed. The results expect to be finished by August 2022. Out of 27 states, 21 offer outpatient dialysis (Figure 1), 14 have state-wide coverage for outpatient dialysis. 5 states changed their laws to cover outpatient dialysis since 2019. 5 states have state-wide access to transplantation.

**Conclusions:** Availability of kidney replacement therapy for undocumented immigrants with kidney failure remains variable by geography in terms of state and institutional policies. Overall, the degree of access by state appears to be expanding, with greater access to maintenance dialysis and transplantation than has been noted previously. This work may be utilized for advocacy efforts to inform state and national policy change.

## Rural Caregivers' Perspectives on Access to Dialysis and Kidney Transplantation

**Nicole J. Scholes-Robertson,<sup>1</sup> Amanda G. Dominello,<sup>1</sup> Martin Howell,<sup>1</sup> Jonathan C. Craig,<sup>2</sup> Germaine Wong,<sup>1</sup> Allison Tong.<sup>1</sup>** *<sup>1</sup>The University of Sydney Faculty of Medicine and Health, Sydney, NSW, Australia; <sup>2</sup>Flinders University, Adelaide, SA, Australia.*

**Background:** Caregivers of patients with chronic kidney disease (CKD) from rural communities play a crucial role in access to dialysis and transplantation and face many challenges including geographical distance, financial hardship, and limited support. This study aimed to describe the perspectives of caregivers of patients with CKD from rural communities on their experiences of accessing kidney replacement therapy to help inform strategies to address their needs.

**Methods:** Semi-structured interviews were conducted. Transcripts were thematically analysed. We followed the consolidated criteria for reporting qualitative research (COREQ) framework.

**Results:** We included 18 participants aged from 20 to 78 years of age; 13 (72%) were female; 2 identified as Aboriginal or Torres Strait Islander, and 13 (72%) were the spouse/partner of the patient. We identified five themes: devastating social isolation (difficult periods of separation, exclusion from peers, forced relocation); financial dependency and sacrifice (burgeoning out-of-pocket costs, disruption to work life, foregoing autonomy); ongoing psychological trauma (concern for neglect and stress on children, long term emotional distress); overwhelmed by multifaceted roles and expectations (patient advocacy, uncertainty in navigating multiple health systems); and persistent burden of responsibility (loss of self-identity, ongoing travel requirements, scarcity of psychosocial support, unpreparedness for treatment regime).

**Conclusions:** Rural caregivers of people with CKD experience an exhausting physical, financial, and psychological burden. Strategies and improved formal respite services are required to address these profound challenges in the rural setting for caregivers of patients with CKD.

FR-PO872

## Using Design Ethnography to Identify Barriers to Dialysis Access in Lagos, Nigeria

Natasha C. Wright, Jacqueline R. Warehime, Benjamin Szot, Carolyn Bernemann, Ibrahim O. Yekinni, Michelle N. Rheault. *University of Minnesota Twin Cities, Minneapolis, MN.*

**Background:** There is limited access to renal replacement therapy (RRT) for end stage kidney disease patients in low- and middle-income countries (LMICs). An estimated 9.1 million people globally will not be able to access RRT by 2030. This growth is aided by advancing age, diabetes, and hypertension with a greater burden expected in LMICs which are experiencing an epidemiological transition from communicable to non-communicable disease. While LMICs may be the most affected, they are also the least equipped; less than 10% of those who need RRT in LMICs are able to access it. In this study, interview methods were used to identify barriers to dialysis treatment for patients in Nigeria, where only HD is available, and to elucidate insight on PD as an alternative treatment.

**Methods:** Semi-structured ethnographic design interviews were conducted in Lagos, Nigeria in January 2020. 33 HD patients were interviewed across 3 dialysis centers. Audio recordings were transcribed and analyzed using descriptive and emotion-based coding in NVivo.

**Results:** Matrix analysis of the descriptive and emotion-based codes revealed three primary themes: (i) The high cost of HD leads to lower treatment frequency compared to optimal prescription. Costs include financial (e.g. treatment cost, lab work) and lost time (e.g. transportation, wages). The descriptive code of cost overlapped with the emotion code of sad ( $n=14$ ), overwhelmed ( $n=20$ ), and stressed ( $n=12$ ). (ii) Family involvement is a critical part of the patient's experience. With this high level of moral and financial support, patients often felt a sense of guilt. (iii) PD is associated with feelings of independence and comfort. Patients preferred PD ( $n=24$ ) compared to HD ( $n=6$ ).

**Conclusions:** The findings support the hypothesis that patients in Nigeria may be interested in and benefit from PD as a treatment option. Patients performed HD treatment less frequently due to high costs which left them feeling weak between treatments, often resulting in lost wages. Patients were drawn to the perceived independence of PD. The majority of patients indicated strong familial support and comfort with the idea of administering treatment in their home. A service to train patients on treatment administration and local PD fluid production were identified as necessary to increase the feasibility of PD adoption.

## FR-PO873

### Relationship Between Driving Time to Transplant Center and Socioeconomic Factors With Early Waitlisting Among Transplant-Referred ESKD Patients

Steph Karpinski,<sup>1</sup> Carey Colson,<sup>1</sup> Adam G. Walker,<sup>1</sup> Scott Sibbel,<sup>1</sup> Michael H. O'Shea,<sup>2</sup> Francesca Tentori,<sup>1</sup> Steven M. Brunelli.<sup>1</sup> <sup>1</sup>*Davita Clinical Research, Minneapolis, MN;* <sup>2</sup>*DaVita Inc, Denver, CO.*

**Background:** Understanding factors contributing to disparities in kidney transplantation in end-stage kidney disease patients is important. Placement on a transplant waitlist is an important gate-keeping step where disparities have been observed. In this study, we sought to estimate the independent effect of driving time to the transplant center on the probability of waitlisting.

**Methods:** This was a retrospective study of 33,158 adult incident dialysis patients in the United States referred for transplant. Bayesian methods were used to model the relationship between driving time from the patient's home to the nearest transplant center and placement on a waitlist within 90 days of referral. We adjusted for causally relevant socioeconomic factors including educational encounters documented by the dialysis organization and US Census Bureau tract income and education data. We simulated observations based on relative levels of socioeconomic advantage (disadvantage and advantage comprising the 25<sup>th</sup> and 75<sup>th</sup> percentiles for listed variables, respectively).

**Results:** Overall, 2.0% of patients were waitlisted within 90 days of referral. The median [interquartile range] for driving time was 27 [14, 65] minutes. There was a non-linear relationship between driving time and probability of waitlisting (left Figure). This non-linear relationship interacts with the level of socioeconomic advantage to vary the slope (right Figure). A sensitivity analysis adjusting for race did not improve model fit.

**Conclusions:** Among the socioeconomically disadvantaged, there was an inverse relationship between driving time and the likelihood of early waitlisting. For those at higher socioeconomic advantage, early waitlisting was most likely for those living 20-30 minutes from a transplant center and did not vary much otherwise.

In right panel, purple vertical lines represent the 25<sup>th</sup>, 50<sup>th</sup>, and 75<sup>th</sup> percentiles of driving time. Probability of waitlisting was reliably higher among advantaged patients compared to disadvantaged patients at each of these percentiles.

FR-PO874

Employing Certified Clinical Transplant Coordinators (CCTC) in Private Practice to Increase Kidney Transplant Evaluations in Pre-Dialysis Patients

Jeffrey Mulhern,<sup>1,2</sup> Molly Porter,<sup>2</sup> Gregory L. Braden,<sup>1,3</sup> Lili C. Quiterio,<sup>2</sup> Joy A. Delbuono,<sup>2</sup> Daniel L. Landry.<sup>1,3</sup> <sup>1</sup>Baystate Medical Center, Springfield, MA; <sup>2</sup>Kidney Care and Transplant Services of New England, West Springfield, MA; <sup>3</sup>University of Massachusetts Chan Medical School TH Chan School of Medicine, Worcester, MA.

**Background:** Preemptive kidney transplantation, the preferred renal replacement modality for advanced CKD patients, remains underutilized due to late referral for care, competing needs of renal replacement preparation, and perhaps practice-based issues. Recent monetary incentives for successful renal transplantation allow resource allocation directed at improving rates of transplant evaluation and implantation. We report initial results of our private practice CCTC team effort to initiate and enhance transplantation discussion, referral and evaluation in our pre-dialysis patients participating in the Kidney Care First (KCF) payment model.

**Methods:** Practice-based CCTC were deployed on 1/1/2022 to approach all KCF patients with a GFR<25 ml/m and begin kidney transplant discussions. The CCTC-patient interactions followed a provider visit in over half the interactions. A specific referral was not required to begin the relationship, and the provider was not required to be the first to discuss renal replacement options.

**Results:** We compare usual care during 2021 with CCTC care during the first 4 months of 2022 in table form.

**Conclusions:** The deployment of a private practice CCTC team has potential benefits compared to prior usual care including a near 5-fold rise in monthly transplant center initial evaluations, a reduction in initial transplant center no-show appointments, and an improvement in the initial transplant center evaluations of Black/African American (B/AA) and Hispanic/Latino (H/L) patients. Although preemptive transplantation success will likely require approaching patients at a higher GFR, the substantial increase in initial pre-dialysis transplant center evaluations strongly supports the continuation of this 'Transplant First' approach to advanced CKD care.

Year	2021	2022

FR-PO875

Variation in Kidney Failure Risk in Preemptively Listed Patients for Kidney Transplantation

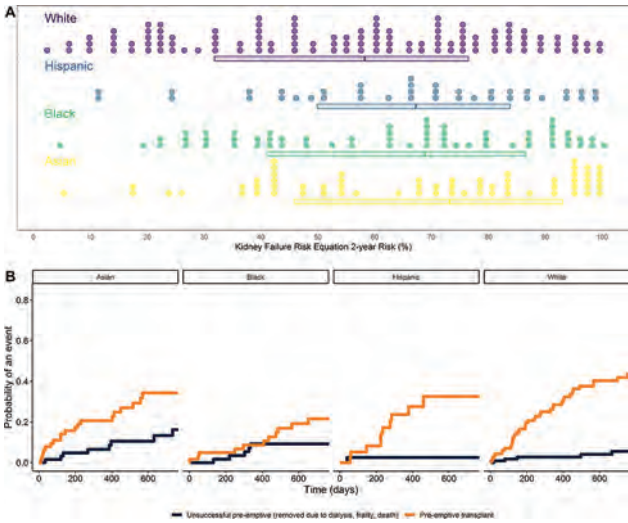

Jamie S. Hirsch, Mersema Abate, Kenar D. Jhaveri, Vinay Nair. *Northwell Health, New Hyde Park, NY.*

**Background:** ESKD progression depends on several factors, therefore a static eGFR cut-off for listing may lead to disparities. The Kidney Failure Risk Equation (KFRE) is a validated score to calculate 2 & 5 yr ESKD risk. We applied KFRE to pts in our pre-emptively listed KT candidates and reviewed transplantation rate.

**Methods:** Adult pts listed pre-emptively between 1/1/12 and 12/31/21 with follow-up through 2/18/22. GFR calculated using 2009 CKD-EPI equation (race coefficient; eGFRcr<sub>2009</sub>), 2021 CKD-EPI equation (race-free; eGFRcr<sub>2021</sub>), and universal eGFR of 20ml/min for comparisons of risk within and between races. Incidence of KT was examined.

**Results:** Of 279 patients, median age- 57 (IQR 46, 65), 173 (62%) male, 115 (41%) White, 61 (22%) Black, 64 (23%) Asian, and 39 (14%) Hispanic. Median eGFRcr<sub>2009</sub> was 14.1 (IQR 10.7-16.9) and eGFRcr<sub>2021</sub> was 14.5 (IQR 10.8-17.5); median Ur alb/crt ratio was 1286 (IQR 426-2480), and the 2-& 5-yr ESKD risk was 64% (IQR 41-83) and 96% (IQR 81-100), respectively. White patients were listed at higher median eGFRcr<sub>2009</sub> and this discrepancy was exacerbated, and most pronounced for Black patients, with eGFRcr<sub>2021</sub>. 2 year KFRE risk was higher for all races regardless of eGFR formula used (eGFRcr<sub>2009</sub>, eGFRcr<sub>2021</sub>, eGFR 20ml/min) as compared with Whites. Figure 1A shows wide variability within races. At last follow-up, 45 White (39%), 23 Asian (36%), 15 Black (25%) and 12 Hispanic (31%) had pre-emptive KT. Black patients had a longer follow-up time without KT and had a lower cumulative incidence of successful KT within 2 years of listing (Figure 1B).

**Conclusions:** Pre-emptively listed KT candidates had a wide variation in 2-yr ESKD risk by KFRE. Risk was lowest in White patients and Black patients had the lowest incidence of KT.

(A) Distribution of 2-year KFRE risk, by race/ethnicity.  
(B) Cumulative incidence of pre-emptive transplant at 2 years of follow up.

FR-PO876

Impact of the ESRD Treatment Choices (ETC) Model on Kidney Transplant Waitlisting by Race and Ethnicity

Vishnu S. Potluri,<sup>1,5</sup> Chen Peng,<sup>3</sup> Yuvaram N. Reddy,<sup>1,5</sup> Sri Lekha Tummalapalli,<sup>2</sup> Qian Huang,<sup>3</sup> Joshua Liao,<sup>4,5</sup> Amol Navathe.<sup>1,5</sup> <sup>1</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>2</sup>Weill Cornell Medicine, New York, NY; <sup>3</sup>University of Pennsylvania, Philadelphia, PA; <sup>4</sup>University of Washington, Seattle, WA; <sup>5</sup>Leonard Davis Institute of Health Economics, Philadelphia, PA.

**Background:** The ESRD Treatment Choices (ETC) Model - implemented in January 2021 - randomized dialysis providers and nephrologists in 30% of US hospital referral regions to receive financial incentives based on rates of home dialysis and access to transplantation. The model also included a health equity incentive to reduce disparities among dually eligible Medicare and Medicaid patients, who are low socioeconomic status and disproportionately Black and Hispanic. In this study, we used data from the US transplant registry to describe the early impact of the model on transplant waitlisting.

**Methods:** We assembled a cohort of adult Medicare beneficiaries on dialysis who were waitlisted for a kidney transplant between Jan 1, 2017 and Sept 30, 2021. The cohort was divided into the intervention and control arms of the ETC model. Kidney transplant waitlisting between groups was evaluated using an interrupted time series design. We used piecewise linear regression to compare slope changes in waitlist additions between the intervention and control arms for the overall population, Black, and Hispanic transplant candidates.

**Results:** Following implementation of the ETC model, there were 4975 waitlist additions in the intervention arm and 8438 additions in the control arm. Post-ETC model, we found no significant difference in kidney transplant waitlist additions between the intervention and control arm for the overall cohort (Figure 1 slope difference 0.87/month p-value 0.068), Black (slope difference 0.25/month, p-value 0.23), and Hispanic transplant candidates (slope difference 0.04/month, p-value 0.75).

**Conclusions:** In the first 9-months following implementation of the ETC model, we did not detect an increase in new kidney transplant waitlist additions overall or among racial and ethnic minorities. Longer-term follow-up is required to determine if the ETC model incentives are sufficient to overcome barriers to transplant waitlisting.

**Funding:** NIDDK Support, Private Foundation Support

## FR-PO877

### Black Americans Experience a Disproportionately Longer Wait Time for Kidney Transplant

Jack R. Fagan, Emily Belowich, Daniel Labson, Mark J. Gooding, Shalini Parekh. *Avalere Health, Washington, DC.*

**Background:** Almost 786,000 individuals in the United States are living with End-Stage Renal Disease (ESRD), and Black Americans show a three-to-four-fold excess risk in incidence rates. To experience higher survival rates and an optimal quality of life, a kidney transplant is needed to live.

**Methods:** We used 100% Medicare Fee-For-Service (FFS) claims data to identify patients who received a kidney transplant between July 2018 to June 2021. Among these patients, we identified individuals with an initial diagnosis of chronic kidney disease (CKD) or ESRD and were enrolled in Medicare FFS continuously in the year prior to diagnosis to confirm a negative diagnosis period. Beneficiaries entitled to Medicare due to ESRD were excluded to ensure full claims history to capture initial diagnosis, resulting in a total of 3,894 patients. For these patients, we evaluated the time between CKD/ESRD diagnosis and transplantation. Separately, we evaluated the total mortality in the years following either an initial CKD or ESRD diagnosis, excluding patients who received a kidney transplant. Mortality was established utilizing certificate of death data that was identified in Medicare FFS Master Beneficiary Summary File, indexed to diagnosis to establish time to death and subsequent mortality rate by year.

**Results:** The average wait time for Medicare FFS beneficiaries from time of initial diagnosis of CKD/ESRD to receipt of a kidney transplant was 4.46 years. Compared to all patients, Black Medicare FFS beneficiaries had a longer average wait time from diagnosis to transplant of 5.09 years ( $P < .0001$ ). Mortality for all patients 4 years post initial diagnosis of CKD/ESRD was 5.03%, and then increased to 6.03% for 5 years, 27.05% for 6 years or greater, with a total mortality of 47.18% for patients 6+ years after CKD/ESRD diagnosis.

**Conclusions:** Black patients, on average, wait an additional 7.56 months to access a transplantation compared to the average patient. These findings underscore the importance of treatment education and timely access to transplantation as CKD/ESRD mortality increases dramatically with time from 2.54% of patients expiring within one year following diagnosis to a cumulative 47.18% of patients expiring 6 years post diagnosis.

## FR-PO878

### Outcome of Kidney Transplantation in Recipients With Intellectual Disability

Tramahn Phan, Md S. Alom, Stacey Mcgahan, Jeremy G. Taylor, Scott E. Liebman. *University of Rochester, Rochester, NY.*

**Background:** Kidney transplantation offers significant mortality and quality of life benefits compared to dialysis. Every eligible end-stage renal disease patient (ESRD) should be evaluated for a transplant. Historically, ESRD patients with intellectual disability (ID) are at a disadvantage during the transplant evaluation process due to concerns related to their understanding of the process and medical compliance. There is a paucity of data evaluating the outcome of kidney transplantation in this group of people.

**Methods:** Our retrospective study investigated the clinical outcomes of kidney transplantation in recipients with ID at the University of Rochester Medical Center (URMC). Subjects were identified using ICD10 codes utilized by the division of Behavioral Pediatrics in identifying intellectual disability. We identified 23 individuals who received 25 allografts between January 1991 and December 2019. Fifteen individuals receive services from Office for People with Developmental Disabilities.

**Results:** The one-year and three-year graft survival rates of ID recipients were 100%. This compares favorably to our institutional outcomes. URMC's one-year graft survival rate is 95.4%; the rate from living donors is 100%, and from deceased donors is 92%. Our three-year graft survival rate is 92.9%; the rate from living donors is 94.5%, and from deceased donors is 91.5%. The mean follow-up time was  $12.6 \pm 7.2$  years. The mean post-transplant vintage was  $11.7 \pm 7.5$  years. There were 4 allograft failures from

recipients. Allograft vintage at the time of failure from two of the subjects was 22.5 years and 17.5 years. In the subject with two episodes of allograft failure, the vintage of the allografts was 5.6 years and 4.7 years. There were 9 rejection episodes; only 2 of these led to graft loss and both occurred in the same subject. Of the subjects with functional grafts, the average creatinine was  $1.3 \pm 0.47$  mg/dL.

**Conclusions:** We believe that ID should not be factored into the kidney transplant evaluation process. If individuals with ID have a good support system, they appear to benefit from transplantation similar to those without ID.

## FR-PO879

### Transplantation Outcome Racial Disparities in Autosomal Dominant Polycystic Kidney Disease

Rita L. McGill, Arlene B. Chapman. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) patients access to pre-emptive and living donor transplantation varies by race throughout the United States. In this analysis, we examined transplant outcomes by race among patients with ADPKD.

**Methods:** OPTN/UNOS files were used to identify patients age  $\geq 30$  with ADPKD who received kidney-only transplants. Race was stratified as White (W), African American (AA), Hispanic (H), and Asian (A). Cox models were used to calculate hazard ratios (HR) for graft failure, using (W) as the reference. The model was then adjusted for age, sex, BMI, cold ischemia time, living donation, pre-emptive transplant, diabetes, use of induction therapy, steroid maintenance, and HLA mismatch.

**Results:** 30898 ADPKD transplant recipients were assessed. Patient characteristics are outlined in Table 1. The unadjusted HR for graft failure among AA was 1.55 (1.45, 1.66)  $P < 0.001$ , and remained 1.30 (1.20, 1.41)  $P < 0.001$  after adjustment. Outcome disparities were not observed among H or A patients with ADPKD. (Table 2)

**Conclusions:** African American ADPKD patients are at higher risk for graft failure after kidney transplant than other patients, above and beyond reduced access to living donor and pre-emptive transplantation. Further work is needed to determine what remediable factors could lead to more equity in transplant outcomes.

FR-PO880

**Sex Disparities in Renal Transplant in Brazil: A Descriptive Analysis**  
Renan G. Diniz, Natacha U. Morales, Luciana G. Lutf, Fernando L. Strufaldi, Claudia C. Albuquerque, Maria cristina R. Castro, Elias David-Neto. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

**Background:** Social disparities in Health Care including sex, ethnic and socioeconomic ones are still prevalent and underestimated mainly in developing countries.  
**Methods:** It was an epidemiological, retrospective and descriptive analysis comparing clinical data among men(M) and women(W) donor and recipients. Medical records from 2010-20 were collected in a center in Brazil. Variables were clinical and epidemiological data, comorbidities, pregnancies, transfusions, priority for end-stage vascular access failure (ESVaf), waiting list, immunologic profile, graft failure cause, mortality cause and rate and graft survival.

**Results:** A total of 1983 medical records were analyzed. The median age was 46,3y among men and 48,6 for women. A total of 48% were women and 52% men. Diabetes was equal among sexes, but more autoimmune diseases were seen in W. Among 437 relative living donors, W had a tendency to donate more than M (60Wx40%M) with mothers donating more than fathers (73W%xM27%). Among not-related donors, wives donate more than husbands (60%Wx40%M). About 75% of women had pregnancies before transplant. W also received more blood transfusions (58,4 x 47%, p=0,00001), data that also justifies the higher number of sensitized women (45% positive PRA in W x 18% in men; p=0,00001). Curiously, 27% of woman recipients were sensitized only due to pregnancies. Women rate in the priority list due to ESVaf were higher (4,9Wx3,7M%; p=0,00001) and they had more time on the waiting list (75Wx62M, P<0,005). There was a tendency for more deaths due to infection in W (54%Wx49%M) and cardiovascular reasons in M (9%Wx14%M); but patient 10y survival was the same (80%Wx78%M). Although not statistically different, graft survival at 10y was higher in women (88%Wx71%M).

**Conclusions:** Despite being a retrospective study, we included several variables of the disparities seen in renal transplantation. There was an association between being W renal recipients and sensitization, priority list inclusion due to ESVaf, number of transfusions and pregnancies, and time on the waiting list, variables that could be better approached in the future. Women looks like to donate more than men and although their higher risk at transplant, they present higher long-term graft survival, suggesting better self-care and adherence to treatment.

FR-PO881

**The Outcomes of Kidney Transplantation in Patients With Different Modalities of Dialysis Under Universal Health Coverage in Thailand**  
Pornpen Sangthawan,<sup>1</sup> Thammasin Ingviya,<sup>2</sup> Siribha Changsirikulchai.<sup>3</sup>  
<sup>1</sup>*Division of Nephrology, Department of Medicine, Faculty of Medicine, Prince of Songkla University, Hat Yai, Thailand;* <sup>2</sup>*Department of Family and Preventive Medicine, Faculty of Medicine, Prince of Songkla University, Hat Yai, Thailand;* <sup>3</sup>*Division of Nephrology, Department of Medicine, Faculty of Medicine, Srinakharinwirot University, Nakhon Naiyok, Thailand.*

**Background:** Thai patients with end-stage kidney disease (ESKD) under the Universal Health Coverage (UC) can access not only dialysis by using peritoneal dialysis (PD) first but also hemodialysis (HD) and kidney transplantation (KT). The previous studies show that KT is the most cost-effective kidney replacement therapy (KRT). There is a controversy about the effect of pre-transplant dialysis modality on graft survival after KT. This study aimed to compare the rates of receiving KT and graft survival between patients with PD and those with HD under UC.

**Methods:** The data of patients who registered with the National Health Security Office (NHSO) Region 4 and received PD, HD, and KT during January 2017-December 2021 were analyzed. The rates of PD or HD patients who received KT were calculated. The characteristics of these patients were identified. The one-year and three-year graft survival were compared between patients with pre-transplantation HD and PD by using Kaplan-Meier analysis.

**Results:** There were 9,169 cases receiving dialysis in the five years of the study period. The number of patients with PD and HD were 5,905 (64.4%) and 3,264 (35.6%), respectively. The number of PD patients receiving KT was 131(2.2%) while the number of HD patients receiving KT was 84 (2.6%). The characteristics and graft survival compared between patients with PD and HD were shown in Table 1.

**Conclusions:** The rates of KT in HD patients were slightly higher than in PD patients. The one-year and three-year graft survival rates were higher than 90% in both PD and HD. The one-year graft survival in PD patients was better than in HD patients but there was no difference in three-year graft survival between these dialysis modalities. The dialysis patients should be encouraged to receive KT.

**Table 1** The characteristics and outcomes of kidney transplantation comparing between patients on PD and HD

Characteristics	PD	HD
Total number of patients	5,905	3,264
Total number to KT, n (%)	131 (2.2)	84 (2.6)
Age at start dialysis (years)		
Median (25%-75% IQR)	38.79 [26.01-48.12]	36.68 [25.05-46.8]
Age at KT (years)		
Median (25%-75% IQR)	40.53 [27.1-49.74]	40.02 [28.18-50.74]
Time interval between start dialysis to KT (years)	1.13	2.52
Gender, n (%)		
Male	83 (63.36)	43 (51.19)
Female	48 (36.64)	41 (48.81)
Diabetes, n (%)	22 (16.79)	18 (21.43)
Graft survival, n (%)		
1 year	96.8 (96.4-97.3)	93.2 (92.3-94.0)
3 year	90.7 (89.9-91.5)	90.5 (89.5 -91.6)

FR-PO882

**Exploring Stigma in the Context of Living Donor Kidney Donor Transplantation (LDKT) Among African, Caribbean, and Black (ACB) Communities in Toronto, Canada**  
Princess N. Okoh,<sup>1,2</sup> Ghazaleh Ahmadzadeh,<sup>1</sup> Ranie Ahmed,<sup>1,2</sup> Priscilla Boakye,<sup>3</sup> Beth Edwards,<sup>1</sup> Paula Neves,<sup>1</sup> Emma S. Rogers,<sup>1</sup> Istvan Mucsi.<sup>1,2</sup> <sup>1</sup>*University Health Network, Toronto, ON, Canada;* <sup>2</sup>*University of Toronto, Toronto, ON, Canada;* <sup>3</sup>*Ryerson University Daphne Cockwell School of Nursing, Toronto, ON, Canada.*

**Background:** From a medical perspective, LDKT is the best treatment option for kidney failure. Patients from ACB communities are much less likely to receive LDKT than White patients. Stigma surrounding kidney failure and LDKT may contribute to this inequity. This qualitative analysis aims to understand the nature of stigma and how it may influence access to LDKT in ACB communities in Toronto, Canada.

**Methods:** Self-identified ACB participants (individuals with [on dialysis or after kidney transplant] and without lived experience with kidney failure; and health care professionals [HCPs]) were recruited using purposive and snowball sampling via community networks and social media. Semi-structured in-depth individual interviews (IDIs) and focus groups (FGs) were conducted, audio-recorded, and transcribed verbatim. Reflexive Thematic Analysis was utilized, drawing on the tenets of Critical Race Theory (CRT) and Intersectionality to consider the effects of racialization and the interlocking effects of co-occurring social identities such as race, class, and health status and access to LDKT. Themes were developed, refined, and finalized by the research team.

**Results:** The sample is comprised of 6 community FGs (n=81), 7 IDIs with HCPs, 9 patient IDIs, and 2 FGs (n=6) with patients with kidney failure. Participants expressed hesitancy around communicating about kidney disease and the need for LDKT due to anticipated and experienced stigma. Participants with kidney failure feared judgment from family, friends, and community (e.g. due to anticipated assumptions about lifestyle choices), as well as from HCPs (e.g. due to anticipated assumptions about health beliefs and behaviours). Participants also described a strong cultural norm of maintaining privacy around health issues, largely limiting any discussion about LDKT.

**Conclusions:** Stigma is a potential barrier to LDKT as it may prevent discussions about kidney failure and treatment options and reduce the chance of identifying potential living donors. Culturally tailored, competent resources co-developed with ACB communities may help reduce stigma in ACB communities and may improve equitable access to LDKT.

FR-PO883

**Rethinking Racial Disparities in Living Donor Kidney Transplantation: A Socioecological Approach**  
Bashir El-Khoury, Tse-Chuan Yang. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

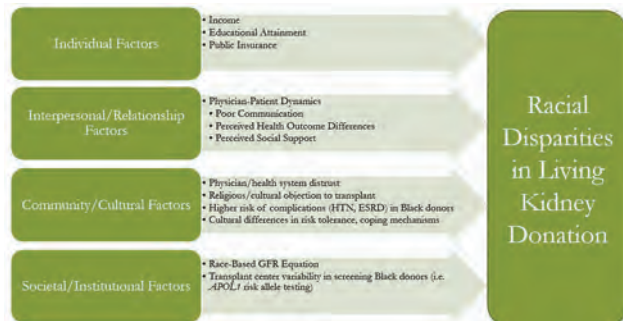

**Background:** The incidence of end stage renal disease (ESRD) is higher among Blacks than other racial or ethnic groups and is up to three times higher than the non-Hispanic white population. Despite kidney transplantation having superior outcomes to dialytic therapies, the disparities in living donor kidney transplantation (LDKT) between Black and non-Hispanic white patients have persisted, even after taking into account individual differences in social determinants. Previous studies have shown that Black patients are less likely to receive a kidney transplant and living-donor transplant than white patients in the United States. I argue that using a socioecological approach should better formulate interdisciplinary and comprehensive interventions to help reduce the racial disparities in living donor kidney transplantation.

**Methods:** A comprehensive literature search was performed using PubMed and relevant articles pertaining to individual factors, interpersonal/relationship factors, community/cultural factors, and societal/institutional factors in living donor kidney transplantation were reviewed.

**Results:** At the individual level, public insurance, income and transplant knowledge have been found to be independently associated with living donor kidney transplantation. The interpersonal/relationship factors shaping the disparities include perceived lack of social support and poor communication. Finally, cultural differences and structural inequities in our health care system including the use of race-based glomerular filtration rate calculators and transplant center variability in the screening of Black donors may also play a role.

**Conclusions:** Numerous factors at each socioecological level are likely maintaining the racial disparities witnessed in living donor kidney transplantation. A multidisciplinary and interprofessional approach is necessary to devise strategies and interventions to eliminate racial disparities and reduce inequity noted in LDKT in the United States. By utilizing a socioecological approach, we may be able to rethink how we address this important issue.

### Incarceration of Black ESKD Patients' Family Members as a Barrier to Living Kidney Donation

Avrum Gillespie,<sup>1</sup> Jonathan Daw,<sup>2</sup> Andrea Corradi,<sup>3</sup> Briana E. Lee,<sup>1</sup> Hannah Calvelli,<sup>1</sup> Sally B. Quinn,<sup>1</sup> Zoe Pfeffer,<sup>1</sup> Heather M. Gardiner,<sup>4</sup> Edward L. Fink,<sup>5</sup> Crystal A. Gadegeku,<sup>6</sup> Peter P. Reese,<sup>7</sup> Zoran Obradovic.<sup>8</sup>  
<sup>1</sup>Lewis Katz School of Medicine at Temple University, Philadelphia, PA; <sup>2</sup>The Pennsylvania State University - University Park Campus, University Park, PA; <sup>3</sup>Georgia Southern University, Statesboro, GA; <sup>4</sup>Temple University College of Public Health, Philadelphia, PA; <sup>5</sup>Temple University College of Liberal Arts, Philadelphia, PA; <sup>6</sup>Cleveland Clinic, Cleveland, OH; <sup>7</sup>University of Pennsylvania, Philadelphia, PA; <sup>8</sup>Temple University, Philadelphia, PA.

**Background:** There are racial disparities in living donor kidney transplantation (LDKT) between Black and White Americans. Few studies have examined how systemic racism has contributed to these disparities. Punitive policies leading to mass incarceration have disproportionately affected Black Americans and are a large contributor to systemic racism in the U.S. In this study, we examine whether the disproportionate impact of mass incarceration may be contributing to racial disparities in LDKT by preventing access to potential living donors because of the incarceration of Black ESKD patients' family members.

**Methods:** This is a cross-sectional interviewer-administered social network survey of prevalent hemodialysis patients as part of a living donor communication intervention conducted in an urban dialysis clinic in the Middle Atlantic region. Participants were asked, "Have any members of your immediate family, NOT including yourself, ever been held in jail or prison for one night or longer?", and the number of family members affected by incarceration. Participants were then asked how many members affected by incarceration could have potentially donated. Chi square and Fisher's exact tests were used to test the statistical significance of the independent variables' association with categorical dependent variables, and a *t* test was used for dependent continuous variables.

**Results:** Between February to March 2022, 23 transplant eligible self-identified Black and Mixed Race ESKD patients participated in the survey. Participant demographics included a mean age of 55 ± 9 years, 65% were female, and 75% had a household income less than \$40,000. 52% of participants reported having a family member incarcerated, with most having 2-3 members. Participants reported that greater than 75% of the family members who were affected by incarceration could have potentially donated. There were no significant differences in family member incarceration and demographic variables.

**Conclusions:** Of the patients surveyed, 39% had at least one incarcerated family member in prison who could have potentially donated if they were not incarcerated. Identifying how systemic racism affects health disparities is the first step to ensuring health equity in kidney transplantation.

### The Impact of Gender Affirming Hormone Therapy on Measures of Kidney Function: A Systematic Review and Meta-Analysis

David T. Collister,<sup>1</sup> Emily Krupka,<sup>2</sup> Thomas W. Ferguson,<sup>2</sup> Reid Whitlock,<sup>2</sup> Adam C. Millar,<sup>3</sup> Mashall Dahl,<sup>4</sup> Raymond Fung,<sup>3</sup> Sofia B. Ahmed,<sup>5</sup> Navdeep Tangri,<sup>2</sup> Michael Walsh.<sup>6</sup>  
<sup>1</sup>University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; <sup>2</sup>University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; <sup>3</sup>University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; <sup>4</sup>The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; <sup>5</sup>University of Calgary Cumming School of Medicine, Calgary, AB, Canada; <sup>6</sup>McMaster University, Hamilton, ON, Canada.

**Background:** Gender affirming hormone therapy (GAHT) modifies body composition and lean muscle mass in transgender persons. We sought to characterize the change in serum creatinine, other kidney function biomarkers, and glomerular filtration rate (GFR) in transgender persons initiating masculinizing and feminizing GAHT.

**Methods:** We searched PubMed, EMBASE, the Cochrane Library, and ClinicalTrials.gov from inception to September 16, 2020 for randomized controlled trials, observational studies, and case series that evaluated the change in serum creatinine, other kidney function biomarkers, and GFR before and after the initiation of GAHT in adult transgender persons. Two reviewers independently screened and abstracted data and disagreements were resolved by a third reviewer. Random effects meta-analysis was performed to determine the change in outcomes over follow-up of 3, 6 and 12 months.

**Results:** Of the 4758 eligible studies, 26 met the inclusion criteria including 9 studies that recruited 488 transgender men and 593 women in which data was meta-analyzed. There was heterogeneity in study design, populations, GAHT routes, and dosing. At 12 months after initiating GAHT, serum creatinine increased by 0.15mg/dL (95% CI 0.00, 0.29) in 370 transgender men and decreased by -0.05mg/dL (95% CI -0.16, 0.05) in 361 transgender women. No study reported the impact of GAHT on albuminuria, proteinuria, cystatin C, or measured GFR.

**Conclusions:** GAHT increases serum creatinine in transgender men and does not impact serum creatinine in transgender women. The impact on GAHT on other kidney function biomarkers and measured GFR is unknown.

## FR-PO886

### Gender Disparity in CKD: Men From Mars, Women From Venus

Manisha Sahay,<sup>1</sup> Vivek Kumar,<sup>2</sup> Monica Kundu,<sup>3</sup> Ashok K. Yadav,<sup>2</sup> Vivekanand Jha.<sup>3</sup>  
<sup>1</sup>ICKD study group <sup>1</sup>Osmania Medical College, Hyderabad, India; <sup>2</sup>Post Graduate Institute of Medical Education and Research, Chandigarh, India; <sup>3</sup>The George Institute for Global Health, Newtown, NSW, Australia.

**Background:** There is no data on sex difference in CKD in developing countries. We examined sex differences in pan-country prospective, observational cohort study

**Methods:** We used data from 1331 women & 2725 men with eGFR 15–60 mL/min/1.73 m<sup>2</sup> or >60 mL/min/1.73 m<sup>2</sup> with proteinuria from different geographical regions & compared demographics, clinical profile, QOL & Outcomes-ESKD (CKD 5/chronic dialysis/kidney transplantation), 50% decline in eGFR & mortality

**Results:** Cause of CKD was DKD (24.9% in men, 25% in women), CIN (22.8% in men, 24% in women) and unknown 20% in men and 18.3% in women. Urine albumin, BMI, waist-hip ratio, LDL, Phosphours, PTH were higher in females while serum haemoglobin and calcium, use of iron, erythropoietin & statin were lower. SGA scores were similar. Men had better QOL. There was no significant difference in renal outcomes or mortality (Fig1,2) Risk factors for mortality, 50% GFR decline, incident ESRD are shown in Table1

**Conclusions:** This largest CKD cohort study with detailed phenotyping, rigorous follow-up showed that Women have poor literacy, QOL, hemoglobin, lower iron, ESA, statin use. Risk of progression to ESKD & mortality slightly more in women.

**Funding:** Government Support - Non-U.S.

Table 1 Risk factors for renal outcomes and all cause mortality

	Males	Females
risk factor for all cause mortality	Age (HR = 1.03, p = 0.01), sedentary lifestyle (HR = 0.62, p = 0.04), history of renal stone (HR = 0.45, p = 0.05), history of CVD (HR = 2.04, p < 0.01) and BMI (HR = 0.92, p = 0.01)	Age (HR = 1.04, p = 0.02)
Risk of ≥50% GFR decline	Systolic BP (HR = 1.01, p = 0.01), NSAID (HR = 2.14, p < 0.01)	Age (HR = 0.97, p = 0.010), ABL systolic bp (HR = 1.04, p < 0.01), diastolic bp (HR = 0.96, p = 0.011) and NSAID (HR = 2.14, p = 0.05)
Risk factors for incident ESRD	age (HR = 0.98, p = 0.01), history of renal stones (HR = 0.54, p = 0.05), systolic BP (HR = 1.02, p < 0.01)	ABL systolic bp (HR = 1.02, p = 0.02) and history of renal stone (HR = 0.34, p = 0.05)

## FR-PO887

## One Year of Women in Nephrology India: Where Do We Stand and Where Are We Headed?

Priti Meena,<sup>1</sup> Urmila Anandh,<sup>2</sup> Divya P. Bajpai,<sup>3</sup> Krithika Mohan,<sup>4</sup> Namrata Parikh,<sup>5</sup> <sup>1</sup>All India Institute of Medical Sciences - Bhubaneswar, Bhubaneswar, India; <sup>2</sup>Yashoda Hospital, Hyderabad, India; <sup>3</sup>King Edward Memorial Hospital, Mumbai, India; <sup>4</sup>Hosmat Hospital, Bengaluru, India; <sup>5</sup>Ottawa Hospital, Ottawa, ON, Canada.

**Background:** Undoubtedly, women have made outstanding achievements in various areas such as education, clinical practice, interventions, and research and thus, have contributed significantly to the field of nephrology across the globe. Women in Nephrology India (WIN-India) is an organization established in August 2021 to provide mentorship and a support system with its diverse goals in the arena of nephrology. Throughout the year the organization has conducted multiple academic activities in the form of live webinars, quizzes, symposiums, clinical case discussions and newsletters.

**Methods:** We evaluated the status of WIN-India in the country and the quality of content of academic activities that WIN-India conducted from August 2021 to April 2022. Study participants were invited to take part in the study using Survey Monkey, an online survey collection tool. The participants of this study were faculty of nephrology, nephrology residents, dietitians, dialysis technicians, and nurses. The survey included 16 questions of which 4 were related to demographic variables, one was for suggestions and weaknesses. The remaining questions elicited the quality of the content of academic activities and the newsletter (on a scale 1-10).

**Results:** A total of 250 responses were received. 225 respondents (90%) were aware of WIN-India. The most common age group of respondents was 25-35 years, and 60% belonged to male sex. The majority of participants were nephrology faculty (50% private practitioners, 36.6% academic nephrologists, and 10% were trainees), Social media was the most popular source for creating awareness about WIN-India. On a scale of 1-10, academic content of the education of WIN-India and letter was reported as 10 by 35% and 30% and 9 by 38% and 35%, of the respondents respectively. 62% of the respondents reported that WIN-India webinars were beneficial in their clinical practice and research projects and 83% felt that WIN-India is a step forward toward improving nephrology education. 80% of individuals were interested in participating in WIN-India activities.

The main feedback was to increase social media coverage to enhance its outreach while others felt that there should be no gender bias.

**Conclusions:** The findings of the study showed that WIN-India successfully provided a platform for academics, mentoring, networking, advocacy, and the development of leadership.

## FR-PO888

## Evaluation of Gender Bias in First Authorship in Nephrology Publications From 2011-2021

Rahul R. Abraham, Oluwadamilola Adisa, Fatima Iqbal, Karina Sulaiman, LSU Health Shreveport, Shreveport, LA.

**Background:** Publishing articles is integral to clinical academia and acts as a benchmark for academic prolificacy. Research participation and expertise are essential in the advancement of academic careers. However, the existence of gender bias in publications is a well-established and undeniable reality. No data exists on publication biases in nephrology. This study was carried out to evaluate gender disparities and their trajectory among popular nephrology journals.

**Methods:** A PubMed search was performed using the easyPubMed package in R, version 4.0.3. The code was written to extract all articles indexed in PubMed from 2011 to 2021 from American nephrology journals with high impact factors were selected – Journal of American Society of Nephrology (impact factor), American Journal of Nephrology, American Journal of Kidney disease, Clinical Journal of the American Society of Nephrology. Gender with predictions >90% were accepted and the remaining were manually searched on the internet. SPSS was used to carry out descriptive statistics, ratios of male to female first authors grouped by years were carried out, followed by Chi-square-tests were used to measure differences in proportions, and Pearson's correlation was carried out. A similar analysis was done for individual journals.

**Results:** 11608 articles were included in the study. Across all journals, the average ratio of male to female first authors improved across the years, from 1.9 to 1.5 (p<0.05). Additionally, in 2011, women accounted for 32% of first authors, a number that rose to 40% in 2021, with the average across the ten years being 37%. Of the four journals analyzed, all except for the American Journal of Nephrology showed an improvement in the ratio of male to female first authors. For the American Journal of the society of Nephrology, the ratio changed from 1.81 to 1.58, p=0.001, for the clinical journal of the American Society of Nephrology, the ratio declined from 1.91 to 1.15, p=0.005 while for the American Journal of Kidney Disease, the ratio declined from 2.19 to 1.19, p=0.002.

**Conclusions:** Gender bias in publications continues to exist in first-author publications in nephrology. However, this review indicates that the gender gap is closing. Multiple factors might be contributory to this. We hope this study lays the groundwork to continue to follow and evaluate gender trends in publication.

## FR-PO889

## A Framework for Anti-Racist Curriculum Changes in Nephrology Education

Paloma C. Orozco Scott, Jerrel L. Catlett, Carina Seah, Staci A. Leisman, Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Despite national commitments to anti-racism, a paucity of guidance exists on how to critically appraise pathophysiological and epidemiological findings with an anti-racist lens. Identifying scientific racism and replacing it with evidence-based rationale is fundamental to anti-racist change. Mention of race within nephrology curricula should not act as a proxy for polygenic contributions, social determinants of health, or systemic healthcare barriers. Anti-racist curricular change necessitates that teachers re-inhabit the role of the learner, entering an interactive and collaborative process of questioning, adjusting, and feedback.

**Methods:** We applied the proposed process to two case-studies: estimated glomerular filtration rate (eGFR) and HIV-associated nephropathy (HIVAN). Citations from widely used nephrology education sources illustrate improper use of race within nephrology.

**Results:** Nephrology educators can apply an inquiry-based process, assessing the problem, themselves, devising solutions, and assessing impact, to identify and intervene upon scientific racism within curricula. Applying this process to the case of HIVAN, we suggest that sources referencing "Black" race as a predominant risk factor should instead center discussion on evidence-based factors such as causal polymorphisms and social determinants that disproportionately impact Black patients.

**Conclusions:** In confronting racial disparities in nephrology, educators must work collaboratively to critically appraise where in their curriculum race is implicitly/explicitly naturalized as a biological variable and the impact their framing of race has on clinical practice.

Text	Quote	Problem	Solution
Robbins and Cotran <sup>1</sup> Pathologic Basis of Disease, Tenth Edition (2021)	"HIV infection can directly or indirectly cause several renal complications... most commonly, a severe form of the collapsing variant of FSGS, termed HIV-associated nephropathy. The latter has been reported in 5% to 10% of HIV-infected individuals in some older series, more frequently in blacks than in whites... There is some data to suggest that HIV can infect tubular epithelial cells and podocytes, but much remains to be known."	Claims more frequent presentation of HIVAN in black patients without consideration of specific cultural, behavioral, and/or environmental factors that may increase the risk of disease. Also does not consider social determinants of health that influence racial disparities in ESKD presentation.	Avoid attributing race as the causal explanation of discrepant disease incidence. Provide historical context and focus on structural and social determinants of health that explain discrepancies in incidence.
Campbell-Welsh-Welsh <sup>2</sup> Urology <sup>10</sup> , Twelfth Edition (2021)	"It has a 12:1 greater incidence in black patients compared with white patients and has become the third leading cause of end-stage renal disease among black patients 20 to 64 years of age. The diagnosis is made by biopsy that demonstrates a collapsing variant of focal segmental glomerulosclerosis, proliferation of renal tubular and vascular cells, tubular microcystic formation, sclerosis, interstitial fibrosis, and infiltration of the interstitium with leukocytes."	Provides epidemiological data for disproportionate incidence of HIVAN in black patients without consideration of specific cultural, behavioral, and/or environmental factors that may increase the risk of disease. Also does not consider social determinants of health that influence racial disparities in ESKD presentation.	Avoid imprecise approximations of ancestry. Instead, reference evidence of known risk variants found more often in patients of African descent, such as APOL1 variants G1 and G2. Should also propose rationale or prevailing theory for why there is increased presentation in African-descent groups (e.g., evolutionary advantage of protective alleles against trypanosomiasis).
Cecil's Essentials of Medicine <sup>11</sup> , Tenth Edition (2022)	"HIVAN occurs almost exclusively in patients of African descent when CD4 levels are low. It is thought to be caused by infection and subsequent expression of HIV viral genes in podocytes."	Gives reference to a broad ancestry group without clear delineation of implicated genes or polymorphisms; author believes contribute to disproportionate HIVAN presentation within this population.	Avoid imprecise approximations of ancestry. Instead, reference evidence of known risk variants found more often in patients of African descent, such as APOL1 variants G1 and G2. Should also propose rationale or prevailing theory for why there is increased presentation in African-descent groups (e.g., evolutionary advantage of protective alleles against trypanosomiasis).

## FR-PO890

## Measuring the Impact of an Interprofessional and Multidisciplinary Graduate Medical Case Conference on Socioeconomic Healthcare Disparities in Nephrology

Morgan Schoer, Gaurav Rajashekar, Frank J. O'Brien, Washington University in St Louis, St Louis, MO.

**Background:** According to the most recent ACGME survey, 70% of fellows reported either no training in cultural competency, or generic training only. Learning to recognize unconscious biases, understand socioeconomic healthcare barriers, and utilize available resources will improve patient care. Specifically in nephrology, in which Black Americans are 4-5x more likely to develop kidney disease than the general population, it is critical that we train fellows how to partner with other health professionals to best navigate cultural differences and advocate for their patients in order to achieve equity and reduce disparities. We developed a specific curriculum at a single large academic institution to address this issue.

**Methods:** We partnered with the rheumatology and infectious diseases divisions to build a four-part curriculum addressing various aspects of health barriers and equity. Each division was tasked to create a one-hour interactive workshop addressing different high-yield topics. Attendings, fellows, social workers, and nurses were invited to participate. Pre- and post-session surveys querying fellows' comfort in identifying and addressing structural and social determinants of health were administered.

**Results:** On a Likert scale from one to five, one being "very uncomfortable" and five being "very comfortable," fellows' (N=16) comfort with understanding and applying St. Louis geopolitical history in the context of medical interactions rose from median value 2.0 to 3.0 (p=0.008). Fellows' comfort in recognizing and strengthening social networks rose from 2.0 to 3.5 (p=0.002). Other metrics showed non-significant improvements.

**Conclusions:** Interprofessional and interdisciplinary case discussions about socioeconomic barriers to healthcare improved fellows' comfort in identifying and addressing structural and social determinants of health.

## FR-PO891

## Identification of Neglected Kidney Diseases: Results From an International Survey

Chee Kay Cheung,<sup>1,2</sup> Monica Moorthy,<sup>3</sup> Olivier Devuyst,<sup>4</sup> Ifeoma I. Ulasi,<sup>5</sup> Jonathan Barratt,<sup>1,2</sup> Vivekanand Jha.<sup>6</sup> <sup>1</sup>University of Leicester, Leicester, United Kingdom; <sup>2</sup>University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; <sup>3</sup>International Society of Nephrology, Brussels, Belgium; <sup>4</sup>Universitat Zurich, Zurich, Switzerland; <sup>5</sup>University of Nigeria, Nsukka, Nigeria; <sup>6</sup>The George Institute for Global Health India, New Delhi, India.

**Background:** Neglected kidney diseases face similar issues to rare kidney diseases: a lack of awareness amongst healthcare professionals, delays in diagnosis, a lack of available or accessible treatments, and low prioritization for research funding. These entities are not well defined, and include both communicable and non-communicable

conditions that affect a broad patient demographic spanning age, gender, ethnicities, and socio-economic groups. Perceptions amongst stakeholder communities of what constitutes a neglected kidney disease are unclear. The aim of this study was to explore views on this topic internationally.

**Methods:** We distributed an online survey to the International Society of Nephrology (ISN) community, that asked respondents to name three neglected kidney diseases, and to specify reasons for their choice. Results from this survey were summarized and grouped according to whether the respondent was from a low- and middle-income country (LMIC) or a high-income country (HIC), according to the Organization for Economic Co-operation and Development (OECD).

**Results:** There were 310 responses from 84 countries. 223 (71.9%) responses were from a LMIC. The top three neglected diseases identified by respondents from a LMIC were diabetic nephropathy, polycystic kidney disease and chronic kidney disease. In contrast, the top three neglected diseases by respondents from a HIC were Fabry's disease, IgA nephropathy and polycystic kidney disease. Conditions found primarily in LMIC such as CKDu (Mesoamerican nephropathy), herbal nephropathy or those due to communicable disease were more likely to be included by respondents from those countries, whereas respondents from HIC were more likely to state ultrarare kidney diseases, such as those due to monogenic causes or disorders of the complement system.

**Conclusions:** Further analysis of the results from this survey will identify what the ISN community consider to be neglected kidney diseases, and the reasons for each choice. Notably, common kidney diseases such as diabetic nephropathy featured frequently in responses from LMIC, which may reflect a lack of access to recently developed therapies. Ongoing work will continue to assess the attitudes of healthcare professionals and the public towards this topic, and help inform the ISN regarding priorities for education, advocacy and research funding.

## FR-PO892

## Challenges in Diversity and Inclusion in Clinical Trial Enrollment in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Denise Foy,<sup>1</sup> Barbara C. Khan,<sup>2</sup> Ryan Rex.<sup>1</sup> <sup>1</sup>Spherix Global Insights, Exton, PA; <sup>2</sup>Palladio Biosciences, Horsham, PA.

**Background:** Increasing diversity and inclusion in clinical trials remains challenging in the ADPKD population, but opportunities exist to support expansion of representation among underserved populations.

**Methods:** Real world analysis conducted in Fall 2020 and 2021 evaluating more than 1,500 ADPKD patient charts (collected in collaboration with 243 US nephrologists). Additional data was collected via an online survey of 102 US nephrologists in May 2022.

**Results:** The large-scale chart audits revealed that the ADPKD patient population is 62% White, 18% African American/Black, 12% Hispanic, and 6% Asian. Socioeconomic status was categorized as primarily middle (61%) and upper class (14%), with only 16% identified as lower income. While two-thirds of survey respondents expressed a willingness to enroll patients into a new clinical trial, the data show the patients more likely to be targeted for enrollment are White, in a higher socioeconomic class, with advanced education, and with commercial insurance, revealing potential bias in patient selection for trials. In addition, the majority of respondents ranked "lower income" as the demographic most underrepresented in clinical trials, followed by Black and Hispanic populations (notably, 34% stated there is no unmet need in particular demographic groups). Barriers to patient enrollment included low trial awareness overall, difficulty in identifying appropriate patients, patient resistance and lack of trust, and the burden of managing the enrollment process. Importantly, 65% of the surveyed physicians said that the FDA draft guidance to increase diversity in clinical trials would influence their decisions on which patients to recommend for a clinical trial. Almost all respondents identified several areas to improve participation in clinical trials, including better/more physician education about trials, patient incentives, easier enrollment processes, and more access to live coordinators and resources.

**Conclusions:** Physicians need more resources and support to identify opportunities to refer patients to clinical trials and increase enrollment of a more diverse patient population. Compelling educational resources are needed to address barriers, especially those that disproportionately impact underrepresented patient groups.

**Funding:** Commercial Support - Palladio Biosciences, Inc, a Centessa Pharmaceuticals company.

## FR-PO893

## Directions for Rural Health Research From the COMPASS Project

Darren W. Schmidt, Jesus E. Fuentes, Heidi Rishel Brakey, Larissa Myaskovsky, Christos Argyropoulos. The University of New Mexico, Albuquerque, NM.

**Background:** The Community Based Study of the Epidemiology of Chronic Kidney Disease in Cuba New Mexico and Surrounding Areas (COMPASS), a kidney health screening initiative in rural New Mexico (NM), was designed to screen for CKD and discover novel related biomarkers. We explored participants' opinions about CKD research and best practices for delivering kidney lab results to patients with a sub-sample of the study population.

**Methods:** Participants were aged 18-80 years, provided informed consent, and had a mailing address in Cuba, NM; we excluded participants with history of renal replacement therapy. We communicated kidney lab results to participants via a letter using the NKfVisualization tools (Fig. 1). We qualitatively interviewed a subset of participants from the main study to explore their thoughts about general research participation and receive feedback on the results letter. Using descriptive qualitative design and a team-based, iterative, process, we elicited themes from transcribed interviews using NVivo qualitative analysis software.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Results:** We interviewed 33 adults: 63% Hispanic; 24% American Indian; and 54.5% female. The most salient themes included positive attitudes toward kidney research; the role of third parties for help interpreting the results letter; and the research participation inspiring lifestyle change (Table 1).

**Conclusions:** Rural community members embraced the opportunity to participate in kidney health research. The NKF visualization tools for displaying lab results were well-received, but patients could use help interpreting results. The letter, however, still inspired positive lifestyle change in rural New Mexican participants.

**Funding:** Private Foundation Support

#### Themes & Related Subject Responses

Positive Perceptions of Kidney Research	Role of Third Parties for Interpretation of Results Letter	Results Letter Inspiring Lifestyle Changes
"...I believe in research studies. I think it's helpful to a total community..."	"...I took it to my doctor because I have issues [understanding the letter], and it was right on point. He was very happy with the letter that you guys sent..."	"I drink a lot more water now. I try to watch what I eat; not too much fatty foods. I've lost like 25 pounds now..."
"I participate because I'm curious about myself, but it's something that I think is good for the community and try to get people involved in..."	"What happened was that all of this helped me understand what was wrong with me, so you guys are great, honestly. What you gave me, I took to the doctor, and he figured out, so it eliminated a lot of things."	"Just drinking more water daily and going for walks more. Just trying to watch what I eat... Just little things like that I kind of changed a little bit. It's been good, so far."
"[Research is] to help people understand stuff, I guess, and what the research is. I don't know what kind of research studies are doing right now... if it was something that might benefit me or my family or somebody that I know that might have something, I'd probably [participate]."	"...we looked at it, and there were a few numbers that we weren't too sure about. We have a friend who's a nurse, and so we let her look over what the study was. She said it was all good."	"It made me aware that what I put into my body is what I'm getting out of it, in terms of alcohol or junk food, and in terms of diabetes... That really did open my eyes to a lot of that stuff, but I thought it didn't apply to me, but I guess I was just fooling myself."

Dear <Participant Name>,

I am writing to inform you about the results of your screening for Chronic Kidney Disease (CKD) that took place on <Date>. Your GFR reading, which measures how well your kidneys are filtering your blood, is <VALUE>. Values less than 60 usually indicate abnormal kidney filtering. The protein (albumin) reading in your urine is <VALUE>. Values lower than 30 usually mean that there is no damage in your kidneys. This can happen even though your kidneys do not filter your blood efficiently.

These readings were obtained in a research laboratory and thus cannot be validly used to direct your health care. You should discuss these readings with your primary care physician who will prescribe the appropriate course of action. In most cases, this would require repeating the tests in a certified laboratory and/or additional testing. If you want to learn more about Kidney Disease, I strongly encourage you to visit the web page of the National Kidney Education Program, hosted by National Institute of Health:

<http://www.niddk.nih.gov/health-information/health-communication-programs/nkdep/learn/Pages/learn.aspx>

#### Stakeholder Perspectives on Engaging Latinx Patients in Kidney-Related Research

Flor Alvarado,<sup>1</sup> Cynthia Delgado,<sup>2,3</sup> Susanne B. Nicholas,<sup>4</sup> Allison Tong,<sup>5</sup> Lilia Cervantes,<sup>6</sup> <sup>1</sup>Tulane University School of Medicine, New Orleans, LA; <sup>2</sup>San Francisco VA Health Care System, San Francisco, CA; <sup>3</sup>University of California San Francisco, San Francisco, CA; <sup>4</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; <sup>5</sup>The University of Sydney School of Public Health, Sydney, NSW, Australia; <sup>6</sup>University of Colorado - Anschutz Medical Campus, Aurora, CO.

**Background:** Latinx patients are disproportionately burdened by kidney disease compared to non-Latinx White patients and are underrepresented in kidney-related research. We aimed to describe stakeholders' perspectives on challenges related to engaging Latinx patients in kidney-related research.

**Methods:** We conducted a thematic analysis of qualitative data from two online moderated discussions and an interactive online survey using open text responses among participants (i.e. stakeholders) with personal and/or professional experience with Latinx patients with kidney disease and their families/caregivers.

**Results:** Among eight stakeholders, there were 3 physicians, 1 nurse, 1 patient with kidney disease who received a kidney transplant, 1 policymaker, 1 PhD-trained disparities researcher, and 1 executive director of a non-profit health organization. The majority of themes (and subthemes) reflected barriers to engagement and recruitment: lack of personal relevance (inability to relate to research staff, perceived low importance of clinical trials, limited opportunities to participate; ambiguity of benefit to self and family); fear and vulnerability (immigration concerns, stigma with seeking care, skepticism of Western medicine); financial and logistical barriers (out-of-pocket costs, transportation issues); and distrust and asymmetry of power (related to limited English proficiency or health literacy, and provider bias). The last theme was on stimulating interest and establishing trust in the research process. (Figure)

**Conclusions:** To overcome barriers to engagement in kidney-related research and establish trust among potential Latinx research participants, investigators can employ culturally responsive and community-based strategies. These strategies can help identify

local health priorities, enhance research recruitment and retention strategies, and establish partnerships that continue to elevate research endeavors aiming to enhance the health of Latinx individuals with kidney disease.

#### FR-PO895

#### Disparities in ESRD and Mortality Among Older and Younger Black and Hispanic Patients in the United States

Jiannong Liu,<sup>1,2</sup> Haifeng Guo,<sup>1</sup> James B. Wetmore,<sup>1,2</sup> David T. Gilbertson,<sup>1,2</sup> Kirsten L. Johansen,<sup>1,2</sup> <sup>1</sup>Hennepin Healthcare Research Institute, Minneapolis, MN; <sup>2</sup>University of Minnesota Medical School Twin Cities, Minneapolis, MN.

**Background:** ESRD incidence is higher among Black and Hispanic than among White individuals. We assessed disparities in incident ESRD and death among older Medicare and younger Medicaid beneficiaries with CKD stage 4 or 5.

**Methods:** Non-Hispanic White, Black, and Hispanic Medicare beneficiaries aged  $\geq 66$  years with Medicare Parts A and B for at least one year and CKD stage 4 or 5 on Jan 1, 2020 were included. In a separate cohort, Medicaid enrollees aged 18-65 years with Medicaid for  $\geq 1$  year and CKD stage 4 or 5 on Jan 1, 2020 were included. Patients were followed from January 1, 2020 to the earliest of death, onset of ESRD, loss of insurance, or Dec 31, 2020. Outcomes were death, ESRD, and the combination. We estimated one-year probabilities of ESRD and death and subdistribution hazard ratios (sHRs) from Fine-Gray models with death and ESRD as competing events and adjusted for age, sex, and comorbidities.

**Results:** 298,658 Medicare and 12,067 Medicaid beneficiaries were included. One-year probability of ESRD was 0.04 and 0.14 for Medicare CKD stages 4 and 5, respectively and 0.19 and 0.23 for death. The corresponding numbers were 0.15, 0.27, 0.07, and 0.09 for Medicaid patients. Black and Hispanic beneficiaries were more likely to reach ESRD than White patients (sHR 1.38-1.57 Medicare; 1.26-1.83 Medicaid, Figure) but were less likely to die (sHR 0.74-0.96 in Medicare and 0.68-0.96 in Medicaid). For the combined outcome, disparities were much greater in the Medicaid cohort (HR 1.14-1.47) than in Medicare (HR 0.85-1.13).

**Conclusions:** Older (Medicare) and younger (Medicaid) Black and Hispanic patients with CKD were at higher risk of ESRD and lower risk of death. However, disparities in risk of ESRD or death were greater in younger than older individuals. Disparities in access to care among younger individuals may be an important driver of observed ESRD disparities.

## FR-PO896

## Understanding Care Gaps in the CKD Clinic

Yuenting D. Kwong, Erik Stewart, Chi D. Chu, Kathleen D. Liu, Lowell J. Lo.  
University of California San Francisco School of Medicine, San Francisco, CA.

**Background:** Use of renin-angiotensin-aldosterone system inhibitors (RAASi) and sodium-glucose co-transporter 2 inhibitors (SGLT2i) in patients with stage 2-4 chronic kidney disease (CKD) and albuminuria can reduce adverse outcomes. Understanding care gaps is necessary for better implementation of guideline concordant care.

**Methods:** In a single-site academic nephrology practice, we performed a cross-sectional analysis to determine the proportion of current RAASi and SGLT2i use in patients with CKD stage 2-4 with urine albumin-to-creatinine ratio (ACR)  $\geq 30$ mg/g (i.e. moderate to severe albuminuria). We assessed for potential gender and racial disparities in the prescription of RAASi and SGLT2i using Pearson's  $\chi^2$  analysis.

**Results:** Of 2458 adults with stage 2-4 CKD, 2046 (83%) had ACR measurements within the last 3 years and 1,281 (62%) of the ACR measurements indicated moderate to severe albuminuria. Among these 1,281 patients, RAASi use was observed in 66% of patients and SGLT2i use was observed in 18.6% of patients. Gender disparities were not observed in RAASi use but SGLT2i use was less common among men. Racial differences were observed with Asian patients having the highest rate of RAASi and SGLT2i prescriptions (76% and 28%, respectively) while White patients had lowest use of RAASi (60%) and Black patients had the lowest use of SGLT2i (12%).

**Conclusions:** Care gaps in RAASi and SGLT2i use can be systemically identified in nephrology clinic and may inform panel management strategies for increasing guideline-concordant care. Factors underlying differences in prescription patterns along gender and racial categories (e.g. patient perception/tolerance/insurance coverage of medications) require further investigation.

Gender and Racial Differences in RAASi and SGLT2i Use Among Patients with Moderate to Severe Albuminuria

	Gender Disparities			Racial/Ethnicity				p-value
	Male	Female	p-value	White	Black	Asian	Other	
N	524	756		554	137	367	212	
RAASi use (%)	68	65	0.31	60	67	76	62	0.31
SGLT2i use (%)	15	21	<0.01	13	12	28	20	<0.01

## FR-PO897

## The European Kidney Function Consortium Estimating Glomerular Filtration Rate Equation for Cystatin C: Results for Europe, the United States, and Africa

Pierre Delanaye,<sup>1</sup> Jonas Björk,<sup>7</sup> Natalie Ebert,<sup>2</sup> Bjorn O. Eriksen,<sup>3</sup> Emmanuelle Vidal-Petiot,<sup>9</sup> Anders O. Grubb,<sup>7</sup> Magnus D. Hansson,<sup>8</sup> Karin Littmann,<sup>8</sup> Toralf Melsom,<sup>3</sup> Andrew D. Rule,<sup>4</sup> Elke Schaeffner,<sup>2</sup> Per-Ola Sundin,<sup>11</sup> Anna Åkesson,<sup>7</sup> Anders Larsson,<sup>5</sup> Etienne Cavalier,<sup>1</sup> Justine B. Bukabau,<sup>6</sup> Ernest K. Sumaili,<sup>6</sup> Martin Flamant,<sup>9</sup> Ulf Nyman,<sup>7</sup> Hans Pottel,<sup>10</sup> EKFC (European Kidney Function Consortium) <sup>1</sup>CHU de Liege - Hopital du Sart Tilman, Liege, Belgium; <sup>2</sup>Charite Universitätsmedizin Berlin, Berlin, Germany; <sup>3</sup>UiT Norges arktiske universitet, Tromsø, Norway; <sup>4</sup>Mayo Foundation for Medical Education and Research, Rochester, MN; <sup>5</sup>Uppsala Universitet, Uppsala, Sweden; <sup>6</sup>Universite de Kinshasa, Kinshasa, Congo (the Democratic Republic of the); <sup>7</sup>Skane's universitetssjukhus Lund, Lund, Sweden; <sup>8</sup>Karolinska Institutet, Stockholm, Sweden; <sup>9</sup>Hopital Bichat - Claude-Bernard, Paris, France; <sup>10</sup>Katholieke Universiteit Leuven - Campus Kulak Kortrijk, Kortrijk, Belgium; <sup>11</sup>Orebro universitet, Orebro, Sweden.

**Background:** The creatinine based European Kidney Function Consortium (EKFC<sub>crea</sub>) equation was recently developed as an optimized full age spectrum equation. In the present study, the new EKFC-equation is applied to serum cystatin C (CysC), by replacing rescaled SCr by rescaled CysC.

**Methods:** Individual data from Sweden (n=243,218) were used to estimate the scaling or normalization factor (Q') for CysC in adults. Scaled SCr/Q was replaced by scaled CysC/Q' in the cystatin C based EKFC-equation (EKFC<sub>CysC</sub>) which was then validated in White and Black subjects from Europe (n=11,231), North America (n=1,093) and Africa (n=508), with measured GFR, SCr, CysC, age, and gender available.

**Results:** Rescaling factor Q' for CysC was estimated at 0.79 for adult females and 0.86mg/L for adult males until age 50 years, and (0.79 or 0.86) + 0.005 x (Age - 50) thereafter. A sex-independent scaling factor of 0.83mg/L (and 0.83 + 0.005 x (Age - 50)) was also evaluated. EKFC<sub>CysC</sub> was (nearly) unbiased and showed prediction performances similar to EKFC<sub>crea</sub> in White Europeans, White North Americans, Black Europeans and Black Africans (P10/P30 equal to 40%/85%). EKFC<sub>CysC</sub> was superior to the KDIGO recommended equation CKD-EPI<sub>crea</sub> and CKD-EPI<sub>CysC</sub>. P10/P30 of the arithmetic mean of EKFC<sub>crea</sub> and EKFC<sub>CysC</sub> was greater than 45%/90% in almost all age-subgroups.

**Conclusions:** In our mixed cohorts from Europe, North America and Africa, EKFC<sub>CysC</sub> has the same mathematical form as EKFC<sub>crea</sub>, with different scaling factors for cystatin C and shows similar performance as EKFC<sub>crea</sub>, and better performance than CKD-EPI<sub>CysC</sub>. Moreover, the EKFC<sub>CysC</sub> equation is independent of race and gender. An extra gain in accuracy (reduced bias, plus 5 percentage points in P10/P30 accuracy) is achieved by combining both EKFC-equations.

Figure 1. Bias (left panel) and P30-accuracy (right panel) versus age for the SCr-based, CysC-based, and combined SCr+CysC equations, EKFC<sub>crea</sub> and CKD-EPI<sub>crea</sub> in the pooled dataset (n=12,832) of White Europeans / North Americans and Black Europeans / Africans. The grey area indicates the region where bias is zero ± 5 (left panel) and the region where P30 > 75% (right panel).

## FR-PO898

## Nephrologists' Perspectives on Kidney and Dialysis Care in Pakistan: A Qualitative Study

Sheza Malik,<sup>1</sup> Ayesha Anwar,<sup>2</sup> Rebecca J. Allen,<sup>3</sup> Fahad Saeed,<sup>4</sup> <sup>1</sup>Rochester General Hospital, Rochester, NY; <sup>2</sup>Allama Iqbal Medical College, Lahore, Pakistan; <sup>3</sup>Mount Saint Joseph University, Cincinnati, OH; <sup>4</sup>University of Rochester Medical Center, Rochester, NY.

**Background:** While most research on kidney care in developing countries has focused on patients, in-depth perspectives of Pakistani nephrologists on kidney and dialysis care are lacking.

**Methods:** Between May 2021 and September 2021, we interviewed 19 nephrologists and nine nephrology fellows working in nine hospitals in Pakistan. Those who hesitated to spare time for the qualitative interviews (n=09) were provided with the opportunity to write their responses to 8 open-ended questions (e.g., 'can you please share some common challenges when a patient needs dialysis?'). For the face-to-face interviews, we recorded and transcribed the conversations. Two reviewers coded the transcripts and used the inductive content analysis approach to formulate themes.

**Results:** We observed the following three main themes: (1) Nephrologists felt privileged when able to relieve patients' suffering. Still, they feared delivering bad news of kidney failure and lifelong dialysis to their patients. (2) Financial issues were the most significant reported barrier to providing maintenance dialysis. (3) Nephrologists were almost evenly divided in their comfort with end-of-life conversation. Some found these discussions challenging, while others found these discussions easy. Other challenges faced by patients with CKD, according to Pakistani nephrologists, included low literacy, limited awareness of kidney disease, fear of dying on dialysis, lack of transportation, poor social support, medical complications of dialysis, and common use of alternative medications.

**Conclusions:** Our study highlights key shortcomings of kidney and dialysis care in Pakistan. Our findings call for raising awareness about kidney disease in the general public. While patients need to be supported financially and psychologically, nephrologists' training in communication skills and end-of-life care is also urgently needed.

## FR-PO899

## Association of Clopidogrel Use With Renal Outcomes in US Veterans

Ruoxue Wu,<sup>1</sup> Diana Tran,<sup>1</sup> John Sy,<sup>3</sup> Csaba P. Kovesdy,<sup>2</sup> Fridtjof Thomas,<sup>2</sup> Keiichi Sumida,<sup>2</sup> Kamyar Kalantar-Zadeh,<sup>1</sup> Elani Streja.<sup>1</sup> <sup>1</sup>University of California Irvine Medical Center, Orange, CA; <sup>2</sup>The University of Tennessee Health Science Center, Memphis, TN; <sup>3</sup>VA Long Beach Healthcare System, Long Beach, CA.

**Background:** Anti-platelet agents like clopidogrel and aspirin have traditionally been used to treat acute coronary syndrome and stroke. However, little is known about the effect on clopidogrel on long-term renal outcomes. We investigated longitudinal data to see if patients using clopidogrel without CKD have an increased risk of developing CKD and ESRD.

**Methods:** 407,343 US veterans without CKD were divided between clopidogrel users and non-users. Cox survival models were utilized to investigate the association between clopidogrel users on with three outcomes of interest: incident CKD, incident ESRD, and death. Hazard ratios for clopidogrel users were calculated with adjustment for demographic, comorbidities, and laboratory data.

**Results:** Clopidogrel users were likely to be older (67.2 ± 9.9 vs 60.2 ± 12.9), male, white, with normal urine albumin levels (<30 mg/dL) and a median Charlson Comorbidity Index of 3. The risk of death was higher among clopidogrel users compared to non-users in unadjusted analysis (HR 1.71, 95% CI 1.69-1.73). Clopidogrel remained associated with CKD in unadjusted and fully adjusted models (HR: 2.24 unadjusted, 95% CI: 2.21-2.27 and HR: 1.42 fully adjusted, 95% CI: 1.40-1.45). With regards to ESRD, clopidogrel use was associated with a higher risk of incident ESRD which became insignificant in our fully adjusted model (HR: 1.79 unadjusted, 95% CI: 1.62-1.97 and HR: 1.00 fully adjusted, 95% CI: 0.88-1.14).

**Conclusions:** Clopidogrel use in non-CKD US veterans is associated with lower risk of mortality, and a higher risk of incident CKD but no association with ESRD.

**Funding:** NIDDK Support, Veterans Affairs Support

**Table.** Models demonstrating the association between clopidogrel exposure and 3 outcomes of interest

Outcome	Model	Clopidogrel	
		HR	95% CI
Death	1	1.71	1.69, 1.73
	2	1.22	1.21, 1.24
	3	0.89	0.88, 0.90
	4	0.87	0.86, 0.87
Incident CKD	1	2.24	2.21, 2.27
	2	1.82	1.80, 1.85
	3	1.38	1.36, 1.41
	4	1.42	1.40, 1.45
Incident ESRD	1	1.79	1.62, 1.97
	2	1.71	1.54, 1.89
	3	1.07	0.94, 1.22
	4	1.00	0.88, 1.14

Model 1 unadjusted; Model 2 adjusted for demographic i.e. age at baseline, female, Black, Other Race, Hispanic, past smoker, current smoker; Model 3 adjusted for demographics and the 15 diseases used to calculate the CCI excluding hemiplegia; Model 4 fully adjusted, adjusted for model 3 in addition to eGFR, UACR, unstable angina, chronic heart disease, atrial fibrillation, cerebral infarction, stenosis of precerebral arteries, peripheral arterial disease, coronary angioplasty status, peripheral vascular angioplasty, aortocoronary bypass graft

FR-PO900

**Association of Niacin Use With Kidney Outcomes**  
Shaun M. Whitecavage,<sup>1</sup> Diana Tran,<sup>1</sup> Keiichi Sumida,<sup>2</sup> Fridtjof Thomas,<sup>2</sup> Csaba P. Kovesdy,<sup>2</sup> Kamyar Kalantar-Zadeh,<sup>1</sup> Elani Streja.<sup>1</sup> <sup>1</sup>University of California Irvine Medical Center, Orange, CA; <sup>2</sup>The University of Tennessee Health Science Center, Memphis, TN.

**Background:** Niacin is a non-statin lipid lowering therapy that has been shown to lower triglycerides and to improve other risk factors for renal outcomes. Despite these favorable data, the effect of niacin on long term kidney outcomes remains unclear.

**Methods:** In a nationwide historic cohort of 1,139,630 US Veterans with normal baseline eGFR, we examined the association of de novo prescription of niacin during 2005-2006 with ESKD, incident CKD (defined as eGFR <60 ml/min/1.73m<sup>2</sup> on two occasions, separated by ≥90 days) and death. Associations were examined in Cox hazard models adjusted for demographics, major comorbidities, and lab measurements. Prescription time-distribution matching was used to control for survival bias.

**Results:** We identified 133,450 new users of niacin. Overall, patients were a mean (SD) 60 (13) years old, with 6% female, 16% Black, and 6% Hispanic. Niacin users were more likely to be male, White, current, or former smokers, with higher frequencies of comorbidities. Niacin was associated with lower risk of death (HR: 0.81, 95% CI: 0.80-0.82) and ESKD (0.85, 0.79-0.92), but with a higher risk of CKD (1.16, 1.15-1.17). The rates at which niacin users experienced death was slower compared to non-users (2.907 versus 3.649). However, the rates at which niacin users experienced ESKD and incident CKD were faster compared to non-users (0.066 versus 0.081 and 3.967 versus 3.018) respectively.

**Conclusions:** Niacin use was associated with a lower risk of ESKD and death, but with higher risk of incident CKD (potentially explained by acute effects on eGFR) in this large national cohort of patients with normal kidney function. Further studies are needed to corroborate the potential benefits of niacin on kidney function and survival.

**Atrial Fibrillation in Non-Dialysis Dependent CKD: Prevalence and Time in Therapeutic Range in Patients Anticoagulated With Vitamin K Antagonists**  
Diana Rodríguez-Espinosa,<sup>1</sup> Jose Jesus Broseta Monzo,<sup>1</sup> Aleix Cases.<sup>2,1</sup> <sup>1</sup>Hospital Clinic de Barcelona, Barcelona, Spain; <sup>2</sup>Universitat de Barcelona, Barcelona, Spain.

**Background:** Atrial fibrillation (AF) and chronic kidney disease (CKD) are two closely related entities since not only do they frequently coexist, but one increases the development and progression of the other and vice versa, as well as sharing many risk factors such as age, arterial hypertension, diabetes mellitus or heart failure. In addition, these patients are more prone to poor therapeutic control, although it has been described that the prevalence of AF in CKD is up to 20% and that these patients tend to achieve an INR in the therapeutic range of around 70%. This study aims to determine the true prevalence of this entity in elderly patients with advanced stages of CKD, as well as to determine the time in which acenocoumarol is maintained in the therapeutic range (TTR) in these individuals.

**Methods:** Retrospective observational study of a randomized sample of non-dialysis dependent CKD (NDD-CKD) patients followed at our hospital. Demographic, medical history, and laboratory data were taken from electronic health records. Time in the therapeutic range was calculated with the Rosendaal method

**Results:** A total of 114 cases were analyzed. The mean age was 79 years, 52.2% were men, their body mass index was 29.24 kg/m<sup>2</sup>, their estimated glomerular filtration rate was 22.9 ml/min/1.73m<sup>2</sup> and their mean Charlson comorbidity index was 8. The prevalence of AF was 35%. And this was significantly associated with the presence of heart failure (52.8% vs 9.3%, p<0.001). Half of the patients were anticoagulated with acenocoumarol and the other half with direct-acting anticoagulants (DOACs). Among the former, the mean TTR was 55%. Only 38.5% of patients anticoagulated with acenocoumarol had optimal TTR (>65%).

**Conclusions:** AF is more prevalent in elderly people with NDD-CKD. This population has greater difficulty than the general population in maintaining an optimal TTR level with vitamin K antagonists, increasing both their risk of bleeding and thrombosis. The population with NND-CKD could benefit from the use of DOACs in the face of this difficulty.

FR-PO902

**Nephrologist Use of Sodium-Glucose Cotransporter-2 (SGLT2) Inhibitors Relative to Other Specialties, 2015-2022**  
Rishav Adhikari, Kunal Jha, Michael J. Blaha. *Johns Hopkins University School of Medicine, Baltimore, MD.*

**Background:** Multiple clinical trials have demonstrated that sodium-glucose cotransporter-2 inhibitors (SGLT2is) slow progression of kidney disease and reduce cardiorenal mortality in patients with chronic kidney disease (CKD). Clinical guidelines recommend these medications for most patients with CKD, but few receive them. In this study, we characterized trends in SGLT2i use by nephrologists compared to other physicians.

**Methods:** We analyzed near-census level data from IQVIA's National Prescription Audit. This audit collects prescription dispensing activity from 93% of U.S. outpatient pharmacies and then projects that data to estimate 100% of prescriptions. We quantified monthly SGLT2i prescriptions from January 2015-April 2022, stratified by prescriber specialty and molecule. We also used physician census data from the AMA Physician Masterfile to calculate prescriptions per physician.

**Results:** From January 2015 - April 2022, monthly prescriptions of SGLT2is by nephrologists increased 35-fold (from 884 to 31,192) (Fig 1) while monthly prescriptions across all specialties increased 4-fold (from 447,915 to 1,807,389). However, nephrologists accounted for only 1.26% of all prescriptions in the final 12 months of the study. Although nephrologists outnumber them by ≈50%, endocrinologists accounted for 11-fold more prescriptions during that period. On a per-physician basis, nephrologists accounted for 21 prescriptions per physician in the final 12 months, while endocrinologists, primary-care physicians, and cardiologists accounted for 316, 33, and 18, respectively. Nephrologists predominantly used dapagliflozin, which was less frequently used by non-nephrologists (52% vs 28% of prescriptions). Notable accelerations in SGLT2i use and shifts in drug choice by nephrologists coincided with the CREDENCE trial, DAPA-CKD trial, and expansion of dapagliflozin's FDA label.

**Conclusions:** Nephrologists have markedly increased use of SGLT2is over the past 7 years, with surges in uptake coinciding with favorable renal outcomes data, but continue to account for a small proportion of overall prescriptions.

FR-PO903

**Renin-Angiotensin Aldosterone System Blockade in Patients With Advanced CKD: A Systematic Review and Meta-Analysis**  
Nicolas Vendeville, Marc-Antoine Lepage, Thomas Mavranakas. *McGill University, Montreal, QC, Canada.*

**Background:** The benefits of renin-angiotensin aldosterone system (RAAS) blockers are not well-established in patients with advanced chronic kidney disease (CKD). These patients may be more sensitive to the functional decrease in glomerular filtration rate (GFR) and increased risk of hyperkalemia that are inherent to RAAS blockade. We conducted a systematic review and meta-analysis to identify potential risks and benefits of RAAS blockade in patients with CKD stage 4-5.

**Methods:** A Medline search was conducted to identify randomized (RCTs) and observational studies with angiotensin converting enzyme inhibitors or angiotensin receptor blockers in patients with advanced CKD, defined as an estimated GFR < 30 mL/min/1.73m<sup>2</sup>. The primary outcome was progression to end-stage renal disease (ESRD).

Secondary outcomes included all cause mortality and major adverse cardiovascular events (MACE). The risk ratio (RR) was estimated using a random-effects model.

**Results:** Eight RCTs (739 patients) and 13 observational studies (59,580 patients) were included. RCTs showed significant reduction in progression to ESRD with the use of RAAS blockade: RR 0.69 (95% confidence interval [CI] 0.56-0.85). Observational studies were suggestive of decreased all-cause mortality with RAAS blockade: RR 0.85 (95% CI 0.78-0.94); but this finding was not reproduced in RCTs. No benefit from RAAS blockade was identified with respect to MACE among patients with advanced CKD.

**Conclusions:** RAAS blockers may be considered in patients with advanced CKD to delay progression to ESRD. However, no clear benefit was identified with RAAS blockade with regards to mortality and MACE in this population.

**Funding:** Government Support - Non-U.S.

### SGLT2i Prescribers Among CKD Patients: Trends in Real-World Data (RWD)

Joseph Stavas,<sup>1</sup> Emily L. Butler,<sup>1</sup> Jenna Abdelhadi,<sup>2</sup> Tancy C. Zhang,<sup>2</sup> Lexie Rubens,<sup>2</sup> Debra E. Irwin.<sup>2</sup> <sup>1</sup>ProKidney, Raleigh, NC; <sup>2</sup>Aetion, New York, NY.

**Background:** Sodium-Glucose Cotransporter-2 Inhibitors (SGLT2i) reduce CKD risks. RWD may provide insight into early adopters of these agents and treatment trends for CKD due to Type 2 Diabetes (T2DKD).

**Methods:** Adults  $\geq 30$  years old with  $\geq 2$  eGFR tests, 90-365 days apart, classifying patients as CKD stages 2-4 were identified in the HealthVerity PrivateSource20 closed claims linked with Veradigm Health Insights EHR and Quest laboratory results data between 1/1/2018 and 09/30/2021. The first eGFR test date was the index date, patients were followed for initiation of SGLT2i and the provider type on the prescription claim was identified. Patients with AKI and SGLT2i prescriptions during baseline were excluded.

**Results:** 5.1% of CKD patients (7094/137,874) Stages 2-4 initiated SGLT2i therapy and the number of CKD patients initiating treatment increased over the study period until 2020 (Fig 1). 94% of new SGLT2i use was among T2DKD. SGLT2i initiation was highest in Stage 2 and 3 (5.8%, 4.1%) followed by Stage 4 (1.5%). As disease severity worsened, the proportion of prescriptions initiated by nephrologists increased (0.7% Stage 2 vs. 19.7% Stage 4). Four specialty groups comprised 79% of prescribers overall, with General Medicine (59%) and Endocrinologists (16%) being the early prescribers, while the proportion of Nephrologists and Cardiologists was low but slightly grew by 2021 (Fig 2).

**Conclusions:** RWD indicates sparse initiation of SGLT2i in CKD patients, with increasing trends until 2020 which may, in part, be COVID-19 related. General Medicine and Endocrinologists were consistently the most common prescribing providers, while Nephrologist prescriptions increased over time and as stage advanced.

### Gender Differences in CKD Progression: Real-World Data (RWD) Analysis

Joseph Stavas,<sup>1</sup> Guido Filler,<sup>2</sup> Debra E. Irwin,<sup>3</sup> Kate Lovett,<sup>3</sup> Rohan J. Shah,<sup>3</sup> Emily L. Butler,<sup>1</sup> Maria E. Ferris.<sup>4</sup> <sup>1</sup>ProKidney, Raleigh, NC; <sup>2</sup>London Health Sciences Centre, London, ON, Canada; <sup>3</sup>Aetion, New York, NY; <sup>4</sup>University of North Carolina System, Chapel Hill, NC.

**Background:** Large population-based studies for CKD progression are scant. RWD may better predict population trends for dialysis initiation by gender.

**Methods:** HealthVerity PrivateSource20 closed claims linked with Veradigm Health Insights EHR and Quest laboratory results data of adults with  $>364$  days of continuous enrollment between 1/1/2017 and 11/30/2021 compared progression of CKD stages  $\geq 3b$  to dialysis, by gender. Patients were required to have  $\geq 2$  eGFR measurements 90-365 days apart and followed until they initiated dialysis or end of available data with the first eGFR as the index date. We excluded pregnancy, AKI, ESKD and dialysis during the baseline period. Covariates included gender, country region, age at index date, Deyo-Chronic Comorbidity Index (CCI) Score, eGFRs, payer types, and comorbidities.

**Results:** 14,172 met the study criteria (Table) with a higher proportion of women patients across all stages ( $p < 0.04$ ). Mean (SD) eGFR test results upon cohort entry were clinically similar for men ( $34.1 \pm 8.0$ ) and women ( $33.8 \pm 8.1$ ). The type of insurance differed between men and women ( $p < 0.05$ ) with men more likely to have commercial insurance and women more likely to have Medicaid with no differences in region. Mean Deyo-CCI scores were significantly ( $p < 0.05$ ) higher for men compared to women and a higher proportion of men had osteodystrophy (2.2% vs 1.6%,  $p = 0.007$ ) while women were more likely to have anemia (21% vs 19.6%,  $p < 0.05$ ). For CKD stages  $\geq 3b$ , the proportion of men who initiated dialysis was significantly higher (2.5% vs 1.9%,  $p < 0.05$ ), and the mean time to initiation of dialysis was significantly shorter ( $510 \pm 340$  vs  $530 \pm 356$  days,  $p < 0.05$ ) compared to women. These results were primarily driven by patients with stage 4 CKD.

**Conclusions:** RWD confirm that CKD prevalence was higher among women while progression to dialysis was only mildly faster among men. Insurance classes, comorbidity scores, anemia and osteodystrophy rates between genders were found to be significantly different.

### Similar Risk of Kidney Function Decline Between Tenofovir Alafenamide and Bisefovir Dipivoxil Maleate in Chronic Hepatitis B

Chan-Young Jung, Hyung Woo Kim, Beom Seok Kim. Yonsei University College of Medicine, Seoul, Republic of Korea.

**Background:** Although tenofovir alafenamide (TAF) and bisefovir dipivoxil maleate (BSV) are potent antiviral agents in the treatment of chronic hepatitis B (CHB) infection. This study compared the risk of kidney function decline among patients with treatment-naïve CHB treated with TAF or BSV.

**Methods:** This multicenter, retrospective, longitudinal cohort study included 556 patients with treatment-naïve CHB treated with TAF ( $n = 366$ ) or BSV ( $n = 190$ ) between November 2017 and August 2021. The primary outcome was chronic kidney disease (CKD) progression, defined as an increase in CKD stage by at least one stage for at least three consecutive months.

**Results:** 1:1 propensity score matching yielded 154 patients in each treatment group. The mean estimated glomerular filtration rate (eGFR) was 100.4 vs. 100.3 mL/min/1.73m<sup>2</sup> in the TAF and BSV groups, respectively. A total of 25 patients developed a progression in

CKD stage  $\geq 1$ , of which 13 and 12 patients were from the TAF and BSV treated groups, respectively (3.1 vs. 3.3 per 1,000 person-years;  $P = 0.751$ ). The unadjusted hazard ratio for risk of progression in CKD stage  $\geq 1$  of the BSV group (vs. the TAF group) was 1.13 (95% confidence interval, 0.50-2.58;  $P = 0.758$ ). This association persisted even after adjusting for potential confounders. Virological, serological, and biochemical responses were also similar between the two treatment groups (all  $P > 0.05$ ).

**Conclusions:** TAF and BSV showed similar risk of kidney function decline in patients with treatment-naïve CHB. Further prospective randomized studies are warranted for validation.

FR-PO907

**Associations of Baseline and Longitudinal Uromodulin With ESKD and Mortality: Results From the AASK Trial**  
Teresa K. Chen,<sup>1</sup> Michelle M. Estrella,<sup>2</sup> Lawrence J. Appel,<sup>1</sup> Aditya L. Surapaneni,<sup>3</sup> Anna Kottgen,<sup>4</sup> Wassim Obeid,<sup>1</sup> Chirag R. Parikh,<sup>1</sup> Morgan Grams.<sup>3</sup> <sup>1</sup>*Johns Hopkins University School of Medicine, Baltimore, MD;* <sup>2</sup>*University of California San Francisco School of Medicine, San Francisco, CA;* <sup>3</sup>*NYU Langone Health, New York, NY;* <sup>4</sup>*Albert-Ludwigs-Universität Freiburg, Freiburg im Breisgau, Germany.*

**Background:** Uromodulin (UMOD), the most abundant protein found in the urine of healthy persons, is produced exclusively by the kidney and has emerged as a promising biomarker of tubule health.

**Methods:** We evaluated associations of serum UMOD levels at baseline and change in UMOD over time with subsequent risk of incident ESKD and mortality among African American Study of Kidney Disease and Hypertension (AASK) trial participants. UMOD levels were measured from stored samples from the 0, 12, and 24-month visits. Covariates included baseline age, sex, systolic blood pressure, smoking, GFR, proteinuria, and randomized treatment groups. In secondary analysis, we evaluated whether randomized blood pressure goal or drug were associated with UMOD slopes.

**Results:** Among 500 participants with baseline serum UMOD levels (mean age 54 years; 37% female), 161 ESKD events occurred over a median of 8.5 years. Each 2-fold higher baseline UMOD level was associated with a 26% lower risk of ESKD (HR: 0.74; 95% CI: 0.59, 0.93). For annual UMOD change, each 1 standard deviation (SD) higher change was associated with a 40% lower risk of ESKD (HR: 0.60; 95% CI: 0.50, 0.71). Baseline UMOD and UMOD change were not associated with mortality (Table 1). UMOD levels declined more steeply with intensive vs. standard BP goals (-2.13% per year), whereas ramipril vs. metoprolol was associated with greater increases (3.32% per year).

**Conclusions:** Among African American adults with CKD and hypertension, higher UMOD levels at baseline and greater increases in UMOD over time were associated with lower risk of subsequent ESKD.

**Funding:** NIDDK Support

Table 1: Associations of baseline UMOD and UMOD slope with ESKD in AASK.

Exposure	Model	ESKD	Mortality
		HR (95% CI) Per 2-fold higher	HR (95% CI) Per 2-fold higher
Baseline UMOD n=500	Unadjusted	0.37 (0.30, 0.44)	0.76 (0.61, 0.94)
	+ age, sex, SBP, BMI, smoking	0.39 (0.32, 0.48)	0.71 (0.57, 0.89)
	+ GFR	0.69 (0.55, 0.87)	0.79 (0.61, 1.04)
	+ log <sub>e</sub> (UPCR)	0.72 (0.57, 0.91)	0.79 (0.60, 1.03)
	+ randomized treatment groups	0.74 (0.59, 0.93)	0.81 (0.61, 1.06)
UMOD slope n=418		HR (95% CI) Per 1 SD higher	HR (95% CI) Per 1 SD higher
	Unadjusted	0.49 (0.43, 0.56)	0.90 (0.73, 1.10)
	+ log <sub>e</sub> (biomarker)	0.53 (0.46, 0.61)	0.96 (0.77, 1.20)
	+ age, sex, SBP, BMI, smoking	0.49 (0.42, 0.57)	0.98 (0.79, 1.22)
	+ GFR	0.50 (0.43, 0.58)	0.99 (0.79, 1.24)
	+ log <sub>e</sub> (UPCR)	0.59 (0.50, 0.70)	0.98 (0.78, 1.24)
	+ randomized treatment groups	0.60 (0.50, 0.71)	1.00 (0.78, 1.27)

Abbreviations: SBP=systolic blood pressure, BMI=body mass index, GFR=glomerular filtration rate; UPCR=urine protein-to-creatinine ratio; HR=hazard ratio; CI=confidence interval; SD=standard deviation. All covariates were measured at baseline.

FR-PO908

**Computer-Based Renal Sonographic Image Analysis on Renal Progression in Patients With Chronic Glomerulopathies**  
Nuntanutch Chanlerdffa, Amnart Chaiprasert, Naowanit Nata, Pamila Tasanavipais, Narittaya Varothai, Paramat Thimachai, Pitchamon Inkong, Wisit Kaewput, Oupphatham Supasindh, Bancha Satirapoj. *Phramongkutklo College of Medicine, Bangkok, Thailand.*

**Background:** Renal sonography is useful diagnostic imaging procedure in chronic glomerulopathies. Quantitative renal echogenicity has not been formerly evaluated regarding its capacity to identify patients at risk for progressive renal disease.

**Methods:** Renal sonography was performed in 79 patients with chronic kidney disease (CKD) including 37 patients with chronic glomerulonephritis (CGN) undergoing renal biopsy and 42 patients with other glomerulopathies. Sonographic images were processing and analysis by computer programs to determine quantitative renal cortical echogenicity. Patients were followed during a three-month period to evaluated renal progression with estimated glomerular filtration rate (GFR).

**Results:** Among 79 patients, 31 (39.24%) patients had renal progression. In patients with CGN undergoing renal biopsy, total renal cortical echogenicity and long axis echogenicity was significantly higher than patients without renal progression. In the multivariable analysis, high renal echogenicity remained significantly associated with increased risk of worsening renal function in CGN patients (HR 1.13, 95%CI 1.01-1.25). Long axis renal echogenicity (AUC 0.71; 95%CI 0.52 to 0.89), combining with other findings (AUC 0.93; 95%CI 0.84 to 1.00) achieved a better score predicting CKD progression in CGN group. Furthermore, renal to liver echogenicity ratio was significantly correlated with interstitial fibrosis and tubular atrophy. Renal/liver echogenicity ratio (AUC 0.83; 95%CI 0.69 to 0.97), combining with other findings (AUC 0.95; 95%CI 0.88 to 1.00) achieved a perfect score predicting IFTA>50% in CGN group.

**Conclusions:** Quantitative renal cortical echogenicity by computer based image analysis might be a useful tool to identify CGN patients with renal progression and related to renal fibrosis.

FR-PO909

**Retinal Photograph-Based Deep Learning Predicts CKD Among People With Preserved Kidney Function**  
Young Su Joo,<sup>1</sup> Geunyoung Lee,<sup>2</sup> Jung Tak Park.<sup>1</sup> <sup>1</sup>*Yonsei University Institute of Kidney Disease, Seodaemun-gu, Seoul, Republic of Korea;* <sup>2</sup>*Medi Whale, Seoul, Republic of Korea.*

**Background:** Predicting kidney disease is challenging, especially in people with preserved kidney function. We developed a novel machine learning based risk scoring system in prediction of future risk of chronic kidney disease (CKD) using retinal photographs and the performance of this risk stratification system was externally validated.

**Methods:** We used 232,779 retinal photographs from three datasets from South Korea, and the UK to train and validate the algorithm. First, using a dataset from a Korean health-screening centre, we trained a deep learning algorithm to predict the probability of the CKD presence (i.e., deep-learning retinal CKD score, RetiCKD). Second, predictability of the RetiCKD was evaluated using Cox hazards models in two separate longitudinal cohorts for future CKD development. Those with eGFR <90 ml/min/1.73m<sup>2</sup> or proteinuria at baseline were excluded. For the UK Biobank cohort, CKD development was defined with ICD-10 and OPCS-4 codes. For the Korean clinical cohort, CKD was defined as  $\geq 2$  occurrence of eGFR <60 ml/min/1.73m<sup>2</sup>.

**Results:** For the 33,814 participants in the UK Biobank cohort, mean age was 54.8 years and 13,670 (44.6%) were males. During a median follow-up of 10.8 years, 879 (1.2%) cases of CKD developed. When the participants were categorized to RetiCKD score tertile, the risk of CKD development increased in the highest tertile than the lowest tertile (Hazard ratio [95% CI], 2.50 [2.03-3.09]). Compared to the eGFR only model, eGFR with RetiCKD model showed superior concordance and reclassification performance ( $\Delta$ C-statistics, 0.052 [95% CI, 0.035-0.069]; net reclassification index [NRI], 0.142 [95% CI, 0.096-0.187]). The Korean clinical cohort consisted of 4,050 diabetes patients. The mean age was 55.9 years and 2,193 (54.1%) were male. CKD occurred in 158 (3.9%) patients during a median follow-up of 6.1 years. CKD development risk was higher in the highest tertile than the lowest tertile (Hazard ratio [95% CI], 4.95 [2.42-10.1]). Predictability improvement was observed in the eGFR with RetiCKD model compared to the eGFR only model ( $\Delta$ C-statistics, 0.039 [95% CI, 0.004-0.075]; NRI, 0.207 [95% CI, 0.049-0.267]).

**Conclusions:** A novel deep-learning and retinal photograph-derived CKD risk score successfully stratified future CKD risk among people with normal kidney function, in both the general population and diabetes patients.

FR-PO910

**Correlation Between Fibrosis-4 Index and Renal Dysfunction but Limited Causality**  
Makoto Araki. *Sapporo Tokushukai Hospital, Sapporo, Japan.*

**Background:** Metabolic dysfunction-associated fatty liver disease has been increasing, with the high prevalence of renal dysfunction complications suggesting a causal relationship. Therefore, we examined whether the fibrosis-4 index (Fib4 index), a well-known marker of liver fibrosis, had a direct effect on CKD.

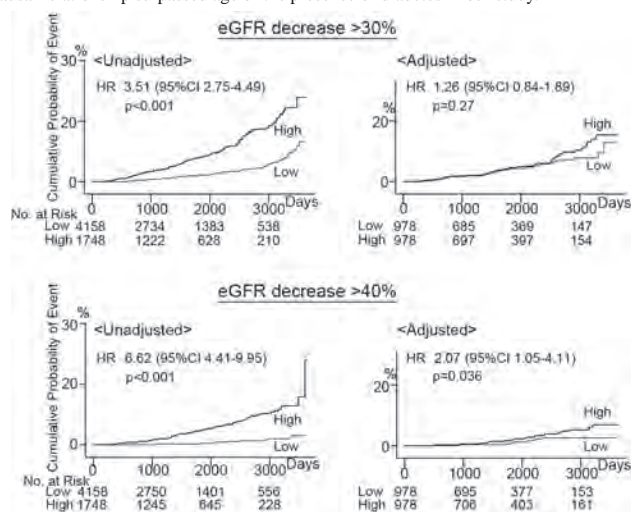

**Methods:** This single-institutional observational study screened subjects measured simultaneously for creatinine, aspartate aminotransferase, alanine aminotransferase,

and platelet levels during annual physical examinations between 2012 and 2021. Those younger than 18 years, undergoing dialysis, and having blood test results for only 1 year were excluded. Patients were then divided into high and low Fib4 index groups based on a cutoff of 1.3, as previously reported, and compared in terms of renal function changes. Both groups were evaluated using time-to-event analysis in terms of a 30% and 40% estimated glomerular filtration rate (eGFR) decline.

**Results:** Among the 93,404 individuals initially assessed, 5,906 satisfied the criteria (mean observation period: 1654 days). High Fib4 index levels were correlated with age (4% of patients under 50 years old; 93% of patients over 70 years old). Univariate analysis via the Log-rank test showed that the high Fib4 index group had significantly worse renal function (Figure), although both groups had a mean age difference of 10 years. Therefore, after adjusting for sex, age, and eGFR in the first year, mean observation period, and number of patients with diabetes using propensity score matching, the difference between both groups nearly disappeared although a significant trend remained (Figure). Furthermore, on multivariate Cox regression analysis, significant findings were found for age and presence of diabetes but not the Fib4 index.

**Conclusions:** Although the Fib4 index was correlated with renal dysfunction, no causal relationship surpassed age or the presence of diabetes in our study.

## FR-PO911

### SGLT2 Inhibitor Reduces eGFR Variability Leading to Improve eGFR Slope in CKD

Yukihito Nakano, Mika Sakaguchi, Yoshihisa Nakatani, Shuji Arima. *Kinki Daigaku Igakubu Daigakuin Igaku Kenkyuka, Osakasayama, Japan.*

**Background:** SGLT2 inhibitor has been demonstrated to improve cardiovascular, kidney outcomes in participants with diabetic kidney disease (DKD). However, there remains to be elucidated about mechanisms of efficacy of SGLT2 inhibitor. SGLT2 inhibition changes intrarenal hemodynamics by tubuloglomerular feedback (TGF) through glucosuria. We examined the estimated glomerular filtration rate (eGFR) slope and variability before and after SGLT2 inhibitor treatment.

**Methods:** We obtained eGFR values from 77 participants diagnosed DKD who have visited our hospital over two years. To estimate eGFR change after SGLT2 inhibitor treatment reliably, we selected eGFR values at least 3 months after the SGLT2 inhibitor prescription. Using a standard linear regression model for individuals, we stored the slope coefficient, the expected eGFR, and the regression residual, respectively. eGFR variability was calculated as  $(\text{mean sqrt} [\text{residual of eGFR}]^2) / (\text{mean observed eGFR} \times 100 (\%))$ .

**Results:** Of 77 participants, median age was 68 years (IQR 55 to 73) and 71.4% were male. 25 (32.5%) participants had a history of cardiovascular disease. Median eGFR at SGLT2 inhibitor prescription was 46 ml/min/1.73m<sup>2</sup> (IQR 32 to 67) and median eGFR slope was 0.99 ml/min/1.73m<sup>2</sup> per year (IQR -4.45 to 0.58). eGFR variability was 5.87% (IQR 4.44 to 7.64). The initial dip was observed in about 80% of participants. We divided the participants into responders and non-responders by the difference of eGFR slope before and after SGLT2 inhibitor initiation. Responders significantly had a reduction in eGFR variability than non-responders (-1.16% vs -0.28%, p<0.05). Also, eGFR variability negatively correlated with the degree of changes in eGFR slope (p=0.31, p<0.01).

**Conclusions:** We confirmed that the initial dip is usually observed in CKD. SGLT2 inhibitor is supposed to be optimize the TGF. Our results suggest that SGLT2 inhibitor stabilizes eGFR by reduces eGFR variability through TGF.

## FR-PO912

### Evaluating Renal Fibrosis Using Diffusion Tensor Imaging (DTI)-MRI

Shimrit Avraham, Rohan S. Virgincar, Joshua Webster, Hans D. Brightbill, Ben Korin, Andrey S. Shaw, Luke Xie. *Genentech Inc, South San Francisco, CA.*

**Background:** The estimated glomerular filtration rate (eGFR) is the standard method to determine kidney function. However, GFR measurements can differ based on the patient sex, age, ethnicity, background, and measurement variability. MRI can potentially allow renal structure and function to be assessed in real-time and noninvasively.

**Methods:** Here, we used diffusion tensor imaging MRI (DTI-MRI) to reveal details about kidney architecture. We characterized normal mouse kidneys and three chronic kidney disease (CKD) mouse models: TLR-7 enhanced lupus, calcium oxalate, and the nephrotoxic nephritis (NTN) model of glomerular injury, to evaluate disease progression.

**Results:** Using DTI-MRI, we were able to detect changes associated with inflammation and interstitial fibrosis and found that MRI diffusivities can distinguish renal injuries in CKD models. In all of the models, we identified decreased axial diffusivity (AD) and fractional anisotropy (FA) over time correlated with histological increased destruction of glomeruli and fibrosis of the kidney. While the TLR-7 enhanced lupus and the calcium oxalate models develop marked inflammation that can interfere with the DTI-MRI signal, the NTN model, which has separate and time-dependent inflammatory and fibrotic stages, allowed us to follow fibrotic processes from early-stage to severe fibrosis. Interestingly, the most significant changes in DTI-MRI were at the cortical-medullary junction and included decreases in FA, apparent diffusion coefficient (ADC), AD, and radial diffusivity (RD). This finding was supported by Masson's trichrome staining, which revealed that most of the fibrosis was also in this same region. This suggests that fibrosis may be more anatomically focused.

**Conclusions:** Taken together, our results show that DTI-MRI is sensitive to inflammation and fibrosis and has the potential to detect early changes of CKD before significant functional decline, demonstrating the advantages of DTI-MRI over traditional measurements.

## FR-PO913

### Differentiating Primary and Secondary Focal Segmental Glomerulosclerosis Using Non-Invasive Urine Biomarkers

Bruce M. Hendry,<sup>1</sup> Justyna Siwy,<sup>2</sup> Harald Mischak,<sup>2</sup> Ralph Wendt,<sup>3</sup> Joachim H. Beige,<sup>3,4</sup> Lorenzo Catanese,<sup>5,6</sup> Michael Wolf,<sup>1</sup> Harald D. Rupprecht.<sup>5,6</sup> <sup>1</sup>Traverse Therapeutics Inc, San Diego, CA; <sup>2</sup>Mosaïques-Diagnostics GmbH, Hannover, Germany; <sup>3</sup>St. Georg Hospital Leipzig, Leipzig, Germany; <sup>4</sup>Martin-Luther-University Halle-Wittenberg, Halle an der Saale, Germany; <sup>5</sup>Klinikum Bayreuth GmbH and Kuratorium für Dialysis und Transplantation (KfH) Bayreuth, Bayreuth, Germany; <sup>6</sup>Friedrich-Alexander-University Erlangen-Nürnberg, Medizincampus Oberfranken, Bayreuth, Germany.

**Background:** Focal segmental glomerulosclerosis (FSGS) includes primary (p) and secondary (s) forms. These subclasses differ in management and prognosis, but differentiation is challenging. We aimed to identify specific urine protein/peptides discriminating between pFSGS and sFSGS, and to combine these into a classifier using machine learning.

**Methods:** 56 urine samples were collected at two different centers (17 pFSGS and 39 sFSGS) prior to biopsy. Samples were analyzed using capillary electrophoresis coupled mass spectrometry (CE-MS). Additional CE-MS datasets were extracted from a urinary proteome database to increase specificity. For biomarker definition, data from additional age/sex matched healthy controls (HC, n=98) and patients with other chronic kidney disease (CKD, n=100) were used. Independent specificity assessment was performed in additional data of HC (n=110) and CKD (n=170).

**Results:** Proteomics data from patients with pFSGS were first compared to HC (n=98). This resulted in 1054 biomarker candidates. Then, the pFSGS group was compared to sFSGS. In the third step, to define biomarkers independent of other forms of CKD, data of pFSGS patients were compared to data from different CKD etiologies (n=100). Only biomarker candidates also significant in the second and third statistical comparison were accepted as specific biomarkers for pFSGS. The 95 biomarkers defined were combined in a classifier, FSGS-95. Total cross validation of this classifier resulted in an area under the receiving operating curve (AUC) of 0.94. The specificity investigated in an additional independent set of HC and CKD of other etiologies resulted in 100% for HC and 92.5% for CKD, respectively. The defined biomarkers are mostly fragments of different collagens (54%) decreased in pFSGS. We also observed reduced abundance of polymeric immunoglobulin receptor fragments and increased alpha-1-antitrypsin, transthyretin, and uromodulin peptides.

**Conclusions:** Based on a preliminary review of CE-MS analysis and leveraging machine learning, development of a urine peptide-based classifier that selectively detects pFSGS is feasible; however, analysis of specificity and sensitivity in an independent sample should be completed to support this approach.

## FR-PO914

### Evaluation of the Biomarker Dickkopf 3 in More Than 1100 CKD Patients of a German Single Center Cohort Using Algorithm-Based Data Analysis

Thomas Weinreich,<sup>1</sup> Eric Seibert,<sup>1</sup> Elias Brohammer,<sup>2</sup> Marcus Rüb,<sup>2</sup> Frank Gehlen,<sup>1</sup> Axel Sikora,<sup>2</sup> Bernd Hohenstein.<sup>1</sup> <sup>1</sup>Nephrological Center Villingen-Schwenningen, Villingen-Schwenningen, Germany; <sup>2</sup>Hahn-Schickard-Gesellschaft für angewandte Forschung eV, Villingen-Schwenningen, Germany.

**Background:** Dickkopf 3 (Dkk3) has been identified as a urinary biomarker and values above 4000 pg/mg creatinine (Cr) were assumed to be linked with the risk of short-term decline of kidney function (J Am Soc Nephrol 29: 2722-2733). However, as of today, there is little experience of DKK3 as a risk marker in everyday clinical practice. We used algorithm-based data analysis to evaluate the potential dependence of DKK3 in a cohort from a large single center in Germany.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Methods:** DKK3 was measured in all CKD patients (pts) in an outpatient clinic from October 1<sup>st</sup> 2018 till Dec. 31 2019, together with calculated GFR (eGFR) and urinary albumin/creatinine ratio (UACR). Pts with a kidney transplant were excluded. Until the end of follow-up Dec 31<sup>st</sup> 2021 repeated measurements (mm) were performed for all parameters. Data analysis was performed using MD-Explorer (BioArtProducts, Rostock, Germany) and Python with multiple libraries. Linear regression models were applied in Pts for DKK3, eGFR and UACR. Comparison of the models was performed with a two-sided Kolmogorov-Smirnov test.

**Results:** 1206 DKK3 mm were performed in 1103 pts (621 male, age 70yrs, eGFR 29.41 ml/min/1.73qm, UACR 800mg/g). 134 pts died during follow-up. DKK3 mean was 2905 pg/mg Cr (max. 20000, 75% percentile 3800). 121 pts had a DKK3 >4000. At the end of follow-up 7% of pts with DKK3<4000 (initial eGFR 17.6) versus 39.6% of pts with DKK3>4000 (initial eGFR 15.7) underwent dialysis. Compared to eGFR and UACR at baseline, DKK3>4000 performed best to predict eGFR for the next 12 months.

**Conclusions:** DKK3>4000 reflected a higher risk of progression towards ESRD despite similar eGFR levels. In this cohort of CKD patient, DKK3 >4000 at baseline predicted the eGFR slope better than eGFR or UACR.

## FR-PO915

### Imputation-Powered Whole-Exome Analysis Identifies Rare Coding Variants and Genes Associated With Kidney Function and Disease in the UK Biobank

Maria-Alexandra Katsara,<sup>1</sup> Eva König,<sup>2</sup> Matthias Wuttke.<sup>1</sup> on behalf of all authors <sup>1</sup>Institute of Genetic Epidemiology, Uniklinik Freiburg, Freiburg, Germany; <sup>2</sup>Institute for Biomedicine, Bolzano, Italy.

**Background:** Chronic kidney disease (CKD) is a major public health concern affecting ~10% of the global adult population. Genome-wide association studies on imputed common genotypes have identified variants associated with kidney function and CKD, but cannot comprehensively investigate rare coding variation. We aimed to identify rare pathogenic variants and genes impacting human kidney function and disease.

**Methods:** A genotype imputation approach was applied to whole exome sequencing data of European ancestry participants from the UK Biobank to increase our sample size from 166,891 to 408,511. We used exome-wide association studies (ExWAS) and gene-level Burden tests in order to identify rare variants and genes associated with different kidney phenotypes including eGFR, UACR, urea, urate and clinically diagnosed CKD. We performed a phenotype-wide association study of the resulting genes.

**Results:** We imputed ~7.5 million exonic variants for 241,620 individuals without WES data. In a validation sample, the overall concordance of sequenced and imputed genotypes was >0.98. We identified 158 rare variants and 106 genes significantly associated with kidney function. Among these genes, there were known monogenic kidney disease genes such as *CUBN* and *PKD2*, for which we highlight novel putatively disease-causing mutations. Furthermore, we implicate genes currently not linked to kidney function and disease in humans, such as *FNIP1* and *EPB41L5*. Disruption of *Fnip1* in mice is sufficient for renal cyst formation, and *Epb41l5*-deficient mice are known to develop focal-segmental glomerulosclerosis. Our results not only establish human relevance, but also identify potentially causal variants. Across the phenotype, we identified numerous instances where the assumed loss-of-function of implicated genes resulted in increased disease risk, often reflecting known clinical signs and symptoms. For example, carriers of rare damaging variants in *COL4A3* showed higher odds of hematuria.

**Conclusions:** Our study underscores the value of imputation-powered analysis and reveals both novel and confirms known variants associated with kidney disease. It generates a comprehensive resource to direct future functional and clinical studies. Results will be shared via an interactive website.

## FR-PO916

### Plasma Proneurotensin and Kidney Outcomes in REGARDS

Alexander L. Bullen,<sup>1,2</sup> Ronit Katz,<sup>3</sup> Mary Cushman,<sup>4</sup> Joachim H. Ix,<sup>1,2</sup> Dena E. Rifkin.<sup>2,1</sup> <sup>1</sup>University of California San Diego, La Jolla, CA; <sup>2</sup>VA San Diego Healthcare System, San Diego, CA; <sup>3</sup>University of Washington, Seattle, WA; <sup>4</sup>University of Vermont, Burlington, VT.

**Background:** Chronic kidney disease is common, costly and it is associated with cardiovascular disease and increased mortality. Early identification of CKD is imperative to prevent progression and potentially reduce cardiovascular morbidity and mortality. Plasma proneurotensin (ProNT) is a precursor of neurotensin (NT). NT and its related peptides have been linked to risk for disease processes related to kidney disease, including cardiovascular disease, and type 2 diabetes mellitus. It is unknown whether ProNT is directly associated with incident CKD.

**Methods:** Among 3914 participants who were part of BioMedioR, a nested cohort within the Reasons for Geographic and Racial Differences in Stroke (REGARDS) who completed the second visit, we measured ProNT by Sphingotest (double monoclonal sandwich immunoassay). Primary outcomes were significant eGFR decline (defined as 30% decline), incident albuminuria (defined as albumin/creatinine greater or equal to 30 at second visit) and incident CKD (defined as eGFR less than 60 ml/min/1.73m<sup>2</sup> plus 40% decline in eGFR). Logistic regression with inverse probability sampling weights for analysis. Sequential models adjusted for age, sex, and race (Model 1); BMI, SBP, DBP, diabetes, smoking, cholesterol and prevalent CVD (Model 2); and baseline eGFR and albuminuria (Model 3). Using model 3, we tested for interaction ProNT and race and explored analyses by race. We used similar models to evaluate for incident albuminuria, excluding albuminuria in model 3.

**Results:** Higher ProNT levels were associated with greater eGFR decline among all participants independent of baseline eGFR and albuminuria (OR: 1.12, 95% CI [1.00,

1.26]) and incident albuminuria (OR: 1.31, 95% CI 1.14,1.50). Higher ProNT levels were also associated with greater incidence of CKD; however, this association was attenuated after including baseline eGFR and albuminuria (OR: 1.25, 95% CI 0.98, 1.59). We did not find any interactions between ProNT and race or sex in any of the three outcomes.

**Conclusions:** Assessment of ProNT provides information about significant eGFR decline and incident albuminuria but not incident CKD among persons at high risk of hypertension and diabetes, known risk factors of incidence and progression of CKD. These associations were independent of race or sex. Further studies should evaluate if ProNT can help tailor treatments to slow progression of CKD in a high-risk population.

## FR-PO917

### Quantification of DNA-Methylation at Loci Associated With Metals, Pesticides, and Temperature Provide No Evidence for a Role of These Exposures in the Aetiology of Mesoamerican Nephropathy

Amin Oomatia,<sup>1</sup> Ali M. Al-Rashed,<sup>1</sup> Marvin A. Gonzalez,<sup>2</sup> Andres Cardenas,<sup>3</sup> Neil Pearce,<sup>4</sup> Simone Ecker,<sup>5</sup> Stephan Beck,<sup>5</sup> Brianna Heggeseth,<sup>6</sup> Olga Chervova,<sup>5</sup> Ben Caplin.<sup>1</sup> The Colt/UK MRC CKDu study group <sup>1</sup>University College London Department of Renal Medicine, London, United Kingdom; <sup>2</sup>Research Centre on Health, Work and Environment at National Autonomous University of Nicaragua, Leon, Nicaragua; <sup>3</sup>School of Public Health, University of Berkeley, Berkley, CA; <sup>4</sup>London School of Hygiene and Tropical Medicine Faculty of Epidemiology and Population Health, London, United Kingdom; <sup>5</sup>University College London Cancer Institute, London, United Kingdom; <sup>6</sup>Macalester College, Saint Paul, MN.

**Background:** Mesoamerican nephropathy (MeN) is a leading cause of death amongst working age men in Central America, yet its aetiology remains unclear. Several potential environmental causes have been proposed including heat-stress, pesticides and heavy metals, but intermittent and cumulative exposures are difficult to capture using biomonitoring. Epigenetic studies have identified DNA-methylation (DNAm) at specific loci associated with these exposures. Therefore, we first conducted an epigenome-wide association study (EWAS) focusing on incident cases. Then, using a hypothesis driven approach, explored the association between DNAm at loci previously associated with implicated exposures and MeN.

**Methods:** MeN cases from a population-based longitudinal study were empirically derived using a hidden Markov model based on departure from a healthy population eGFR distribution. Our data consisted of 2-3 blood samples collected across a 5-year period from each of 57 incident-cases (pre- and post-evidence of disease onset), 57 matched-controls and 16 established cases. DNAm was quantified (Illumina MethylationEPIC BeadChip) in a total of 320 blood-samples. Raw data were processed using established pipelines. Associations between differentially methylated positions (DMPs) and MeN were examined using covariate-adjusted mixed-effect models, allowing for repeat measures. DMPs previously reported to associate with ambient temperature, arsenic, cadmium, chromium and pesticides, were collated from a systematic search, and potential association of MeN with these loci was investigated.

**Results:** The EWAS demonstrated no DMPs associated with MeN at standard epigenome-wide statistical thresholds. Furthermore, hypothesis driven analyses examining the coefficients of DMPs reported to be associated with ambient temperature, pesticides and metals, demonstrated no associations with MeN. Further calculations suggested adequate power to detect biologically important differences.

**Conclusions:** DNAm studies in our dataset do not support the hypotheses that pesticides, temperature or the examined metals have a causal role in early-stage MeN. Therefore, other aetiological factors should be considered.

**Funding:** Private Foundation Support, Government Support - Non-U.S.

## FR-PO918

### Serum Metabolomic Markers of Protein Intake and Incident CKD Risk

Lauren Bernard,<sup>1,2</sup> Jingsha Chen,<sup>1</sup> Hyunju Kim,<sup>1</sup> Kari E. Wong,<sup>9</sup> Lyn M. Steffen,<sup>5</sup> Bing Yu,<sup>3</sup> Eric Boerwinkle,<sup>3,4</sup> Eugene P. Rhee,<sup>8,7</sup> Andrew S. Levey,<sup>6</sup> Morgan Grams,<sup>2,1</sup> Casey Rebholz.<sup>1,2</sup> <sup>1</sup>Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; <sup>2</sup>Johns Hopkins University School of Medicine, Baltimore, MD; <sup>3</sup>The University of Texas Health Science Center at Houston, Houston, TX; <sup>4</sup>Baylor College of Medicine Human Genome Sequencing Center, Houston, TX; <sup>5</sup>University of Minnesota School of Public Health, Minneapolis, MN; <sup>6</sup>Tufts University School of Medicine, Boston, MA; <sup>7</sup>Harvard Medical School, Boston, MA; <sup>8</sup>Massachusetts General Hospital, Boston, MA; <sup>9</sup>Metabolon Inc, Research Triangle Park, NC.

**Background:** Untargeted metabolomics is a promising approach for capturing dietary intake with less bias than traditional methods of dietary assessment. An important application of this technique is the identification of biomarkers of specific dietary protein sources, which may explain the diet-chronic kidney disease (CKD) relationship.

**Methods:** We analyzed dietary data collected from an interviewer-administered questionnaire and 359 serum metabolites at visit 1 (1987-1989) in the Atherosclerosis Risk in Communities (ARIC) study (n=3,724). Multivariable linear regression models were used to estimate cross-sectional associations between specific sources of protein (red and processed meat, nuts, legumes) previously associated with CKD risk in the ARIC study and serum metabolites. For metabolites that were significantly associated with these dietary protein sources, we assessed their prospective associations with incident CKD

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

using Cox regression models. Bonferroni correction was used to account for multiple comparisons in the cross-sectional analysis. *A priori*, we expected metabolites positively associated with red and processed meat to be associated with higher risk of CKD and metabolites positively associated with nuts or legumes to be inversely associated with CKD.

**Results:** There were 31 significant protein-metabolite associations. Six metabolites were representative of red and processed meat consumption. Five metabolites were associated with nut intake, including 4-vinylphenol sulfate and tryptophan betaine, and no metabolites were associated with legume intake. Higher levels of two metabolites (glucose, 10-nonadecenoate) were associated with higher intake of red and processed meat and higher risk of incident CKD (**Table**). Higher levels of catechol sulfate were positively associated with nut intake and higher risk of incident CKD.

**Conclusions:** We identified candidate biomarkers of specific dietary protein sources. Glucose and 10-nonadecenoate may serve as metabolomic markers of the red and processed meat-CKD association.

**Funding:** NIDDK Support, Other NIH Support - R03 DK128386

Table. Potential Metabolomic Markers of Dietary Protein Intake-CKD Association					
Metabolite	Protein Source	Cross-Sectional Analysis with Dietary Protein <sup>a</sup>		Prospective Analysis with CKD (N=3724; incident CKD=1411) <sup>b,c</sup>	
		$\beta$ (SE)	P value	HR (95% CI)	P value
catechol sulfate	Nuts	0.20 (0.04)	$1.41 \times 10^{-3}$	1.10 (1.03-1.20)	0.02
glucose	Red and Processed Meat	0.02 (0.01)	$1.93 \times 10^{-4}$	1.69 (1.33-2.18)	$5.98 \times 10^{-3}$
10-nonadecenoate (19:1n7)	Red and Processed Meat	0.05 (0.01)	$2.10 \times 10^{-3}$	1.17 (1.02-1.34)	0.02

<sup>a</sup>Linear regression models adjusted for age, sex, race, study center, body mass index, total energy intake, estimated glomerular filtration rate (eGFR) based on creatinine, smoking status, physical activity, education, alcohol consumption, total fruit intake, total vegetable intake, dairy intake, whole grains intake, and refined grains intake.

<sup>b</sup>Cox regression models further adjusted for hypertension, coronary heart disease, and diabetes.

<sup>c</sup>Incident CKD was defined as meeting at least one of these criteria: 2021 eGFR <60 with a 25% eGFR decline at any subsequent study visit relative to baseline, ICD-9/10 hospitalization codes related to CKD stage 3+, ICD 9/10 mortality codes related to CKD stage 3+, or end-stage kidney disease in the US Renal Data System (USRDS) registry. Abbreviations: CI, confidence interval; CKD, chronic kidney disease; HR, hazard ratio; SE, standard error.

**Ultrasonographic Assessment of Normal Kidney Size in Malawi**  
Laura Carey,<sup>1,3</sup> Sylvester Kaimba,<sup>3</sup> Karen Chetcuti,<sup>2,4</sup> Elizabeth Joekes,<sup>1,4</sup> Benno Kreuels,<sup>5</sup> Marc Y. Henrion,<sup>1,3</sup> Jamie Rylance.<sup>1,3</sup> <sup>1</sup>*Liverpool School of Tropical Medicine, Liverpool, United Kingdom;* <sup>2</sup>*University of Malawi College of Medicine, Blantyre, Malawi;* <sup>3</sup>*Malawi Liverpool Wellcome Trust, Blantyre, Malawi;* <sup>4</sup>*Worldwide Radiology, Liverpool, United Kingdom;* <sup>5</sup>*Bernhard-Nocht-Institut für Tropenmedizin, Hamburg, Germany.*

**Background:** Sonographic assessment of kidney size is needed to make diagnostic and therapeutic decisions. However, there is a paucity of normative data from sub-Saharan Africa (SSA). We determined estimates of kidney size based on age, sex, and HIV status, among apparently healthy outpatient attendees of Queen Elizabeth Central Hospital radiology department, Blantyre, Malawi.

**Methods:** We performed a cross-sectional study of 320 adults attending the radiology department between October 2021 and January 2022. The sample was stratified by age, sex, and HIV status. Bilateral renal ultrasound was performed using a Mindray DP-50 machine and a 5MHz convex probe. Participants with kidney disease, hypertension, diabetes, BMI >35, heavy alcohol intake, smoking and ultrasonographic abnormalities were excluded. Predictive linear modelling was used to construct reference ranges for kidney size.

**Results:** There were 162/320 (51%) male participants. The median age was 47 (IQR 34-59), 138/320 (43%) were living with HIV, 134/138 (97%) were receiving antiretroviral therapy. The mean ( $\pm$  SD) size of the right kidney was 9.61 cm (0.93) in males and 9.38 cm (0.98) in females, and 9.76 cm (0.90) and 9.54 cm (0.97) for the left kidney in males and females respectively.

**Conclusions:** For the first time in Malawi, we provide estimates of normal kidney size using ultrasound, and a population specific reference for assessment of kidney disease.

**Funding:** Government Support - Non-U.S.

Predicted ranges (blue) and 95% confidence intervals (orange) of kidney size dependent on a.) sex b.) HIV status

FR-PO920

**Urinary Epidermal Growth Factor Is a Distal Tubule Marker for Kidney Health in the General Population**  
Frank Geurts,<sup>1</sup> Anna C. van der Burgh,<sup>1</sup> Robert A. Fenton,<sup>2</sup> Layal Chaker,<sup>1</sup> Ewout J. Hoorn.<sup>1</sup> <sup>1</sup>*Erasmus MC, Rotterdam, Netherlands;* <sup>2</sup>*Aarhus Universitet, Aarhus, Denmark.*

**Background:** Kidney health is usually assessed by glomerular rather than tubular markers. In the kidney EGF is exclusively expressed in the distal tubule. In patients with chronic kidney disease (CKD) urinary epidermal growth factor (uEGF) correlates with interstitial fibrosis and tubular atrophy and predicts kidney failure. Here, we hypothesize that uEGF is a distal tubule marker of kidney health in the general population.

**Methods:** To assess uEGF as tubular marker, it was initially measured before and three months after kidney donation (n = 19). Tubule segment-specific proteins were also quantified in urinary extracellular vesicles (uEV) using immunoblot. Next, uEGF was measured in the Rotterdam Study (n = 2382), a population-based cohort with long-term follow-up (median 13.0 years). The association between uEGF excretion and estimated glomerular filtration rate (eGFR, median of 7 eGFRs available) was assessed using multivariable linear regression. Furthermore, multivariable Cox regression analysis was used to analyze kidney outcomes (eGFR < 60 or 45 ml/min/1.73m<sup>2</sup>, 40% loss of eGFR). eGFR, albumin creatinine ratio (ACR), age, sex, body mass index, hypertension, diabetes, smoking status, history of cardiovascular disease and total cholesterol were used as covariates. uEGF was measured in 24 h urine (kidney donors) or spot urines (general population, normalized to creatinine, uEGF/cr).

**Results:** Kidney donation decreased eGFR from 91 to 58 ml/min/1.73m<sup>2</sup> (36% reduction, 95%CI 31-42%), while uEGF excretion reduced from 28 to 14  $\mu$ g/day (51% reduction, 95%CI 46-58%). In uEVs, proximal tubule markers increased while distal tubule proteins remained unchanged. In the population-based cohort, uEGF/cr correlated with baseline eGFR ( $\beta$  0.02, 95%CI 0.02-0.03) and ACR ( $\beta$  -0.09, 95%CI -0.15- -0.03). uEGF/cr was inversely associated with incident eGFR < 60 ml/min/1.73m<sup>2</sup> (HR 0.85, 95%CI 0.76-0.95). Similar results were obtained using an outcome of two consecutive eGFR measurements < 60 ml/min/1.73m<sup>2</sup> (HR 0.81, 95%CI 0.69-0.94), eGFR < 45 ml/min/1.73m<sup>2</sup> (HR 0.84, 95%CI 0.69-1.02) and 40% loss of eGFR (HR 0.83, 95%CI 0.7-0.98).

**Conclusions:** Urinary EGF is a distal tubule marker that is not affected by glomerular hyperfiltration and proximal tubule hypertrophy. In the general population, uEGF/cr is associated with incident CKD independent of eGFR and ACR.

FR-PO921

**Urine Creatinine Excretion and Mortality in CKD: From the KNOW-CKD Study**  
Jihyun Yang,<sup>1</sup> Sang-Eun Kim,<sup>1</sup> Kyu-Beck Lee,<sup>1</sup> Hyang Kim,<sup>1</sup> Kook-Hwan Oh,<sup>2</sup> Young Youl Hyun.<sup>1</sup> <sup>1</sup>*KNOW-CKD Investigators* <sup>1</sup>*Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea;* <sup>2</sup>*Seoul National University College of Medicine, Seoul, Republic of Korea.*

**Background:** Previous studies have shown that low muscle strength or function is a risk factor for poor prognosis in chronic kidney disease (CKD). However, the prognosis associated with low muscle mass is uncertain. 24-hour urine creatinine excretion is surrogate marker of muscle mass. The aim of this study is to investigate the relationship between urine creatinine excretion and mortality in predialysis CKD patients.

**Methods:** We analyzed 1,620 patients from the Korean Cohort Study for Outcome in Patients with CKD (KNOW-CKD). Participants were divided into four groups according to their sex-specific quartiles of baseline 24-hr urinary creatinine excretion (UCr). The study end point was all-cause death.

**Results:** During a follow-up of 10,519 person-years (median 7.0 years), 123 patients (7.6%) died, with a corresponding death rate of 11.7 (95% CI 9.8-14.0) per 1,000 patients-years. 65 (16.4%), 28 (6.8%), 21 (5.3%) and 9 (2.2%) patients from each 1st

to 4th quartile group of sex-specific UCR died. In multivariate Cox proportional hazard analysis, there was a graded association of UCR with all-cause mortality. The adjusted hazard ratios (95% CI) of 2nd to 4th quartile were 0.51 (0.32-0.82), 0.48 (0.28-0.82) and 0.25 (0.12-0.53) compared with the 1st quartile.

**Conclusions:** Higher creatinine excretion is associated with lower risk of mortality in predialysis CKD patients. This association was independent of various conventional and CKD-related risk factors.

**Funding:** Government Support - Non-U.S.

Causal Effects of Kidney Function on Various Biochemical Parameters: A Mendelian Randomization Study

Sehoon Park, Yong Chul Kim, Seung Seok Han, Hajeong Lee, Kwon Wook Joo, Yon Su Kim, Dong Ki Kim. *Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

**Background:** The causal effects of the estimated glomerular filtration rate (eGFR) on various biochemical parameters should be further investigated. Mendelian randomization (MR) provides opportunity to investigate causal estimates minimally affected from confounding effects or reverse causation.

**Methods:** In this MR study, genetic instruments for eGFR were developed from the CKDGen data from subjects of European ancestry (N=567,460). Two-sample MR analysis was performed on 60 biochemical parameters measured in 337,138 white UK Biobank participants of British ancestry. Both the inverse variance-weighted method and pleiotropy-robust MR sensitivity analyses were performed. Additional nonlinear MR analysis was performed to investigate the shapes of the causal estimates according to eGFR values.

**Results:** A higher genetically predicted eGFR was significantly associated with higher lymphocyte percentage, HDL cholesterol, and alanine aminotransferase. The causal estimates indicated that a higher genetically predicted eGFR was associated with a lower urea, urate, insulin growth factor-1, and triglycerides levels. The parameters with significant but non-linear causal estimates were hemoglobin concentration, calcium, vitamin D, and urine creatinine values, identified by non-linear MR.

**Conclusions:** In conclusion, eGFR levels may causally related to various biochemical parameters with diverse patterns.

FR-PO923

Clinical Characteristics Associated With Higher Mayo Clinic Chronicity Score

Dries Deleersnijder,<sup>1,2</sup> Evert J. Cleenders,<sup>1</sup> Wim Laurens,<sup>3,4</sup> Amélie Dendooven,<sup>5,6</sup> Johan M. De Meester,<sup>3</sup> Ben Sprangers.<sup>1,2</sup> FCGG collaborative group <sup>1</sup>Katholieke Universiteit Leuven, Leuven, Belgium; <sup>2</sup>Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium; <sup>3</sup>AZ Nikolaas, Sint-Niklaas, Belgium; <sup>4</sup>Universiteit Gent, Ghent, Belgium; <sup>5</sup>Universitair Ziekenhuis Gent, Ghent, Belgium; <sup>6</sup>Universiteit Antwerpen, Wilrijk, Belgium.

**Background:** The Mayo Clinic Chronicity Score (MCCS) is a standardized scoring system to uniformly grade chronic changes in kidney biopsies. The Flemish Collaborative Glomerulonephritis Group (FCGG) registry is the first multicenter native kidney biopsy registry in Europe to systematically collect MCCS in all included biopsies.

**Methods:** From 2018-2019, MCCS was available for 890 included adult biopsies (each containing ≥10 glomeruli). The association between MCCS and sex, age, kidney injury, proteinuria and nephrological diagnosis was determined using a multiple linear regression model. A linear mixed-effect model showed no significant confounding pathologist-effect.

**Results:** Sex was not associated with significant changes in MCCS (Table 1). Increasing patient age was associated with only mild increase in MCCS. When compared to patients with normal kidney function, chronic kidney disease (CKD) was associated with a large MCCS increase (2.596, 95% CI [2.079, 3.112], P<0.001). Nephrotic-range proteinuria was associated with a smaller MCCS increase (0.982 (95% CI [0.520, 1.444], P<0.001), likely because it may reflect both disease activity and chronicity. When compared to IgA nephropathy, diagnoses of FSGS, nephrosclerosis, diabetic kidney disease and hyperoxaluria/hypercalcemic nephropathy were all associated with significantly higher MCCS.

**Conclusions:** CKD and diagnoses of FSGS, nephrosclerosis, diabetic kidney disease and hyperoxaluria/hypercalcemic nephropathy were associated with highest degrees of chronicity in native kidney biopsies in Flanders, Belgium.

Table 1: Multiple linear regression analysis of clinical characteristics and MCCS

Tubulointerstitial nephritis	-1.061	[-1.761, -0.360]	0.003

The β indicates the change in estimated MCCS, P-values < 0.05 considered significant (bold).

<sup>a</sup>: only diagnoses with a significant result for β shown; <sup>b</sup>: Fabry disease and tuberous sclerosis; <sup>c</sup>: enteric hyperoxaluria and hypercalcemic nephropathy; <sup>d</sup>: non-specific nephrotoxicity and nephropathy due to analgesic drugs, lithium or tacrolimus.

## FR-PO924

## Estimating Underdetection of CKD in Real-World Health Systems

Chi D. Chu,<sup>1</sup> Fang Xia,<sup>2</sup> Yuxian Du,<sup>2</sup> Delphine S. Tuot,<sup>1</sup> Michael Shlipak,<sup>1</sup> Julio Lamprea,<sup>1</sup> Rakesh Singh,<sup>2</sup> Ralph Gualtieri,<sup>2</sup> Sheldon X. Kong,<sup>2</sup> Todd E. Williamson,<sup>2</sup> Michelle M. Estrella.<sup>1</sup> <sup>1</sup>University of California San Francisco, San Francisco, CA; <sup>2</sup>Bayer Corporation, Whippany, NJ.

**Background:** Albuminuria testing is widely underused in persons at risk for CKD but is crucial to guide implementation of evidence-based treatments to prevent CKD progression and reduce cardiovascular morbidity. We aimed to estimate the extent of albuminuria underdetection due to lack of testing in a large real world US cohort of patients with hypertension or diabetes.

**Methods:** We used National Health and Nutrition Examination Survey (NHANES) 2007-2018 data and the Optum EHR 5PCT Database, which includes EHR data from diverse US healthcare organizations. We included persons aged  $\geq 18$  years with hypertension, diabetes, or both. Using NHANES, we developed a logistic regression model to predict albuminuria (urine albumin/creatinine ratio  $\geq 30$  mg/g) using age, sex, race-ethnicity, systolic blood pressure, diabetes, heart failure, coronary artery disease, and eGFR. Our Optum EHR study population included patients with  $\geq 2$  outpatient visits from January 1, 2017 to December 31, 2018. Among those who did not have albuminuria testing during this period, we applied the prediction model from NHANES to estimate the prevalence of albuminuria.

**Results:** The albuminuria prediction model had c-statistics of 0.73 for NHANES and 0.68 when applied to the subset of Optum patients with albuminuria testing. The Optum study population included 192,108 patients (mean age  $60 \pm 15$  years; 26% with diabetes; mean eGFR  $84 \pm 21$  mL/min/1.73m<sup>2</sup>). 18% had albuminuria testing (n=33,629), of whom 34% had albuminuria (n=11,525), representing 6.0% of the total study population. Among patients who had not been tested (n=158,479), the predicted prevalence of albuminuria was 15% (n=23,369). Thus, the projected proportion of patients with albuminuria who had been detected was only 11,525/34,894 (33%). In the top quintile of predicted risk, only 37% had been tested (14,033/38,421).

**Conclusions:** In a real-world patient population with hypertension or diabetes, we estimated that approximately 2/3 of patients with albuminuria are undetected due to lack of testing. Improving detection of CKD represents a significant missed opportunity to optimize care delivery for reducing CKD progression and its cardiovascular complications.

## Height Loss Is Associated With Decreased Kidney Function: The Japan Specific Health Checkups (J-SHC) Study

Takaaki Kosugi,<sup>1</sup> Masahiro Eriguchi,<sup>1</sup> Hisako Yoshida,<sup>2</sup> Hikari Tasaki,<sup>1</sup> Masatoshi Nishimoto,<sup>1</sup> Masaru Matsui,<sup>1</sup> Ken-ichi Samejima,<sup>1</sup> Kunitoshi Iseki,<sup>3</sup> Shouichi Fujimoto,<sup>3</sup> Tsuneo Konda,<sup>3</sup> Toshiki Moriyama,<sup>3</sup> Kunihiro Yamagata,<sup>3</sup> Ichiei Narita,<sup>3</sup> Masato Kasahara,<sup>3</sup> Yugo Shibagaki,<sup>3</sup> Masahide Kondo,<sup>3</sup> Koichi Asahi,<sup>3</sup> Tsuyoshi Watanabe,<sup>3</sup> Kazuhiko Tsuruya.<sup>1,3</sup> <sup>1</sup>Department of Nephrology, Nara Medical University, Kashihara, Japan; <sup>2</sup>Department of Medical Statistics, Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan; <sup>3</sup>Steering Committee of The Japan Specific Health Checkups (J-SHC) Study, Fukushima, Japan.

**Background:** Height loss that occurs with aging is a common phenomenon associated with musculoskeletal abnormalities, such as osteoporosis and sarcopenia. Notably, such height loss is also associated with cardiovascular disease and mortality. However, the relationship between height loss and kidney outcome remains unclear.

**Methods:** This is a longitudinal study based on data from the J-SHC Study from 2008 to 2014. The first three visits (visits 1–3) were used to estimate height loss, and kidney outcomes were evaluated using data from visit 3 to the last visit. Of 933,488 participants, we excluded participants based on the following criteria: 1)  $\leq 4$  visits during the study period, 2) less than three measurements of height during visits 1–3, 3) missing serum creatinine at baseline (visit 3), 4) a height below or above 3 standard deviations, 5) a baseline serum creatinine level of  $\geq 8$  mg/dL or  $< 0.3$  mg/dL. The annual height change (cm/year) for each participant was estimated using mixed-effects model, and participants were divided into five groups according to the quintile of the rate (Q1 to Q5). The association between height change and the incidence of 1.5-fold increase in serum creatinine level from baseline was analyzed using Cox regression analysis. The decline rates of eGFR (mL/min/1.73 m<sup>2</sup>/year) among the groups were compared using a linear mixed-effects model.

**Results:** The median rate of height change was  $-0.11$  cm/year. During the median follow-up period of 26 months, 1,941 of 187,682 participants developed a 1.5-fold increase in serum creatinine levels. The adjusted hazard ratio (95% confidence interval) in participants with the steepest category of height loss (Q1) was 1.45 (1.26–1.67) compared with the reference (Q4). The decline rate of eGFR in Q1 ( $-1.25$  mL/min/1.73 m<sup>2</sup>/year) was significantly higher than that of Q4 ( $-0.92$  mL/min/1.73 m<sup>2</sup>/year) ( $p$  for interaction  $< 0.001$ ).

**Conclusions:** Height loss is associated with a rapid decline in kidney function.

**Funding:** Government Support - Non-U.S.

## FR-PO926

## Five-Year Risk of ESKD in the US Population: Implications for Kidney Care Referral

Maria Clarissa Tio,<sup>1</sup> Rajesh Talluri,<sup>1</sup> Aliba Syed,<sup>2</sup> Elani Streja,<sup>2</sup> Sriram Sriperumbuduri,<sup>1</sup> Yoshitsugu Obi,<sup>1</sup> Michael Hall,<sup>1</sup> Kamyar Kalantar-Zadeh,<sup>2</sup> Tariq Shafi.<sup>1</sup> <sup>1</sup>University of Mississippi Medical Center, Jackson, MS; <sup>2</sup>University of California Irvine, Irvine, CA.

**Background:** CKD definition and stratification are based on eGFR and albuminuria as both relate to the risk of ESKD. Unlike eGFR, the Kidney Failure Risk Equation (KFRE) was specifically developed to predict the risk of ESKD. However, the distribution of this risk in the US population is unknown.

**Methods:** We used data from the 2017-2020 National Health and Nutrition Examination Survey (NHANES; N=8,016), to calculate the 5-year ESKD risk using the 8-variable KFRE among adults with CKD (either an ACR  $> 30$  mg/g or eGFR [CKD-EPI 2021]  $< 60$  mL/min/1.73m<sup>2</sup>). We categorized the 5-year ESKD risk as  $< 1\%$ , 1–4.9%, 5–9.9%, and  $\geq 10\%$  and compared its distribution across CKD stages. We also calculated the US population eligible for nephrology evaluation using two of the UK National Institute for Health and Care Excellence (NICE) 2021 criteria (ESKD risk  $\geq 5\%$  or ACR  $\geq 600$  mg/g).

**Results:** The prevalence of CKD was 14% in the US. The mean age of US CKD population was 60 years and 57% were female. Of the 31.1 million US adults classified as CKD, 25 million (81%) had a  $< 1\%$  risk (Table 1); 2 million (7%) had a  $\geq 5\%$  risk of ESKD in 5 years. In CKD stage G3A with ACR  $< 30$  mg/g, the median [interquartile range] 5-year ESKD risk was 0.5% [0.36%–0.75%] and none had a risk of  $> 5\%$ . Using the NICE criteria, 3.2 million (10.4%) of those with CKD warrant referral for nephrology care.

**Conclusions:** Calculation of 5-year ESKD risk can help identify and prioritize patients that need nephrology care. The 5-year ESKD risk should be incorporated in the definition, categorization, and Nephrology referral recommendations for CKD.

**Funding:** Other NIH Support - NIGMS

CKD Stage	N (Weighted US Population)	5-Year ESKD Risk in the US Population			
		$< 1\%$	1% to $< 5\%$	5% to $< 10\%$	$\geq 10\%$
G1	12.8 million	12.8 million (100.0%)			
G2	6.0 million	5.8 million (96.6%)	203,131 (3.4%)		
G3A	8.9 million	6.7 million (75.3%)	2.1 million (23.5%)	79,739 (0.9%)	17,720 (0.2%)
G3B	2.5 million	81,060 (3.3%)	1.6 million (63.7%)	542,856 (22.1%)	270,200 (11.0%)
G4	731,644		2,927 (0.4%)	69,506 (9.5%)	659,211 (90.1%)
G5	294,112				294,112 (100.0%)

## FR-PO927

## Seven-Year Follow-Up in a Population at Risk of Mesoamerican Nephropathy: Associations With Early Evidence of Kidney Injury and Incident CKD

Marvin A. Gonzalez,<sup>1,2</sup> Brianna Heggseth,<sup>3</sup> Nicholas P. Jewell,<sup>4</sup> Dorothea Nitsch,<sup>4</sup> Neil Pearce,<sup>4</sup> Ben Caplin.<sup>1</sup> Colt/MRC CKDu study group <sup>1</sup>University College London, London, United Kingdom; <sup>2</sup>Universidad Nacional Autónoma de Nicaragua Leon, Leon, Nicaragua; <sup>3</sup>Macalester College, Saint Paul, MN; <sup>4</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom.

**Background:** Mesoamerican Nephropathy (MeN) is a leading contributor to premature mortality in Central America but the primary cause remains unclear. Early disease is challenging to identify given absent urinary abnormalities and variation in eGFR within and between healthy individuals. We explored the incidence of CKD as well as evidence of early kidney injury (EKI) in the at-risk population from NW Nicaragua.

**Methods:** We conducted a community-based study of 2 cohorts (n=351 and 420) of adults aged 18–30, collecting questionnaire data, and bi-annual/annual eGFR measures for 7 and 4 years follow-up respectively. We used Hidden Markov Modelling to estimate EKI, the point of sustained departure from the healthy eGFR distribution, and examined associations between time-updated exposures and both incident CKD and EKI using Cox-proportional hazards and fractional regression respectively.

**Results:** CKD occurred in men only (incidence rates of 0.8%/year and 0.5%/year in the two cohorts). 14% of men and 3% of women experienced EKI. Cumulative time spent in sugarcane work and symptoms of excess occupational sun exposure associated with incident CKD. Other risk factors associated with EKI (Table). Weight loss and cramps remained independently associated with EKI in multivariable models.

**Conclusions:** CKD burden in this population is high. Risk factors for established disease are occupational but a symptom constellation suggesting an alternative exposure is associated with EKI, supporting separate initiating and exacerbating factors in MeN. The initiating factor remains unknown, but identifying episodes of EKI may facilitate efforts to uncover it. Meanwhile interventions to reduce the impact of exacerbating factors should be vigorously pursued.

**Funding:** Private Foundation Support, Government Support - Non-U.S.

Table: Selected associations between exposures and early kidney injury		
Exposure	OR	(95% CI)
<i>Occupation since last visit (yes versus no)*</i>		
Supacane	1.59	(0.96 to 2.61)
Paid agricultural	1.03	(0.66 to 1.61)
Unpaid agricultural	0.97	(0.61 to 1.55)
<i>Occupational environment (all yes versus no except where stated)</i>		
Work outdoors (regularly or more frequently versus less frequently)	1.60	(0.94 to 2.58)
Work in a very hot environment (regularly or more frequently versus less frequently)	1.10	(0.68 to 1.82)
<i>Symptoms of excess sun exposure at work</i>		
Agrochemical use	1.60	(1.05 to 2.61)
	1.19	(0.74 to 1.92)
<i>Social factors, yes versus no unless otherwise stated</i>		
Piped water source	0.61	(0.34 to 1.09)
Daily water intake	per litre	1.11
Premature birth	1.01	(0.31 to 3.34)
<i>Medical factors, since last visit, yes versus no unless otherwise stated</i>		
Mean systolic blood pressure (measured, at this visit)	per 10mmHg	1.04
Mean Diastolic blood pressure (measured, at this visit)	per 10mmHg	1.22
Weight loss of more than 2.5kg (measured, since last visit)		1.99
Diagnosis of UTI		1.27
NSAIDs regularly or more frequently		2.10
Paracetamol regularly or more frequently		0.66
<i>Symptoms, since last visit, more frequent than 'never' or 'almost never' versus 'never' or 'almost never', unless otherwise stated</i>		
Any back pain		1.07
Any unintentional weight loss		1.53
Dysuria		0.84
Cramps		2.27
Fever		1.57
Nausea		1.88
Diarrhoea		0.65
Vomiting		2.26

OR, odds ratio; 95% CI, 95% confidence interval; UTI, urinary tract infection. Adjusted for age, sex, study visit and follow-up duration. \*Participants could report more than one occupation at each study visit. Coefficients in bold where 95% confidence intervals exclude unity.

Frailty Is Associated With Hospitalizations in Adults With CKD: Findings From the CRIC Study

Mary Hannan,<sup>1</sup> Jinsong Chen,<sup>1</sup> Ana C. Ricardo,<sup>1</sup> Milda R. Saunders,<sup>2</sup> Julia Brown,<sup>1</sup> Anna C. Porter,<sup>1</sup> James P. Lash.<sup>1</sup> The CRIC Study Investigators <sup>1</sup>University of Illinois Chicago College of Medicine, Chicago, IL; <sup>2</sup>University of Chicago Department of Medicine, Chicago, IL.

**Background:** Adults with chronic kidney disease (CKD) experience high rates of hospitalization. Although the association between frailty and high hospitalization risk is established in the general population, it has not been examined in patients with CKD. The objective of this study is to evaluate frailty status as a predictor of hospitalizations in adults with CKD.

**Methods:** We utilized data on 2539 participants from the Chronic Renal Insufficiency Cohort (CRIC) Study. Frailty status was assessed using five criteria (slow gait speed, muscle weakness, low physical activity, exhaustion, and unintentional weight loss). Hospitalizations were ascertained based on self-report and review of medical records. Cardiovascular disease (CVD) hospitalizations were defined as those from a disease of the circulatory system. Analysis was conducted using multivariable Poisson regression adjusting for relevant covariates.

**Results:** Baseline age was 62.0 years, 46% were female, mean eGFR was 45.2 mL/min/1.73m<sup>2</sup>, and median urine protein was 0.2 mg/day. In the sample, 12% were frail, 51% pre-frail, and 37% non-frail. Over a median follow-up of 8.61 years, there were 19,630 hospitalizations. The rates of all-cause, CVD, and non-CVD related hospitalizations were highest for those who were frail. On multivariable analysis, both pre-frailty and frailty status were associated with having higher risk for all-cause, CVD, and non-CVD related hospitalizations.

**Conclusions:** Frailty status is associated with higher risk for hospitalizations in adults with CKD. Future work is needed to evaluate whether interventions to improve frailty status reduce the risk of hospitalization in this high risk population.

**Funding:** NIDDK Support, Private Foundation Support

	Frailty Status	Rate of Hospitalization (per 100 person years)	Adjusted Rate Ratio (95% CI)*
All Cause Hospitalization	Non-frail	16.4 (15.3,17.5)	Reference
	Pre-frail	25.8 (24.4,27.3)	1.59 (1.43,1.58)
	Frail	35.1 (31.3,39.4)	1.92 (1.82,2.03)
CVD Hospitalization	Non-frail	4.7 (4.2,5.1)	Reference
	Pre-frail	8.0 (7.5,8.6)	1.46 (1.34,1.58)
	Frail	11.2 (9.9,12.8)	1.83 (1.64,2.03)
Non-CVD Hospitalization	Non-frail	14.1 (13.1,15.1)	Reference
	Pre-frail	21.8 (20.6,23.1)	1.52 (1.44,1.61)
	Frail	30.3 (27.0,34.0)	1.94 (1.83,2.07)

FR-PO929

Full Age Spectrum eGFR Formula Corrected by Height to Adapt to a Population Endemic for Mesoamerican Nephropathy as a Tool to Diagnose and Follow Up CKD

Antonino Sidoti,<sup>1,2</sup> Maria Jose Sequeira,<sup>2</sup> Paolo Mazzacani.<sup>2</sup> Clinica Nefrologia Fundacion Coen Chinandega <sup>1</sup>Nefrologia Valdesa, Poggibonsi, Italy; <sup>2</sup>Fundacion Coen, Chinandega, Nicaragua.

**Background:** We have to diagnose monitor for developing CKD and follow up people age 12-20 affected and by Mesoamerican Nephropathy. Recommendation is from NKDEP to notate values from Schwartz formula (Schw) above 75 mL/min' as 75 mL/min' due to inaccuracy. CKD-EPI is not suitable to a pediatric cohort, we have to follow children after their passage to adult age. Our attention is focused on Full Age Spectrum formula (FAS) (Pottel: 2017, 2020) that is recommended to be adapted whenever used to the population at hand.

**Methods:** We completed 1099 records with creatinine, height, weight, age. FAS was winsored at 169.5 mL/min' using Q-Q graph, as a consequence Schw was winsored at 169.5. Adjustment of FAS for height (FASAdj) was accomplished using a people categorization via Schw values for eGFR < 60 n=11, < 75 n=153 and above 75 mL/min' n= 935 and applying FAS Pearson coefficients via a sub-categorization by sex also. Bland-Altman analysis was performed using Schw as standard method.

**Results:** Fig 1 and Fig 2 show Bland-Altman analysis for eGFR < 60 and < 75 mL/min'. On the whole cohort mean difference between Schw and FASAdj was -11.98, 1.96 SD lies between +9.42 and -33.39.

**Conclusions:** FASAdj seems suitable as a tool for diagnosis and follow up of CKD, is adapted to the population to monitor; differences from Schw seem not clinically significant particularly in the eGFR level below 75 mL/min'.

## Hospitalization Lengths of Stay Among a National Cohort of Advanced CKD Patients Treated With Conservative Management vs. Dialysis

Amy S. You,<sup>1</sup> Kamyar Kalantar-Zadeh,<sup>1</sup> Yoko Narasaki,<sup>1</sup> Dana B. Mukamel,<sup>1</sup> Susan T. Crowley,<sup>2</sup> Ji Hoon Yoon,<sup>1</sup> Csaba P. Kovessy,<sup>3</sup> Danh V. Nguyen,<sup>1</sup> Connie Rhee,<sup>1</sup> <sup>1</sup>University of California Irvine, Irvine, CA; <sup>2</sup>Yale University, New Haven, CT; <sup>3</sup>The University of Tennessee Health Science Center, Memphis, TN.

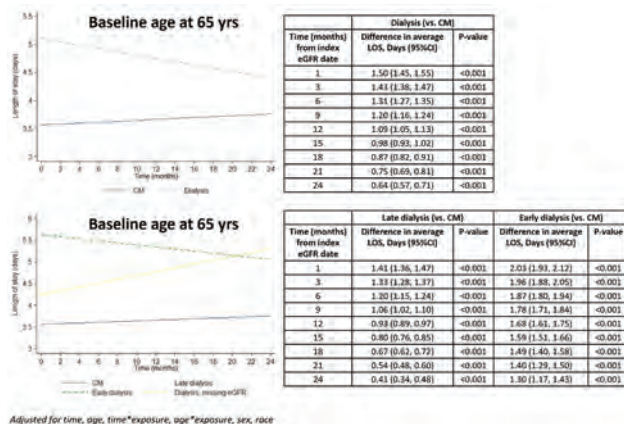

**Background:** While dialysis has been the prevailing treatment paradigm in advanced CKD patients progressing to ESKD, this approach may lead to loss of independence/function and greater healthcare utilization in certain groups. We compared the impact of dialysis vs. conservative management (CM) on hospitalization lengths of stay (LOS) in advanced CKD.

**Methods:** We examined a national cohort of advanced CKD patients treated with CM vs. dialysis over 1/07-6/20 from the Optum Labs Data Warehouse, which contains de-identified administrative claims, including medical and pharmacy claims and enrollment records for commercial and Medicare Advantage enrollees as well as EHR data. In primary analyses, patients were categorized according to receipt of CM, defined as not receiving dialysis within 2-yr of the index eGFR (1<sup>st</sup> eGFR<25), vs. dialysis. We compared LOS among patients treated with CM vs. dialysis hospitalized within 2-yr of their index eGFR using linear mixed effects models that separately considered fixed age of the cohort (65-years), with varying time of hospitalization from the index eGFR, as well as a fixed time of hospitalization from the index eGFR (12 months) with varying age.

**Results:** Among 169,479 advanced CKD patients who were hospitalized within 2-yr of the index eGFR, there were a total of 620,168 hospitalizations over this period. In analyses considering fixed age, dialysis patients had longer average LOS vs. CM patients, with differences attenuating over time (Fig A). In analyses considering fixed time of hospitalization from the index eGFR, dialysis patients >20-yr had longer average LOS vs. CM patients, with differences increasing with older age (Fig B).

**Conclusions:** Compared to dialysis, CM patients had shorter LOS across varying time points and ages. Further studies are needed to examine the comparative effectiveness of CM vs. dialysis transition on CKD outcomes.

## FR-PO931

## Incident Events and Their Combinations After 6.5 Years of Follow-Up in the German Chronic Kidney Disease Study

Fruzsina K. Kotsis,<sup>1,2</sup> Inga Steinbrenner,<sup>1</sup> Jan Lipovsek,<sup>1</sup> Helena Stockmann,<sup>3</sup> Ulla T. Schultheiss,<sup>1,2</sup> GCKD Investigators <sup>1</sup>Institute of Genetic Epidemiology, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany; <sup>2</sup>Renal Division, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany; <sup>3</sup>Charite Universitätsmedizin Berlin, Berlin, Germany.

**Background:** Chronic kidney disease (CKD) patients are at an increased risk for adverse cardiovascular, non-cardiovascular events, and early mortality. Yet, a detailed analysis of the spectrum and patterns of adverse events from large CKD cohorts is lacking. We studied incident events, their combinations and mortality in the prospective German CKD (GCKD) study.

**Methods:** Incident events in the GCKD study are continuously adjudicated from hospital discharge records and death certificates following a standardized event catalogue containing: cardiovascular ("A"), cerebrovascular ("B"), peripheral arterial occlusive disease, ("C"), kidney ("E"), cancer ("G"), infection ("H"), and death ("F") events. Event frequencies and their combinations were compared by sex. Incidence rates per 1000 patient-years (IR +/- recurrent events) were calculated. Combinations of events (intersection plot) were considered per participant regardless of time.

**Results:** Out of 5217 participants 60% were men. Over 6.5 years, 2933 participants (65.5% men) experienced at least one event. Incidence rates were overall (o) 97 (IR -); 338 (IR +). Men (m) experienced more events (108 IR -; 392 IR +) than women (w) (82 IR -; 260 IR +, respectively). Incidence rates were: A (o: 46; 114; m: 54; 135; w: 36; 82), E (o: 46; 75; m: 52; 85; w: 38; 61), H (o: 40; 66; m: 42; 68; w: 37; 63), F (o: 22; m: 28;

w: 14; respectively). For 1314 participants, events in only one category (mainly A, E, H) were observed (Figure 1). In total, 787 participants experienced a combination of two events (66% men) and 467 a combination of 3 events (67% men). The most frequent combinations were (E, H; n=176) and (A, E, H; n=154).

**Conclusions:** This study provides a comprehensive overview of incident adverse events, their combinations, and differential events by sex in CKD patients under regular nephrological care. Cardiovascular, kidney and infection events were most frequent, and men experienced more events than women. Frequent events occurred in patients that also experienced an event of another category.

**Funding:** Government Support - Non-U.S.

Figure 1: Combination of incident events and number of patients by main event category.

## Long-Term Exposure to High Perceived Temperature and Risk for Mortality Among Patients With CKD

Boram Weon,<sup>1</sup> Jeonghwan Lee,<sup>2,1</sup> Jung Pyo Lee,<sup>2,1</sup> Chun Soo Lim,<sup>2,1</sup> <sup>1</sup>Seoul National University Boramae Medical Center, Seoul, Republic of Korea; <sup>2</sup>Seoul National University College of Medicine, Seoul, Republic of Korea.

**Background:** With the global warming, the interest in health risks from the high temperature exposure is growing. The Perceived Temperature (PT) is an equivalent temperature based on a complete heat budget model of the human body. We aimed to analyze the effect of PT on the overall mortality among chronic kidney disease (CKD) patients.

**Methods:** A total of 32,870 patients with CKD living in Seoul metropolitan region were recruited in a retrospective cohort (2001-2018). PT during summer season (from July to September, at each year) was calculated using various climate factors including air temperature nearby automated weather station, dew point temperature, wind velocity, height of anemometer above ground, and total cloud amount. We assessed the association of PT using inverse distance weighting (IDW) on mortality in CKD patients in the Cox proportional hazard model that was adjusted for sex, age, body mass index, eGFR, hypertension, and diabetes mellitus.

**Results:** During the 6.14±3.96 years, 3,863 deaths (13%) were observed. We confirmed the significant effects of PT (average PT: hazard ratio [HR] 1.21, 95% confidence interval [CI] 1.18-1.23; minimum PT: HR 1.02, 95% CI 1.00-1.05; maximum PT: 1.20, 95% CI 1.18-1.22) on mortality in CKD patients in univariable analysis. In multivariable analysis, average PT (HR 1.22, 95% CI 1.19-1.25) and maximum PT (HR 1.20, 95% CI 1.17-1.23) showed increased risk for overall mortality among CKD patients.

**Conclusions:** Long-term exposure to high PT during summer season increased the risk of mortality among CKD patients.

## FR-PO933

## Monoclonal Gammopathy of Undetermined Significance (MGUS) and Risk of CKD: Results of the Population-Based Iceland Screens, Treats, or Prevents Multiple Myeloma (iStopMM) Study

Thorir E. Long,<sup>1,2</sup> Olafur S. Indridason,<sup>3</sup> Sæmundur Rögnvaldsson,<sup>4,3</sup> Elias Eythorsson,<sup>3,2</sup> Sigrún Thorsteinsdóttir,<sup>5</sup> Thorvaldur J. Love,<sup>2,3</sup> Runolfur Palsson,<sup>3,2</sup> Sigurdur Y Kristinnsson,<sup>2,3</sup> iStopMM research group <sup>1</sup>Skane universitetssjukhus Lund, Lund, Sweden; <sup>2</sup>Heilbrigdisvisindasvid - Haskoli Island, Reykjavik, Iceland; <sup>3</sup>Landspítali, Reykjavik, Iceland; <sup>4</sup>University of Iceland, Reykjavik, Iceland; <sup>5</sup>Rigshospitalet, Copenhagen, Denmark.

**Background:** The prevalence of both monoclonal gammopathies of undetermined significance (MGUS) and chronic kidney disease (CKD) increase with age. In recent years, studies have shown association between MGUS and CKD, suggesting an underdiagnosis of monoclonal gammopathies of renal significance (MGRS). The aim of this study was to examine the risk of CKD in participants with MGUS compared with those without MGUS for the first time in a screened cohort, to estimate the prevalence of MGRS.

**Methods:** A total of 75,422 participants of the iStopMM study were screened for MGUS. CKD was defined as proteinuria, hematuria or estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m<sup>2</sup>, present for >90 days. Participants with lymphoproliferative disorders or without data on kidney function were excluded. Risk of CKD was evaluated with multivariable logistic regression. Power analysis yielded 90% power to detect 1.5% absolute difference between groups.

**Results:** Of the participants, 35,202 had available urine measurements and 69,120 data on eGFR, median (range) age was 61 (52-70) years, 44.8% were men. MGUS was detected in 4547 (6.6%) participants, 2242 (3.2%) of which were non-IgM, 703 (1.0%) IgM, 1295 (1.9%) LC-MGUS, and 307 (0.4%) bclonal. A total of 6680 (9.7%) participants had CKD, 14.8% in the MGUS group and 9.3% in the group without MGUS. In an age- and sex-adjusted analysis, there was no significant association between non-IgM MGUS,

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

IgM MGUS, or bclonal MGUS and CKD (Table I). Participants with LC-MGUS were less likely to have CKD than those without MGUS. The inverse correlation between age and eGFR was similar in the groups with and without MGUS ( $r = -0.56$ ).

**Conclusions:** In this large population-based screening study, we observed no increase in the risk of CKD in individuals with MGUS. This finding suggests a low prevalence of MGRS in the general population.

**Funding:** Private Foundation Support, Government Support - Non-U.S.

Table I. Risk of chronic kidney disease in subgroups of MGUS compared with persons without MGUS. Logistic regression adjusted for age and sex (n = 69120).

Variable	Adjusted OR (95% CI)	p-value
No MGUS	1.00	
- Non-IgM MGUS	1.06 (0.93 - 1.20)	0.382
- IgM MGUS	1.01 (0.82 - 1.24)	0.901
- LC-MGUS	0.39 (0.31 - 0.49)	<0.001
- Bclonal MGUS	0.93 (0.68 - 1.26)	0.665
Age (per year)	1.12 (1.12 - 1.13)	<0.001
Sex (male)	0.98 (0.93 - 1.04)	0.557

The adjusted model included age and sex

FR-PO934

**Performance of Race Neutral CKD-EPI 2021 eGFR Equations in Indian Population**  
Prabhjot K. Johal,<sup>1</sup> Ashok K. Yadav,<sup>1</sup> Vivek Kumar,<sup>1</sup> Vivekanand Jha.<sup>2</sup> <sup>1</sup>Post Graduate Institute of Medical Education and Research, Chandigarh, India; <sup>2</sup>The George Institute for Global Health, New Delhi, India.

**Background:** Recently, race neutral CKD-EPI 2021 equations have been described. As these equations are being adopted in clinical use, it is important to validate these estimating glomerular filtration rate (eGFR) equations in Indian population. We present the performance of these equations against measured GFR (mGFR) in Indian subjects.

**Methods:** In the ongoing 'Indian GFR study', healthy individuals or stable patients with chronic kidney disease (CKD) are being enrolled with the objective of testing performance of eGFR equations in Indian population. Demographic details, anthropometric measurements, diagnosis, treatment and dietary details are being recorded. GFR was measured using urinary clearance of inulin in the first 130 subjects. Thereafter, it is being measured by plasma clearance of iothexol. Bias, precision, and accuracy of CKD-EPI 2021 equations were calculated. We present data of participants whose measurements were available till October 2021.

**Results:** mGFR was available for 412 participants (187 healthy and 225 with CKD). Average age was 47.2±11.5 years, 50% being males. Mean mGFR in study population was 54.23±30.21 ml/min/1.73m<sup>2</sup>. eGFR using CKD-EPI<sub>Cr2021</sub> and CKD-EPI<sub>Cr-cys2021</sub> were 73.45±38.37 ml/min/1.73m<sup>2</sup> and 60.81±33.58 ml/min/1.73m<sup>2</sup>, respectively. Bias for CKD-EPI<sub>Cr2021</sub> and CKD-EPI<sub>Cr-cys2021</sub> equations were -19.22±21.55 ml/min/1.73m<sup>2</sup> and -6.58±19.19 ml/min/1.73m<sup>2</sup>, respectively. eGFR by CKD-EPI<sub>Cys</sub> had least bias and highest P<sub>30</sub> (table 1).

**Conclusions:** Race neutral CKD-EPI 2021 equations did not enhance performance of eGFR equations in Indian subjects. There is a need for extensive validation of eGFR equations in Indian population.

**Funding:** Government Support - Non-U.S.

Table 1. Performance of GFR estimating equations as compared to measured GFR

Method	Bias	95% Limits of agreement	Precision (95% CI)	Accuracy	
				RMSE	P <sub>30</sub> (%)
CKD-EPI <sub>Cr2009</sub>	-17.04±21.36	24.82 to -58.90	-19.11 to -14.97	27.31	43.20
CKD-EPI <sub>Cr2021</sub>	-19.22±21.55	23.01 to -61.45	-21.31 to -17.13	28.86	41.50
CKD-EPI <sub>Cr-cys2012</sub>	-0.86±18.40	35.20 to -36.92	-2.64 to 0.91	18.40	59.95
CKD-EPI <sub>Cr-cys2021</sub>	-6.58±19.19	31.03 to -44.19	-8.44 to -4.72	20.27	55.83
CKD-EPI <sub>Cys</sub>	3.56±19.29	41.36 to -34.24	1.69 to 5.43	19.59	60.92

P30: Percentage of participants with eGFR within ±30% of mGFR, RMSE: root mean square error

FR-PO935

**Polygenic Burden as a Predictor of Age at Onset of ESRD**  
Kane E. Collins,<sup>1</sup> Edmund H. Gilbert,<sup>1</sup> Katherine A. Benson,<sup>1</sup> Elhussein A. Elhassan,<sup>2</sup> Graham M. Lord,<sup>3</sup> Gianpiero Cavalleri,<sup>1</sup> Peter J. Conlon.<sup>2,1</sup> <sup>1</sup>Royal College of Surgeons in Ireland, Dublin, Ireland; <sup>2</sup>Beaumont Hospital, Dublin, Ireland; <sup>3</sup>King's College London, London, United Kingdom.

**Background:** There are a large number of well-established clinical risk factors for age of onset of ESRD including diabetes, hypertension, heart disease, and obesity. Patients with CKD have also been shown to have a significant enrichment of rare variation in genes related to kidney disease. However, little research has been done to investigate the role of burden from common genetic risk factors on age of onset of ESRD, as quantified using polygenic risk scores (PRS) which estimates the cumulative effect of common genetic variation on an individual's disease status. Here, we investigate the association between polygenic burden for hypertension, albuminuria, eGFR and kidney volume (KV) and age of onset of ESRD.

**Methods:** We utilised 2,122 genotyped kidney transplant recipients from across the UK and Ireland (UKIRTC) and 5,519 ancestry matched controls. For these transplant recipients, we used age of transplant as a proxy for age of onset of ESRD. We also used 190 genotyped Irish individuals with Polycystic Kidney Disease (PKD). We calculated PRSs for each trait using large published GWASs of European ancestry. We then investigated the relationship between age of onset of ESRD and polygenic burden in each cohort separately and then together.

**Results:** The UKIRTC recipients had a higher polygenic burden than healthy controls for reduced eGFR (p-value 0.006) and albuminuria (p-value 0.056). The PKD patients also had increased burden for albuminuria (p-value: 0.003). Taken together, all the patients from the two cohorts had higher polygenic burden for albuminuria and reduced eGFR than healthy controls (p-values: 0.003, 0.01 respectively). We compared age of onset of ESRD between individuals in the top 20% of polygenic risk for each trait to those in the bottom 80% and found an Odds Ratios (OR) of 3.75 for hypertension (p-value: 0.052) and 0.261 for reduced eGFR (p-value: 0.051).

**Conclusions:** These observations support the hypothesis that individuals with CKD have higher common variant burden for traits related to reduced kidney function and that polygenic burden is a borderline statistically significant predictor of age of onset of ESRD. A larger sample size may verify the magnitude of this effect. If replicated in a larger dataset, these findings could lead to modifications of screening and treatment of ESRD.

**Funding:** Government Support - Non-U.S.

FR-PO936

**Prevalence and Awareness of Kidney Disease Among Individuals With Prediabetes**  
Yiting Li,<sup>1</sup> Michael Heung,<sup>1</sup> Tiffany C. Veinot,<sup>1</sup> Brenda W. Gillespie,<sup>1</sup> Yun Han,<sup>1</sup> William H. Herman,<sup>1</sup> Alain Koyama,<sup>2</sup> Meda E. Pavkov,<sup>2</sup> Rajiv Saran,<sup>1</sup> Jennifer L. Bragg-Gresham.<sup>1</sup> <sup>1</sup>University of Michigan, Ann Arbor, MI; <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA.

**Background:** About 96 million US adults have prediabetes; 80% are unaware they have the condition. Prediabetes can progress to type 2 diabetes and complications such as chronic kidney disease (CKD). Here we compare the prevalence of CKD and its awareness among those with prediabetes and diabetes in the US.

**Methods:** Analysis included 47,000 U.S. adults aged 20+ years in the National Health and Nutrition Examination Survey (NHANES, 2001 to Mar 2020). Prediabetes was defined as HbA1c 5.7% to 6.4%; diabetes (DM) by self-report, medication, or HbA1c ≥ 6.5%. CKD was defined by eGFR < 60 ml/min/1.73m<sup>2</sup> or albuminuria. CKD awareness and health behaviors were self-reported and nutritional intake was estimated from daily recall questionnaires. Survey weighted logistic regression was used to model changes in prevalence and awareness over time.

**Results:** Compared to adults with diabetes, those with prediabetes were younger and more likely to be female and Black (p<0.001). Those with prediabetes had a lower, though substantial comorbidity burden: 19% with CKD but only 7% aware of their condition. During the study, CKD prevalence among individuals with prediabetes decreased from 22% to 17% (p=0.03), with no significant change in age and comorbidities, but with improvements in lifestyle behaviors (p<0.001): increase in moderate physical activity (45.7% to 66.3%) and decline in sugar intake (123 g to 108 g). In addition, CKD awareness among individuals with prediabetes rose from 4.8% to 8.1%, although not statistically significant (p=0.18).

**Conclusions:** Nearly 1 in 5 individuals with prediabetes has CKD, yet only 7% were aware of their kidney disease. While improvements have been seen, opportunities remain to intervene at this potentially reversible stage, including improvement in diagnosis and awareness of prediabetes and in response to the high burden of CKD even among those with prediabetes.

Characteristics of Adults by Diabetes Status (NHANES 2001-Mar 2020)				
Measure	Mean (SEM) or %			
	Diagnosed DM	Undiagnosed DM	Prediabetes	No Diabetes
CKD (%)	40.4	30.6	18.9	9.3
CKD Awareness (%)	15.8	3.5	6.9	7.3
Age (years)	59.6(0.3)	56.8(0.5)	55.9(0.2)	43.8(0.2)
Male (%)	51.8	53.7	47.5	47.9
Race (%)				
Non-Hispanic White	61.8	50.7	61.7	71.7
Non-Hispanic Black	14.3	17.1	15.8	8.6
Non-Hispanic Other Race	8.6	11.5	8.2	8.7
Hispanic	15.3	20.7	14.2	10.6
BMI ≥ 30 kg/m <sup>2</sup> (%)	60.6	69.2	46.5	29.3
CVD (%)	27.2	34.7	12.6	4.9
Hypertension (%)	72.5	82.5	50.6	27.3

DM: self-reported, taking medication, or hemoglobin (Hb)A1c ≥ 6.5%; BMI: measured body mass index; CVD: self-report cardiovascular disease; No Diabetes includes individuals with HbA1c < 5.7% and no report of diabetes diagnosis.

## FR-PO937

**Predicting Rapid eGFR Decline in the CURE-CKD Registry**

Tyler A. Davis,<sup>1</sup> Panayiotis Petousis,<sup>1</sup> Davina J. Zamanzadeh,<sup>1</sup> Keith C. Norris,<sup>1</sup> Obidiugwu Duru,<sup>1</sup> Katherine R. Tuttle,<sup>2</sup> Alex Bui,<sup>1</sup> Susanne B. Nicholas,<sup>1</sup> Majid Sarrafzadeh,<sup>3</sup> CURE-CKD <sup>1</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; <sup>2</sup>Providence St Joseph Health, Spokane, WA; <sup>3</sup>University of California Los Angeles Department of Computer Science, Los Angeles, CA.

**Background:** Patients with rapid eGFR decline tend to progress to kidney failure. Automated tools can identify individuals at risk of severe kidney function decline and facilitate disease mitigation. We describe a machine learning model for predicting the risk of rapid eGFR decline (>40% over 2 years) and identify specific populations with elevated risk using the CURE-CKD Registry.

**Methods:** Variables include age, sex, race and ethnicity, ACE inhibitor/ARB, SGLT2 inhibitor, GLP-1 receptor agonist, NSAID, and PPI use, eGFR, systolic blood pressure (SBP), HbA1C, hypertension, type 2 diabetes, and chronic kidney disease (CKD) based on ICD-9/10 coding from patients with CKD (N=234,219) and at-risk for CKD (N=935,329) with CKD-EPI eGFR  $\geq 15$  mL/min/1.73 m<sup>2</sup> and 2 years of follow-up. We trained, tuned, and validated a gradient boosted tree ensemble model (GBTe) using a 60/20/20 train/validation/test split. We computed the risk distribution of all 8,503,055 subpopulations, based on all possible expert defined combinations of the above variables, and compared each risk distribution to the whole population's risk distribution using the Kolmogorov-Smirnov (KS) test. Subgroups with the highest risk of eGFR decline were identified using the KS test (Holm-Bonferroni method with  $\alpha=0.05$ ).

**Results:** The GBTe model achieved an area under the precision-recall curve (PR-AUC) of 0.099 and an area under the receiver operating characteristic curve of 0.75 on the test set. 480,344 subpopulations were significantly above average predicted risk in the test set. We identified the most frequent predictors of rapid eGFR decline across the highest risk subpopulations. Of the top 100 significantly higher risk subpopulations the following variables are the most frequent: CKD (100%), PPI use (100%), SBP  $>140$  mmHg (98%), HbA1C  $>8\%$  (87%), and age 45-66 years (79%). Patients in these 100 subpopulations were 13.7 times more likely to experience rapid decline than the overall study population.

**Conclusions:** We developed a methodology that uses a risk model for rapid eGFR decline to identify subpopulations with significantly high risk for rapid eGFR decline. These subpopulations are strong candidates for closer study and early intervention.

**Funding:** Other NIH Support - NIMHD

## FR-PO938

**Relationship of Light-Intensity and Moderate-to-Vigorous Intensity Physical Activity Habits for Kidney Dysfunction: A General Population Cohort Study**

Goro Sakurai, Tadashi Toyama, Akinori Hara, Yuta Yamamura, Shiori Nakagawa, Megumi Oshima, Taro Miyagawa, Hisayuki Ogura, Shinji Kitajima, Norihiko Sakai, Miho Shimizu, Takashi Wada, Yasunori Iwata. Department of Nephrology and Laboratory Medicine, Kanazawa University Kanazawa Daigaku, Kanazawa, Japan.

**Background:** There are limited studies considering exercise intensities and their frequencies in relation to kidney dysfunction.

**Methods:** A community-based historical cohort study was conducted including Japanese general people aged  $\geq 40$  years. Participants were divided into four categories according to the combination of their exercise habits: regular light-intensity physical activity (R-LPA: 1.5 to 3.0 metabolic equivalents [METs] at least 60 minutes a day) and occasional moderate-to-vigorous physical activity (O-MVPA:  $> 3.0$  METs at least 30 minutes twice a week). The outcome was the incidence of a 40% decrease in estimated glomerular filtration rate (eGFR) from baseline. Cox proportional hazards models were used to examine the association of exercise habits.

**Results:** A total of 72,999 people were included. During the mean follow-up of 5.9 years, 2,989 (4.1%) participants achieved the outcome. Compared to the people with neither R-LPA nor O-MVPA, the adjusted hazard ratios were 0.94 (95% CI: 0.85, 1.03;  $p=0.182$ ) for R-LPA alone, 0.97 (95% CI: 0.85, 1.10;  $p=0.618$ ) for O-MVPA alone, and 0.83 (95% CI: 0.76, 0.91;  $p<0.001$ ) for a combination of R-LPA and O-MVPA. There was a significant interaction between sex and exercise habits.

**Conclusions:** In general people, a combination of R-LPA and O-MVPA was associated with a lower risk of kidney dysfunction compared with no exercise habit. Future studies are warranted to determine the exercise intensity and duration that protects kidney function.

## FR-PO939

**Stratifying Patient Risk for eGFR Decline Over a Year**

Zahra Mahmoodzadeh,<sup>1</sup> Keith C. Norris,<sup>1</sup> Katherine R. Tuttle,<sup>2</sup> Alex Bui,<sup>1</sup> Susanne B. Nicholas,<sup>1</sup> CURE-CKD Registry Team <sup>1</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; <sup>2</sup>Providence St Joseph Health, Spokane, WA.

**Background:** Electronic health records (EHR) data enables assessment of patient-level risk by advanced data-driven artificial intelligence. This study used curated EHR data to stratify patients' risk of eGFR decline over a 1-year prediction period. We tested a 2-stage model that first predicted the risk of unstable eGFR (decline  $>5$  mL/min/1.73 m<sup>2</sup>) in the next year. For an unstable patient, a second model estimated the patient's expected eGFR in the next year.

**Methods:** We designed a 2-stage modeling technique with a binary classifier sequentially connected to a regressor, using the CURE-CKD data of 857931 patients. The binary classifier predicts the chance of having a stable eGFR (decline  $<5$  mL/min/1.73 m<sup>2</sup>) over the next year, given a set of static (sex; race; rural-urban commuting area codes; hypertension, type 2 diabetes (DM), pre-DM, and CKD based on ICD coding) and temporal observations (past 2 years of eGFR, medications (ACEI/ARB, SGLT2 inhibitor, GLP1 RA, MRA, NSAID, PPI) and age. If the likelihood of remaining stable is  $<50\%$ , the patient's information is passed to a second model trained to estimate the eGFR in the next year. The first model is a deep neural network consisting of a convolutional neural network (CNN-processes longitudinal patient data; trained on the whole training set) concatenated to a feedforward neural network (FNN-processes static patient data). The second stage model is an extreme gradient boosting regressor, trained on a cohort of the training set with eGFR decline  $>5$  mL/min/1.73 m<sup>2</sup> in a 1-year prediction window. Both models were trained, validated, and tested on a 60/20/20 split.

**Results:** The first model's area under the receiver operating curve was 0.814. When the classification threshold was set to 50%, the classifier accuracy reached 76%, and the precision reached 70%. The second model achieved the mean absolute error (MAE) of 3.47 and root mean squared error of 4.59, while the best stand-alone regressor trained on the whole training set had MAE of 5.73. Therefore, the 2-stage modeling technique increased the eGFR prediction accuracy for more critical patients.

**Conclusions:** Our 2-step model stratified patient risk for eGFR decline over a 1-year period. The model can support clinical decision-making on the risk of  $>5$  mL/min/1.73 m<sup>2</sup> eGFR decline in the next year. If the chance is high, the second model can estimate the eGFR value for the next year.

## FR-PO940

**The Association Between Mean Blood Pressure and the Rate of Progression of CKD Is Dependent on the Underlying Disease**

Tatsuo Kondo, Tsutomu Inoue, Daichi Fukaya, Hiroaki Amano, Yusuke Watanabe, Koji Tomori, Hirokazu Okada. Saitama Ika Daigaku, Iruma-gun, Japan.

**Background:** The correction of intraglomerular pressure suppresses glomerulosclerosis thereby retarding CKD progression in animal models whereas the degree of increase in intraglomerular pressure in the human kidney in patients with CKD is assumed to vary with etiology. In this study, we examined the association between mean blood pressure (mBP) and the rate of progression of CKD, with a focus on different etiologies.

**Methods:** We recruited patients with chronic glomerulonephritis (CGN), diabetic kidney disease (DKD), or nephrosclerosis (HNS). The progression rate was defined as the SLOPE:  $\Delta\text{eGFR}/\text{year}$  (mL/min/1.73m<sup>2</sup> per year). Regression coefficients for predicting the SLOPE using each risk factor were examined using Bayesian analysis. A model with linear combination of each explanatory variable was assumed.

**Results:** A total of 167 patients (37.7% female; mean observation period, 3.17 years; eGFR,  $43.89 \pm 23.54$ ; urinary protein (UP),  $1.54 \pm 2.01$  g/gCr; mBP,  $96.90 \pm 9.58$  mmHg) with CGN (n=64), DKD (n=26), or HNS (n=77) were included. The mean SLOPE values for CGN, DKD, and HNS were -3.15, -5.19, and -1.91, respectively, and ANOVA showed significant differences among groups ( $p<0.01$ ). Multiple regression analysis using age, gender, and known risk factors revealed that UP and mBP were significant explanatory variables for the SLOPE. In addition, the interaction was also significant for mBP (age\*etiology,  $p=0.08$ ; UP\*etiology,  $p=0.05$ ; mBP\*etiology,  $p=0.01$ ). After adjusting for age and UP, the coefficient of mBP was estimated for each etiology. Model: SLOPE=normal (intercept+age+UP+mBP\*etiology,  $\sigma^2$ ), prior distribution Normal (0, 100),  $\sigma^{-2}$ -iy (0.01, 0.01), iter=12500, burn-in=2500, chains=4. All MCMC sampling results were well-converged. The mean values [95% Cred. Inter.] for the MCMC samples of CGN, DKD, and HNS were -0.063 [-0.113, -0.013], -0.020 [-0.035, -0.005], and -0.003 [-0.016, 0.010], respectively. The mBP did not affect the SLOPE in HNS.

**Conclusions:** Unlike UP, the association between mBP and SLOPE is dependent on the underlying disease/etiology of CKD. Factors associated with decreased renal function differ depending on the primary disease, and careful consideration is needed to construct a renoprotective strategy with antihypertensive therapy, particularly for patients with HNS.

## FR-PO941

**Impact of Conservative Management vs. Dialysis on Survival Among US Veterans With Advanced CKD**

Connie Rhee,<sup>1</sup> Yoko Narasaki,<sup>1</sup> Susan T. Crowley,<sup>2</sup> Csaba P. Kovessdy,<sup>3</sup> Dana B. Mukamel,<sup>1</sup> Amy S. You,<sup>1</sup> Ji Hoon Yoon,<sup>1</sup> Danh V. Nguyen,<sup>1</sup> Kamyar Kalantar-Zadeh.<sup>1</sup> <sup>1</sup>University of California Irvine, Irvine, CA; <sup>2</sup>Yale University, New Haven, CT; <sup>3</sup>The University of Tennessee Health Science Center, Memphis, TN.

**Background:** Among  $>1$  million US Veterans with CKD,  $\sim 10\%$  of those with advanced kidney disease annually progress to ESKD in whom dialysis is the dominant treatment paradigm. Given high rates of early mortality, healthcare utilization, and withdrawal experienced by dialysis patients, we examined the impact of non-dialytic conservative management (CM) vs. dialysis on survival.

**Methods:** Using linked national VA, USRDS, and Medicare data, we examined Veterans with advanced CKD ( $\geq 2$  eGFRs  $<25$  separated by  $\geq 90$  days) categorized according to receipt of CM, defined as those who did not receive dialysis within 2-yrs of the index eGFR (1<sup>st</sup> eGFR  $<25$ ), vs. receipt of dialysis within 2-yrs of the index eGFR. We compared survival among CM vs. dialysis patients matched by propensity score (PS) to account for differences in demographics, comorbidities, laboratory tests, medications,

and treatment factors (hospitalization, nephrology care within 1-yr of index eGFR) in a 1:1 ratio with a caliper distance of  $\leq 0.2$  using complete case analysis.

**Results:** In the PS-matched cohort of 34,628 patients, 17,314 vs. 17,314 were in the CM vs. dialysis groups, respectively, among whom baseline characteristics were well-balanced. In the overall cohort, there were 24,677 death events over a median (IQR) follow-up of 3.7 (2.2, 5.7) yrs. In the main PS-matched unadjusted model, compared with CM, dialysis was associated with higher all-cause mortality: HR (95%CI) 1.11 (1.08-1.14). Similar findings were observed in analyses doubly-adjusted for PS covariates: HR (95%CI) 1.08 (1.05-1.10) for dialysis (Fig).

**Conclusions:** In PS-matched analyses, compared with CM, transition to dialysis was associated with higher death risk in US Veterans. Further studies are needed to examine the comparative effectiveness of CM vs. dialysis transition on other hard endpoints and patient-centered outcomes.

**Funding:** NIDDK Support

#### FR-PO942

##### Lower Central Venous Catheter Rates With Use of Kidney Failure Risk Reporting

Joanna Willetts,<sup>1</sup> Diana Strubler,<sup>4</sup> Yue Jiao,<sup>1</sup> Sheetal Chaudhuri,<sup>1</sup> John W. Larkin,<sup>1</sup> Len A. Usvyat,<sup>1</sup> Sam Gopal,<sup>4</sup> Timothy McNamara,<sup>3</sup> Franklin W. Maddux.<sup>2</sup> <sup>1</sup>Fresenius Medical Care, Global Medical Office, Waltham, MA; <sup>2</sup>Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany; <sup>3</sup>Fresenius Medical Care North America, Waltham, MA; <sup>4</sup>Acumen Physician Solutions, Nashville, TN.

**Background:** About 80% of kidney failure patients initiate hemodialysis (HD) with a central venous catheter (CVC), a rate that has been unchanged for decades (USRDS 2021). There is an unmet need to reduce CVC use at the transition to HD, which may be secondary to the dynamic nature of chronic kidney disease (CKD) progression and barriers in patient education/literacy. Since 2018, an electronic health record (EHR) system for CKD practices made a glomerular filtration rate (GFR) forecast reporting tool available to nephrologists. This report is based on a machine learning model that predicts the bi-monthly change in GFR over the next year. To understand the potential impacts of this risk reporting, we assessed its use by nephrologists and the CVC rates among patients who progressed to kidney failure and started HD.

**Methods:** We used data from an EHR system for CKD practices in the United States. We included data from nephrologists with  $\geq 15$  patients who progressed from CKD to kidney failure and initiated HD from April 2018-2020. We categorized nephrologists by use of the GFR forecast tool. Frequent users accessed the tool for  $>5\%$  of their CKD patients, occasional users accessed the tool for 0-1% of their CKD patients, and non-users never accessed the tool, then we assessed CVC rates at HD initiation.

**Results:** Among 677 nephrologists, 34 were frequent users, 177 were occasional users, and 466 never used the GFR forecaster. Nephrologists provided care to 459,586 CKD patients, of which 26,164 progressed to kidney failure and started HD. Patients treated by nephrologists who were frequent users of the risk report had a 4.9 and 4.2 percentage point lower CVC rate at the start of HD compared to occasional and non-users of the tool, respectively (Figure 1).

**Conclusions:** We found frequent use of a kidney failure risk report associates with lower CVC rates at HD initiation. CVCs continue to be the primary access type used at the start of HD. Adoption of kidney failure risk reporting may provide some help through decision support and a way to enhance patient education in care planning.

**Funding:** Commercial Support - Fresenius Medical Care

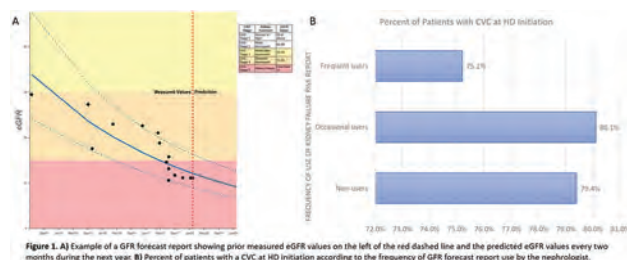

Figure 1. A) Example of a GFR forecast report showing prior measured eGFR values on the left of the red dashed line and the predicted eGFR values every two months during the next year. B) Percent of patients with a CVC at HD initiation according to the frequency of GFR forecast report use by the nephrologist.

#### FR-PO943

##### Pilot Feasibility of Coordinated Multidisciplinary Model Can Improve Management and Outcomes of Patients With CKD Under University Healthcare in Thailand

Manoch Rattanasompattikul,<sup>1</sup> Nuttawut Rongkiettechakorn,<sup>1</sup> Malinporn Jampong,<sup>1</sup> Sumana Masoodi,<sup>2</sup> Moltira Promkan,<sup>2</sup> Aungkura Supokawej.<sup>2</sup> <sup>1</sup>Golden Jubilee Medical Center, Faculty of Medicine Siriraj Hospital, Phuthamonthon, Thailand; <sup>2</sup>Mahidol University Faculty of Medical Technology Salaya Campus, Salaya, Thailand.

**Background:** Thailand's renal care system is an evolving educational healthcare system. The limitation of the data system for chronic kidney disease (CKD) patients is the lack of the generation of data that can be analyzed. An appropriate kidney care model for individual hospitals allows for better and safer care at lower cost, enhancement of public health, and patient empowerment is needed. A learning CKD care system should aim to collect, accumulate and analyze data, interpret results, deliver a tailored message, and take action to change practices.

**Methods:** Adult non-pregnant participants 18 years of age or older with diagnosed CKD stages G3 toward G5ND (non-dialysis) were enrolled in the CKD clinic of Golden Jubilee Medical Center between April 2019 and March 2021. A robust and efficacious CKD clinic is always underpinned by applicable workflow (Figure 1).

**Results:** There were 454 patients identified as requiring multidisciplinary care (65% male; 35% female; mean age 72), and the majority of these were in stages 3a, 3b, and 4 CKD (34%, 31%, and 19%). Compliance with established practice guidelines prior to clinic restructuring and post-intervention were 30% vs. 31% for ASA use; 22% vs. 35% for vitamin D supplement; 44% vs. 48% for ACEi/ARB use; 78% vs. 95% for statin use. The age and gender adjustment identified the odds ratio (OR) of eGFR  $< 30$  ml/min/1.73m<sup>2</sup> as an independent risk factor for serum bicarbonate below 22 mEq/L was 5.02; 2.49-10.13;  $P < 0.001$ .

**Conclusions:** Through the established database and data analysis, an integrated care system should improve clinical outcomes and achieve the most cost effective care. Awareness of the process is important for clinicians who are aiming to advocate for effective changes in prevention or improvement of outcomes in CKD clinics.

**Funding:** Government Support - Non-U.S.

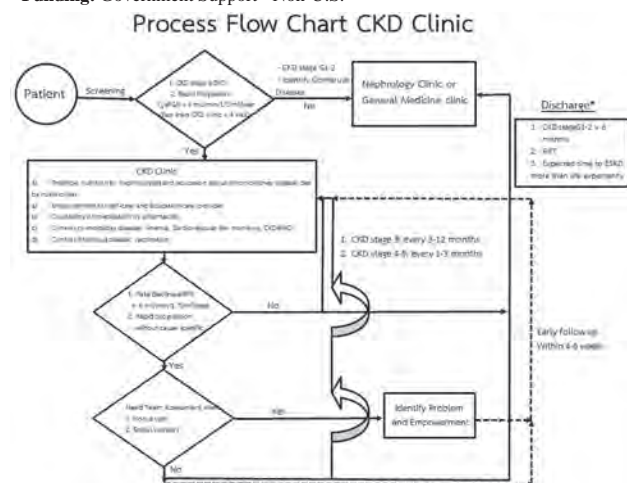

Figure 1.

## FR-PO944

## Associations of Urine Albumin to Protein Ratio With Histopathologic Lesions, Clinicopathologic Diagnoses, and Kidney Disease Progression

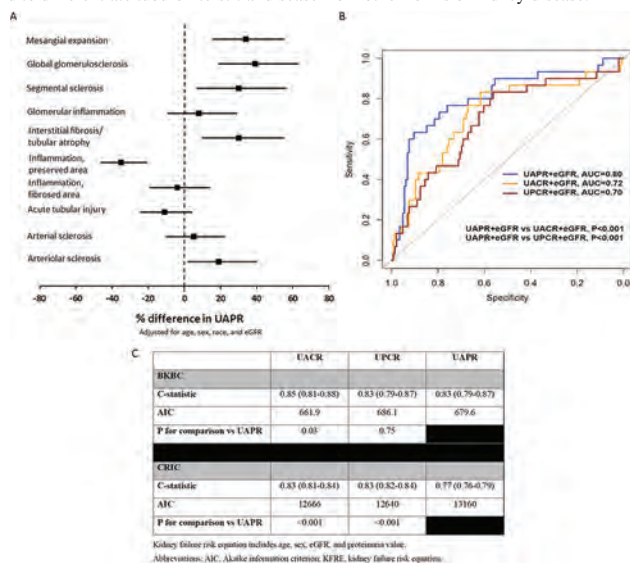

Anand Srivastava,<sup>1</sup> Afolarin A. Amodu,<sup>2</sup> Jing Liu,<sup>2</sup> Ashish Verma,<sup>2</sup> Suraj Sarvode Mothi,<sup>3</sup> Ragnar Palsson,<sup>3</sup> Isaac E. Stillman,<sup>5</sup> Bryan R. Kestenbaum,<sup>4</sup> Sushrut S. Waikar,<sup>2</sup> <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>Boston University School of Medicine, Boston, MA; <sup>3</sup>Brigham and Women's Hospital, Boston, MA; <sup>4</sup>University of Washington School of Medicine, Seattle, WA; <sup>5</sup>Beth Israel Deaconess Medical Center, Boston, MA.

**Background:** The relative content of urine albumin to other proteins may provide additional information on the site of the kidney lesion. The urine albumin to protein ratio (UAPR) may aid in the differential diagnosis of kidney disease but has not been studied in depth.

**Methods:** We evaluated the UAPR, UACR, UPCR, in 338 individuals who underwent clinically indicated native kidney biopsies from the Boston Kidney Biopsy Cohort (BKBC) Study and 2288 individuals with common forms of CKD from the Chronic Renal Insufficiency Cohort (CRIC) Study. Two kidney pathologists adjudicated biopsy specimens for semiquantitative scores of histopathology in BKBC. Multivariable linear regression models tested the association of UAPR with histopathologic lesions. We constructed receiver operating characteristic curves to compare the ability of UAPR, UACR, and UPCR to distinguish tubulointerstitial disease from other forms of kidney disease. We compared the performance of the kidney failure risk equation to predict 5-year risk of ESKD from proportional hazards models using UAPR, UACR, and UPCR through a likelihood ratio test.

**Results:** In BKBC and CRIC, the mean age was 53±17 and 57±11 years, mean baseline eGFR was 54.7±34.9 and 41.9±14.7 ml/min/1.73m<sup>2</sup>, median UPCR was 1.62 [0.6–3.7] and 0.5 [0.2–1.5] g/g creatinine, and median UAPR was 0.69 [0.55–0.77] and 0.50 [0.33–0.67] respectively. More severe chronic glomerular, tubulointerstitial, and vascular lesions were associated with higher UAPR. Inflammation of intact tubulointerstitial area was associated with lower UAPR (Figure 1A). UAPR outperformed UACR and UPCR to discriminate between tubulointerstitial disease and other forms of kidney diseases (Figure 1B). UAPR did not outperform UACR and UPCR as a predictor of kidney failure (Figure 1C).

**Conclusions:** UAPR may hold promise to identify specific histopathologic lesions and to differentiate tubulointerstitial disease from other forms of kidney disease.

## FR-PO945

## Importance of Promoting CKD Health Literacy in the Younger Generation: Data From the Niigata Prefectural Health and Nutrition Survey and Questionnaire Survey of High School Students in Japan

Yuya Suzuki,<sup>1</sup> Ryohei Kaseda,<sup>1</sup> Yusuke Nakagawa,<sup>1</sup> Mizuki Takeuchi,<sup>2</sup> Junko Nakamura,<sup>2</sup> Minako Wakasugi,<sup>1</sup> Ichiei Narita.<sup>1</sup> <sup>1</sup>Niigata University, Niigata, Japan; <sup>2</sup>Niigata University of Health and Welfare, Niigata, Japan.

**Background:** Promoting health literacy is important for preventing chronic kidney disease (CKD). However, few studies have investigated the level of CKD awareness. This study aimed to clarify the level of CKD awareness for providing helpful information to narrow down the target of CKD educational activities.

**Methods:** We analyzed data regarding CKD awareness from the Niigata Prefectural Health and Nutrition Survey conducted in 2019, Japan (N=1,225). Furthermore, we conducted a questionnaire survey among high school students (N=103).

**Results:** The proportion of people who had heard of CKD was 40.6% (men 32.9%, women 47.5%). When stratified by age, people aged 20–39 had heard less about CKD than those aged 40–59, and those over 60 (20.5%, 31.6%, and 51.5%, respectively). As the level of awareness regarding the term “CKD” was poor in the people aged 20–39, we

thereafter studied the CKD knowledge of high school students. The proportion of students who had heard of CKD was only 3.8%. While 80.5% of students knew that the function of kidney is to excrete waste products, 12.6% knew that kidney regulates blood pressure, and 24.3% knew its function of adjusting water content and electrolytes.

**Conclusions:** The level of awareness regarding the term “CKD” was poor in men aged 20–39. Additionally, high school students lacked knowledge of CKD and detailed kidney function. Educational activities for CKD should be more effective for the younger generations, and more in line with their diverse lifestyles. We have just begun activities for promoting CKD health literacy among teenage students, such as through giving lectures in high school classes.

**Funding:** Government Support - Non-U.S.

## FR-PO946

## Mechanistic Evaluation and In Vivo Validation of a Novel HIPK2 Inhibitor as Anti-Fibrosis Therapy for Kidney Disease

Kyung Lee,<sup>1</sup> Ye Feng,<sup>1</sup> Yibang Chen,<sup>1</sup> Richard T. Beresin,<sup>4</sup> Robert Drakas,<sup>2,3</sup> John C. He.<sup>1</sup> <sup>1</sup>Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; <sup>2</sup>Rila Therapeutics Inc., San Francisco, CA; <sup>3</sup>Shang Pharma Innovations Inc., San Francisco, CA; <sup>4</sup>ChemPartner Co., San Francisco, CA.

**Background:** HIPK2 is a multifaceted kinase that potentiates key pathways implicated in CKD pathogenesis (*i.e.*, TGF-β/Smad3, NF-κB, Wnt/β-catenin, and p53 signaling). Substantial experimental evidence indicates the renoprotective effects of HIPK2 loss. Since global HIPK2 KO mice are viable, fertile, and without overt defects, HIPK2 is considered an optimal druggable target for CKD and fibrosis. However, some oncogenic concerns remained with p53 inactivation with HIPK2 loss. We recently developed a small molecule HIPK2 inhibitor (HIPK2i) that allosterically inhibits HIPK2-Smad3 interaction without altering its kinase activity. It effectively and selectively mitigated TGF-β/Smad3 signaling in kidney tubular cells and kidney fibrosis, without affecting p53. Based on this parental HIPK2i molecule, we have developed superior HIPK2i analogs, including HIPK2i-174, with improved physicochemical properties with acceptable safety profiles. We examined the specific pathways inhibited by HIPK2i-174 in tubular cells and its effects in vivo.

**Methods:** We examined HIPK2i-174-affected gene expression by RNA sequencing and its effects on Smad3 phosphorylation and protein-protein interaction by IP/MS analysis in kidney cells. To expand the in vivo efficacy profile of HIPK2i-174, we have narrowed the effective dose range of HIPK2i-174 in Tg26 HIVAN model of CKD. We also examined the effects of concurrent treatment of ACE inhibitor, Ramipril, and HIPK2i-174 in Col4a3-deficient Alport syndrome mice.

**Results:** RNAseq analysis confirmed that HIPK2i-174 treatment effectively and selectively blocked TGF-β signaling in primary kidney tubular cells. HIPK2i-174 affected Smad3 phosphorylation and decreased its activity. It inhibited Smad3's interaction with several proteins including TAK, Ezrin, and EIF3F following TGF-β stimulation. In vivo, 30mg/kg dose of HIPK2i-174 was equally effective in attenuating proteinuria and fibrosis in Tg26 mice in comparison to higher doses (60 and 90mg/kg), and concurrent treatment of Ramipril and HIPK2i-174 in Col4a3-deficient Alport syndrome mice showed synergistic renoprotective effects with improved survival rate.

**Conclusions:** New HIPK2i-174 demonstrates favorable drug-like properties, safety profiles, and in vivo efficacy in CKD models, indicating its potential as a novel anti-fibrosis therapy in CKD.

**Funding:** Commercial Support - Rila Therapeutics, Inc.

## FR-PO947

## Renal Dysfunction due to Mitral Valve Repair-Induced Hemosiderosis With Partial Recovery After Corrective Surgery

Nicole Fernandez,<sup>1</sup> Gilad S. Guez,<sup>1</sup> Abdelaziz A. Elsanjak,<sup>1</sup> Christine A. Vanbeek,<sup>2</sup> <sup>1</sup>LewisGale Medical Center, Salem, VA; <sup>2</sup>AmeriPath Inc, Oklahoma City, OK.

**Introduction:** Renal hemosiderosis (RH) occurs when free hemoglobin is filtered by glomeruli and reabsorbed by proximal tubular cells (PTC). Hemosiderin subsequently accumulates within PTC lysosomes. Various conditions associated with intravascular hemolysis may lead to RH. Mechanical hemolysis is a known complication of severe heart valve disease and heart valve replacement. However, biopsy-proven RH is rarely reported following mitral valve (MV) repair. Here, we describe a case of renal dysfunction due to RH after MV repair with follow-up after corrective surgery.

**Case Description:** 77 year-old male with history of severe MV regurgitation and atrial fibrillation. He underwent a MV repair that included triangular resection, primary leaflet repair, and cosgrove posterior annuloplasty ring. This resulted in significant improvement in cardiac function. Baseline serum Cr was 0.9 mg/dL. 3 months post-procedure, he developed gross hematuria. U/A showed 3+ blood, 1+ protein, and 2-5 RBCs. Macrocytic anemia (Hb 7.6 g/dL, MCV 117 fL) and hemolysis (LDH 2,043 U/L, haptoglobin <20 mg/dL) were also noted. Peripheral smear was negative for schistocytes. Platelet count was normal. Serum Cr was elevated at 2.1 mg/dL. Renal biopsy showed abundant golden refractile granules within PTC cytoplasm on the H&E stain (Fig. 1A), which were confirmed to be hemosiderin on the Prussian Blue stain (Fig. 1B). Arteriosclerosis and mild interstitial fibrosis (~20%) were present. Glomeruli were normal. Transesophageal echo showed new mild MV regurgitation with a posteriorly directed annuloplasty ring and new small ventricular septal defect. He then underwent a corrective surgery. His hemolytic anemia and hemoglobinuria resolved within 2 months and serum Cr improved to 1.3 mg/dL.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Discussion:** The few prior case reports of MV repair-induced RH had clinical manifestations ranging from asymptomatic urinary abnormalities to renal dysfunction and did not describe repeat surgery. This case demonstrates that corrective surgery can lead to resolution of hemolysis and at least partial recovery of renal dysfunction.

## FR-PO948

### Coping and Adverse Kidney Outcomes

Tessa K. Novick,<sup>1</sup> James Custer,<sup>1</sup> Alan B. Zonderman,<sup>2</sup> Michele K. Evans,<sup>2</sup> Melissa D. Hladek,<sup>3</sup> Marie Kuczmarski,<sup>2</sup> Deidra C. Crews.<sup>3</sup> <sup>1</sup>The University of Texas at Austin Dell Medical School, Austin, TX; <sup>2</sup>National Institute on Aging, Bethesda, MD; <sup>3</sup>Johns Hopkins University, Baltimore, MD.

**Background:** We evaluated whether coping behaviors were associated with incident CKD and rapid kidney function decline, and whether coping behaviors mediated associations between depressive symptoms and outcomes.

**Methods:** We used data from the Healthy Aging in Neighborhoods of Diversity across the Life Span study for this analysis. Adaptive and maladaptive coping behaviors were measured using the Brief COPE Inventory at study visit 1, and analyzed as 2 continuous scales, with higher numbers reflecting higher self-reported use of the coping behaviors. We used multivariable logistic regression to assess the odds of incident CKD (eGFR <60 ml/min/1.73m<sup>2</sup> and ≥25% decline at study visits 3 or 4 in relation to visit 1) and rapid kidney function decline (loss of >3 ml/min/1.73m<sup>2</sup> per year) per point increase in coping scales. We evaluated for mediation of the relationship between depressive symptoms using the Center for Epidemiologic Studies Depression scale at visit 1 and outcomes by coping scales.

**Results:** Among 2336 participants, after a median of 8.2 years of follow-up, incident CKD and rapid kidney function decline occurred in 139 (9%) and 453 (31%) of participants. After multivariable adjustment, higher adaptive coping was associated with reduced odds of incident CKD (adjusted OR 0.97 per 1-point increase in adaptive score, 95% CI 0.95 – 0.99; Table 1). Higher adaptive coping mediated the association between high versus low depressive symptoms and incident CKD (average causal mediation effect [ACME] 0.009, p = 0.03 for adaptive; ACME -0.002, p = 0.90 for maladaptive). Coping behaviors were not associated with rapid decline, nor did they mediate associations between depressive symptoms and rapid decline.

**Conclusions:** Adaptive coping behaviors could represent a target for CKD prevention interventions.

**Funding:** Other NIH Support - National Institute on Aging

Table 1. Primary analysis- associations between coping scales and adverse kidney outcomes.

Primary Analysis: OR (95% CI) of the outcome per 1-point increase in coping scale		
Exposure	Model 1	Model 2
Incident CKD (N = 1173; Events = 113)		
Adaptive	0.98 (0.95 – 0.998)	0.97 (0.95 – 0.99)
Maladaptive	1.02 (0.98 – 1.05)	1.02 (0.98 – 1.06)
Rapid kidney function decline (N = 1147; Events = 341)		
Adaptive	0.99 (0.98 – 1.00)	0.99 (0.98 – 1.00)
Maladaptive	1.00 (0.98 – 1.02)	1.00 (0.98 – 1.02)

Model 1: coping scales + adjustment for age, sex, race, baseline eGFR, and poverty status.

Model 2: model 1 + adjustment for baseline hypertension and diabetes status.

## FR-PO949

### Calcific Non-Uremic Arteriolopathy: An Uncommon Disease Presenting Uncommonly

Stephanie M. Floyd,<sup>1,3</sup> Kristen N. Tillquist,<sup>1,3</sup> Ankur Shah.<sup>2,3</sup> <sup>1</sup>Kent Hospital, Warwick, RI; <sup>2</sup>Rhode Island Hospital, Providence, RI; <sup>3</sup>Brown University Warren Alpert Medical School, Providence, RI.

**Introduction:** Calcific uremic arteriolopathy (CUA) is a rare and devastating disease presenting with painful necrotic ulcers and eschars on extremities and areas of high adiposity, typically in patients with ESKD. It is commonly thought to be a manifestation of dysregulation of parathyroid hormone, calcium and phosphorus metabolism commonly seen in dialysis patients. However, studies have shown a subset of patients without pre-existing kidney disease who develop ‘non-uremic CUA’. We present a rare case of CUA in a patient without CKD in the setting of decompensated alcohol cirrhosis and warfarin use.

**Case Description:** A 39-year-old woman with alcoholic cirrhosis decompensated by encephalopathy, portal vein thrombosis transiently on warfarin, hyponatremia, and paracentesis dependent ascites presented with 2 weeks of bilateral leg pain and rash. Pain predated the lesions which blistered and progressed to a dark purple scabbed area. She had no history of kidney disease or hyperparathyroidism. Presenting exam was notable

for exquisitely tender purpuric plaques on bilateral thighs with right thigh erythema, induration and ulceration. Lab work showed Na 123 mmol/L, sCr 0.99 mg/dL, Ca 9.4 mg/dL, Po4 4.3 mg/dL and iPTH 65 pg/mL. Punch biopsy of the lesions revealed deposition of calcifications around small vessels and adipocyte lobules with fibrin thrombi and ischemic necrosis of the epidermis consistent with calciphylaxis. Sodium thiosulfate (STS) was started, with dose adjustment due to acidemia. Lesions remained stable for much of the hospitalization. Hospital course was complicated by hepatorenal syndrome, hyponatremia, and gastrointestinal bleeding. She developed worsening hemodynamic compromise and expired after transition to hospice.

**Discussion:** This case of CUA in the absence of kidney disease highlights risk factors that should increase clinical suspicion and multidisciplinary approach required to manage this disease. Pain often precedes the development of visible lesions as it did for our patient. Given the severity of the disease there should be a high clinical suspicion prompting early investigation of suspicious lesions. Management includes STS with close monitoring for acidemia. Second line therapies include bisphosphonates and hyperbaric O<sub>2</sub>. This case highlights underappreciated risk factors, the need for multidisciplinary care, early diagnosis, and difficulty in management.

## FR-PO950

### IL-33 (Interleukin 33)/ST2 (Interleukin 1 Receptor-Like 1) “Alarmin” Signaling Axis Regulates Innate Immune Response in Kidney Injury

Vikram Sabapathy, Gabrielle Costlow, Saleh Mohammad, Sanja Arandjelovic, Rahul Sharma. University of Virginia, Charlottesville, VA.

**Background:** Macrophages (MΦs) following kidney injury play a vital role in inflammation, repair, and fibrosis. MΦs are a highly heterogeneous class of cells that are activated upon tissue injury or inflammation. IL-33 is a nuclear-localized ‘alarmin’ cytokine that is typically released upon tissue damage. IL-33 signals through a receptor complex of IL-1 receptor-like 1 (IL1RL1), also known as ST2. ST2 is expressed in a variety of immune cells, including myeloid-derived cells such as MΦs. The MΦ regulation by IL-33 following its release with respect to kidney injury is unknown.

**Methods:** For myeloid cell-specific deletion of ST2, ST2<sup>fl/fl</sup> mice were crossed with LysM<sup>Cre</sup> mice. To examine the physiological relevance of endogenously expressed ST2+ myeloid cells during renal injury, we performed acute and chronic ischemia perfusion injury studies. The structure and function of the kidney were probed using flow cytometry, histology, immunohistochemistry, quantitative gene expression, and biochemical analysis. The invitro efferocytosis assay, RNA Seq, and seahorse assay were carried out using peritoneal MΦs and bone-marrow-derived MΦs.

**Results:** We hypothesized that the ST2 receptor could play a vital role in activating and mobilizing immune cells to the injury site. Preliminary results from metanalysis of single-cell RNA seq data analysis indicated high expression of ST2 receptor on macrophages. The *in vivo* data from the acute injury model indicated a loss of ST2 on myeloid cells resulted in attenuation of renal injury. On the contrary, results from the chronic injury model showed absence of IL33/ST2 signaling resulted in exacerbation of injury. Intriguingly, efferocytosis assay on both peritoneal and bone-marrow-derived MΦs demonstrated loss of ST2 on MΦs, resulting in a decrease in functional phagocytosis. Through seahorse assay, it was also observed that ST2 deficient peritoneal macrophages exhibited altered mitochondrial metabolism. RNA-seq data and gene ontology analysis showed loss of ST2 affects critical genes responsible for macrophage homeostasis.

**Conclusions:** Activation of the IL-33/ST2 signaling axis on MΦs is essential for the regulation of inflammation, apoptosis, and repair in renal tissue during inflammation and injury.

**Funding:** NIDDK Support

## FR-PO951

### LncRNA Antisense Noncoding RNA in the INK4 Locus (ANRIL) Mediates Endothelial Dysfunction Through Brain-Derived Neurotrophic Factor Downregulation in CKD

Hong Su, Zhimei Lv, Rong Wang. Department of Nephrology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China.

**Background:** Cardiovascular risk is increased in chronic kidney disease (CKD), endothelial dysfunction is the earliest phenomena of cardiovascular diseases, which could be induced by accumulation of uremic toxins in CKD. long non-coding RNA (lncRNA) antisense non-coding RNA in the INK4 locus (ANRIL) has been reported to be associated with a variety of vascular disease. And evidence also suggested that it may be involved in the occurrence and development of vascular disease in CKD.

**Methods:** The endothelial function in adult patients with CKD were evaluated and plasma ANRIL levels were measured. C57Bl/6J wild type or ANRIL knockout mice subjected to CKD were used to evaluate the role of ANRIL in vascular endothelial injury *in vivo*. Meanwhile, endothelial cells were incubated with serum derived from CKD patients and uremia toxins, then ANRIL expression was detected and the proteins that interact with ANRIL were explored. By making use of the gain- and loss-of-function approaches, ANRIL biological function and underlying mechanism were confirmed.

**Results:** In humans, the circulating ANRIL levels were increased and correlated with vascular endothelial dysfunction in patients with CKD, also negatively correlated with plasma brain-derived neurotrophic factor (BDNF) concentration. Then we found that ANRIL deficiency reversed the endothelial dysfunction and relative BDNF abnormal expression in CKD mice. In addition, serum derived from CKD patients and uremia toxins induced ANRIL upregulation in endothelial cells, and ANRIL mediated endothelial dysfunction through BDNF downregulation. Mechanically, we verified the binding of ANRIL to histone methyltransferase Enhancer of zeste homolog 2 (EZH2). Further

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

experiments found increased EZH2 and histone H3 lysine 27 trimethylation levels at the BDNF promoter region. Collectively, we demonstrated that ANRIL mediate BDNF transcriptional suppression through recruitment of EZH2 to the BDNF promoter region, then regulated the proteins expression related to endothelial function.

**Conclusions:** In the present study, we provide the evidence that ANRIL were associated with endothelial dysfunction in CKD, and ANRIL mediated endothelial dysfunction through BDNF downregulation. This may provide a new theoretical basis for the occurrence and development of endothelial dysfunction in CKD.

### Genetic and Pharmacological Activation of Endothelial Tie2 in Experimental CKD Alleviate Endothelial Injury and Reduces Tubulointerstitial Fibrosis by Decreasing Tubular PDGFB

Riikka S. Pietilä,<sup>1</sup> Susan E. Quaggin,<sup>3</sup> Christer Betsholtz,<sup>1,2</sup> Marie Jeansson.<sup>1,2</sup>  
<sup>1</sup>Uppsala Universitet, Uppsala, Sweden; <sup>2</sup>Karolinska Institutet, Stockholm, Sweden; <sup>3</sup>Northwestern University Feinberg School of Medicine, Chicago, IL.

**Background:** Progressive renal diseases are associated with loss of peritubular capillaries. Both mouse models and patients show a decline of endothelial tyrosine kinase receptor (Tie2) signaling in CKD. We hypothesized that loss of Tie2 signaling in blood vessels leads to endothelial dysfunction, resulting in ischemia and tubular injury with onset of Pdgfb expression. Pdgfb is a mitogen for fibroblasts/pericytes and tubular overexpression leads to activation and ECM production. Furthermore, we investigate if Tie2 activation can alleviate kidney injury in experimental CKD with a Tie2 activating antibody or by genetic deletion of Veptp (a negative Tie2 regulator).

**Methods:** To investigate this, we utilized inducible endothelial specific Tie2 knockout mice with endothelial lineage reporter also crossed to Pdgfra-H2b-GFP as a myofibroblast reporter. Mice were subjected to experimental CKD, the UUO model. Capillary density and perfusion, tubulointerstitial fibrosis, and Pdgfb expression were evaluated in renal cortex 1-10 days after UUO. To reduce kidney injury by increasing Tie2 signaling, mice with endothelial Veptp deficiency and mice treated with a Tie2 activating antibody were investigated after UUO.

**Results:** Endothelial loss of Tie2 in experimental CKD resulted in increased endothelial injury, loss of fenestrations, decreased perfusion, and increased tubulointerstitial fibrosis. We found no colocalization of endothelial lineage reporter and Pdgfra-H2b-GFP, hence, no evidence of endothelial-mesenchymal transition. Treatment with Tie2 activating antibody, or genetic deletion of endothelial Veptp, both reduced endothelial injury and maintained capillary density after UUO. UUO induced overexpression of Pdgfb was reduced by both Tie2 activating antibody and Veptp knockout as well as tubulointerstitial fibrosis.

**Conclusions:** Our results suggest that endothelial health is upstream of tubulointerstitial fibrosis and therapies to preserve vascular function are essential in CKD. In addition, we demonstrate that Tie2 signaling affects blood vessel function and that Tie2 activating agents should be explored as therapies for patients with CKD.

## FR-PO953

### Porcupine in the Kidney Protects Against Nephrotoxic Serum Nephritis by Inhibiting Innate Immune Signals

Xiaohan Lu, Jiafa Ren, Yi Wen, Ting Yang, Steven D. Crowley. Crowley Lab Duke University, Durham, NC.

**Background:** 10% of the world's population suffers from chronic kidney disease (CKD), and glomerulonephritis is a prominent cause of CKD. Wnt/ $\beta$ -catenin signaling can protect the renal tubule by modulating apoptosis and survival pathways. All 19 Wnt ligand isoforms must undergo porcupine (PORCN)-dependent Wnt O-acylation to be secreted. Therefore, we hypothesized that PORCN could mitigate CKD by driving Wnt secretion in the nephron.

**Methods:** To examine the role of tubular PORCN in CKD, we bred 129/SvEv *PORCN<sup>lox/lox</sup>* mice with the Pax8-rtTA and Tet-On lines to generate inducible renal epithelial cell PORCN knockout mice (PORCN iKKO). Mice with all 3 transgenes were used as the PORCN iKKO group, whereas mice lacking Pax8-rtTA or Tet-On transgene acted as wild-type (WT) controls. After 14 days of nephrotoxic serum nephritis (NTS), kidney injury was assessed by BUN, renal pathology, and kidney mRNA levels of injury/fibrosis biomarkers. The expression of cytokines and other innate immune signaling components was determined by real-time PCR. A TNF $\alpha$  antagonist (R7050, 12mg/body weight) was administered by intraperitoneal injection every other day during NTS.

**Results:** At baseline, mRNA levels for PORCN are reduced by 88% in the PORCN iKKO kidneys compared to WT littermates with preserved PORCN expression in other tissues. On day 14 of NTS, PORCN iKKO mice exhibited higher BUNs ( $202 \pm 12$  vs.  $101 \pm 38$ , mg/dL;  $p < 0.01$ ), and renal mRNA levels for NGAL ( $6.1 \pm 1.14$  vs.  $1.0 \pm 0.35$  au,  $p = 0.0013$ ), KIM-1 ( $2.5 \pm 0.65$  vs.  $1.0 \pm 0.26$  au,  $p = 0.046$ ), collagen I ( $2.4 \pm 0.31$  vs.  $1.0 \pm 0.38$  au,  $p = 0.025$ ), and fibronectin ( $2.5 \pm 0.35$  vs.  $1.0 \pm 0.27$  au,  $p = 0.006$ ) compared to WT. Renal protein levels for collagen I and fibronectin recapitulated the mRNA patterns. In the diseased kidneys, PORCN iKKO had a higher cytokine mRNA level for TNF $\alpha$  ( $2.6 \pm 0.67$  vs.  $1.0 \pm 0.30$  au,  $p = 0.036$ ) than WT at day 14 NTS. In addition, mRNAs for CD74 ( $2.7 \pm 0.53$  vs.  $1.0 \pm 0.44$  au,  $p = 0.038$ ) and OPN ( $3.6 \pm 0.68$  vs.  $1.0 \pm 0.49$  au,  $p = 0.012$ ), which are linked in a signaling network that lies downstream of Wnt/ $\beta$ -catenin were significantly increased in PORCN iKKO kidneys during NTS. Blockade of TNF $\alpha$  signaling blunted the exaggerated kidney injury in PORCN iKKO mice.

**Conclusions:** PORCN in the kidney limits autoimmune nephritis severity, suggesting that activation of PORCN-dependent Wnt/ $\beta$ -catenin signaling in the renal tubule may ameliorate CKD.

### Cellular Senescence in Repeated Low-Dose Repeated Cisplatin-Induced CKD

Siyao Li,<sup>1,2</sup> Man J. Livingston,<sup>2</sup> Zheng Dong.<sup>2</sup> <sup>1</sup>Central South University, Changsha, China; <sup>2</sup>Augusta University Department of Cellular Biology and Anatomy, Augusta, GA.

**Background:** Recent studies have implicated renal tubular cell senescence in the development of chronic kidney pathologies or CKD after acute kidney injury (AKI). Here we investigate the role of cellular senescence in chronic renal injury following cisplatin exposure, and the therapeutic potential of the senolytic drug ABT-263 in cisplatin-induced AKI to CKD progression.

**Methods:** BUMPT cells and C57/B6 Mice were subjected to repeated low-dose cisplatin (RLDC) treatment for in vitro and in vivo studies, respectively. In BUMPT cells, morphological change and senescent markers were measured after RLDC treatment. The conditioned medium derived from control (CT-CM) or RLDC(RLDC-CM) treated BUMPT cells were added to NRK49F fibroblasts to examine the effects on fibroblasts. Following RLDC treatment, BUMPT cells were treated with ABT-263 to investigate its specificity and validity in killing senescent cells. Clonogenic assay was conducted to test the pro-regenerative effect of ABT-263. In vivo, after 4wks of RLDC treatment, mice were given 4 consecutive cycles of ABT-263 injection. Then, GFR was monitored, and the mice were sacrificed 1 day later to collect blood and kidney tissues for analysis.

**Results:** In Vitro, RLDC induced an enlarged and flattened morphology in BUMPT cells, and decreased cell proliferation. These cells showed notably increased fibrotic markers and typical senescent changes, including positive SA- $\beta$ gal staining, increases of p21, p53, decreases of LaminB1, and elevated transcription of CDKN1A and CDKN2A. Moreover, RLDC-CM induced higher expression of fibrotic markers in NRK49F cells, indicating the production and secretion of pro-fibrotic factors by RLDC-treated tubular cells. ABT-263 selectively killed senescent cells and promoted cell regeneration as shown by higher clonogenic activities. In Vivo, ABT-263 suppressed the expression of p53, p21 and p16, abolished SA- $\beta$  gal staining, and decreased the  $\gamma$ H2AX/Ki67<sup>+</sup> senescent cells. Mice treated with ABT-263 after RLDC showed improved renal function, better kidney structure, and attenuated fibrosis.

**Conclusions:** Tubular cell senescence is an important factor in the pathogenesis of chronic kidney problems following cisplatin exposure. Clearance of senescent cells by senolytic drugs may be a useful therapeutic strategy for improving kidney repair and functional recovery after cisplatin chemotherapy in cancer patients.

### Cooperative Action of p53 and Autophagy Delays Kidney Aging by Suppressing DNA Damage and the Senescence-Associated Secretory Phenotype

Satoshi Minami,<sup>1</sup> Takeshi Yamamoto,<sup>1</sup> Yoshitsugu Takabatake,<sup>1</sup> Atsushi Takahashi,<sup>1</sup> Tomoko Namba,<sup>1</sup> Jun Matsuda,<sup>1</sup> Shinsuke Sakai,<sup>1</sup> Jun Nakamura,<sup>1</sup> Shihomi Maeda,<sup>1</sup> Sho Matsui,<sup>1</sup> Motoko Yanagita,<sup>2</sup> Yoshitaka Isaka.<sup>1</sup> <sup>1</sup>Department of Nephrology, Osaka University Graduate School of Medicine, Suita, Japan; <sup>2</sup>Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.

**Background:** p53 is a crucial tumor suppressor and has long been recognized to suppress cancer through the induction of cell-cycle-arrest or apoptosis programs. Recently the diverse and global functions of p53 in the kidney under disease pathogenesis, especially acute kidney injury (AKI), has been studied intensively; however, its pathophysiological role in kidney aging remains uncertain.

**Methods:** Using proximal tubular epithelial cell (PTEC)-specific *p53*-deficient (*p53<sup>fl/fl</sup>*-TSKO) mice and PTEC-specific *atg5*-deficient (*atg5<sup>fl/fl</sup>*-TSKO) mice, we investigated the role of p53 and a possible interplay between p53 and autophagy in the aged kidney. To examine whether and how the interaction between p53 and autophagy impinges on kidney aging, we assessed the phenotypes of PTEC-specific *p53* and *atg5*-deficient (TSDKO) mice at 24 months.

**Results:** *p53<sup>fl/fl</sup>*-TSKO at 24 months exhibited DNA damage, thereby upregulating autophagy. On the other hand, aged *atg5<sup>fl/fl</sup>*-TSKO mice activated p53. Aged TSDKO mice deteriorated renal histology and function, accompanied by accelerated tubular senescence and the senescence-associated secretory phenotype (SASP), thus facilitating tertiary lymphoid tissues (TLTs) development. Mechanistically, autophagy suppressed the SASP by degrading cytoplasmic chromatin fragments (CCFs) in aged kidneys.

**Conclusions:** p53 and autophagy cooperatively delay kidney aging by suppressing DNA damage and the SASP. These findings provide key insights into the pathophysiology of kidney aging and clues to a novel intervention that might prevent age-related kidney disease and maintain kidney health.

## FR-PO956

**Empagliflozin Reduces Kidney Fibrosis and Improves Kidney Function by Alternative Macrophage Activation in Rats With 5/6-Nephrectomy**

Hongwei Wu, Berthold Hoher. *Universitätsklinikum Mannheim, Mannheim, Germany.*

**Background:** Sodium glucose cotransporter 2 (SGLT2) inhibitors originally developed for the treatment of type 2 diabetes are clinically very effective drugs halting chronic kidney disease progression. The underlying mechanisms are, however, not fully understood.

**Methods:** We generated single-cell transcriptomes of kidneys from rats with 5/6 nephrectomy before and after SGLT2 inhibitors treatment by single-cell RNA sequencing.

**Results:** Empagliflozin treatment decreased BUN, creatinine, and urinary albumin excretion compared to placebo by 39.8%, 34.1%, and 55%, respectively ( $p < 0.01$  in all cases). Renal interstitial fibrosis and glomerulosclerosis were likewise decreased by 51% and 66.8%, respectively ( $p < 0.05$  in all cases). 14 distinct kidney cell clusters could be identified by scRNA-seq. The polarization of M2 macrophages from state 1 (CD206<sup>+</sup>CD68<sup>+</sup> M2 macrophages) to state 5 (CD206<sup>+</sup>CD68<sup>+</sup> M2 macrophages) was the main pro-fibrotic process, as CD206<sup>+</sup>CD68<sup>+</sup> M2 macrophages highly expressed fibrosis-promoting genes and can convert into fibrocytes. Empagliflozin remarkably inhibited the expression of fibrosis-promoting (*IFG1* and *TREM2*) and polarization-associated genes (*GPNMB*, *LGALS3*, *PRDX5*, and *CTSB*) in CD206<sup>+</sup>CD68<sup>+</sup> M2 macrophages and attenuated inflammatory signals from CD8<sup>+</sup> effector T cells. The inhibitory effect of empagliflozin on CD206<sup>+</sup>CD68<sup>+</sup> M2 macrophages polarization was mainly achieved by affecting the mTOR-mitophagy pathway.

**Conclusions:** The beneficial effects of empagliflozin on kidney function and morphology in 5/6 nephrectomized rats with established CKD are at least partially due to an inhibition of CD206<sup>+</sup>CD68<sup>+</sup> M2 macrophage polarization by targeting mTOR and mitophagy pathways and attenuating inflammatory signals from CD8<sup>+</sup> effector T cells.

**Excessive Mitochondrial Copper Load Driven by Upregulated Copper Transporter 1 Contributes to Mitochondrial Dysfunction and Renal Fibrosis**

Saiya Zhu, Chen Yu. *Shanghai Tongji Hospital, Shanghai, China.*

**Background:** Copper is an essential trace element for eukaryotes. Our previous study indicated that intracellular copper overload plays an important role in renal fibrosis. However, the underlying mechanism remains largely unknown. In this study, we found copper ions in cells were mainly accumulated in mitochondria, which damage the structure and function of mitochondria. Furthermore, copper transporter 1 (CTR1), the major transporter for copper influx, was significantly increased in fibrotic kidneys. The activity of cytochrome c oxidase (COX), a copper coenzyme mediating the final step in the electron transport chain, was decreased. Downregulation of CTR1 decreased mitochondrial copper overload. Therefore, we proposed that CTR1 might be involved in mitochondrial copper overload and renal fibrosis.

**Methods:** Expression of CTR1 was examined in fibrotic kidneys of patients, ischemia-reperfusion injury (IRI 28d) mice model and TGF- $\beta$ 1-treated tubular epithelial cells. We also use stable CTR1 knockdown cell lines in vitro, and in vivo, we use CTR1 transgenic mice subjected to IRI operation. Copper chelator tetrathiomolybdate (TM), ICP-MS, mitoSOX Red, electron microscopy, realtime-PCR and western blot analysis were applied in the current study.

**Results:** We found that stimulated by TGF- $\beta$ 1, COX activity was declined. Mitochondria and cytosol, especially mitochondria, accumulated a large amount of copper in fibrotic kidney tissues. Furthermore, we found CTR1 expression was increased in fibrotic kidneys from chronic kidney disease patients, in vivo and in vitro. More importantly, compared to WT mice, CTR1<sup>-/-</sup> mice subjected to ischemia-reperfusion injury (IRI) had reduced mitochondrial copper level, and ameliorated mitochondrial function and renal fibrosis, as evidenced by improving mitochondrial structure, inhibiting mtROS

production and reducing expression of  $\alpha$ -smooth muscle actin ( $\alpha$ -SMA), collagen I and fibronectin. In addition, mitochondrial function and kidney fibrosis were improved in IRI mice kidney after TM treatment.

**Conclusions:** Collectively, our study showed that copper overload in mitochondria could damage mitochondrial function and lead to renal fibrosis. Among which CTR1 plays an incomparable role in the mitochondrial copper overload. Copper overload inhibits the activity of COX and impairs mitochondria, subsequently leading to renal fibrosis.

## FR-PO958

**Kidney Tubule Polyploidization Is a Novel Target to Block CKD Progression After AKI**

Letizia De Chiara, Elena Lazzeri, Paola Romagnani. *Universita degli Studi di Firenze, Firenze, Italy.*

**Background:** Acute Kidney Injury (AKI) is characterized by a rapid deterioration of kidney function and represents a global healthcare issue. In addition, AKI survivors frequently develop chronic kidney disease (CKD). Tubular epithelial cells (TC) respond to AKI by triggering polyploidy, a condition in which a normally diploid cell acquires additional sets of chromosomes. Polyploidy offers several advantages and in the kidney we have demonstrated to be an adaptive response to survive after AKI. However, polyploidization in the absence of damage drives CKD progression. Building on these novel paradigms we hypothesized that: 1) polyploid TC are a heterogeneous population with distinctive features and 2) polyploid TC may represent a novel target to successfully prevent CKD progression.

**Methods:** We employed in vivo models based on the Fluorescence Ubiquitin Cell Cycle Indicator (FUCCI) technology in combination with YAP1 modulation or conditional deletion. In these models, mice were subjected to ischemia reperfusion injury or nephrotoxic AKI. Mice were treated with different combination of compounds at different times and analyzed by single cell-RNA sequencing (scRNA-seq) analysis, cell sorting, FACS analysis, super-resolution microscopy.

**Results:** After AKI, YAP1 is activated triggering TC polyploidization. Conditional TC deletion of YAP1 resulted in a reduced number of polyploid cells, worsened kidney function and a dramatic reduction of mouse survival. However, delayed block of YAP1-driven polyploidy after AKI by pharmacological inhibition prevented AKI-CKD transition by attenuating continuous cycles of polyploidization in TC. Senolytic therapy proved that cycling polyploid TC were responsible for the senescent profibrotic phenotype acquired over the time by polyploid TC and the primary trigger of CKD progression. scRNA-seq and tubular specific YAP1 deletion triggered after AKI excluded any systemic effect of compound administration and demonstrated that the observed protective effect is mediated exclusively by TC and not by other cells.

**Conclusions:** In conclusion, we demonstrated that: 1) continuously cycling polyploid TC and not growth arrested polyploid TC are senescent and the primary driver of CKD; 2) blocking cycling polyploid TC in the right window of opportunity is sufficient to prevent AKI-CKD transition with important translational implications in clinical setting.

## FR-PO959

**Hematopoietic Cell Kinase (HCK) Is a Key Regulator of Macrophage Function in Kidney Fibrosis**

Chengguo Wei, Man Chen, Weijia Zhang, Kyung Lee, John C. He. *Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY.*

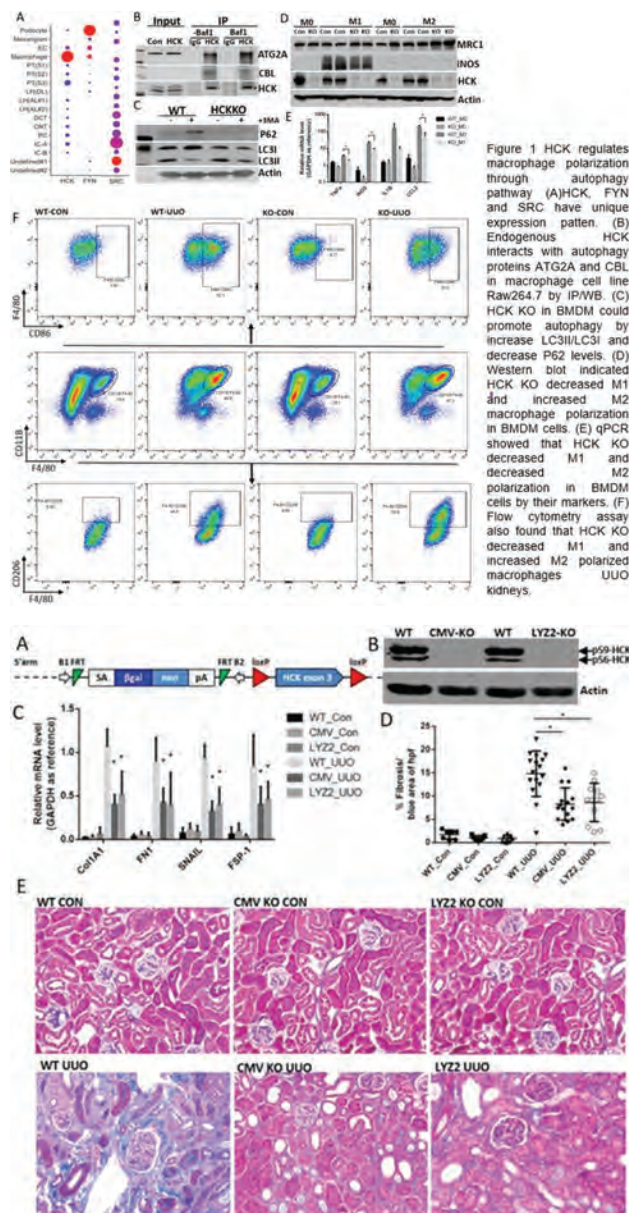

**Background:** Our previous study identified HCK as a regulator of renal fibrosis. We recently find HCK could regulate autophagy in macrophages. Here we tested HCK's role in macrophage function in the context of renal fibrosis.

**Methods:** Bone marrow-derived macrophage (BMDM) and RAW264.7 macrophage in vitro and UUO in vivo for global, macrophage HCK-KO and WT mice were used to determine the effects of HCK on macrophage autophagy and activation.

**Results:** Single cell sequencing data confirmed that HCK is mainly expressed in macrophages (Fig. 1A). IP/MS identified HCK interacts with autophagy proteins ATG2A and CBL(data not shown) and confirmed by IP/WB (Fig. 1B) in macrophage cell line RAW264.7. KO of HCK increased autophagy activity as increased LC3II/LC3I ratio and decreased P62 in BMDM (Fig. 1C). We also found KO of HCK decreased macrophage M1 polarization and increased M2 polarization in BMDM by qPCR, WB(Fig. 1D, 1E), and flow cytometry (Fig. 1F). In the UUO model, we found that global and macrophage-specific HCK-KO mice had significantly attenuated tubulointerstitial fibrosis with decreased mRNA profibrotic markers (Fig. 2C) and Masson's trichrome staining (Fig. 2D, 2E).

**Conclusions:** HCK promotes kidney fibrosis by suppressing macrophage autophagy and inducing macrophage polarization.

**Figure 2. HCK knockout globally and in macrophage ameliorated kidney fibrosis in a murine UUO model.** (A) Strategy of loxP-HCK knock-out mice. (B) Western blot indicated HCK KO in BMDM. (C) mRNA-levels of pro-fibrotic markers by qPCR for control and UUO kidneys. (D) Morphometric quantification (n = 5 animals; 5 random hpf/animal) of the fibrosis positive area for Masson stain. (E) Masson trichrome stain of representative 200X images from WT, global (CMV KO) and macrophage (LY2Z KO) HCK knockout mice at 7 days post-UUO (D). (C and D) \*p < 0.05.

## FR-PO960

### The Neuropeptide SP/NK-1R Axis Promotes Renal Interstitial Fibrosis via MAPK Pathway in Unilateral Ureteral Obstruction Mice

Enyi Zhu, Ming Zhong, Yang Liu, Yu Liu, Jinhong Li, Zhihua Zheng. The Seventh Affiliated Hospital Sun Yat-sen University, Shenzhen, China.

**Background:** Renal interstitial fibrosis is considered to be the major contributor to chronic progressive kidney function loss, and suggested as a significant predictor of renal survival in chronic kidney disease. The potential mechanism which initiates the profibrogenic process during kidney injury is not completely understood. Substance P (SP) is a proinflammatory neuropeptide that binds to its high-affinity receptor neurokinin-1 receptor (NK-1R) and it has been involved in multiple fibrotic diseases. However, the role of SP/NK-1R axis in renal interstitial fibrosis is largely undefined.

**Methods:** To investigate the role of SP/NK-1R in renal interstitial fibrosis, mice were administrated with NK-1R pharmacological inhibitor or SP during unilateral ureteral obstruction (UUO) and NK-1R<sup>-/-</sup> mice were subjected to UUO. Cell counting,

colony formation, apoptosis, cell cycle and RNA-seq analysis were performed in tubular epithelium cells to explore the mechanism of SP/NK-1R.

**Results:** SP and NK-1R were overexpressed in renal tubular epithelial cells of mice after UUO. In addition, pharmacological and genetic inhibition of NK-1R resulted in reduction of interstitial inflammation, fibrosis and renal cell apoptosis, whereas SP treatment aggravated UUO-induced progressive damage. *In vitro*, SP administration suppressed growth of NK-1R-overexpressed HK-2 cells, and promoted apoptosis, G2/M arrest and expression of profibrogenic genes, which could be dramatically rescued by NK-1R inhibitor. Mechanistically, RNA-seq analysis revealed that differential expressed genes between NK-1R-overexpressed HK-2 cells with and without SP treatment were mainly enriched in MAPK signaling. Consistently, phosphorylated p38/JNK levels were increased in SP-treated cells and mice obstructed kidneys. Furthermore, inhibition of NK-1R decreased expression of phosphorylated p38/JNK in SP-treated cells and mice subjected to UUO. In support, the p38 or JNK specific inhibitors partly alleviated SP-mediated effect, and intriguingly, combined use of p38/JNK inhibitors further ameliorated it.

**Conclusions:** These results demonstrate that neuropeptide SP/NK-1R axis plays an important role in kidney interstitial fibrosis via activating the MAPK pathway of renal tubular epithelial cells, which may be a promising therapeutic target for chronic kidney disease.

## FR-PO961

### Arginine Metabolism Regulates the Transcription Factor Nrf2 and Prevents Renal Interstitial Fibrosis Through Tubular Spermidine Production

Seishi Aihara, Kumiko Torisu, Toshiaki Nakano, Takanari Kitazono. Kyushu University, Fukuoka, Japan.

**Background:** Our previous research showed that arginase 2 (ARG2) is a mediator of ischemia-reperfusion injury in the kidney through regulation of nitrosative stress. However, the physiologic role of ARG2 or the metabolite polyamines in renal interstitial fibrosis remains poorly understood.

**Methods:** Metabolic change in kidney fibrosis was examined using unilateral ureteral obstruction (UUO) model mice by mass spectrometry. In human proximal tubule cells (HK-2), changes in expression of ARG2 and its metabolites, polyamines and spermidine (Spd), during oxidative stress were examined. The effects of Spd on Nrf2 activation and autophagy were investigated. UUO models of wild type and Arg2 knockout (KO) mice were employed and kidney fibrosis was evaluated.

**Results:** "Arginine and proline metabolism" and "arginine biosynthesis" were most altered in UUO kidney. In HK-2 cells, the expression of ARG2 and polyamines were increased in hydrogen peroxide-treated cells. Furthermore, the polyamines and Spd were decreased in ARG2 knockdown. Spd strongly induced Nrf2, an antioxidant transcription factor, accompanied with induced expression of target genes and also strongly induced autophagic flux. Fibrotic signals such as TGFβ1 and collagen I in renal tubules were suppressed by Spd. The kidney of mice lacking Arg2 showed significantly exacerbated fibrosis and increased expression of collagen I, αSMA and TGFβ compared to the wild type UUO kidney. An activation of Nrf2 and downstream gene expression were suppressed in Arg2 knockout UUO kidneys.

**Conclusions:** Our data support that arginine metabolism is activated to produce Spd, which activates Nrf2 and autophagy, resulting in a protective effect against kidney fibrosis.

## FR-PO962

### The Protective Role of GPER1 Against Renal Fibrosis

Xiangchen Gu,<sup>1,2</sup> Lin Xie,<sup>2</sup> Min Chen,<sup>2</sup> Yi Wang,<sup>2</sup> Jingyuan Xie.<sup>1</sup> <sup>1</sup>Department of Nephrology, Shanghai Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; <sup>2</sup>Department of Nephrology, Yueyang Hospital of Integrated Traditional And Western Medicine, Shanghai University of Traditional Chinese Medicine, Shanghai, China.

**Background:** Male patients have a higher prevalence of CKD and increased rates of ESRD than those observed in female patients. Many factors are believed to be involved in this phenomenon. Whether GPER1 (G protein-coupled estrogen receptor1), a de-novo estrogen receptor, plays a protective role against renal fibrosis remains unclear.

**Methods:** Using CRISPR/Cas9 gene-editing technique, we generated *Gper1* global knockout mice. We subjected the mice to Aristolochic acid (AA) and Folic acid (FA) injection. We further analyzed the differentially expressed genes by bulk RNA-sequencing. We also cultured primary tubular epithelial cells from wild-type and *Gper1*<sup>-/-</sup> mice and treated the cells with TGFβ1. Finally, we treated AA-injected and FA-injected mice with a GPER1 agonist.

**Results:** In both AA and FA injection models, *Gper1* knockout mice exhibited more severe renal fibrosis, increased inflammation infiltration, and decreased fatty acid oxidation, compared to wild-type mice. Bulk RNA sequencing also indicated a down-regulation of fatty acid oxidation and upregulation of inflammation in *Gper1*<sup>-/-</sup> renal tissues. In primary cell culture, TGFβ1-treated *Gper1*<sup>-/-</sup> TECs showed a reduction in the fatty acid oxidation pathway. Further, GPER1 agonist ameliorated renal fibrosis in AA-injected and FA-injected mouse models.

**Conclusions:** These results suggest that GPER1 may play a protective role against renal fibrosis through the fatty acid oxidation pathway. Activation of GPER1 expression may provide a new therapeutic target for CKD treatment.

**Funding:** Government Support - Non-U.S.

## FR-PO963

**Macrophage-Specific Deletion of Cytosolic Nucleotide Sensors Ameliorates Kidney Fibrosis and Inflammation**

Andrea Sanchez-Navarro, Poonam Dhillon, Katalin Susztak. *University of Pennsylvania, Philadelphia, PA.*

**Background:** The cytosolic DNA sensors, such as cGAS-STING are part of the innate immune system providing the first line of defense against cytosolic viruses and prime and activate the adaptive immune system. Our previous studies suggested that global deletion or pharmacological inhibition of STING ameliorates fibrosis. Here we analyzed the cell-type specific role of cGAS-STING.

**Methods:** We generated a macrophage-specific cGAS and STING knockout mice by crossing the cGAS<sup>flx</sup> and STING<sup>flx</sup> mice with Lyz2-Cre animals. We induced kidney injury by unilateral ureteral obstruction (UUO) or cisplatin injection. The degree of kidney injury was estimated based on blood biomarkers, BUN, creatinine, renal histology and kidney gene and protein expression changes by QRT-PCR and Western blots, respectively. We studied macrophages (RAW264.7) cells in vitro using cGAS and STING siRNA.

**Results:** Mice with macrophage-specific deletion of cGAS or STING was healthy at baseline. Wild type cisplatin injected animals had increased expression of kidney injury markers (Ngal, Kim1), which was lower in cGAS and STING knock-out mice. UUO mice showed higher expression of fibrosis associated markers, which again was ameliorated in macrophage specific cGAS and STING knock-out mice. Markers of inflammation Mcp1, Interleukin-6 (Il-6) and Interleukin-1 $\beta$  (Il-1 $\beta$ ) was markedly lower in both models. Expression of Il-6 and Il-1 $\beta$  was lower peritoneal macrophages isolated from Lyz2Cre-STING mice. Moreover, silencing STING in cultured mice macrophages cell line ameliorated M1 pro-inflammatory polarization and enhanced M2 anti-inflammatory polarization.

**Conclusions:** cGAS-STING mediated macrophage polarization play an important role in the inflammatory and profibrotic response in kidney injury and fibrosis.

**Funding:** NIDDK Support

## FR-PO964

**Transcription Factor Foxp2 Promotes TGF- $\beta$ 1-Induced Kidney Fibrosis in Obstructive Nephropathy**

Yixin Zou, Wai Han Yiu, Sarah W.Y. Lok, Jingyuan Ma, Loretta Y.Y. Chan, Sydney C. Tang. *The University of Hong Kong, Hong Kong, Hong Kong.*

**Background:** Forkhead Box P2 protein (Foxp2) is a transcription factor involved in multiple biological activities including organ development, tissue injury and tumor growth. Recent studies showed that Foxp2 regulates epithelial-mesenchymal transition (EMT) during tumorigenesis. Given that EMT is a crucial process in kidney fibrosis, we aim to investigate whether Foxp2 has a functional role in the progression of chronic kidney disease.

**Methods:** Foxp2 expression was evaluated in cultured tubular epithelial cells (C1.1) treated with TGF- $\beta$ 1 (10ng/mL). Foxp2 was knocked down by siRNA prior to TGF- $\beta$ 1 stimulation. Tubule-specific Foxp2 knockout (Ksp-Foxp2 KO) mice and wild type control (WT) were generated by Cre-LoxP strategy and subjected to unilateral ureteral obstruction (UUO). Kidneys were collected at day 7 after UUO for the assessment of kidney fibrosis by real-time qPCR, Western blotting and immunohistochemical staining.

**Results:** In C1.1 cells, Foxp2 expression was significantly induced by TGF- $\beta$ 1, which was partly inhibited by Smad3-specific inhibitor. Knocking down Foxp2 significantly suppressed the expression levels of TGF- $\beta$ 1-induced fibrotic markers collagen 1, PAI-1 and restored the loss of epithelial marker E-cadherin. In the UUO kidneys, TGF- $\beta$ 1 expression level was lower in Ksp-Foxp2 KO group compared to that of WT. Collagen deposition and expression of fibrosis markers fibronectin and PAI-1, and macrophage infiltration were greatly reduced in UUO kidneys from Foxp2 KO compared to WT group.

**Conclusions:** Foxp2 promotes TGF- $\beta$ 1-induced EMT and fibrotic changes in obstructed kidneys and may become a novel therapeutic target for kidney fibrosis.

**STING Facilitates Renal Fibrosis Induced by Ischemia-Reperfusion Injury Through Regulation of Glycolysis**

Anni Jiang. *Department of Nephrology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

**Background:** Renal fibrosis is the main pathological manifestation of chronic kidney disease (CKD). Studies have shown that the hypoxic microenvironment caused by ischemia-reperfusion injury (IRI) plays a key role in the progression of CKD, but the specific mechanism is not clear. A recent research hotspot, stimulator of interferon genes (STING), has been shown to have an important role in immune and inflammatory responses associated with kidney diseases, and its functional significance in the field of CKD remains poorly understood. Our aim was to investigate the role and mechanism of STING in IRI-associated renal fibrosis.

**Methods:** Wild-type C57BL/6J male mice were selected to interfere with the expression of STING by renal injection of STING lentivirus and intraperitoneal injection of STING inhibitor C-176. The model of IRI was established by unilateral renal pedicle clamping, and the mice were euthanized 7 days after reperfusion. In vitro, human kidney 2 (HK2) transfected with STING lentivirus were stimulated by hypoxia for 48 hours. Blood was collected from mice for serum biochemistry, and kidney tissue and HK2 cells

were collected to detect the expression of STING and glycolysis changes (extracellular acidification rate, hexokinase activity and phosphofructokinase activity). The interaction of STING and its downstream interferon regulatory factor 3 (IRF3) with 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase 3 (PFKFB3) was detected by immunoprecipitation.

**Results:** The expression of STING increased significantly in the model of renal fibrosis induced by IRI. In vitro, hypoxic stimulation caused epithelial mesenchymal transformation (EMT) in HK2 cells with concomitant upregulation of STING expression. Seven days after IRI, fibrosis markers and glycolysis levels were less elevated in the kidneys of mice with inhibited STING expression than in those of wild-type mice. Immunoprecipitation showed that STING/IRF3 interacted with PFKFB3 and that inhibition of STING expression in HK2 cells reduced the level of hypoxia-induced glycolysis and blocked EMT.

**Conclusions:** STING activated in hypoxic environment regulates the level of glycolysis through IRF3/PFKFB3 pathway, which leads to EMT in renal tubular epithelial cells and promotes the progression of renal fibrosis. Down-regulation of STING attenuates IRI-induced renal fibrosis by inhibiting the level of glycolysis.

**RIPK3-MLKL Signaling Drives Mitochondrial Dysfunction and Kidney Fibrosis During CKD**

Anjali Srivastava, Bhawna Tomar, Shrikant R. Mulay. *CSIR-Central Drug Research Institute, Lucknow, India.*

**Background:** TGF $\beta$  is believed to be a major driver of kidney fibrosis involved in all forms of chronic kidney diseases (CKD). Despite several reports, anti-TGF $\beta$  therapies have consistently failed to reduce kidney fibrosis in CKD patients indicating the need for novel therapeutic strategies. Here, we aim to investigate the molecular mechanisms of kidney fibrosis during CKD.

**Methods:** We performed a series of in-vitro and in-vivo experiments using murine fibroblasts cell lines and an oxalate-induced CKD mouse model, respectively. We used biochemical analysis, RNA sequencing, histology, immunohistochemistry, immunoblotting, etc. techniques to understand the extent of injury, inflammation, and fibrosis in the kidney.

**Results:** First we analyzed increased expressions of necroptosis signaling molecules (RIPK1, RIPK3, MLKL) and profibrotic markers in both humans and oxalate-induced mice fibrotic kidneys subjected to RNA seq. Next, using CRISPR/Cas9 we generated stable Ripk3 and MLkl-deficient murine fibroblasts. Further, we suppressed the expression of RIPK3 and MLKL specifically in kidneys by renal intraparenchymal injections of lentivirus containing CRISPR gRNAs for either RIPK3 or MLKL along with Cas9 protein preceding oxalate-induced CKD. Knockdown of either RIPK3 or MLKL exerted overall renoprotective effects and rmTGF $\beta$ -induced fibrotic response. Moreover, CKD mice were administered either TGF $\beta$  signaling inhibitor SIS3 or RIPK1 inhibitor necrostatin-1s, RIPK3 inhibitor dabrafenib with or without SIS3. Similarly, fibroblasts were treated with inhibitors before rmTGF $\beta$  exposure. Inhibition of RIPK3 or MLKL also prevented overall fibrotic response. Interestingly, rmTGF $\beta$  exposed RIPK3-MLKL deficient fibroblasts did not induce mitochondrial ROS. Declined mitochondrial genes expression and impaired oxidative phosphorylation was observed in CKD mice kidneys subjected to RNA seq. Also, we observed RIPK3-MLKL translocation on mitochondria isolated from oxalate-induced CKD mice kidneys and rmTGF $\beta$  exposed fibroblasts, confirming that mitochondrial RIPK3 and MLKL translocation induce mitochondrial dysfunction.

**Conclusions:** We show that TGF $\beta$  induces translocation of RIPK3-MLKL to mitochondria, where it induces ROS production subsequently leading to Smad2/3 phosphorylation and ECM production. Together, RIPK1, RIPK3, MLKL, and Smad2/3 are molecular targets to inhibit kidney fibrosis during CKD.

## FR-PO967

**Reduction of DUSP4 Enhances Macrophage Infiltration and Contribution to Renal Fibrosis**

Marina Rousseau, Pedro M. Geraldes. *Universite de Sherbrooke, Sherbrooke, QC, Canada.*

**Background:** Chronic kidney disease (CKD) affects 15% of the world population and is the leading cause of end-stage kidney disease in which 45% of patients are patients with diabetes. Patients with advanced CKD will eventually need dialysis or renal transplantation. Renal interstitial fibrosis (RIF) is an essential characteristic of CKD and is associated with renal function decline. Although macrophages are known to play a role in the generation of fibrosis, their contribution to RIF is not well elucidated. Our laboratory has previously shown reduced DUSP4 expression in the kidney of diabetic mice and patients, and the deletion of DUSP4 in diabetic mice lead to RIF. Objective: Evaluate the role of DUSP4 in macrophage related RIF generation.

**Methods:** Mice with (*Dusp4*<sup>WT</sup>) or without DUSP4 (*Dusp4*<sup>KO</sup>) were subjected to toxin- (4 weeks of adenine-rich diet) and obstructive-induced (UUO) RIF. Renal function was evaluated by 24-hour urinary albumin excretion. To evaluate the role of DUSP4 in macrophage infiltration, *Dusp4*<sup>WT</sup> and *Dusp4*<sup>KO</sup> were irradiated and transplanted with the bone marrow of the opposite group (generating WT mice specifically DUSP4 KO in the macrophages (*Dusp4*<sup>WT/mBKO</sup>) and DUSP4 null mice with regular expression of DUSP4 in the macrophages (*Dusp4*<sup>KO/mBWT</sup>)).

**Results:** The adenine diet increased albuminuria in *Dusp4*<sup>WT</sup> mice, phenomenon exacerbated in DUSP4 null mice. Adenine and UUO models were associated with increased RIF (Masson Trichrome), RIF markers (Col1, TGF- $\beta$ , KIM-1 gene expression), macrophage infiltration (F4/80 immunohistochemistry), inflammation

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

markers (IL-1 $\beta$ , TNF- $\alpha$  and CD206 gene expressions), and myofibroblast deposition ( $\alpha$ -SMA immunohistochemistry) in *Dusp4*<sup>WT</sup> mice. DUSP4 deletion worsened the above characteristics as well as aggravated tubular atrophy. Furthermore, macrophage and myofibroblast markers colocalized in the interstitial space of *Dusp4*<sup>WT</sup> mice, suggesting macrophage contribution to RIF. Interestingly, the adenine diet administered to *Dusp4*<sup>WT/mΦKO</sup> mice worsened albuminuria to levels similar to *Dusp4*<sup>KO</sup> mice, while *Dusp4*<sup>KO/mΦWT</sup> albuminuria levels were lower. Likewise, *Dusp4*<sup>WT/mΦKO</sup> exhibited similar amounts of RIF compared to whole-body *Dusp4*<sup>KO</sup> mice while *Dusp4*<sup>KO/mΦWT</sup> exhibited lower levels of RIF compared to whole-body *Dusp4*<sup>KO</sup> mice.

**Conclusions:** The loss of DUSP4 in macrophages contributes to macrophage infiltration and total RIF in the progression of CKD.

**Funding:** Government Support - Non-U.S.

### Integrin-Linked Kinase Depletion Exerts Protective Effects in Vascular Fibrosis Associated With CKD

Sofia Campillo de Blas,<sup>1,2</sup> Elena Gutierrez Calabres,<sup>1,2</sup> Mariano de la Serna,<sup>3,2</sup> Natalia Canales Bueno,<sup>2,1</sup> Cristina González Valero,<sup>1,2</sup> Mercedes Griera,<sup>1</sup> Sergio De frutos garcia,<sup>4</sup> Diego Rodríguez puyol,<sup>5,6</sup> Laura Calleros,<sup>1,2</sup> <sup>1</sup>Department of Systems Biology, Physiology Unit, University of Alcalá, Alcalá de Henares, Spain; <sup>2</sup>NOVELREN, Instituto Ramon y Cajal de Investigación Sanitaria (IRYCIS), Fundacion Renal Iñigo Alvarez de Toledo (FRIAT) and REDinREN, (ISCIII), Madrid, Spain; <sup>3</sup>Biomedical Research Foundation, Hospital Universitario Principe de Asturias, Alcalá de Henares, Spain; <sup>4</sup>Department of Systems Biology, Physiology Unit, University of Alcalá, Biomedical Research Foundation, Hospital Universitario Principe de Asturias, Alcalá de Henares, Spain; <sup>5</sup>Nephrology Unit, Hospital Universitario Principe de Asturias, Biomedical Research Foundation, Hospital Universitario Principe de Asturias, Department of Systems Biology, Physiology Unit, University of Alcalá, Alcalá de Henares, Spain; <sup>6</sup>Graphenano Medical Care S.L., NOVELREN, Instituto Ramon y Cajal de Investigación Sanitaria (IRYCIS), Fundacion Renal Iñigo Alvarez de Toledo (FRIAT) and REDinREN, (ISCIII), Madrid, Spain.

**Background:** Cardiovascular diseases are one of the most common causes of morbidity and mortality in chronic kidney disease (CKD) patients. Integrin-linked kinase (ILK) is a serine/threonine protein kinase and a scaffold protein between the extracellular matrix and intracellular signaling pathways. The aim of this study was to investigate the role of ILK in CKD-associated vascular damage.

**Methods:** We induce CKD in both wild-type (WT) and adult conditional ILK knock-down (cKD-ILK) by feeding mice with a 0.2% adenine-supplemented diet during 2, 4 or 6 weeks. Animals receiving this diet develop a tubulointerstitial damage resembling CKD observed in humans. Aortic tissue mRNA levels of ILK, fibrosis markers as the extracellular matrix proteins collagen type I, fibronectin and the profibrotic cytokine TGF- $\beta$ 1 were determined by RT-qPCR. By *in vitro* experiments in human aortic-vascular smooth muscle cells (HA-VSMC), we tested the effect of uremic toxins, indoxyl- and p-cresyl sulfate (IS and pCS), on ILK activity and ILK and fibrosis markers expression. We transfected the cells with ILK-specific siRNA to verified the effect of ILK-deletion in vascular fibrosis.

**Results:** We found a progressive and significant increase in the mRNA expression of ILK in adenine-fed WT mice that was not observed in cKD-ILK mice on the same diet. Moreover, a significant increase in mRNA levels of fibrosis markers and TGF- $\beta$ 1 in the adenine-fed WT mice was also observed, which was significantly lower in adenine-fed cKD-ILK mice. Interestingly, we found statistically significant correlations between the vascular mRNA content of ILK and the fibrosis markers and TGF- $\beta$ 1 ( $p < 0.0001$ ,  $r$  between 0.81 and 0.82). *In vitro* experiments show an increase of ILK activity and fibrosis markers expression in the HA-VSMC treated with IS and pCS, while this increase was reversed in ILK-deleted cells.

**Conclusions:** ILK depletion protects against vascular fibrosis associated with CKD and TGF- $\beta$ 1 and consequent fibrosis increase is probably associated with an ILK-dependent mechanism. Therefore, ILK could be a potential therapeutic target for the prevention or treatment of development of vascular fibrosis in renal patients.

### Resident Memory T Cells in Aristolochic Acid-Induced CKD

Kyle H. Moore,<sup>1,2</sup> Elise Erman,<sup>2</sup> Matthew D. Cheung,<sup>2</sup> James F. George,<sup>2</sup> Anupam Agarwal,<sup>1</sup> <sup>1</sup>The University of Alabama at Birmingham Division of Nephrology, Birmingham, AL; <sup>2</sup>The University of Alabama at Birmingham Department of Surgery, Birmingham, AL.

**Background:** Chronic Kidney Disease (CKD) is a significant health burden affecting millions of Americans. No current therapeutics can halt or reverse the progression of CKD. The immune system, inflammation, and fibrosis are known to be involved in the progression of CKD, but specific contributions of T cells and how they become involved in the pathophysiological process remain poorly understood.

**Methods:** Mice were injected with 2mg aristolochic acid (AA) per kg body weight i.p. (saline control) for five consecutive days to induce a prolonged decline in kidney function. Glomerular filtration rates (GFRs) were measured using FITC-sinistrin clearance at baseline before injury, and at one day, two weeks, four weeks, and six weeks after their first AA injection. Blood was collected and kidneys were harvested and processed for flow cytometry, imaging, and single cell RNA sequencing. Serum creatinine (Scr) was measured using LC-MS/MS.

**Results:** There were no signs of acute injury one day post-injection, but by two weeks, AA mice had reduced GFR and increased Scr. At six weeks GFRs of AA mice remained low compared to controls (114 mL/min vs 220 mL/min, respectively), and Scr remained elevated (0.29 mg/dL AA vs 0.09 mg/dL Vehicle). The numbers of intrarenal CD45+ cells, CD4+ T cells, and CD8+ T cells were significantly elevated at two, four, and six weeks post-injury. Interestingly, CD103+ resident memory T cells (TRMs) expanded to represent 54% of the CD8+ and 36% of the CD4+ populations (7% and 3% in controls). CD8+ TRMs had increased expression of GZMB and PRF1. At six weeks there were also histological signs of interstitial fibrosis and tubular atrophy.

**Conclusions:** There was sustained impairment of kidney function in animals treated with AA, as indicated by reduced GFR and increased Scr at least six weeks after injury. There was also a sustained increase in CD4+ and CD8+ T cells with a large expansion of TRMs expressing apoptotic cytokines. TRMs have been recently characterized as non-circulating immune cells that contribute to chronic inflammation and, based on our findings, may contribute to inflammation in CKD. Future studies will aim to fully describe the cytokine profile of kidney TRMs in order to determine their role in tubular apoptosis and interstitial fibrosis.

### Pharmacological Inhibition of Lysine-Specific Histone Demethylase 1 With GSK-LSD1 Ameliorates Renal Fibrosis

Baihai Jiao,<sup>1</sup> Hao Du,<sup>1</sup> Melanie Tran,<sup>1</sup> Bo Song,<sup>1</sup> Yanlin Wang,<sup>1,2</sup> <sup>1</sup>University of Connecticut School of Medicine, Farmington, CT; <sup>2</sup>VA Connecticut Health System - Newington Campus, Newington, CT.

**Background:** Renal fibrosis is a pathological hallmark of chronic kidney disease (CKD) which is characterized by tubular epithelial cell dedifferentiation, fibroblast activation, and excessive production and deposition of extracellular matrix resulting in progressive loss of kidney function. However, the molecular mechanisms of renal fibrosis are not fully elucidated. In this study, we investigated the role of lysine-specific histone demethylase 1 (LSD1) in the regulation of tubular epithelial cell dedifferentiation and fibroblast activation during the development of CKD.

**Methods:** To examine the role of LSD1 in renal fibrosis *in vivo*, wild-type (WT) mice were subjected to unilateral ureteral obstruction (UUO) and treated with a selective LSD1 inhibitor GSK-LSD1 or vehicle for 10 days. Cultured tubular epithelial cells and fibroblasts were used to examine the role of LSD1 in the regulation of tubular epithelial cell dedifferentiation and fibroblast activation *in vitro* respectively.

**Results:** The expression of LSD1 was increased in tubular epithelial cells and myofibroblasts of the UUO kidneys and human kidneys with CKD. Compared with vehicle-treated mice, pharmacological inhibition of LSD1 with GSK-LSD1 significantly repressed UUO-induced histone H3K4 demethylation and Smad3 phosphorylation, reduced tubular epithelial cell dedifferentiation, suppressed myofibroblasts accumulation, and attenuated total collagen deposition and extracellular matrix protein production in the kidneys in response to UUO. Furthermore, pharmacological inhibition of LSD1 with GSK-LSD1 or genetic knockdown of LSD1 with sgRNA eliminates tubular epithelial cell dedifferentiation and fibroblast activation, which is associated with decreased histone H3K4 demethylation and Smad3 phosphorylation.

**Conclusions:** Our study identifies LSD1 as a critical factor in tubular epithelial cell dedifferentiation, fibroblast activation, and kidney fibrosis through regulation of histone H3 methylation and Smad3 phosphorylation. Therefore, LSD1 may represent a novel therapeutic target for chronic kidney disease.

### Single-Cell Transcriptomic Profiling of Kidney Fibrosis Identifies a Novel Fibroblast Marker and Putative Disease Target

Valeria Rudman-Melnick, Mike Adam, Prasad Devarajan. Devarajan lab Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

**Background:** Fibrosis is a key underlying process in CKD, resulting in renal parenchymal remodeling and progressive functional decline with prominent mortality. Cellular identity of renal fibrosis along with putative molecular targets regulating it remain elusive.

**Methods:** We used 10x Chromium and Drop-seq platforms to create transcriptomic profiles of two clinically relevant unilateral ischemia/reperfusion (UIR) and ureter obstruction (UUO) murine models of renal fibrosis. Moreover, we used primary human *in vitro* model of epithelial-to-mesenchymal transition (EMT) to identify novel putative CKD targets.

**Results:** Using scRNA-seq, we observed several novel injury induced kidney cell clusters, including three distinctive stromal populations, and identified Gucy1a3 as a novel specific marker of renal fibroblasts. Both CKD models exhibited robust nephrogenic program reactivation and intercellular communications, particularly between activated fibroblasts and tubular epithelial cells (TECs). We revealed elevation of fibrogenic factors in the injured TECs, including Ahnak which we previously reported in AKI. We showed that AHNAK ablation causes elevation of EMT and downregulation of epithelial markers

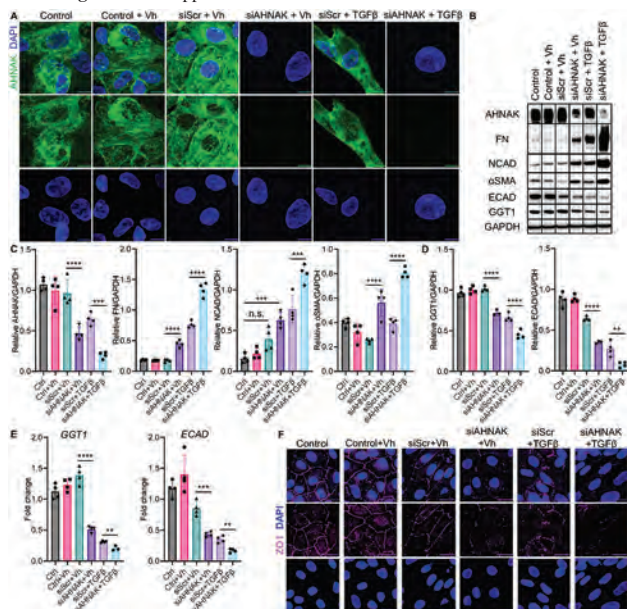

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

in primary human renal proximal tubular epithelial cells (RPTECs) with and without TGF $\beta$  (Figure 1). We also found that p38, p42/44, pAKT, BMP and MMP signaling underlies AHNAK effects in primary human *in vitro* model of EMT.

**Conclusions:** Our novel findings, including identification of Gucy1a3 as a specific kidney fibroblast marker and AHNak as an injury target, might improve our understanding and approach to halting kidney fibrosis.

**Funding:** NIDDK Support

### Major Vault Protein Contributes to Tubulointerstitial Inflammation and Fibrosis Through PI3K/AKT Signaling in a Murine Model of CKD

Cheuk Yin Wong, Susan Yung, Caleb C. Chan, Tak Mao D. Chan. *The University of Hong Kong, Hong Kong, Hong Kong.*

**Background:** Chronic kidney disease (CKD) is characterized by progressive tubulointerstitial fibrosis and tubular atrophy, influx of immune cells, and progression to kidney failure. We previously demonstrated that major vault protein (MVP), a key component of the vault complex, was increased in proximal renal tubular epithelial cells (PTEC) in CKD patients. We further investigated the role of MVP in tubulointerstitial inflammation and fibrosis.

**Methods:** CKD was induced in wild-type (WT) and MVP-knockout (KO) mice by feeding with casein-based chow containing 0.2% adenine for 8 weeks; and mice fed casein-based chow served as non-CKD control. Mice were sacrificed and renal cortical tissue harvested for qPCR, immunohistochemistry, and flow cytometry analysis. MVP-deficient HK-2 cells were generated using CRISPR/Cas 9; and non-transfected cells served as control.

**Results:** WT mice with CKD showed increased MVP expression in PTEC compared to control WT mice without CKD. WT mice with CKD showed marked tubular atrophy, macrophage infiltration, and increased expression of pro-inflammatory and pro-fibrotic mediators comprising CCL2, CCR2, CCL5, CCR5, TNF- $\alpha$ , IL-6, VCAM-1,  $\alpha$ -smooth muscle actin, vimentin, fibronectin, and collagen. Increased CD45<sup>+</sup> immune cells and F4/80<sup>+</sup> CD11b<sup>+</sup> macrophages were shown with flow cytometry. In MVP KO mice with CKD the histopathological abnormalities were less severe, with reduced expression of pro-inflammatory and pro-fibrotic mediators and decreased AKT phosphorylation. Exogenous TNF- $\alpha$  increased MVP expression and CCL2 secretion in non-transfected HK-2 cells, mediated in part through increased PI3K/AKT phosphorylation. In contrast, MVP-deficient HK-2 cells showed significantly less AKT phosphorylation and CCL2 secretion upon exposure to TNF- $\alpha$ .

**Conclusions:** Our data suggest that MVP contributes to the pathogenesis of renal tubulointerstitial inflammation and fibrosis in CKD through increased PI3K/AKT phosphorylation.

**Funding:** Government Support - Non-U.S.

## FR-PO973

### KLF5 Is Upregulated via NFkB to Promote Renal Injury and Fibrosis After Cisplatin Nephrotoxicity

Zhengwei Ma, Xiaoru Hu, Zheng Dong. *Augusta University Medical College of Georgia, Augusta, GA.*

**Background:** Acute and chronic nephrotoxicity are the major side effects of cisplatin during chemotherapy in cancer patients. Kruppel Like Factor 5 (KLF5) is a transcriptional factor that has been implicated in renal pathogenesis such as diabetic kidney diseases. The roles and regulation of KLF5 in acute and chronic nephrotoxicity are unclear.

**Methods:** Changes in KLF5 expression were investigated in acute cisplatin and repeated low dose cisplatin treatment (RLDC) treated BUMPT cells *in vitro* and in C57BL/6 mice *in vivo*. Homozygous kidney proximal tubule *Klf5* knockout (*PT-Klf5-KO*) and wild-type (WT) mice were given one injection of 20mg/kg cisplatin to examine acute kidney injury. Heterozygous *Klf5* WT or KO (*PT-Klf5*<sup>flx/+</sup>, with Cre- or Cre+) mice were subjected to 4 weekly injections of 7mg/kg cisplatin to examine chronic kidney injury 1 week later. The effect of KLF5 inhibition (ML-264 or KLF5 knockdown) was investigated in RLDC-treated HK2 cells. The expression of fibrotic proteins and renal injury were analyzed.

**Results:** Both acute cisplatin and RLDC induced KLF5 protein and mRNA in the kidney *in vivo* and in BUMPT cells *in vitro*. KLF5 was mainly induced in proximal tubules after RLDC treatment by IHC staining. KLF5 inhibition by ML-264 or KLF5 knockdown decreased the induction of fibronectin, vimentin, and profibrotic cytokine CTGF in RLDC-treated HK2 cells. There was less cleaved caspase 3 in the kidney in homozygous *Klf5* knockout mice after acute cisplatin treatment. Unexpectedly, RLDC induced more KLF5 in the kidney in heterozygous *PT-Klf5* KO mice compared to their WT littermates by immunoblot and IHC staining. Heterozygous KLF5 KO mice showed more renal injury, including higher KIM1, p-p53(Ser15), cleaved caspase 3 levels, and more apoptotic tubular cells. Heterozygous *Klf5* KO mice showed higher BUN and lower eGFR levels than WT mice, indicating declined renal function. RLDC induced more FN, Collagen I,  $\alpha$ -SMA, and Vimentin in the kidney in heterozygous *Klf5* KO mice. Upregulation of KLF5 by RLDC is NFkB dependent in RLDC *in vitro*, and JSH23, an NFkB inhibitor, reduced the induction of KLF5 protein and mRNA by RLDC. Chip analysis showed that KLF5 was a direct transcriptional target of NFkB.

**Conclusions:** KLF5 is upregulated by acute cisplatin and RLDC treatment and promotes renal injury and renal fibrosis. The upregulation of KLF5 is NFkB dependent.

**Funding:** NIDDK Support, Veterans Affairs Support

## FR-PO974

### Disruption of Annexin A2 Protects Against Obstruction-Induced Kidney Fibrosis and Inflammation

Ling Lin, Kebin Hu. *Penn State College of Medicine, Hershey, PA.*

**Background:** Annexin A2, a member of the Ca<sup>2+</sup>- and phospholipid-binding protein family, forms the heterotetramer through binding with S100A10, and acts as a cell surface receptor for tissue plasminogen activator (tPA) and plasminogen. It regulates fibrinolysis and hemostasis; and has been implicated in the pathogenesis of cardiovascular diseases and cancers. However, little is known regarding the role of annexin A2 in chronic kidney disease (CKD). Our previous *in vitro* work has shown that annexin A2 mediates NF- $\kappa$ B activation and promotes macrophage M2 to M1 phenotypic change, suggesting a critical role of annexin A2 in kidney fibrogenesis and inflammation.

**Methods:** We induced a classic CKD model, unilateral ureteral obstruction (UUO), in wildtype C57BL/6 mice and examined the renal expression of annexin A2 during the course of CKD. We also induced UUO in the novel annexin A2 knockout mice and their wildtype controls and evaluated the renal fibrosis and inflammation in these mice.

**Results:** It was found that expression of annexin A2 was dramatically induced in the obstructed kidneys, as early as 3 days after UUO; and the upregulation continued up to 14 days after UUO. With the progression of kidney fibrosis, as indicated by increased fibronectin deposition in a time-dependent manner, annexin A2 was dramatically induced, and its induction correlated with the content of kidney fibrosis. Intriguingly, double immunostaining analysis found that annexin A2 was dramatically induced in the renal interstitium, primarily in F4/80 positive macrophages. We further found that, after obstructive injury, annexin A2 knockout mice displayed significantly reduced tubular epithelial damage and dramatically decreased deposition of matrix components such as collagen and fibronectin than that of their littermates. Additionally, immunostaining showed that obstruction-induced infiltration of F4/80-positive macrophages was alleviated in the fibrotic kidneys from annexin A2 knockout mice.

**Conclusions:** Thus, it is clear that annexin A2 promotes kidney fibrosis and macrophage infiltration after obstructive injury.

**Funding:** NIDDK Support, Other U.S. Government Support

## FR-PO975

### Scavenging Lipid Oxidation Products Improves Intestinal Inflammation and Integrity After Renal Injury

Jianyang Zhong, Haichun Yang, Sean S. Davies, Valentina Kon. *Vanderbilt University Medical Center, Nashville, TN.*

**Background:** Kidney disease affects intestinal structure and function. We previously showed that kidney injury amplifies intestinal lymphangiogenesis and increases mesenteric lymph flow that enhances systemic delivery of gut-originating harmful substances, including the highly reactive product of lipid oxidation, isolevuglandin (IsoLG). IsoLG is best known for its harmful effects to modify apolipoprotein A-I (apoA1)/high-density lipoprotein (HDL) which promotes atherosclerosis. 2-Hydroxybenzylamine (2-HOBA)

is a selective scavenger of IsoLG that protects proteins and lipids from being modified. Since oxidation and lipoprotein modification prevails across the entire spectrum of kidney disease, we investigated the potential benefit of 2-HOBA on intestinal disruption following kidney injury.

**Methods:** Puromycin nephrotoxicity (PAN) was induced in Sprague Dawley rats, while saline-injected rats served as control (Cont). Half of the PAN rats were treated with water containing 2-HOBA (1 g/L). Eight days after induction of PAN injury, mesenteric lymph, intestine, blood, and urine were collected for analysis.

**Results:** PAN rats had significant proteinuria and ascites. Mesenteric lymph of PAN injured rats contained 1.8-fold higher level of IsoLG-modified apoA1 vs Cont which was decreased by 63% in mesenteric lymph of 2-HOBA treated rats. PAN increased macrophage infiltration, evidenced by greater number of CD68-positive cells which was lessened by 2-HOBA. PAN injury caused a significant increase in intestinal expression of inflammatory genes, including monocyte-chemoattractant protein-1, interleukin 17A, interleukin 10, and tumor necrosis factor- $\alpha$  vs Cont. Vascular cell adhesion molecule 1 which maintains intestinal integrity was also increased in PAN vs Cont. All these injury-driven changes were attenuated by 2-HOBA.

**Conclusions:** Scavenging the lipid oxidation product lessened kidney injury-induced mesenteric lymph IsoLG modification of apoA1 together with reduction in intestinal inflammation and disruption of integrity. Our data support a novel therapeutic approach to CKD provoked intestinal dysfunction.

**Funding:** NIDDK Support

### Impact of IL-11 as a Renal Fibrosis Marker in CKD Using Mouse Model

Yaeim Kim,<sup>1</sup> Sunhwa Lee,<sup>5</sup> Hyung Ah Jo,<sup>6</sup> Kyung Don Yoo,<sup>2</sup> Jin hyuk Paek,<sup>1</sup> Woo Yeong Park,<sup>1</sup> Kyubok Jin,<sup>1</sup> Seungyeup Han,<sup>1</sup> Dong Ki Kim,<sup>3,4</sup> Yon Su Kim,<sup>3,4</sup> Seung Hee Yang,<sup>4</sup> <sup>1</sup>Keimyung University School of Medicine, Daegu, Republic of Korea; <sup>2</sup>Ulsan University Hospital, Ulsan, Republic of Korea; <sup>3</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>4</sup>Seoul National University College of Medicine, Seoul, Republic of Korea; <sup>5</sup>Kangwon National University Hospital, Chuncheon, Kangwon, Republic of Korea; <sup>6</sup>Inje University Ilsan Paik Hospital, Goyang, Republic of Korea.

**Background:** Fibrosis is a common pathophysiology of chronic kidney disease (CKD) progression, but the role of IL-11, which is highly expressed in the fibroblast remains elusive. Herein, we aimed to evaluate the role of IL-11 in the fibrosis pathway and apoptosis.

**Methods:** We examined the impact of IL-11 in the UUO model using B6 mouse aging 7 to 8 weeks. An *in-vitro* experiment was performed using primed human tubular epithelial cells (hTECs) to figure out the role of recombinant IL-11 induced fibrosis. In addition, we examined the change in the expression of phosphorylated STAT3 (pSTAT3) and IL-18 after treated recombinant TGF $\beta$  (rTGF $\beta$ ) and rTGF $\beta$  with an IL-11 blockade antibody (Ab) via fluorescence-activated cell sorting (FACS). Finally, we evaluated an impact on apoptosis using TGF $\beta$  and TGF $\beta$  with an IL-11 blockade Ab.

**Results:** Expression of IL-11 in bulk-tissue RNA-sequencing was significantly higher in the kidney lysates from the UUO model than those from sham. The levels of IL-11 expression in kidney sections from the UUO model were remarkably correlated with the intensity of COL1 in the look-up section. Likewise, two days after treating rIL-11 with doses of 100 or 500 ng/mL in hTEC, the expression of COL1 mRNA was dose-dependently increased. rTGF $\beta$  treatment significantly increased the expression of COL1, STAT3, and CXCL1 mRNA, while IL-11 blockade Ab restored the mRNA expressions of the molecules. Also, rTGF $\beta$  treatment increased the expression of pSTAT3 and IL-18. IL-11 blockade Ab significantly abrogated these expressions by 60% and 33% in pSTAT3 and IL-18, respectively. Finally, the Annexin V assay revealed relevant increases in apoptotic cells treated with rTGF $\beta$ , and IL-11 blockade Ab significantly attenuated the increase.

**Conclusions:** IL-11 has a role in the induction of fibrosis. The inhibition of IL-11 significantly attenuates the fibrotic changes, indicating that IL-11 pathway could be a treatment target for CKD progression.

## FR-PO977

### Deletion of PTP4A1 Ameliorate Renal Fibrosis Induced by Unilateral Ureteral Obstruction (UUO) in Mice

Dae Eun Choi,<sup>1</sup> Hyunsu Choi,<sup>2</sup> Wonjung Choi,<sup>2</sup> Yoon-Kyung Chang,<sup>2</sup> <sup>1</sup>Chungnam National University, Daejeon, Republic of Korea; <sup>2</sup>Catholic University of Korea Daejeon St Mary's Hospital, Daejeon, Republic of Korea.

**Background:** Inhibitors of protein tyrosine kinases (PTP) has been investigated as potential anti-fibrotic agents. PTP4A1 belongs to a sub-class of three prenylated PTP. PTP4A1 has known as promoting growth and migration of tumor cells. The role PTP4A1 has little known in kidney. We evaluated whether the PTP4A1 could be target of renal fibrosis.

**Methods:** 10 week old male background PTP4A1 KO mice and wild type mice were divided into 4 groups; wild, PTP4A1 KO, wild with UUO, and PTP4A1 KO with UUO. Mice were sacrificed at 7 days after surgery and kidney tissue were collected. Molecular study and Histologic examination were performed.

**Results:** PTP4A1 KO with UUO mice showed decrease of renal tubule-interstitial damage and fibrosis compared to wild type UUO mice. PTP4A1 KO with UUO reduced the renal expression of  $\alpha$ -SMA and TGF- $\beta$  in UUO kidney, compared to wild type with UUO mice. Wild type with UUO kidney showed decrease of renal expression of

E-cadherin, compared to sham mice. However, PTP4A1 KO UUO showed increase of renal expression of E-cadherin, compared to Wild type UUO mice. In vitro, silencing of PTP4A1 in TGF- $\beta$  treated HK2 cell showed increase of E-cadherin and decrease of phosphorylation of AKT and GSK3 $\beta$ .

**Conclusions:** PTP4A1 KO ameliorate renal fibrosis in UUO kidney.

## FR-PO978

### Association of Aging-Related Decline in Quinolinolate Phosphoribosyl Transferase Expression and Expression of Profibrotic Genes

Marie Christelle Saade, Amanda J. Clark, Brenda Mendoza Flores, Samir M. Parikh. Parikh Lab The University of Texas Southwestern Medical Center Department of Internal Medicine, Dallas, TX.

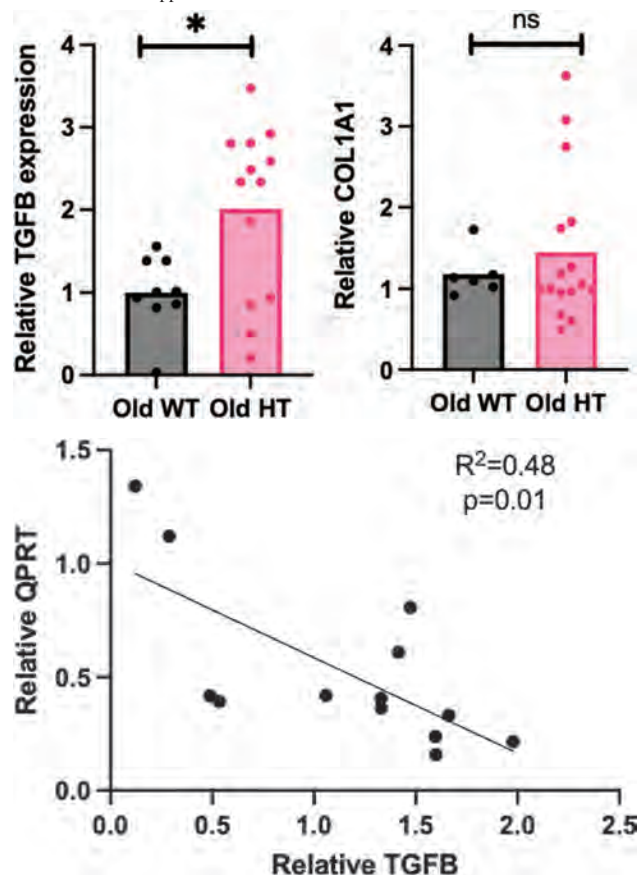

**Background:** De novo nicotinamide adenine dinucleotide (NAD<sup>+</sup>) biosynthetic pathway was shown to be impaired in chronic kidney disease (CKD) and routine aging with a particular role for quinolinolate phosphoribosyl transferase (QPRT), a bottleneck enzyme of the de novo NAD<sup>+</sup> pathway. Yet, it is still undetermined whether QPRT and generalized NAD<sup>+</sup> biosynthetic suppression is simply correlated with CKD progression or whether loss of these pathways may drive disease progression. Therefore, we investigated aged QPRT deficient mice.

**Methods:** Custom QPRT +/- were bred and aged under routine care on a normal chow diet. Expression of QPRT and fibrotic genes TGF $\beta$  and COL1A1 was measured in QPRT +/- (HT) and wildtype (WT) littermates at an 8-week-old "young" time point and a 72-week-old "aged" time point. Serum blood urea nitrogen (BUN) and creatinine were measured using a commercial kit and capillary electrophoresis respectively.

**Results:** QPRT expression significantly declined with age in HT and WT mice. Old WT mice expressed less QPRT than young HT mice. In the aged group, TGF $\beta$  expression was significantly higher in aged HT mice despite unchanged BUN and creatinine. There was no significant difference between young and old HT vs WT COL1A1 gene expression, though expression trended higher in aged HT. (Figure 1) TGF $\beta$  expression significantly correlated with QPRT expression in both old and young mice populations (Figure 2).

**Conclusions:** Our data demonstrate a suppression of kidney QPRT expression with age. QPRT reduction may exacerbate fibrotic gene expression even in the absence of overt kidney disease.

## FR-PO979

**Chemokine Ligand 14 Is a Pro-Fibrotic Stimulus in CKD Progression Through Regulating the GATA2 Transcription Factor**

Sunhwa Lee,<sup>1</sup> Yong Chul Kim,<sup>2</sup> Seung Seok Han,<sup>2,3</sup> Dong Ki Kim,<sup>2,3</sup> Yon Su Kim,<sup>2,3</sup> Seung Hee Yang.<sup>2,3</sup> <sup>1</sup>Kangwon National University Hospital, Chuncheon, Kangwon, Republic of Korea; <sup>2</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>3</sup>Seoul National University College of Medicine, Seoul, Republic of Korea.

**Background:** Chemokine ligand 14 (CCL14), a ligand for CCR1, has been known as a M2 polarizing marker and chemotactic cytokine. By performing urine proteomic analysis of chronic kidney disease patients, we previously found out CCL14 expression tends to increase in patients with progressive CKD and GATA2 could be possible upstream transcription factor. To validate pathophysiologic role of CCL14 and its molecular pathway, we performed in vitro and in vivo evaluations.

**Methods:** To determine how CCL14 is involved in the fibrosis process, recombinant CCL14(9-74) were treated in primary cultured tubular epithelial cells (hTECs). Moreover, anti-CCL14 blocking antibody were treated in fibrosis induced hTECs using rTGFβ (2ng/ml) or Hypoxia (1% O<sub>2</sub>, 72hrs). Fibronectin, collagen IV, E-Cadherin, CCL14, CCR1 and GATA2 level was evaluated. And cell apoptosis and necrosis was also measured using an Annexin-PI assay. For in vivo validation, we used C57BL/6 unilateral ureteral obstruction (UUO) model to re-inforce the CCL14/CCR1/GATA2 pathway in chronic kidney disease progression. We also further performed GATA2 immunohistochemistry staining in kidney specimens of CKD patients.

**Results:** Recombinant CCL14 itself increased the expression of fibronectin in hTECs. Adding anti-CCL14 with rTGFβ showed decreased expression level of collagen IV and increased cell junction marker, E-cadherin. Annexin-PI assay result showed decreased apoptotic cell count with anti-CCL14 stimulation. In hypoxia-induced hTECs, anti-CCL14 antibody significantly suppressed the mRNA expression levels of fibronectin, αSMA, and periostin. In addition, decrease in the expression of CCR1 receptor and GATA2 transcription factor were also observed. In C57BL/6 UUO mouse model, on the 7<sup>th</sup>, and 14<sup>th</sup> day after operation, GATA2 mRNA expression were significantly increased. Similarly, in human kidney specimens, the expression level of GATA2 transcription factor increases as the chronic kidney disease stage progresses.

**Conclusions:** CCL14 could play a pro-fibrotic role in CKD progression via regulations of CCR1 receptor and GATA2 transcription factor. Since CCL14 acts not only as a biomarker of increased expression in CKD progression, but also as a direct pro-fibrotic stimulus, it can be considered as a target for the treatment of chronic kidney disease.

**Funding:** Government Support - Non-U.S.

## FR-PO980

**Fn14 Knockout Ameliorates Cisplatin-Induced Nephrotoxicity in Mice by Reducing Inflammation, Preventing Tubular Cell Death, and Decreasing Renal Fibrosis**

Ross Villiger,<sup>1</sup> Michael Ortega,<sup>2,1</sup> Malia H. Harrison-Chau,<sup>1</sup> Geetika Y. Patwardhan,<sup>1</sup> Ben Fogelgren.<sup>1</sup> <sup>1</sup>University of Hawai'i at Manoa, Honolulu, HI; <sup>2</sup>Queen's Medical Center, Honolulu, HI.

**Background:** Tumor necrosis factor receptor superfamily 12A (TNFRSF12a), also known as Fn14, is a transmembrane cytokine receptor often upregulated in damaged tissues or in malignancies. Fn14 has a single known ligand, the cytokine TWEAK, although at high concentrations, Fn14 can self-oligomerize. Primarily associated with activating the non-canonical NF-κB pathway, TWEAK-Fn14 signaling can also contribute to multiple downstream cellular pathways, including cell death and fibrosis, depending on contributions from other TNF receptors and the cell microenvironment. We detected strong upregulation of the Fn14 gene in stressed cells of the kidney and urinary tract, and the goal of this study was to determine if Fn14 signaling contributes to the pathogenesis of chronic kidney disease (CKD).

**Methods:** With CRISPR-Cas gene editing, we generated a novel Fn14-knockout mouse (Fn14-KO). We challenged male and female wild-type C57BL/6J and Fn14-KO mice to a repeated low dose regimen of cisplatin to model CKD. After the dosing regimen, we analyzed blood biochemistry, renal histopathology, and renal gene expression using the NanoString nCounter platform.

**Results:** The Fn14-KO mouse demonstrated complete absence of Fn14 protein, was fertile, and lacked gross abnormalities. Compared to wild-type mice, Fn14-KO mice had reduced cisplatin-induced nephrotoxicity assessed by blood biochemistry and renal histopathology. Cisplatin-treated wild type mice showed substantial renal tubular cell death, which was absent in Fn14-KO kidneys. Transcriptomic data revealed significant reductions in genes associated with inflammation and fibrosis in the Fn14-KO kidneys, which correlated with histopathological findings.

**Conclusions:** Fn14 signaling contributed to tubular cell death and renal fibrosis in this mouse model of CKD. Blocking TWEAK-Fn14 signaling may help ameliorate cisplatin-induced nephrotoxicity and other forms of CKD, although targeting the Fn14 receptor may be more effective if it can self-activate with high expression.

**Funding:** NIDDK Support, Other NIH Support - NIGMS

## FR-PO981

**Role of Kidney Derived Extracellular Vesicles Containing Mitochondrial Proteins and Splicing Factors in Renal Fibrosis**

Krishna P. Maremanda,<sup>1,2</sup> Chitran Roy Chowdhury,<sup>1</sup> Amrendra K. Ajay,<sup>1,2</sup> Venkata Sabbiseti.<sup>1,2</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA.

**Background:** Extracellular vesicles (EVs) are lipid bilayer nanoparticles enriched with biomolecules such as DNAs, RNAs, protein and lipids. They help in cellular communication and have potential theranostic applications based on their nature and origin. Organ-specific EVs have been shown to play pathophysiological role including fibrosis.

**Methods:** Here we describe the role of kidney specific EVs in initiating and promoting kidney fibrosis in mouse models. Kidneys were isolated from three mechanistically different animal models of chronic kidney injury which includes mice treated with Folic acid (FA), aristolochic acid (AA), and unilateral ureteral obstruction (UUO).

**Results:** Kidney specific EVs were isolated by restricted enzymatic digestion followed by differential centrifugations. Isolated EVs were characterized using TEM and by western blotting for enrichment of different exosomal protein markers, including CD63, flotillin-1, and alix. Enriched EVs from kidneys isolated from untreated and FA-treated mice were used for differential gene expression and proteomic studies. Gene expression analysis showed that these EVs were enriched in various splicing factors, including SRp40 along with its interacting lncRNA partners such as NEAT1, which are shown to be upregulated in fibrotic conditions. We also found that EVs isolated from fibrotic kidneys are enriched with various pro-fibrotic signaling molecules including EDAA+ Fn, Col1A1 and TGF-β1. Proteomic analysis showed several differentially expressed proteins in various EVs isolated from fibrotic kidneys.

**Conclusions:** We found novel targets for kidney fibrosis in EVs.

## FR-PO982

**Cluster of Differentiation-14 Contributes to Tubulo-Interstitial Fibrosis in a Murine Model of CKD**

Tak Mao D. Chan, In Young Oh, Jing Yu, Susan Yung. *Department of Medicine, School of Clinical Medicine, the University of Hong Kong, Hong Kong SAR, Hong Kong.*

**Background:** Chronic kidney disease (CKD) is characterized by progressive tubulo-interstitial fibrosis and tubular atrophy, leading to kidney failure. CD14 is a GPI-anchored membrane protein that functions as a pattern recognition receptor in sepsis. We previously demonstrated that tubulo-interstitial CD14 expression was increased in kidney biopsies showing CKD from patients without sepsis. We further investigated the role of CD14 in the pathogenesis of tubulo-interstitial inflammation and fibrosis in CKD.

**Methods:** CKD was induced in wild-type (WT) and CD14-knockout (KO) mice by feeding with casein-based chow containing 0.2% adenine for 8 weeks. Mice were sacrificed, kidneys were harvested and histopathological changes examined. Mice fed casein-based chow served as non-CKD controls. The role of CD14 in inflammatory and fibrotic processes was investigated in HK-2 cells that overexpressed CD14.

**Results:** Tubulo-interstitial CD14 expression was increased in WT CKD mice compared with non-CKD WT controls. WT CKD mice showed tubular atrophy, influx of F4/80<sup>+</sup>CD260<sup>+</sup> macrophages and increased tubulo-interstitial α-smooth muscle actin, fibronectin and collagen expression. CD14-KO mice with CKD showed less severe histopathological abnormalities and reduced immune cell infiltration, with decreased expression of mediators of fibrosis. HK-2 cells overexpressing CD14 showed increased fibronectin expression and IL-6, IL-8 and MCP-1 secretion compared to non-transfected cells, mediated in part through increased p38 MAPK and PI3K phosphorylation, and TGF-β1 stimulation further augmented fibronectin expression and cytokine secretion.

**Conclusions:** Our data suggest that CD14 contributes to tubulo-interstitial inflammation and fibrosis in murine adenine-induced CKD.

**Funding:** Government Support - Non-U.S.

## FR-PO983

**Possible Role of Calpains 2 and 5 in CKD Progression and Renal Fibrosis**

Elena Gutierrez Calabres,<sup>1,2</sup> Sofia Campillo de Blas,<sup>1,2</sup> Mariano de la Serna,<sup>3,2</sup> Natalia Canales Bueno,<sup>2,1</sup> Cristina González Valero,<sup>1,2</sup> Mercedes Griera,<sup>4,1</sup> Sergio De frutos garcia,<sup>4,5</sup> Laura Calleros,<sup>1,2</sup> Diego Rodriguez puyol.<sup>6,4</sup>  
<sup>1</sup>Department of Systems Biology, Physiology Unit, Universidad of Alcalá, Alcalá de Henares, Spain; <sup>2</sup>NOVELREN, Instituto Ramon y Cajal de Investigación Sanitaria (IRYCIS), Fundación Renal Iñigo Álvarez de Toledo (FRIAT) and REDinREN, (ISCIII), Madrid, Spain; <sup>3</sup>Biomedical Research Foundation, Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain; <sup>4</sup>Graphenano Medical Care S.L., NOVELREN, Instituto Ramon y Cajal de Investigación Sanitaria (IRYCIS), Fundación Renal Iñigo Álvarez de Toledo (FRIAT) and REDinREN, (ISCIII), Madrid, Spain; <sup>5</sup>Department of Systems Biology, Physiology Unit, Universidad of Alcalá and Biomedical Research Foundation, Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain; <sup>6</sup>Nephrology Unit and Biomedical Research Foundation, Hospital Universitario Príncipe de Asturias and Department of Medicine and Medical Specialties, Universidad de Alcalá, Alcalá de Henares, Spain.

**Background:** Calpains (CAPN) are intracellular cysteine proteases that play an important role in multiple biological processes linked to tissue damage and repair mechanisms, such as epithelial-mesenchymal transition and fibrosis. These two phenomena are critical in the development of chronic kidney disease (CKD), but a relationship between them and CAPN in CKD has not been definitively proved. The aim of this study was to investigate the possible role of CAPN in the development of CKD and renal fibrosis in an experimental model of CKD induced by adenine and in human kidney proximal tubular cells (HK-2).

**Methods:** Tubulointerstitial damage resembling that is observed in human CKD was induced in mice fed an adenine-rich diet (0.2%, for 5 days and 2 weeks). *In vitro* experiments were performed in TGF- $\beta$  HK-2 treated cells (1 ng/ml, different times), and two CAPN inhibitors (calpeptin, calpain inhibitor III, 50  $\mu$ M). Mice renal function was assessed by measuring plasma BUN and creatinine. Fibrosis markers (collagen type I and fibronectin) were determined by RT-qPCR. Protein content of CAPN 2 and 5 were analyzed by western blot. CAPN activity was analyzed by fluorescence assays.

**Results:** Our results show a progressive worsening of renal function and fibrosis in adenine-fed mice, with increased BUN, creatinine, COL I and FN mRNA expression, being significantly higher at 2 weeks of treatment. Protein content of CAPN 2 and 5 was significantly higher in animals that received adenine for 2 weeks when compared to control, together with a statistically significant increased renal CAPN activity. Our results point out that CAPN 2 and 5 content in renal tissue increases as CKD and fibrosis progresses. To verify this potential relationship, we induced fibrosis in HK-2 cells with TGF- $\beta$ , that increased COL I and FN mRNA expression, as well as CAPN 2 and 5 levels. The two CAPN inhibitors prevented the TGF- $\beta$ -induced increase in CAPN activity and COL I expression.

**Conclusions:** We suggest a direct relationship between the fibrosis observed in CKD and the cellular content of CAPN, which could be involved in the genesis or progression of kidney disease. Thus, effective CAPN blockade or downregulation could be useful as a therapeutic strategy to prevent CKD.

## FR-PO984

**4-(2-Aminoethyl) Benzenesulfonyl Fluoride Hydrochloride (AEBSF) Reduced Kidney Fibrosis in Part by Targeting CREB3L1 in Myofibroblasts**

Ayaha Yamamoto, Masanori Obana, Yasushi Fujio. *Osaka Daigaku, Suita, Japan.*

**Background:** Since kidney fibrosis is a critical event for the onset of renal failure, novel therapeutic agents to prevent and/or mitigate kidney fibrosis are urgently needed. Previously, we found that cAMP-responsive element binding protein 3-like 1 (CREB3L1), a transcription factor, exacerbated kidney fibrosis, using conventional knockout mice. However, it is unclear that pharmacological approach to inhibit CREB3L1 is useful for the treatment of kidney fibrosis. CREB3L1 is cleaved by site-1/2 protease, resulting in activation. In this study, we examined whether 4-(2-aminoethyl) benzenesulfonyl fluoride hydrochloride (AEBSF), a site-1 protease inhibitor, suppressed kidney fibrosis.

**Methods:** CREB3L1 expression in human and murine kidneys was examined by immunohistochemistry with anti-CREB3L1 and  $\alpha$ -SMA antibodies. To examine the effects of CREB3L1 in myofibroblasts on kidney fibrosis, myofibroblast-specific CREB3L1 knockout (cKO) mice were subjected to unilateral ureteral obstruction (UUO). Day 7 after UUO, kidney fibrosis was examined by Sirius Red staining, hydroxyproline assay and immunofluorescence analysis. Cultured TGF- $\beta$ 1-stimulated NRK49F cells (myofibroblasts) were treated with AEBSF. In addition, C57BL/6 mice were intraperitoneally injected with AEBSF for 9 consecutive days starting 2 days before UUO.

**Results:** CREB3L1 was increased in myofibroblasts in human and murine fibrotic kidneys. Kidney fibrosis was attenuated in CREB3L1 cKO mice compared with control mice. In addition, CREB3L1 cKO mice showed reduced number of Ki-67-positive proliferative myofibroblasts in fibrotic kidneys, suggesting that CREB3L1 in myofibroblasts may be therapeutic target for kidney fibrosis. AEBSF suppressed CREB3L1 activation in myofibroblasts. Significantly, AEBSF treatment reduced kidney fibrosis after UUO(hydroxyproline content: PBS-contralateral; 0.17 $\pm$ 0.03  $\mu$ g/mg, PBS-UUO; 0.32 $\pm$ 0.06  $\mu$ g/mg, AEBSF-contralateral; 0.12 $\pm$ 0.03  $\mu$ g/mg, AEBSF-UUO; 0.25 $\pm$ 0.05  $\mu$ g/mg, n = 9 for PBS, n = 6 for AEBSF).

**Conclusions:** AEBSF could be a novel therapeutic tool for kidney fibrosis by targeting CREB3L1 in myofibroblasts.

## FR-PO985

**Testing the Relationship Between NBL1 and CKD in a Cisplatin-Induced Mouse Model**

Rei Buñi, Susan M. Sheehan, Ron Korstanje. *The Jackson Laboratory, Bar Harbor, ME.*

**Background:** Increased serum levels of neuroblastoma suppressor of tumorigenicity 1 (NBL1), a bone morphogenetic protein (BMP) inhibitor, have been associated with a faster decline in kidney function in patients with diabetes, and *in vitro* experiments have shown a linkage between increased NBL1 levels and podocyte apoptosis. We aim to discover the causality-effector relationship and the role of NBL1 in kidney disease.

**Methods:** We obtained a transgenic (TG) mouse model that has a cDNA copy of *Nbl1* behind a chicken B-actin promoter in a DBA/2 and B6J mixed background. In addition, a knockout (KO) model was created using CRISPR technology in the B6J background. We induced chronic kidney disease (CKD) by following a low dose cisplatin protocol for 4 weeks. Wild type (WT), TG, and heterozygous KO mice received either cisplatin (treatment) or saline (control) for 4 weeks. Urine, serum, and kidneys were collected 3 days after the last treatment.

**Results:** We observed substantial decrease in weight for all mice that received cisplatin with no significant differences between genotypes. In addition to podocyte number as measured by staining with a podocyte marker-specific, we will present our results including measurements of albuminuria, BUN, and histology to establish whether there is a causal relationship between NBL1 and CKD.

**Conclusions:** Previous literature suggest NBL1 has a damaging effect on podocytes, and we speculate that white blood cells expressing NBL1 drive the mechanism. Results from our measurements of changes in podocytes due to differences in serum NBL1 levels expressed in white blood cells from our WT, TG, and heterozygous KO mouse models could lead to identification of pathways useful for drug targets.

**Funding:** Other NIH Support - DK131019, DK131061

## FR-PO986

**Empagliflozin Attenuates Renal Fibrosis Through the DsbA-L-CAS-STING Pathway in Unilateral Ureteral Obstruction Model**

Junghyun Cho, Eui Suk Chung, Haekyung Lee, Soon hyo Kwon. *Soonchunhyang University Hospital, Seoul, Republic of Korea.*

**Background:** Chronic kidney disease (CKD) is associated with an increase in morbidity and mortality. Renal fibrosis is a common pathway leading to the progression of CKD. Recent studies have reported an improvement of CKD with use of sodium glucose cotransport 2 inhibitors (SGLT2i) in both patients with DM and those without it. However, the mechanism of SGLT2i's effect upon CKD has not been elucidated. In current study, we examined the effect of SGLT2i on renal fibrosis in rats caused by unilateral ureteral obstruction (UUO).

**Methods:** Sprague Dawley rats were randomly divided into two groups (each n=8). One group was treated by Empagliflozin after UUO induction while the other group was left untreated. Kidneys were harvested two weeks after UUO. We evaluated the mitochondrial damage pathway presumed to contribute to the inflammation.

**Results:** UUO has resulted in marked renal fibrosis and triggered the activation of the cGAS-STING pathway. Empagliflozin has been shown to attenuate renal fibrosis and decrease the activation of the cGAS-STING pathway. The expression of disulfide-bond A oxidoreductase-like proteins (DsbA-L) was increased in the Empagliflozin group (Figure 1).

**Conclusions:** These findings suggest that SGLT2i attenuates the development of renal fibrosis via inhibition of mitochondrial damage.

## FR-PO987

**BCL2 Associated Athanogene 2 (BAG2) Mediates Kidney Fibrosis Through TGF-β1 Signaling Pathway**

Min ji Sung,<sup>1</sup> Hyun-Ju An,<sup>1</sup> Min Heui Ha,<sup>1</sup> Hyeyun Jeong,<sup>2</sup> Yu ho Lee,<sup>2</sup> Taeyoung Yang,<sup>2</sup> Dong Ho Yang,<sup>2</sup> So-young Lee.<sup>2</sup> <sup>1</sup>CHA University - Bundang Campus, Seongnam, Gyeonggi-do, Republic of Korea; <sup>2</sup>CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea.

**Background:** Kidney fibrosis, regardless of its etiology, is the inevitable consequence of almost chronic kidney diseases. Transforming growth factor-β1 (TGF-β1) plays a central role in kidney fibrotic disease. Therefore, it is important to find novel targets that regulate TGF-β1 signaling. An increasing number of studies have revealed that BAG2 is involved in the pathogenesis of various diseases, including cancer. However, the regulatory mechanisms of BAG2 in kidney fibrosis remain unclear.

**Methods:** Expression of BAG2 was validated by western blot, RT-PCR and FACS in unilateral ureteral obstruction (UUO) and adenine-diets WT or BAG2 knockout mouse model. The molecular mechanism study was performed in TGF-β1-induced human kidney proximal tubular cells (HKC-8) cells by gene expression analysis, and BAG2 lentiviral knockdown and overexpression cell lines. Human serums were isolated from patients with renal failure and healthy controls and BAG2 expression level was detected by ELISA.

**Results:** In the Kidney fibrosis mouse model, mRNA and protein showed that compared with the control group, the expressions of BAG2, and fibrotic marker were all increased, FACS analysis also shows that BAG2 increased during fibrotic changes. At the same time, overexpression of BAG2 suppressed enhancements on epithelial to mesenchymal transition and fibrosis via the TGF-β1 / SMAD3 / BAG2 complex. Also, BAG2 was increased in serum from chronic kidney disease patients.

**Conclusions:** This is, to our knowledge, the first report about the function of BAG2 in kidney fibrosis. These results demonstrate that BAG2 regulates kidney fibrosis via the TGF-β1 signaling and suggest that BAG2 is a potential therapeutic target for the treatment of kidney fibrosis.

**Funding:** Government Support - Non-U.S.

## FR-PO988

**The Probiotic *Lactiplantibacillus paraplantarum* Modulates Serum and Intestinal Environments of Phosphorus in CKD Rats**

Sung Jin Moon,<sup>1</sup> Jwa-kyung Kim,<sup>3</sup> Hyo Jin Kim.<sup>2</sup> <sup>1</sup>Catholic Kwandong University International Saint Mary's Hospital, Incheon, Republic of Korea; <sup>2</sup>Seoul National University, Gwanak-gu, Seoul, Republic of Korea; <sup>3</sup>Hallym University, Chuncheon, Gangwon-do, Republic of Korea.

**Background:** The human gastrointestinal tract contains more than 100 trillion microorganisms, including >1000 species of bacteria. Despite many studies linking gut microbes to human diseases, most of the mechanisms by which lactic acid bacteria have beneficial effects on the human body are related to immune modulation. Controlled studies of the ability of lactic acid bacteria to absorb phosphorus directly in the intestine and thereby control serum phosphorus level in *in vivo* uremic animal models are limited.

**Methods:** We screened lactic acid bacteria living in Korean fermented foods to identify those that absorb the most phosphorus and noted *Lactiplantibacillus paraplantarum* KCCM 11826P (Fig 1). Genomic sequencing and CKD animal experiments were performed to explain the mechanism.

**Results:** That *L. paraplantarum* strain has a polyP gene cluster, so it absorbs phosphorus better than other bacteria and can suppress strains that produce indole. Supplementing the diets of 5/6 nephrectomized rats with the *L. paraplantarum* strain significantly decreased serum phosphate level (by 22%) and reduced blood indoxyl sulfate concentration by 40%.

**Conclusions:** Our results suggest that *Lactiplantibacillus* preparations could be used for multiple purposes, such as removal of phosphorus and uremic toxins from CKD patients, and demonstrate the novel concept of a probiotic phosphate binder.

**Funding:** Commercial Support - Funding from MH corporation from South Korea

**Fig 1. Experimental procedure to screen a probiotic strain possessing a high phosphate absorbing ability.** Isolation of *L. paraplantarum* KCCM 11826P by comparison of phosphate consumption.

## FR-PO989

**Inhibition of TGF-β Unlocks Multiple Proximal Tubule Functions In Vitro**

William H. Fissell,<sup>1</sup> Rachel C. Evans,<sup>1</sup> Kuniko Hunter,<sup>3</sup> Harold D. Love,<sup>1</sup> Shuvo Roy.<sup>2</sup> The Kidney Project <sup>1</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>2</sup>University of California San Francisco, San Francisco, CA; <sup>3</sup>Vanderbilt University, Nashville, TN.

**Background:** Renal proximal tubule cells are both essential to renal function and vulnerable to toxins and ischemia. In vitro, renal tubule cells quickly lose structural, biochemical, and functional features characteristic of their identity. This dedifferentiation of cell culture stress limits the use of tubule cell culture in drug screening and tissue engineering. We examined the role of TGF-β in the dedifferentiation of cell culture stress.

**Methods:** Renal proximal tubule epithelial cells were grown to confluence in 50:50 DMEM/F12 on permeable supports under constant fluid shear stress. Half the wells (n=12) were treated with an inhibitor of TGF-β receptor 1, SB431542. Another 12 wells served as controls. Cells were cultured over 300 days. Confluence of the monolayer was assessed by dextran leak and all experiments were performed only on confluent monolayers. Apical-basal fluid transport, organic anion excretion, and glucose transport were measured. Inhibitors of NHE3 (tenapanor), OAT3 (probenecid), and SGLT2 (phlorizin) were used to examine the specificity of response.

**Results:** Renal tubule cells in control wells did not transport fluid volume, glucose, or organic anions; concentrations in apical and basolateral compartments were identical. Cells treated with SB431542 showed tenapanor-inhibitable volume transport, probenecid-inhibitable para-amino hippurate excretion, and phlorizin-inhibitable glucose uptake.

**Conclusions:** Startlingly, inhibition of a single cytokine receptor, TGF-βR1, was necessary and sufficient to unlock a wide range of differentiated tubule cell functions over a very prolonged period of time. It may be possible to extend the medical use of cell culture to applications requiring stable quantitative fidelity between the *in vitro* and *in vivo* phenotypes.

**Funding:** Private Foundation Support

## FR-PO990

**Transcription Factor PKNOX2 in Myofibroblasts and Tubular Epithelial Cell Contributes to Their Function and Survival During Kidney Fibrosis Progression**

Masanori Obana, Ayaha Yamamoto, Yasushi Fujio. *Osaka Daigaku, Suita, Japan.*

**Background:** PBX/Knotted Homeobox 2 (PKNOX2), a nuclear transcription factor, belongs to the Three Amino acid Loop Extension (TALE) class of homeodomain proteins. We found that PKNOX2 was increased in murine fibrotic kidneys using microarrays. However, the pathophysiological roles of PKNOX2 in kidneys remain unclear. The aim of this study is to elucidate the role of PKNOX2 in fibrotic kidneys.

**Methods:** To assess the relevance of PKNOX2 to kidney fibrosis, murine unilateral ureteral obstruction (UUO) model was induced and the spatiotemporal expression of PKNOX2 was examined using quantitative PCR, western blotting and immunofluorescence. To examine the function of PKNOX2, lentiviral shRNA knockdown system was performed in myofibroblast cell line NRK49F cells and tubular cell HK-2 cells. After NRK49F cells were treated with TGF-β1, cell migration was examined using scratch assay. The viability of myofibroblasts and tubular cells was analyzed using CellTiter Blue assay and TUNEL staining.

**Results:** The mRNA and protein expression of PKNOX2 was increased after UUO in a time-dependent manner. Immunofluorescence revealed that the number of PKNOX2-expressing myofibroblasts was increased, whereas the expression of PKNOX2 was decreased in tubular epithelial cells after UUO. PKNOX2 was upregulated by TGF-β1 in NRK49F cells. PKNOX2 knockdown reduced TGF-β1-induced migration of NRK49F cells and differentiation of fibroblasts into myofibroblasts. The viability was suppressed in PKNOX2-knockdown NRK49F cells either in the presence or absence of TGF-β1 (Cell viability vs control (%): shcontrol-TGFβ1+; 139.8±46.9, shpknox2#1-

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

TGF $\beta$ 1+; 34.0 $\pm$ 10.5, shPknx2#2-TGF $\beta$ 1+; 34.0 $\pm$ 12.3, n=6). Interestingly, knockdown of PKNOX2 also decreased the viability and increased apoptosis of HK-2 cells (Cell viability (%): shcontrol; 100.0 $\pm$ 3.6, shPKNOX2#1; 84.8 $\pm$ 6.0, shPKNOX2#2; 63.9 $\pm$ 12.7, n=6).

**Conclusions:** PKNOX2 regulates (myo) fibroblast functions and tubular cell survival during kidney fibrosis progression.

## FR-PO991

### Repeated Episodes of Ischemia/Reperfusion Induced Hemoxygenase-1 (HO-1) and Anti-Inflammatory Reactivity and Protect Against Chronic Kidney Injury

Juan Antonio Ortega-Trejo, Rosalba Pérez-Villalva, Andrea Sanchez Navarro, Norma Bobadilla. *Molecular Physiology Unit, Instituto de Investigaciones Biomédicas, UNAM, Mexico City, Mexico.*

**Background:** Repeated episodes of ischemia/reperfusion (IR) induce protection against acute kidney injury (AKI), but their long-term effects are unknown. This study was designed to evaluate the transition to chronic kidney disease (CKD) after three moderate and three severe episodes of IR compared to a single episode of IR.

**Methods:** AKI was induced in male Wistar rats that received a single IR (1IR) or three episodes of IR separated by an interval of 10 days (3IR) of moderate (20 min, n=8) or severe (45 min, n=8) bilateral renal ischemia, in both cases, sham operated groups were included (n=6). AKI to CKD transition was evaluated after 9 months. The immediate effects of IR were studied in another set of experiments done 24 h after in the 1IR group (n=5) and after the last IR in the 3IR group (n=8).

**Results:** IR induced AKI that improved before the next episode of IR in the 3IR group. During the subsequent 9-months, the 1IR group (underwent moderate or severe IR) developed CKD, evidenced by progressive proteinuria and renal fibrosis. In contrast, the late adverse effects of IR were markedly ameliorated in the 3IR groups. The immediate response after the 3<sup>rd</sup> IR episode was a robust increment in the expression of hemoxygenase-1 (HO-1), IL-10, TGF- $\beta$  and CD206 positive infiltrating cells, and a decrease of IL-6, TNF- $\alpha$ , and phosphorylation of NF- $\kappa$ B-p65. Interestingly, most CD206 positive cells co-localized with HO-1 in the interstitium. These results contrasted with the response to a single IR episode. In addition, repeated episodes of IR downregulated the expression of CHOP and BiP, endoplasmic reticulum (ER) stress markers.

**Conclusions:** AKI induced by IR results in progressive CKD. Repeated episodes of IR induced overexpression of HO-1, anti-inflammatory activity, reduced RE stress and long-term renal protection.

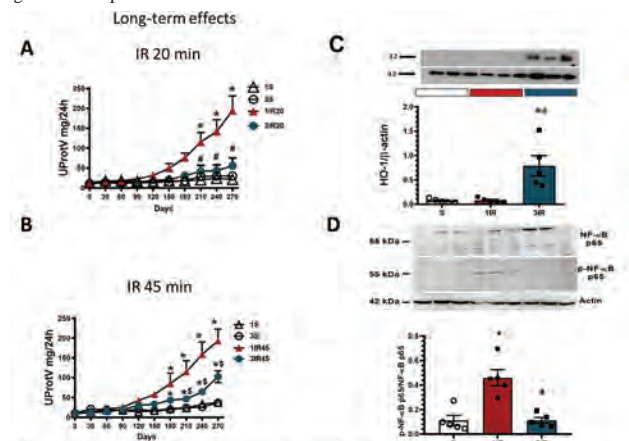

Figure 1. Long-term and acute effects of repeated episodes of ischemia/reperfusion. Proteinuria of animals with A) IR 20 min, B) IR 45 min at long-term of following. Immediate expression of C) HO-1 and D) NF- $\kappa$ B-p65 after the last IR episode.

## FR-PO992

### Hypoxia Induces Metabolic Alterations in Kidney Organoids

Akihiro Minakawa, Matthew Fischer, Jamal El Saghir, Chenchen He, V. Vega-Warner, John R. Hartman, Felix H. Eichinger, Jennifer A. Schaub, Subramaniam Pennathur, Matthias Kretzler, Jennifer L. Harder. *University of Michigan Division of Nephrology, Ann Arbor, MI.*

**Background:** Kidney hypoxia may contribute to development and progression of kidney disease, but the mechanism is difficult to model *in vivo*. The aim of this study was to demonstrate the relevance of a newly developed *in vitro* hypoxic kidney organoid model.

**Methods:** Kidney organoids containing multiple cell types and organ-specific architecture were generated from human pluripotent stem cells (PSCs) and placed in a hypoxia chamber filled with 1% O<sub>2</sub> for 3 and 24 hours. Samples were analyzed for alterations in gene expression of HIF1A and its known targets (qRT-PCR, ELISA of cell lysates and supernatant, IF), and in functional metabolites (LC-MS of <sup>13</sup>C glucose flux) followed by transcriptional pathway analysis (TPA).

**Results:** Hypoxia induced nuclear accumulation of HIF1A, and increased transcription and/or protein levels of known HIF1A targets (VEGF and SLC2A1), glycolytic genes (HK1, HK2 and ENO1) and lactate synthesis. Genes related to Acetyl CoA synthesis (LDHA and PDK1) were suppressed. A flux analysis of glucose metabolism demonstrated

that glycolysis increased, and oxidative phosphorylation decreased in organoids exposed to a hypoxic environment. TPA revealed Glycolysis, Sirtuin Signaling, Cell Cycle Control of Chromosomal and mitochondrial dysfunction as top canonical pathways, with HIF1A being the most significant upstream regulator.

**Conclusions:** Our hypoxic kidney organoid model successfully recapitulates key transcriptional, protein and metabolic alterations generated by hypoxic conditions. This novel *in vitro* model will facilitate investigations into hypoxia's contribution to kidney cell dysfunction, especially in combination with other kidney cell stressors such as inflammation. In the future, a comparison of the hypoxic response of kidney organoid and human kidney cells at a single cell level may help to identify what cell type specific transcriptional alterations are associated with disease development related to hypoxia.

## FR-PO993

### A Novel, Small-Molecule Inhibitor of Ketoheokinase Attenuates Tubular Injury, Immune Cell Infiltration, and Renal Failure in Models of Acute and Chronic Kidney Injury

Natalie Sroda,<sup>1</sup> Shawn S. Badal,<sup>1</sup> Ivan G. Gomez,<sup>1</sup> Maile Velasquez,<sup>1</sup> Frank Y. Ma,<sup>2</sup> Zachary A. Kasun,<sup>1</sup> Petr Jansa,<sup>1</sup> David J. Nikolic-Paterson,<sup>2</sup> John T. Liles.<sup>1</sup> <sup>1</sup>Gilead Sciences Inc, Foster City, CA; <sup>2</sup>Monash Medical Centre Clayton, Clayton, VIC, Australia.

**Background:** Acute or chronic injury to proximal tubule cells (PTECs) causes endogenous production of fructose via the polyol pathway and increases ketoheokinase (KHK) activity. KHK activation causes sustained ATP depletion, cell death and propagation of inflammation cascades, which contributes to loss of kidney function. Here we describe the therapeutic activity of a potent small molecule inhibitor of KHK in models of kidney tubular injury.

**Methods:** The biochemical potency of KHK inhibitor (KHKi), GS-9328, was characterized (IC<sub>50</sub> <50nM) and then evaluated in an ischemia/reperfusion injury (IRI) mouse model (17min ischemia, 24hr reperfusion, -1hr pre-treatment; 115 mg/kg/PO BID); and in an adenine injury rat model (6 weeks 0.25% adenine in diet, 2 week treatment, 60 mg/kg/PO BID). Tubular injury was assessed by histology (PAS), *Kim1* mRNA levels, infiltrating immune cells via flow cytometry, and function by serum levels of creatinine (sCr) and BUN.

**Results:** In the IRI model KHKi administration reduced the percentage of damaged tubules (128%; P<0.001) and kidney *Kim1* mRNA levels (152%, P<0.001), and protected against renal failure based on sCr (0.23 $\pm$ 0.05 vs veh 1.15 $\pm$ 0.09 mg/dL) and BUN (36.8 $\pm$ 7.9 vs veh 126.7 $\pm$ 20.8 mg/dL). In the adenine model, the administration of KHKi began after animals had impaired kidney function (avg sCr = 0.67 $\pm$ 0.02 vs. control diet 0.23 $\pm$ 0.02 mg/dL). Animals treated with KHKi had significantly greater kidney function at the end of the study (sCr = 1.01 $\pm$ 0.06 vs veh 1.26 $\pm$ 0.06 mg/dL & BUN= 46 $\pm$ 1.8 vs veh 59.2 $\pm$ 3.1 mg/dL). KHKi also significantly reduced immune cell infiltration into the kidney cortex [e.g. CD45 (125%; P<0.05), CD8143%; P<0.05]] as assessed by flow cytometry. Finally, to extend translatability of these findings, we confirmed upregulation of the polyol pathway in human CKD datasets via RNA and protein levels of Aldose Reductase.

**Conclusions:** A novel, potent small molecule inhibitor of KHK is efficacious at preventing kidney function decline in rodent models of acute and chronic tubular injury. These data support KHK as a therapeutic target for kidney disease indications where tubular injury plays a major role.

## FR-PO994

### Renoprotective Effect of Phosphodiesterase (PDE) 3A Mutations in a Rat Model of CKD

Theda U. Bartolomeaus,<sup>1,2</sup> Reika Langanki,<sup>2</sup> Olena Potapenko,<sup>1</sup> Anastasiia Sholokh,<sup>2,1</sup> Kerstin Zuehlke,<sup>2</sup> Sylvia Bähring,<sup>1</sup> Michael Bader,<sup>2</sup> Sofia K. Forslund,<sup>1,2</sup> Lajos Marko,<sup>1,2</sup> Enno Klusmann,<sup>1,2</sup> <sup>1</sup>Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>Max-Delbrück-Centrum für Molekulare Medizin in der Helmholtz-Gemeinschaft, Berlin-Buch, Germany.

**Background:** Hypertension is associated with chronic kidney disease (CKD) in more than 80% of cases. Along with diabetes, hypertension is considered as a major risk factor. Here, we are studying a Mendelian form of hypertension (HTNB) that is associated with activating mutations in the *PDE3A* gene. Without treatment, mutation leads to premature death caused by stroke, but remarkably patients are free from impaired kidney function and other forms of target-organ damage. Here, we tested *PDE3A* as a target for renoprotection against CKD.

**Methods:** *PDE3A*-activating (d3aa), *PDE3A*-deleted (functional DEL), and littermate wild-type (WT) rat strains were generated and CKD was induced by bilateral renal ischemia by clamping renal artery for 45 minutes. Blood pressure was continuously measured by telemetry 2 weeks before and 4 weeks after renal ischemia. Renal function was assessed before, 24 hours and 4 weeks after CKD induction. After 4 weeks, kidneys were harvested for further analysis.

**Results:** Serum creatinine was significantly elevated 4 weeks after CKD induction (baseline 0.33, 0.31 and 0.34 mg/dL vs. 0.48, 0.49 and 0.38 mg/dL at 4 weeks, in d3aa, WT and functional DEL, respectively). Rats with *PDE3A*-activating mutation had significantly higher systolic blood pressure than WT or functional DEL animals (142 vs 121 and 115 mmHg, respectively). Despite high blood pressure, d3aa animals had similar serum creatinine, blood urea nitrogen and cystatin-C levels before, 24 hours after and 4 weeks after bilateral renal ischemia. The same was true for gene expression of renal

damage markers lipocalin-2 (Ngal) and kidney injury molecule-1 and fibrosis markers collagen 1 or fibronectin. Western blot and histology confirmed gene expression data.

**Conclusions:** Our data argue that PDE3A modulation can be a useful approach in hypertension associated CKD.

## FR-PO995

### DZNep, a Histone Modification Inhibitor, Inhibits HIF1 $\alpha$ Binding to TIMP2 Gene by Reducing Open Chromatin Area

Tomotaka Yamazaki, Imari Mimura, Masaomi Nangaku. Division of Nephrology and Endocrinology Tokyo Daigaku Daigakuin Igakuken Kenkyuka Igakubu, Bunkyo-ku, Japan.

**Background:** Even after complete resolution of acute kidney injury (AKI), some patients develop chronic kidney disease (CKD) and end-stage renal failure. The mechanism of AKI to CKD is thought to be that transient AKI damage may cause the epigenetic changes, such as histone modification and DNA methylation, that lead to CKD progression. Our previous report showed that 3-Deazaneplanocin A (Dznep), a histone modification inhibitor, suppressed renal fibrosis and the expression of Tissue Inhibitor of Metalloproteinase 2 (TIMP2), which is thought to be a profibrotic factor, in ischemia-reperfusion mice. In this study, we investigated the epigenetic regulation of TIMP2 in tubular cells.

**Methods:** Human kidney-2 (HK-2) cells were treated with Dznep and examined for histone methylation and open chromatin status by Western-blotting, Chip-qPCR and Formaldehyde-Assisted Isolation of Regulatory Elements (FAIRE)-qPCR. The relationship with hypoxia-inducible factor 1 $\alpha$  (HIF1 $\alpha$ ) was also examined by Chip-qPCR and reporter assay.

**Results:** In HK-2 cells, TIMP2 expression was upregulated under hypoxia and suppressed by Dznep. Dznep treatment had a repressive effect on various histone methylation such as H3K4me3, H3K27me3 and H3K9me3. The Chip-qPCR of H3K4me3 for TIMP2 gene region showed that Dznep treatment reduced H3K4me3. The FAIRE-qPCR of TIMP2 gene region showed that Dznep treatment suppressed the percentage of open chromatin area, which was elevated by hypoxia. In addition, the Chip-qPCR of HIF1 $\alpha$  for TIMP2 gene showed that Dznep inhibited the binding region of HIF1 $\alpha$ , which was elevated by hypoxia. The reporter assays for the binding region of HIF1 $\alpha$  showed enhanced transcriptional activity by hypoxia.

**Conclusions:** Dznep suppresses the expression of TIMP2, which is elevated by hypoxia, by altering the histone methylation state of TIMP2 gene, decreasing the percentage of open chromatin, and inhibiting HIF1 $\alpha$  binding.

### Urate Regulates Mitochondrial Function in a URAT1 Dependent Manner in Renal Epithelial Cells

Owen M. Woodward,<sup>1</sup> Victoria L. Halperin Kuhn,<sup>1</sup> Allison C. Lane-Harris,<sup>1</sup> Ava M. Zapf,<sup>1</sup> Krister Bamberg,<sup>2</sup> <sup>1</sup>University of Maryland School of Medicine, Baltimore, MD; <sup>2</sup>AstraZeneca Translational Sciences and Experimental Medicine, Early Cardiovascular, Renal and Metabolism (CVRM), Biopharmaceuticals R&D, Gothenburg, Sweden.

**Background:** Alterations in cell metabolism in the proximal tubule are a recognized component in the initiation and progression of chronic kidney disease (CKD). Previously, we used whole kidney RNAseq to determine genes and pathways that were differentially expressed in a genetic mouse model of hyperuricemia (*Uox-iKO*). The pathways most affected in the *Uox-iKO* males were related to metabolism and oxidative phosphorylation. The *Uox-iKO* male animals also showed significant increases in urinary lactate excretion after induction of *Uox* KO. Here, we focused on the role of renal urate handling in controlling lactate secretion and mitochondrial function in human renal epithelial cells. Lactate is a substrate of URAT1 (*SLC22A12*) moving in *trans* with the apical entry of

urate from the renal tubule lumen. We hypothesized that increased extracellular urate will promote the secretion of lactate via URAT1 and alter cellular respiration and mitochondrial function.

**Methods:** Using cultured primary normal human cortical renal epithelial cells (NHCRE) we measured the effect of chronic extracellular urate on intracellular lactate and oxygen consumption rate using the Seahorse XFe96 analyzer.

**Results:** In NHCRE cells we found that chronic exposure to increased extracellular urate (500 $\mu$ M from 24hrs to 2 weeks) significantly lowered intracellular lactate in the presence of either high (4.5g/l) or reduced glucose (1g/l), and that additional extracellular lactate rescued intracellular levels. Further, the application of probenecid, a general anion transporter blocker with affinity for URAT1, or verinurad, a specific URAT1 inhibitor, abolished the effects of extracellular urate on lactate levels, though URAT1 inhibition alone had no effect. Next, we measured the oxygen consumption rate (OCR, normalized to cell number) in NHCRE cells using the Seahorse analyzer. We found chronic exposure to increased extracellular urate (500 $\mu$ M for 24 hours) significantly increased basal respiration and the maximum respiratory capacity. Both effects were abolished in the presence 0.5 $\mu$ M of verinurad.

**Conclusions:** We conclude that increased tubular urate alters intracellular lactate levels and mitochondrial function in a URAT1 dependent manner, providing mechanistic evidence that urate alters cell metabolism in the proximal tubule and may contribute to kidney disease progression.

## FR-PO997

### ALDH2 Expression Is Reduced in Human and Mouse Renal Tissue Following CKD

Jjen Chiu,<sup>1</sup> Amrendra K. Ajay,<sup>1,2</sup> Kavya M. Shah,<sup>2</sup> Li-Li Hsiao,<sup>1,2</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA.

**Background:** Chronic kidney disease (CKD) poses a tremendous socioeconomic burden in addition to increasing rates of morbidity and mortality, and several East Asian countries have a much higher prevalence of CKD compared to the global average. The ALDH2 E504K polymorphism is found in 35-45% of East Asian populations and has been linked to a higher risk of various cardiovascular diseases, neurological disorders, and cancers. However, despite the high prevalence of the ALDH2 polymorphism and of CKD among East Asian populations, little is known about the role of ALDH2 in CKD.

**Methods:** ALDH2 expression patterns in kidney tissue were determined via immunohistochemical staining of mouse kidneys and human kidney biopsy samples. To explore the role of ALDH2 in CKD, ALDH2 expression was studied *in vivo* using an aristolochic acid-induced CKD mouse model and *in vitro* via human renal proximal tubular epithelial cells (RPTECs). RPTECs were further utilized and cultured with the profibrotic protein TGF- $\beta$  to investigate the role of ALDH2 in kidney fibrosis.

**Results:** ALDH2 was highly expressed in the renal proximal tubules of healthy human and mouse kidneys. ALDH2 expression was significantly downregulated in CKD patients and inversely correlated with the severity of CKD, in human and mouse studies. Mechanistically, it was demonstrated that a deficiency in ALDH2 expression was associated with kidney fibrosis *in vitro*, due to the role of ALDH2 protein in modulating the epithelial-mesenchymal transition.

**Conclusions:** ALDH2 has a specific and localized expression pattern in the kidneys, and a deficiency in ALDH2 expression is linked to kidney fibrosis. These findings may have significant clinical implications in the development and progression of kidney disease, especially among East Asian populations.

**Funding:** Other NIH Support - American Heart Association

## FR-PO998

### A Molecular Mechanism Study to Reveal Hirudin Downregulation to PI3K/AKT Signaling Pathway With PDGFB in Renal Fibrosis Treatment

Ying Li,<sup>1</sup> Haitao Tu,<sup>2</sup> <sup>1</sup>Chongqing Traditional Chinese Medicine Hospital, Chongqing, China; <sup>2</sup>The First Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China.

**Background:** Chronic kidney disease, also known as CKD, is a prevalent chronic disease jeopardizing public health; however, there is no an efficient therapy to prevail over this disease. Our study was committed to revealing the hirudin's regulation to chronic kidney disease as well as the molecular mechanism.

**Methods:** We built renal fibrosis model on animal levels, which was subsequently given with hirudin disposal, then we performed the HE and Masson to evaluate for renal fibrosis (RF) and had our detection to relevant marker proteins of RF with western blot. Finally, we detected on the expressions of PDGFRBB, PDGFR $\beta$  and the PI3K-AKT pathway.

**Results:** Our outcomes of the animal level demonstrated that the conditions of severe tubular dilatation or atrophy, interstitial fibrosis, inflammatory cell infiltration, and massive deposition of interstitial collagen in model group were withdrew after the addition of hirudin. WB results showed that the marker proteins of RF, PDGFRBB, PDGFR $\beta$  and the PI3K-AKT signal molecules were significantly reduced by addition of hirudin.

**Conclusions:** The declining in PDGFR $\beta$  phosphorylation because of the hirudin's interaction with PDGF-BB is capable of suppressing PI3K-AKT signaling pathway as well as the EMT.

**Funding:** Government Support - Non-U.S.

## FR-PO999

## Cadherin-11 Inhibitor SD-133 Prevents Renal Fibrosis in a Model of Tubulointerstitial Disease in Male Mice

Shania R. Davidson,<sup>1,2</sup> Sharmila Adapa,<sup>1</sup> Katherine C. Allen,<sup>1</sup> Bryce A. Jones,<sup>1</sup> Katelyn Dial,<sup>1</sup> Komuraiah Myakala,<sup>1</sup> Xiaoxin Wang,<sup>1</sup> Moshe Levi.<sup>1</sup>  
<sup>1</sup>Georgetown University Medical Center, Washington, DC; <sup>2</sup>Howard University College of Arts and Sciences, Washington, DC.

**Background:** Fibrosis of the kidney is the last and highly morbid stage of various types of chronic kidney diseases. The progressive decline of kidney function is the result of prolonged states of inflammation and maladaptive repair mechanisms of extracellular matrix and transmembrane proteins. Cadherin-11 is transmembrane cell junction protein upregulated in various organs within fibrotic diseases, including the kidney. With this, we hypothesized that Cadherin-11 antagonism is nephroprotective in the adenine model of kidney disease.

**Methods:** 12-week-old male 129S1/SvImJ mice were fed chow or chow supplemented with adenine (0.2% w/w) ad lib for 7 weeks. Mice were injected IP with vehicle (30% PEG-400) or Cadherin-11 antagonist SD-133 (40 mg/kg BW) 3 days per week for the duration of the study. GFR was measured in vivo by transdermal clearance of FITC-Sinistrin. Plasma and organs were later collected following euthanasia and processed for biochemical analysis.

**Results:** Mice fed the adenine diet had decreased body weight compared to control mice, but bodyweight was unchanged between vehicle and SD-133 treatment groups. Plasma creatinine increased with disease and was unchanged with SD-133 treatment. Additionally, there was an increase in BUN ( $P<0.0001$ ), but there was no change with SD-133 treatment. In vivo measurements showed that GFR was decreased with disease ( $P<0.0001$ ), but again there was no change with SD-133 treatment. However, on western blot, fibronectin and phosphorylated SMAD3 were increased with disease ( $p<0.001$ ) and reduced with SD-133 treatment ( $p<0.05$ ).

**Conclusions:** Cadherin-11 antagonism did not exhibit beneficial kidney effects in the adenine diet model using male mice on the 129S1/SvImJ background at the 7-week timepoint as determined by BUN, plasma creatinine, and in vivo GFR measurements. However, western blots showed that Cadherin-11 antagonism reduced renal fibrosis and inhibited the pro-fibrotic SMAD3 pathway, therefore indicating that Cadherin-11 antagonism was nephroprotective in this model.

**Funding:** NIDDK Support

## Metabolomics and Mechanistic Approaches to Identify Therapeutic Targets for Progressive Kidney Disease

Afaf Saliba, Hongping Ye, Kumar Sharma. Center for Precision Medicine, The Laboratory of Dr. Kumar Sharma The University of Texas Health Science Center at San Antonio, San Antonio, TX.

**Background:** The role of MDM2 in chronic kidney disease has not yet been clarified. Thus, we aim to (1) establish the link between MDM2 loss and skewed metabolic pathways in the DKD kidney and (2) screen precise therapeutic pathways that improve mitochondrial function.

**Methods:** (1) To elucidate a metabolic mechanism through which MDM2 absence reduces mitochondrial biogenesis and promotes kidney dysfunction, we developed transgenic 3-4 months mice with doxycycline-inducible deletion of MDM2 in renal tubule cells (MDM2cKO). We performed ZipChip CE MS metabolomics analysis on MDM2cKO kidneys and plasma samples. (2) To determine if AMPK activation could benefit tubular epithelial cells, we transfected HK2 cells with siRNA-MDM2 (HK2; MDM2KD) vs. siRNA-scramble, treated the cells with AICAR (AMPK activator) and performed Annexin V apoptosis assay.

**Results:** (1) While the control group ( $n=19$ ) survived at 100% during the doxycycline treatment, the MDM2cKO mice group ( $n=8$ ) had a 65% survival percentage at day 6 and 0% survival beyond day 8. In addition to substantial increase in the Blood Urea Nitrogen (BUN) (300-fold increase) in the cKO compared to control mice, we observed a significant decrease in PGC-1α (master regulator of mitochondrial biogenesis) and MCCC2 kidney mRNA levels. MCCC2 is an essential enzyme for Leucine (Leu) metabolism. ZipChip MS analysis revealed a significant decrease in Alanine (Ala) levels in the MDM2cKO plasma. Both Leu and Ala are essential to support mitochondrial biogenesis. (2) Annexin V assay on MDM2KD HK2 cells showed a significant decrease in apoptotic cells with AMPK stimulation (HK2; MDM2KD:  $66.67\% \pm 7.572$ ; HK2; MDM2KD + AICAR  $1\text{mmol/L}$ :  $30.67\% \pm 9.452$ ;  $p=0.0068$ ).

**Conclusions:** MDM2cKO mice are models for metabolic progressive kidney disease associated with decreased mitochondrial biogenesis and altered Leu and Ala metabolism. AMPK stimulation *in vitro* significantly improved cell survival upon loss of MDM2 in HK2 cells. We are currently exploring mechanisms that connect MDM2 to Leu and Ala and testing AMPK activation role in improving kidney function, metabolic outcome, and survival of MDMcKO mice. The outcomes of this study will lead to improved treatment approaches for metabolic-related kidney diseases such as DKD.

**Funding:** Other NIH Support - The project described was supported by the National Center for Advancing Translational Sciences, National Institutes of Health, through Grant TL1 TR002647. **Psoralen Ameliorates Renal Fibrosis Induced by Unilateral Ureteral Obstruction in Mice**

Tae won Lee,<sup>1</sup> Eunjin Bae,<sup>1,3</sup> Se-Ho Chang,<sup>2,3</sup> Dong Jun Park,<sup>1,3</sup> <sup>1</sup>*Gyeongang National University Changwon Hospital, Changwon, Gyeongangnam-do, Republic of Korea;* <sup>2</sup>*Gyeongang National University Hospital, Jinju, Gyeongangnam-do, Republic of Korea;* <sup>3</sup>*Gyeongang National University Graduate School of Medicine, Jinju, Gyeongangnam-do, Republic of Korea.*

**Background:** Renal fibrosis arises in most progressive renal diseases, regardless of the disease underlying end-stage kidney disease. Psoralen (PSO), a major active component extracted from *Psoralea corylifolia* L. seed, has several biological effects. However, the role of psoralen in renal fibrosis is still unclear. This study was undergone to evaluate the PSO on the development and progression of renal fibrosis induced by unilateral ureteral obstruction (UO) in mice model.

**Methods:** The mice were divided into four groups: PSO (20 mg/kg, i.g., n = 5), PSO + Sham (n = 5), UO (n = 10), and PSO + UO (n = 10). PSO was intragastrically administered 24 hour before the UO and continued afterward for 7 days and all mice were killed 7 days after UO.

**Results:** Severe tubular atrophy, tubular injury, and tubulointerstitial fibrosis were significantly developed in UO mice. Higher expression of TGF- $\beta$ 1 is accompanied by elevated  $\alpha$ -SMA and p-Smad2/3 after 7 post-UO. However, PSO treatment reduced tubular injury and interstitial fibrosis and the expression of TGF- $\beta$ 1,  $\alpha$ -SMA, and p-Smad2/3. Furthermore, level of macrophages (represented by F4/80 positive cells) and inflammasome reflected by inflammasome markers such as NLRP3 and cCASP-1 were significantly decreased by PSO treatment.

**Conclusions:** This is the first study to show that PSO reduces renal fibrosis in UO mice model. These results suggest that PSO had merits of further exploration as a therapeutic agent in the management of chronic kidney disease.

## FR-PO1002

**Cyclosporine A and Paraquat Induce Lysosomal Deacidification in Proximal Tubular Cells In Vitro**

Sylvina da Silva Fernandes, Gerd Schreurs. Lab of Pathophysiology - CINAC *Universiteit Antwerpen, Antwerpen, Belgium.*

**Background:** Chronic interstitial nephritis in agricultural communities (CINAC) is a chronic toxin-induced nephropathy of which the underlying molecular mechanism and causal toxins are unknown. Due to the geographical distribution of CINAC cases in and around agricultural communities, we and others suspect that environmental toxins could play a role in disease development. Recently, we discovered a diagnostic lesion in CINAC renal biopsies encompassing large dysmorphic lysosomes in proximal tubular cells (PTCs). The same phenotype was found in PTCs of transplant patients receiving nephrotoxic calcineurin inhibitors (CNIs) as immunosuppressive therapy. Hence, it is hypothesized that CINAC is caused by exposure to an (unknown) environmental toxin, which affects the lysosomal system. In search for the CINAC culprit(s), we therefore aimed to optimize a *in vitro* assay to assess effects on PTC lysosomal function.

**Methods:** Since impaired lysosomal acidification indicates a functional defect, the central approach to the assay consists in exposing PTCs to various toxins and quantifying acidification. HKC-8 cells were exposed to Bafilomycin A1 (Baf), an inhibitor of lysosomal acidification (positive control), Cyclosporine A (CsA, a CNI) or Paraquat (PQ, a herbicide). For each toxin a sub-toxic dose was chosen from a concentration range based on cell death quantification using Sytox Green. Lysosomal acidification was assessed by incubating cells with LysoTracker (LT) (50 nM, 30 minutes) followed by flow cytometric quantification. To correct for the size of the lysosomal compartment in these cells, a Western Blot targeting LAMP-1, a lysosomal protein, was performed.

**Results:** In the optimized assay, HKC-8 cells were incubated with normal medium (Control), 10nM Baf, 25  $\mu$ M CsA and 100  $\mu$ M PQ for 6 hours. The mean LT Red signal, relative to control, was significantly lower ( $p < 0.01$ ) in all three conditions. No significant difference in LAMP-1 abundance was found, indicating no significant contribution of lysosome to the LT signal. CsA exposure caused a significant increase in granularity as measured by flow cytometry and observed visually as clear, irregular vacuoles under brightfield microscopy.

**Conclusions:** Both CsA and PQ induce lysosomal deacidification in PTCs *in vitro*, but only CsA causes an increase of granules. Immunostains are planned to identify the nature of these granules.

**Funding:** Government Support - Non-U.S.

## FR-PO1003

**Mycophenolic Acid Decreases TGF- $\beta$ 1 Induced Fibronectin Expression Through Inhibition of F-actin Polymerization and Downregulation of SMAD3 Phosphorylation in Human Proximal Tubular Epithelial Cells**

Tsz Wai Tam, Susan Yung, Tak Mao D. Chan. *The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong.*

**Background:** Despite advances in immunosuppressive treatment, many patients with lupus nephritis (LN) develop chronic kidney disease (CKD) characterized by increased TGF- $\beta$ 1 expression and accumulation of matrix proteins in the tubulo-interstitium leading to progressive kidney failure. Fibronectin serves as a scaffold for the deposition of other matrix proteins. We previously reported that mycophenolic acid (MPA) inhibited fibronectin expression in proximal tubular epithelial cells (PTEC) in murine LN. This

study investigated the mechanism through which TGF- $\beta$ 1 induced fibronectin expression in PTEC and how MPA exerted its anti-fibrotic effect.

**Methods:** Confluent growth arrested PTEC were stimulated with TGF- $\beta$ 1 (1 ng/ml) in the presence or absence of MPA (5  $\mu$ g/ml), LY2109761 (specific inhibitor of TGF- $\beta$ RI/II activity, 1  $\mu$ M), SIS3 (specific SMAD3 inhibitor, 7 $\mu$ M), PD98059 (specific ERK inhibitor, 50  $\mu$ M) or cytochalasin B (inhibitor of actin polymerization, 2  $\mu$ M), for up to 48 h, and cells were harvested for qPCR, Western blot and immunohistochemistry.

**Results:** TGF- $\beta$ 1 induced fibronectin expression in a time-dependent manner, accompanied by increased SMAD2, SMAD3, TGF- $\beta$ RI and TGF- $\beta$ RII expression and F-actin polymerization with the formation of thick stress fibres that traversed the cells. Constitutive fibronectin expression was mediated through ERK phosphorylation, whereas fibronectin induced by TGF- $\beta$ 1 was mediated through SMAD2, SMAD3 and ERK phosphorylation. MPA inhibited fibronectin expression through suppression of F-actin polymerization, decreased TGF- $\beta$ RII expression and phosphorylation of SMAD3 and ERK, but had no effect on SMAD2 phosphorylation.

**Conclusions:** MPA inhibits fibronectin synthesis in PTEC by targeting TGF- $\beta$ 1 canonical and non-canonical signaling pathways and F-actin reorganization. The results could have implications on the intervention of CKD due to LN or other causes.

**Enhancer of Zeste Homolog 2 Promotes Renal Interstitial Fibrosis Through Downregulation of Phosphoenolpyruvate Carboxykinase 1 Mediated Gluconeogenesis**

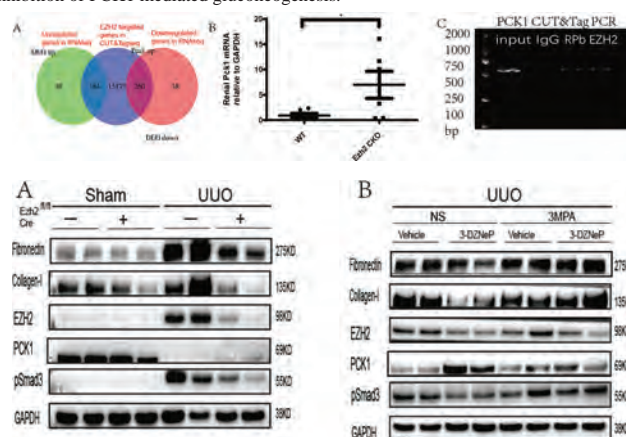

Yanze Wang, Ming Wu, Chaoyang Ye. *Shuguang Hospital, Shanghai, China.*

**Background:** Renal fibrosis is the common pathological pathway of various chronic kidney diseases progressing to the end stage of renal failure. The methyltransferase enhancer of zeste homolog 2 (EZH2) has been identified as a therapeutic target to inhibit renal interstitial fibrosis. However, the mechanism underlying the role of EZH2 in renal fibrosis is not completely understood.

**Methods:** Unilateral ureteral obstruction (UO), unilateral ischemia-reperfusion injury (UIRI) mouse models were established. PCR, cleavage under targets and tagmentation (CUT&Tag) and Western blotting was performed to evaluate the expression of EZH2 and phosphoenolpyruvate carboxykinase 1 (PCK1).

**Results:** By using EZH2 inhibitor 3-DZNEP and *Ezh2* conditional knockout mice, we confirmed the pro-fibrotic effect of EZH2 in unilateral ureteral obstruction (UO). Through RNA sequence and cleavage under targets and tagmentation (CUT&Tag) sequence analysis, we found that the phosphoenolpyruvate carboxykinase 1 (PCK1), a critical enzyme in gluconeogenesis, is negatively regulated by EZH2 in fibrotic kidneys, which was further confirmed by quantitative PCR, CUT&Tag and Western blotting. We further showed that deletion or inhibition of EZH2 inhibited renal fibrosis and enhanced PCK1 expression and activity in unilateral ischemia-reperfusion injury (UIRI) and folic acid induced mouse nephropathy. Moreover, the dysregulated production of renal glucose and lactate in mouse UO kidneys was restored after EZH2 inhibition by 3-DZNEP. Finally, inhibition of PCK1 by 3-mercaptopropionic acid (3-MPA) abrogated the anti-fibrotic effect of 3-DZNEP in UO kidneys.

**Conclusions:** We conclude that EZH2 promotes renal interstitial fibrosis through inhibition of PCK1 mediated gluconeogenesis.

## FR-PO1005

**CDK5 Deletion Prevents Proximal Tubule Cell Maladaptive Dedifferentiation and Kidney Fibrosis**

Sho Sugahara, Kensei Taguchi, Bertha C. Elias, Craig R. Brooks. *Vanderbilt University Medical Center, Nashville, TN.*

**Background:** Acute kidney injury (AKI) occurs in more than 20% of hospitalized patients. AKI not only increases morbidity and mortality risks in patients, but also dramatically increases the incidence of chronic kidney disease (CKD), involving progressive fibrosis and loss of organ function, in a process termed AKI-to-CKD transition. Maladaptive repair and dedifferentiation of proximal tubular cells is a hallmark of AKI-to-CKD transition. Cyclin-dependent kinase 5 (CDK5) is a kinase first identified

in neuronal cells that regulates cell cycle exit in basal conditions, while hyperactivation of CDK5 and promotes dedifferentiation, G2/M arrest, and neuronal pathology. The role of CDK5 in kidney tubular cells is largely unknown.

**Methods:** CDK5fl/fl mice were bred to Six2-Cre to generate tubule specific CDK5 knockout (CDK5<sup>Amh</sup>). Wild-type, CDK5fl/fl, and CDK5<sup>Amh</sup> mice aged 8-12 weeks were subjected to unilateral ureter obstruction (UUO) model. Inhibition of CDK5 was performed in wild-type mice and primary cultured proximal tubular cells with/without aristolochic acid and markers of dedifferentiation and fibrosis were compared.

**Results:** Kidney injury increased total CDK5 and phospho-CDK5 levels in proximal tubule cells, which correlated with increased markers of dedifferentiation and fibrosis. Despite having similar levels of G2/M arrest as CDK5fl/fl controls following UUO, CDK5<sup>Amh</sup> mice had reduced renal fibrosis following injury. CDK5<sup>Amh</sup> mice had markedly reduced numbers of dedifferentiated tubule cells and decreased expression of profibrotic and dedifferentiation markers, compared to injured CDK5fl/fl mice. Administration of a specific inhibitor of hyperactive CDK5, GLX, to wild-type mice subjected to UUO suppressed dedifferentiation and fibrosis similar to CDK5<sup>Amh</sup> mice. Suppression of CDK5 in cultured proximal tubular cells resulted in a decrease in profibrotic cytokine secretion and a reduction in dedifferentiation markers, while overexpression of CDK5 induced dedifferentiation.

**Conclusions:** CDK5 is a novel regulator of AKI-to-CKD transition. Elevated CDK5 in proximal tubule cells increases cell dedifferentiation and secretion of profibrotic cytokines, resulting in exacerbation of fibrosis. Inhibition of proximal tubular dedifferentiation by targeting CDK5 may be a new therapeutic strategy for AKI-to-CKD transition.

### Single-Cell Analysis Identifies the Interaction of Altered Renal Tubules With Basophils Orchestrating Kidney Fibrosis

Tomohito Doke, Amin Abedini, Daniel Aldridge, Jihwan Park, Michael S. Balzer, Rojesh Shrestha, Gaia M. Coppock, Christopher A. Hunter, Katalin Susztak. *University of Pennsylvania, Philadelphia, PA.*

**Background:** Inflammation is an important component of fibrosis; however, immune processes that orchestrate kidney fibrosis are not well understood. Here we apply single-cell sequencing to a mouse model of kidney fibrosis. We identify a subset of kidney tubule cells with a profibrotic-inflammatory phenotype characterized by the expression of cytokines and chemokines associated with immune cell recruitment.

**Methods:** Single-cell libraries were generated from the control and unilateral ureteral obstruction (UUO) model of kidney fibrosis and patient samples using the 10x system and sequenced 77,393 high-quality mice and 13,380 human cells after quality control. Clustering and data processing and cell trajectory analysis followed established pipelines. Bulk RNA sequencing and in silico deconvolution was used to define cell fractions. Flow sorting (FACS) with established antibodies and in situ hybridization (ISH) were used for validation. Two complementary methods were used to delete basophils, using the Mcpt8Cre-DTR mice and MAR-1 antibody. Flow sorted basophils were analyzed in vitro.

**Results:** Unbiased clustering identified 28 cell populations in renal fibrosis. Sub-clustering of UUO proximal tubule cells (PT) cells identified 8 PT cell types including profibrotic PT cells that expressed a proinflammatory gene signature (Il3a, Tnfrsf12a, Cd74, Pdgfrb, Cxcl1, Cxcl10, and Cxcl16). Receptor-ligand interaction analysis and experimental validation indicate that CXCL1 secreted by profibrotic tubules recruits CXCR2+ basophils. Basophils were identified based on the expression of Mcpt8, Fcεr1a, and Cd200r3, and their presence were validated by FACS and ISH. In mice, these basophils are an important source of IL-6 and recruitment of Th17 cells. Genetic deletion or antibody-based depletion of basophils as well as IL-6 receptor blockade results in reduced renal fibrosis. Human kidney single-cell, bulk gene expression, and immunostaining validated the functional role of basophils in patients with kidney fibrosis.

**Conclusions:** Collectively, we identify profibrotic proximal tubules activating basophils and Th17 cells as important contributors to the development of renal fibrosis and suggest that targeting these cells might be a useful clinical strategy.

**Funding:** NIDDK Support

## FR-PO1007

### Intrinsic TGF-β Signaling in Proximal Tubule Metabolism and Response to Chronic Injury

Merve Kayhan,<sup>1</sup> Judith Vouillamoz,<sup>1</sup> Milica Bugarski,<sup>1</sup> Andrew Hall,<sup>1</sup> Leslie S. Gewin,<sup>2</sup> Roland H. Wenger,<sup>1</sup> Stellan Nlandu khodo.<sup>1</sup> <sup>1</sup>University of Zurich, Zurich, Switzerland; <sup>2</sup>Washington University in St Louis, St Louis, MO.

**Background:** The proximal tubule (PT) is the most metabolic and pivotal renal segment in the pathogenesis of chronic kidney disease (CKD). Excessive TGF-β signaling and mitochondria dysfunction are two features of CKD, however, how intrinsic TGF-β signaling and mitochondria interplay in PT response to chronic injury is unknown. We recently reported the beneficial effect of intact TGF-β signaling in PT response to chronic injury; our RNAseq analysis revealed mitochondria as the most affected cellular component in PT cells lacking the TGF-β receptor (TβRII). We therefore hypothesized that intrinsic TGF-β signaling is crucial for PT mitochondrial integrity and response to chronic injury.

**Methods:** To test this, mice lacking TβRII in the PT (γGT-Cre;Tgfb2<sup>fl/fl</sup>) and their floxed littermates were injured using aristolochic acid (AA) model of CKD, and PT mitochondria and renal outcomes were analyzed.

**Results:** Electron and multiphoton intravital microscopy showed severe mitochondrial injury and dysfunction in AA-injured γGT-Cre;Tgfb2<sup>fl/fl</sup> mice as compared to their floxed littermates. FACS analysis showed increased adaptive immune response, especially the

Cgas/Sting/IFNγ axis in γGT-Cre;Tgfb2<sup>fl/fl</sup> mice. Consistently, 10X spatial transcriptomics confirmed increased cortical injury and fibrosis, and decreased renal function (BUN) in γGT-Cre;Tgfb2<sup>fl/fl</sup> mice. Further analysis revealed impaired expression of electron transport chain (ETC) proteins (Complex I), mitochondrial biogenesis and mitophagy (mito-QC reporter mice) associated with oxidative stress and a metabolic rewiring towards aerobic glycolysis (Seahorse) in the absence of TβRII. Treatment of PT cells with NAD+ increased ATP production and reduced oxidative stress in PT cells lacking TβRII.

**Conclusions:** This study points out the role of TGF-β signaling in maintaining PT metabolism partly by controlling ETC proteins expression, mitochondrial biogenesis and mitophagy, and how this role affects PT response to CKD.

**Funding:** Government Support - Non-U.S.

## FR-PO1008

### Investigating Lysozyme as a Mediator of Tubular Epithelial Inflammation: An Example of CKD Knowledge Graph Target Discovery and Validation

Kevin Woollard,<sup>1</sup> Barbara Musial,<sup>1</sup> Karolina A. Nilsson,<sup>1</sup> Elena Liarte Marin,<sup>1</sup> Lisa Buval,<sup>1</sup> Iain MacPhee,<sup>1</sup> Maria Ryaboshapkina,<sup>1</sup> Ufuk Kirik,<sup>1</sup> Dirk S. Paul,<sup>1</sup> Mohammad Bohlooly,<sup>1</sup> Andrea Taddei,<sup>2</sup> Delphine M. Rolando,<sup>2</sup> Andres Mori,<sup>2</sup> Claus Bendtsen,<sup>1</sup> Pernille B. Laerkegaard Hansen.<sup>1</sup> <sup>1</sup>AstraZeneca, Cambridge, United Kingdom; <sup>2</sup>BenevolentAI, London, United Kingdom.

**Background:** Lysozyme (Lyz) is an antimicrobial enzyme catalysing hydrolysis of bacterial cell walls. Lyz was identified as a potential target for CKD by applying an AI-driven drug discovery approach to a Knowledge Graph. Clinical evidence included nephropathy of chronic myelomonocytic leukaemia associated with increased circulating levels of Lyz with tubular kidney staining. Orthogonal genetic support from Mendelian mutations as cause for renal amyloidosis, and common variants in *LYZ* associated with increased monocyte counts, associated with systemic inflammation and cardiovascular risk in CKD. Published data shows circulating levels of Lyz is associated with decline in renal function and predict worse CKD survival. Therefore, we wanted to investigate if Lyz is a mediator of kidney injury using in-vitro models of tubular inflammation using proximal tubular epithelial cells (PTEC).

**Methods:** Primary PTEC were cultured with human Lyz at physiological concentrations (0-50ug/ml) over 0-30mins-7hrs-2days. We measured markers of PTEC injury, inflammation, ROS, ER stress, MAPK signalling and viability.

**Results:** Overall while we saw a dose dependent increase in KIM-1/clusterin, there was very limited or no change in cytokines (IL8, IL1b, TNFa, IL6), ROS, ER stress, MAPK phosphorylation or cell death after Lyz treatment at all time points. We confirmed PTEC intracellular Lyz uptake using in-direct fluorescence assays. We examined Lyz expression directly from PTEC or primary macrophages in response to CKD inflammatory triggers. We could not detect any expression from PTEC, but potent secretion from macrophages. Therefore, we tested PTEC:macrophage co-culture. Like Lyz incubation alone, activated macrophages secreting lysozyme did not overtly lead to PTEC inflammation.

**Conclusions:** Our data show that Lyz has limited effect on PTEC inflammation in-vitro. These observations may indicate that elevated Lyz seen in CKD patients could be a marker of disease or of systemic inflammation in CKD. However, in-vivo data would be needed to draw firm conclusions on the relationship between long-lasting chronic exposure to elevated Lyz levels and tubular damage in CKD patients.

## FR-PO1009

### The VEGF Inhibitor Soluble FLT1 Does Not Aggravate AKI-to-CKD Transition

Cleo C. Van Aanhold, Angela Koudijs, Kyra L. Dijkstra, Cees van Kooten, Jan A. Bruijn, Hans J. Baelde. *Leids Universitair Medisch Centrum, Leiden, Netherlands.*

**Background:** Soluble Fms-like tyrosine kinase 1 (sFLT1) is an endogenous VEGF inhibitor. sFLT1 critically maintains the podocyte cytoskeleton and has anti-inflammatory effects in diabetic kidney disease (DKD). However, sFLT1 has also been related to peritubular capillary (PTC) loss which contributes to chronic kidney damage following acute kidney injury (AKI-to-CKD transition). Here, we studied whether overexpression of sFLT1 aggravates experimental AKI-to-CKD transition and whether sFLT1 is increased in human kidney fibrosis.

**Methods:** Mice were transfected with a *sFlt1* DNA construct via electroporation. After confirming transfection efficacy, control and sFLT1-treated mice underwent renal unilateral IRI and were sacrificed after 28 days; untreated mice underwent sham surgery. Serum KIM-1 was measured by ELISA. Sirius red, F4/80 and endomucin stainings were quantified in renal cortex and medulla. Glomerular and cortical *sFLT1-i13* mRNA expression was measured in biopsies obtained from DKD patients (n=23) and unaffected tumour-nephrectomy tissues as a control (n=14).

**Results:** At 48h after IRI, serum KIM-1 was increased compared to sham and baseline; however, sFLT1 did not affect serum KIM-1, indicating similar levels of AKI in sFLT1 and control mice. One month after IRI, cortical and medullary fibrosis and the number of macrophages were increased compared to sham; the PTC number was decreased in IRI mice. Overexpression of sFLT1 did not increase the amount of fibrosis or renal macrophages in IRI mice; further, sFLT1 had no effect on the PTC number in IRI mice. Finally, *sFLT1* mRNA levels were similar in fibrotic and normal kidney biopsies; in fibrotic kidney cortex tissues, high *sFLT1* levels correlated with increased thrombospondin and decreased syndecan-1 mRNA levels, which may reflect renal endothelial protection.

**Conclusions:** sFLT1 does not aggravate experimental AKI-to-CKD transition: sFLT1 has no effect on chronic renal fibrosis, macrophage infiltration and PTC loss after IRI. Moreover, *sFLT1* expression is not increased in human CKD; in contrast, renal sFLT1 levels are correlated with markers of nephroprotection. Because we previously found that sFLT1 has profound anti-inflammatory potential in DKD, our findings suggest that sFLT1 can be administered at a therapeutically effective dose without aggravating maladaptive kidney damage.

## SA-PO001

### Computational Segmentation of Glomeruli to Align Histomorphology With Spatial Transcriptomic Signature

Brandon Ginley,<sup>1</sup> Ricardo Melo ferreira,<sup>2</sup> Ulysses G. Balis,<sup>4</sup> Sanjay Jain,<sup>3</sup> John E. Tomaszewski,<sup>1</sup> Tarek M. El-Achkar,<sup>2</sup> Michael T. Eadon,<sup>2</sup> Pinaki Sarder.<sup>1</sup> Kidney Precision Medicine Project <sup>1</sup>University at Buffalo, Buffalo, NY; <sup>2</sup>Indiana University, Bloomington, IN; <sup>3</sup>Washington University in St Louis, St Louis, MO; <sup>4</sup>University of Michigan Michigan Medicine, Ann Arbor, MI.

**Background:** Glomerular histomorphology establishes kidney disease diagnosis and prognosis. Spatial transcriptomics facilitates spatial resolution of molecular signatures superimposed upon histology. We trained a machine learning (ML) method to automatically segment glomeruli and quantify pixel level image features to align with spatial transcriptomics (ST) performed on the same section.

**Methods:** Brightfield histology images of 17 kidney disease biopsies and 3 reference kidney sections were used for training a deep learning model for glomerular segmentation. We used 3 additional reference images for testing. Unsupervised clustering of ML features was performed across all glomeruli using Seurat. Transcriptomic signatures of 10X Visium ST spots were deconvoluted with Seurat 3.2.3 transfer scores using the kidney precision medicine project (KPMP) snRNA-seq atlas as reference. Association between cell type composition and ML classification was assessed.

**Results:** The ML glomerular segmentation achieved sensitivity/specificity/precision 0.88/1.0/0.97. The glomeruli were classified into 3 clusters; with cluster one statistically associated with increases in degenerative podocyte; and a second cluster with a glomerular capillary signature ( $p < 0.033$ ).

**Conclusions:** Our pipeline will serve as a framework to map molecular to histomorphologic data over large areas captured from large sample libraries, and will aide in the development of kidney precision medicine.

**Funding:** NIDDK Support

## SA-PO002

**Computational Assessment of Glomerular Basement Membrane Width and Podocyte Foot Process Width in an Animal Model of Podocytopathy**  
Aksel D. Laudon,<sup>1,2</sup> Connor Kim,<sup>1</sup> Yingzhe Qian,<sup>1</sup> Zhaoze Wang,<sup>1</sup> Qin Ye,<sup>1</sup> Vijaya B. Kolachalama,<sup>2</sup> Joel M. Henderson,<sup>2</sup> Weining Lu.<sup>2,1</sup> <sup>1</sup>Boston University College of Engineering, Boston, MA; <sup>2</sup>Boston University School of Medicine, Boston, MA.

**Background:** Transmission electron microscopy (TEM) measurements of glomerular basement membrane (GBM) width and podocyte foot process width (FPW) are important diagnostic tools for podocytopathy. Currently, these measurements in TEM images are performed manually, which limits experimental ultrastructural analysis. Here, we describe a computational approach to measure GBM width and podocyte FPW of healthy and pathological kidney specimens using TEM images from Integrin-Linked Kinase podocyte-specific knockout mice (ILK cKO), an animal model of podocytopathy.

**Methods:** We obtained TEM images from five wildtype (WT) littermates and five ILK cKO mice at 4 weeks of age. We developed a computational approach with two stages: a pre-trained U-Net-based machine learning framework for GBM segmentation and an image processing algorithm for GBM width and FPW measurement. We evaluated its performance in a five-fold cross-validation study. Segmentation accuracy was assessed in terms of Jaccard index, the ratio of the size of intersection to the size of union for

an image's predicted GBM and manually annotated reference GBM label. Automated measurements were compared to corresponding manual measurements between WT and ILK cKO mice.

**Results:** The cross-validation study resulting mean TEM image Jaccard index was 0.56 for WT and 0.66 for ILK cKO. Automated mean GBM width and FPW closely matched manual measurements for WT ( $p = 0.63$ ,  $p = 0.31$ ) but differed for ILK cKO specimens ( $p = 0.06$ ,  $p = 0.06$ ). Automated GBM width ( $p = 0.008$ ) and FPW ( $p = 0.03$ ) measurements were significantly wider for ILK cKO than WT mice, which aligns with known morphology.

**Conclusions:** We developed a machine-learning based approach to measure GBM width and FPW in TEM images for an animal model of podocytopathy. Our results suggest that automated measurements could distinguish healthy from pathological kidneys. Our tool provides high-throughput, objective morphological analysis and could potentially facilitate podocytopathy and other glomerular disease research and diagnosis in the future.

## SA-PO003

### Computational Characterization of Lymphocytic Inflammation on Digital Kidney Biopsies

Xiang Li,<sup>1</sup> Gina Sotolongo,<sup>5</sup> Jeffrey B. Hodgin,<sup>3</sup> Yvonne M. Mowery,<sup>1</sup> Lawrence B. Holzman,<sup>2</sup> Laura H. Mariani,<sup>3</sup> Yijiang Chen,<sup>4</sup> Anant Madabhushi,<sup>4</sup> Jarcy Zee,<sup>2</sup> Andrew Janowczyk,<sup>4</sup> Laura Barisoni,<sup>1</sup> Kyle Lafata.<sup>1</sup> <sup>1</sup>Duke University, Durham, NC; <sup>2</sup>University of Pennsylvania, Philadelphia, PA; <sup>3</sup>University of Michigan, Ann Arbor, MI; <sup>4</sup>Case Western Reserve University, Cleveland, OH; <sup>5</sup>Duke University Hospital, Durham, NC.

**Background:** Dispersion patterns of inflammatory cells in kidney tissue are hypothesized to be associated with patient outcomes, yet remain challenging to quantify visually in a standardized fashion. This study developed a deep learning (DL) model to automatically identify lymphocytic inflammation on H&E images.

**Methods:** 18 FFPE kidney specimens with moderate to severe inflammation were H&E stained and scanned at 40x, then rescanned after IHC staining for CD3/CD20 (T+B lymphocytes). After co-registering H&E and IHC, lymphocytes were identified as IHC-positive cells, with all other cells being negative. A Hover-Net DL model was trained to segment these IHC-positive cells using 6 whole slide images (WSIs) and tested on 12 WSIs. Model generalization was evaluated on NEPTUNE WSIs (visual inspection). Cell graphs were calculated to characterize the topology of the lymphocytic microenvironment. The predicted topology on H&E was compared to the measured topology on IHC via the structural similarity index measure (SSIM).

**Results:** The training and testing datasets included 22,732 nuclei (12,618 lymphocytes) and 7,984 nuclei (3,712 lymphocytes), respectively. The model precision, recall, f1, and AUC were 0.69, 0.77, 0.73, and 0.74, respectively. The topology-pattern level similarity was high, with mean SSIM of 0.82±0.05 between H&E and IHC WSIs. In the NEPTUNE dataset, the DL model correctly differentiated lymphocytic from non-lymphocytic inflammation.

**Conclusions:** Co-registering retained H&E and IHC WSIs provides an efficient way of generating large quantities of training material for DL. Here, our model accurately recapitulated lymphocyte topology patterns using only H&E. These patterns will subsequently be tested for outcome prediction in glomerular diseases.

**Funding:** NIDDK Support, Other U.S. Government Support

## SA-PO004

**AI in the Loop: Using Ensemble Model Agreement as a Surrogate for Segmentation Confidence in Renal Stone CT Evaluations**

Timothy L. Kline, Mayo Foundation for Medical Education and Research, Rochester, MN.

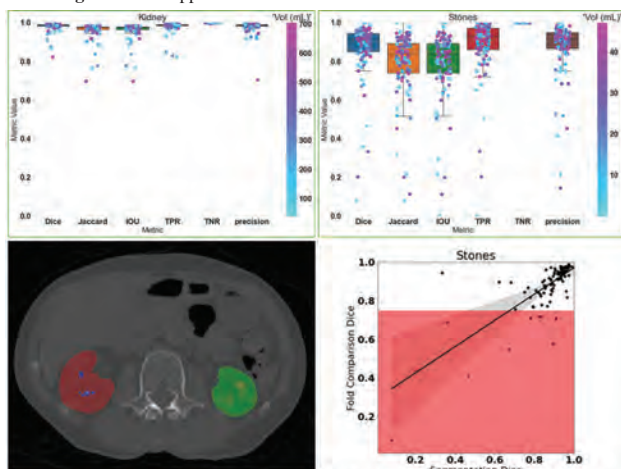

**Background:** Deep learning-based semantic segmentation has been shown to perform at the level of human readers in a wide range of medical image processing tasks. However, the ability to automatically: (i) flag out of domain cases, or (ii) identify cases where a model may be less confident, has received much less attention. Here we develop an approach to provide insights into model confidence that can be built on top of common approaches for model ensembling. We show the utility of the approach in a highly imbalanced problem of segmentation of both kidneys, as well as renal stones.

**Methods:** A total of 400 non-contrast CT images were curated from our institutions image archive. Both kidneys and renal stones were segmented by quality review of previously developed segmentation algorithms. A deep learning framework was used to develop a 5-fold ensemble model in both 2D and 3D (300 cases for training/validation, 100 for testing). The individual folds and ensemble models were evaluated by similarity metrics. The variability of the models between different folds and input image dimensionality was used to establish our framework for creating an ‘AI in the Loop’ method to automatically flag cases the models were less confident about.

**Results:** The automated models achieved excellent performance for segmentation of kidneys and renal stones on the hold-out test set. The mean±SD of Dice was 0.97±0.03 and 0.89±0.15 for kidney and stones, respectively. Comparing individual models to each other demonstrated how disagreement between models could be used as a surrogate for model confidence.

**Conclusions:** We developed a framework for automatically assessing model confidence by comparison of models trained on different data subsets and different model architectures. This approach will have utility in automated pipelines to draw attention to potential failure cases.

**Funding:** NIDDK Support

**Figure 1.** Similarity metrics for kidney (top left) and stones (top right) highlight the high degree of accuracy of the automated model. Example visualization of the segmentation for right kidney (red), left kidney (green), right renal stones (blue), and left renal stones (yellow) is shown in the bottom left panel. Comparison of model agreement (‘Fold Comparison Dice’) with overall segmentation agreement shows a strong correlation. In this example, a threshold of 0.75 (red overlay) would automatically flag ~10% of the cases that need review.

## SA-PO005

**Fully Automated Segmentation of Kidneys and Exophytic Cysts Using Deep Convolutional Neural Networks in Subjects With Autosomal Dominant Polycystic Kidney Disease**

Youngwoo Kim,<sup>1</sup> Seon-ah Bu,<sup>1</sup> Kyongtae T. Bae,<sup>2</sup> KITECH <sup>1</sup>Korea Institute of Industrial Technology, Cheonan, Republic of Korea; <sup>2</sup>The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong.

**Background:** In diagnosing autosomal dominant polycystic kidney disease (ADPKD), total kidney volume (TKV) is a critical imaging biomarker. Nevertheless, manual computation of TKV, particularly with the exclusion of exophytic cysts, is laborious and time consuming. We developed a fully automated segmentation method for TKV using a deep learning network to selectively segment kidney regions while excluding exophytic cysts.

**Methods:** We used abdominal T<sub>2</sub>-weighted magnetic resonance images from 210 ADPKD subjects who were divided into two groups: 157 to train the network and 53 to test. With a 3D U-Net architecture using dataset fingerprints, the network was trained by K-fold cross-validation in that 80% out of 157 cases were for training and the remaining 20% cases for validation. To assess the performance of the automated segmentation method in reference to the manual method, three metrics were analyzed: Dice similarity coefficient (DSC), intra-class correlation coefficient (ICC), and Bland-Altman analysis.

**Results:** Excellent geometric concordance was achieved between the automated and manual reference methods (DSC: 0.962±0.018, on average) on the test datasets

with widely varying volumes of kidneys (1058.5±706.8 ml, range: 178.9–2776.0 ml) and exophytic cysts (549.0±559.1 ml, range: 113.4–2497.6 ml). The ICC was 0.9994 ( $P < 0.001$ ; CI: 0.9991–0.9996) with a minimum bias of -2.424 ml (95% limits of agreement: -49.80, 44.95).

**Conclusions:** A fully automated segmentation method that we developed measures TKV with exclusion of exophytic cysts as accurately as the level of a human expert. This technique will be useful in clinical studies that require automated computation of TKV to evaluate progression and treatment response of ADPKD.

**Funding:** Government Support - Non-U.S.

## SA-PO006

**Development of a Multimodal “Kidney Age” Prediction Based on Automatic Segmentation CT Image in Patients With Normal Renal Function: A Preliminary Report**

Zuoxian Hou, Peng Xia, Gu-Mu-Yang Zhang, Hao Sun, Limeng Chen. Peking Union Medical College Hospital, Beijing, China.

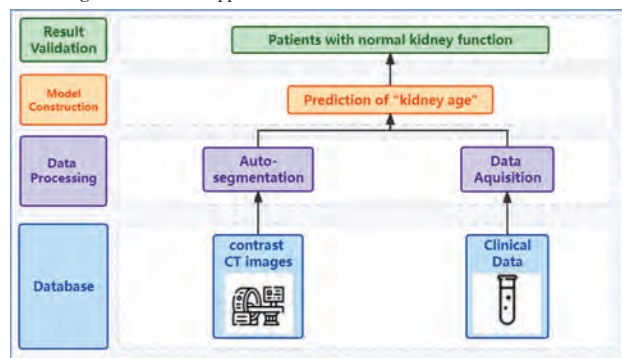

**Background:** The physiology volumes of the kidney cortex and medulla are presumed to change with age. We established a machine learning model to predict the “Kidney Age” in patients with normal serum creatinine (Scr) levels based on clinical data and an auto-segmentation algorithm separating the kidney cortex and medulla using contrast CT images.

**Methods:** We recruited 238 patients with normal Scr levels and contrast CT images between Oct 2021 and Feb 2022 in Peking Union Medical College Hospital with their demographic and clinical data. An auto-segmentation method was used for both cortex and medullary separation and their volume calculation, respectively. We combined the kidney volume, as well as clinical data for multimodal features of the machine learning model. All data were separated into a training dataset (85%) with ten-fold cross-validation and a test dataset (15%) for accuracy validation. Multiple machine learning models (n=100) with different initial weights are ensembled to reduce the prediction error. The performance of model was measured by the 95% confidential interval generated from the mean value and standard deviation.

**Results:** A total of 149 female patients and 89 male patients were included, with a mean age of 48.9±14.7 years old and Scr of 64.49±13.97 μmol/L. Their mean total kidney volume was 284.23±55.34 mm<sup>3</sup>, using the algorithm separating the kidney volumes of cortex and medulla. The predicted “Kidney Age” is approximately close to the patients’ true age, with 92% prediction within the 95% confidential interval. The associated factors of the “Kidney Age” were eGFR ( $r=-0.516$ ,  $p<0.001$ ), hypertension ( $r=0.448$ ,  $p<0.001$ ), diabetic ( $r=0.364$ ,  $p<0.001$ ), kidney cortex volume ( $r=-0.374$ ,  $p<0.001$ ), and cortex ratio ( $r=-0.267$ ,  $p<0.001$ ).

**Conclusions:** We established a machine learning model for predicting the “Kidney Age” of patients with normal kidney function based on contrast CT images and clinical data.

**Funding:** Government Support - Non-U.S.

Process of multimodal machine learning algorithm

## SA-PO007

**ADPKD Segmentator: A Cloud-Based Prognostic Tool for Autosomal Dominant Polycystic Kidney Disease**

Vincenzo Carbone,<sup>1</sup> Alessia Baretta,<sup>1</sup> Cristiana Corsi,<sup>2</sup> Roberta Bursi,<sup>1</sup> <sup>1</sup>InSilicoTrials Technologies, Trieste, Italy; <sup>2</sup>Università degli Studi di Bologna, Bologna, Italy.

**Background:** ADPKD is characterized by the growth of numerous cysts in the kidneys, leading to an increment of Total Kidney Volume (TKV) and progressive decline in renal function. FDA and EMA accept TKV as a prognostic biomarker for disease progression, however TKV calculation from medical images is labor-intensive. ADPKD Segmentator is a user-friendly cloud-based tool for fast and accurate ADPKD classification, based on automated kidney and cysts segmentation from MRI.

**Methods:** An online tool was designed on Microsoft Azure Cloud to automatize the set-up and running of a previously developed software implemented in MATLAB to automatically detect kidney and cysts contours from MRI. Through the web interface, the user is only requested to upload the MRI dataset and select one point inside kidney’s parenchyma in the central slice. Then, TKV is automatically calculated and ADPKD

Classification is obtained (Figure 1). The MRI dataset is anonymized before upload to the cloud; data and results are stored in a secure and reliable environment controlled by the user.

**Results:** The proposed solution is very fast and precise compared to manual segmentation of medical images (Figure 1). Moreover, it is faster and more accurate than the commonly used ellipsoid-based method, resulting in a manifold reduction of misclassification error (Table 1). Another advantage is its usability, with no specific computational expertise, numerical software or dedicated hardware required, since all computations are run remotely in the cloud.

**Conclusions:** ADPKD Segmentator provides a reproducible and precise morphologic classification of the renal and cysts volume of ADPKD patients. It represents an extremely useful tool for clinicians, potentially helping in monitoring disease progression, supporting correct therapy administration, and effective stratification of patients. Also, it would represent a great benefit for the patient, since the tool analyzes medical images obtained without the use of contrast medium.

	ADPKD SEGMENTATOR	ELLIPSOID-BASED METHOD
Manual Intervention:	< 1 min	up to 5 min
Absolute mean error	$2.4\% \pm 2.7\%$	$7.4\% \pm 5.1\%$
Misclassification error	2.5%	13.7%

## SA-PO008

### Design of a Polyethersulfone-Based Self-Anticoagulant Endotoxin Hemoperfusion Adsorbent for Sepsis Treatment

Yupei Li, Baihai Su. *West China Hospital of Sichuan University, Chengdu, China.*

**Background:** Sepsis is life-threatening and associated with high mortality. Currently available endotoxin adsorption columns still face significant drawbacks, such as low endotoxin adsorption capacity and unwanted need for systemic heparin anticoagulation or regional citrate anticoagulation. This work aimed to develop a polyethersulfone-based self-anticoagulant endotoxin hemoperfusion adsorbent to evaluate its hemocompatibility and endotoxin adsorption performance *in vitro* and *in vivo*.

**Methods:** First, polyethersulfone-based self-anticoagulant beads (namely, RAHM beads) filled with polyacrylic acid and poly(2-acrylamide-2-methyl propane sulfonic acid) copolymer networks were prepared by phase inversion and *in situ* polymerization technology, and polyethyleneimine was grafted onto the surface of RAHM beads to obtain RAHM@PEI beads. Second, the surface morphology and specific surface area of RAHM and RAHM@PEI beads were systematically analyzed. Third, the hemocompatibility of RAHM and RAHM@PEI beads was evaluated by measuring complement C3a, platelet count, plasma clotting time and hemolysis ratio *in vitro*. Finally, the feasibility of the RAHM/RAHM@PEI-based endotoxin adsorption column in LPS-induced beagle sepsis models was investigated.

**Results:** Both RAHM and RAHM@PEI beads had high specific surface areas and mesoporous structures and exhibited excellent anticoagulant properties by partially inhibiting the activity of the intrinsic coagulation factors FVIII, FIX, FXI and FXII. With PEI grafting on their surfaces, the endotoxin adsorption capacity of RAHM@PEI beads was significantly higher than that of RAHM beads (164.9 vs. 82.5 EU/g). *In vivo* animal experiments further showed that the RAHM/RAHM@PEI-based endotoxin adsorption cartridge significantly alleviated the decrease in leukocyte and neutrophil counts in LPS-induced beagle sepsis models without obvious adverse effects. Moreover, plasma levels of cytokines (IL-8 and TNF- $\alpha$ ) and neutrophil infiltration and bleeding in the alveolus were also significantly reduced after the use of our endotoxin adsorption cartridge.

**Conclusions:** Our data show that the RAHM and RAHM@PEI beads have high endotoxin adsorption capacities and good anticoagulant properties and are thus promising hemoperfusion sorbents to treat severe septic patients.

**Funding:** Government Support - Non-U.S.

### In Vitro Effect of Cartridge Functionalized With Antibiotic on a Bacterial Population in Hemoperfusion Treatment

Massimo de Cal,<sup>1,2</sup> Anna Lorenzin,<sup>1,2</sup> Claudio Ronco,<sup>1,2</sup> Monica Zanella.<sup>1,2</sup>  
<sup>1</sup>Ospedale San Bortolo di Vicenza, Vicenza, Italy; <sup>2</sup>IRRV, Vicenza, Italy.

**Background:** HA380 (Jafon, China) is an hemoperfusion (HP) cartridge applied in septic patients that often developed AKI. We have demonstrated that vancomycin (Van) is absorbed by HA380 during *in vitro* HP. We recreated an *in vitro* HP treatment in presence of bacteria to assess the effect of cartridge pre-treated with Van solution.

**Methods:** We compared the effect of 2 mini-modules of the HA380 cartridge. Saline solution enriched with 1g of Van was circulated in HP in one of the cartridges and 545mg of antibiotic were adsorbed by the sorbent beads. We injected  $10^6$  S.aureus bacteria sensitive to Van in 800mL of blood and incubated at 37°C. After 24h blood was partitioned into 3 reservoirs: 200mL were maintained as a negative control; 300mL were

circulated in the mini-module previously used with Van solution; 300mL in the other cartridge. The circulations were performed, simultaneously, in a closed-loop at 250mL/min with a dedicate testing platform for 120 minutes (Figure). Blood was maintained at 37°C and stirred. Blood samples were drawn at T0 (before partition), T1 and T2 (after 1 and 2 hours of circulation) from the 3 reservoirs. Samples were cultured in cna agar plates to assess the bioburden and in DB Bactec bottles to estimate the time after which the bacteria replication reaches the predetermined growth threshold.

**Results:** At T0, T1 and T2 in negative control and in the mini-module without antibiotic, growth of bacteria was detected at 1h and 30 minutes and plates showed  $2 \times 10^6$  bacteria. At T1 and T2 in the mini-module with Van, growth was detected respectively at 7h and 8h and plates showed  $10^6$  bacteria.

**Conclusions:** The functionalized mini-module has been more effective in the reduction of the bioburden as the bound Van could be still active.

Figure: Experimental set-up of the HP treatments.

## SA-PO010

### Addressing Barriers to Peritoneal Dialysis: Can It Look Pretty?

Fatima Ayub,<sup>1</sup> Larissa N. Whale,<sup>2</sup> Makenzie Kapales,<sup>2</sup> Jose A. Sanchez Gracias,<sup>2</sup> Tayte A. Stephens,<sup>2</sup> Christopher Schaefer,<sup>2</sup> Andrew Tegel,<sup>2</sup> Manisha Singh.<sup>1</sup>  
<sup>1</sup>University of Arkansas for Medical Sciences, Little Rock, AR; <sup>2</sup>University of Arkansas Fayetteville, Fayetteville, AR.

**Background:** Peritoneal dialysis (PD) is an effective renal replacement strategy for patients with end-stage renal disease that utilizes the abdominal peritoneum to filter toxins. PD offers a patient survival comparable to in-center hemodialysis while preserving residual kidney function and empowering patient autonomy. The usual PD catheters have a 16 cm tubing set protruding from the patient's abdomen which can have negative implications on their self-image. This set is in part the PD catheter, and in part a transfer set. For the ease of design, we first worked on the transfer set. We present an improved retractable transfer set to address one of the barriers to PD. We believe that this designed set is the first of its kind.

**Methods:** Our project started with a patient-centered survey of PD patients assessing the need for a modified PD tubing set. Most patients wanted to try a smaller catheter set. We studied multiple designs including spiral, retractable and collapsible bulbs. We used Solidworks to design one of the desired tubes and created negative molds for casting and prototyping by 3D printers. Liquid silicone was used to form the 3D shape of a transfer set. We were able to create 3 prototypes. The first prototype utilized Ultimaker as the 3D printer for the mold using PLA filament with PVA supports. For the second, we used the Formlabs resin printer with photopolymer resin. Lastly, for the third prototype, we utilized an elastic photopolymer resin with the formlabs printer to create the model of a transfer set.

**Results:** The final design for our PD transfer set has a bendy narrow section that is 7cm when extended and much smaller when collapsed, sandwiched between two connector portions, one fits into the transfer set clamp and the other connects the transfer set to other parts of the catheter. It wasn't until the catheter was printed on the Formlabs Resin

printer without a mold that a successful prototype was created. Flow simulations were also conducted and it was determined that the new design kept the desired flow rate of 0.2 L/min.

**Conclusions:** A PD catheter with a retractable transfer set was modeled and verified as a viable option for a new PD catheter product. Our ultimate goal is to design the catheter portion of the set retractable as well. A shorter set will decrease the negative self-image of our patients.

### Bilirubin Removal by Plasmafiltration-Adsorption: Ex Vivo Adsorption Kinetic Model

Matteo Marcello,<sup>1,2</sup> Anna Lorenzin,<sup>3,1</sup> Massimo de Cal,<sup>3,1</sup> Claudio Ronco,<sup>1,3</sup> Monica Zanella.<sup>3,1</sup> <sup>1</sup>International Renal Research Institute of Vicenza, Vicenza, Italy; <sup>2</sup>Università Vita Salute San Raffaele, Milano, Italy; <sup>3</sup>Ospedale San Bortolo di Vicenza, Vicenza, Italy.

**Background:** The removal of bilirubin from blood in patients with severe liver dysfunction is an important blood purification goal. Accordingly, we conducted an ex-vivo study to assess the ability of a novel bilirubin adsorptive cartridge to remove bilirubin from plasma.

**Methods:** We studied the BS330 Plasma Bilirubin Adsorption Column cartridge (Jafron Biomedical, Zhuhai City, China). Our experiment was conducted using a minimodule downscaled 1:3 containing approximately 131 g of BS330 sorbent bead. Using a dedicated machine for extracorporeal treatment simulation named GALILEO, we set up an ex-vivo circulation experiment in which a solution of hyperbilirubinemic plasma was pumped in the circuit and through the cartridge (Figure). Using synthetic bilirubin powder, we obtained a plasma solution with a bilirubin concentration of 92.8 mg/dL. The adsorption trend was evaluated as the bilirubin concentration gap ( $\Delta C$ ) between inlet (C<sub>pin</sub>) and outlet (C<sub>pout</sub>) lines. Removal ratio (RR) at a given time point was calculated as mass adsorbed at a given time point.

**Results:** The change in concentration across the cartridge at 30 minutes was 16.5%. The capacity of the cartridge to adsorb bilirubin and cartridge saturation was reached at 750 minutes, 759 mg of bilirubin has been retained with a Removal Ratio of 78.1 %. Therefore, the adsorption capacity of the resin was estimated at 5.76 mg of bilirubin per gram of sorbent. The dynamic adsorption curve (Figure) indicates a fast and efficient removal of bilirubin by BS330 in the beginning of perfusion with a Removal Ratio of 42.6% at 120 minutes.

**Conclusions:** Our findings provide the first assessment of bilirubin adsorption in an ex-vivo model of plasma perfusion and can be used to design interventional studies in humans with appropriately sized cartridges applied for an optimal time period.

Bilirubin adsorption kinetics. Blue line represents the fall of bilirubin concentration during time. Vertical bars represent total mass adsorbed at each time point.

### Effect of Endothelial Nitric Oxide Synthase Expression Levels on the Hemodynamic Parameters in Murine Arteriovenous Fistulas

Shelly R. Baltazar,<sup>1</sup> Brayden Fairbourn,<sup>1</sup> Hannah M. Northrup,<sup>1</sup> Timmy C. Lee,<sup>3</sup> Yan-Ting E. Shiu.<sup>1,2</sup> <sup>1</sup>The University of Utah, Salt Lake City, UT; <sup>2</sup>VA Salt Lake City Health Care System, Salt Lake City, UT; <sup>3</sup>The University of Alabama at Birmingham, Birmingham, AL.

**Background:** The arteriovenous fistula (AVF) is the preferred hemodialysis vascular access but has a high maturation failure rate, which is a significant clinical problem. The creation of AVFs causes aberrant blood flow at and near the AVF anastomosis that may cause maturation failure. Endothelial nitric oxide synthase (NOS3) generates nitric oxide (NO), a vasodilator. Our group previously reported that NOS3 expression levels affect AVF development (i.e., lumen size) in a mouse model. Specifically, the AVF lumen in NOS3 overexpression (OE) was larger (favored AVF remodeling) than in NOS3 knock out (KO) or wild type (WT) mice at Day 7 and Day 21 post AVF creation (Kidney360, 1(9): 925, 2020). In this study, we performed MRI-based computational fluid dynamics (CFD) simulations in a similar model. We hypothesized that blood flow in OE is less aberrant than that in KO and WT.

**Methods:** Carotid-jugular AVFs were created in C57BL/6 mice with three conditions: NOS3 OE, NOS3 KO, and WT control. MR images of AVFs were taken on Day 7 and Day 21 post AVF creation for each strain (n=2-3 per condition, 17 mice total) and used for CFD simulations to quantify the wall shear stress (WSS) and vorticity of the AVF vein.

The WSS and vorticity were averaged over the third cardiac cycle and 5 mm from the anastomosis through the AVF vein.

**Results:** On Day 7, the WSS ( $67.56 \pm 137.9$  dyn/cm<sup>2</sup> for OE,  $120.0 \pm 241.3$  dyn/cm<sup>2</sup> for KO,  $104.1 \pm 181.0$  dyn/cm<sup>2</sup> for WT) and vorticity ( $1146 \pm 1827$  1/s for OE,  $1739 \pm 2766$  1/s for KO,  $1608 \pm 2506$  1/s for WT) were not statistically different among the three groups. On Day 21, OE had lower WSS ( $13.67 \pm 16.17$  dyn/cm<sup>2</sup>) and vorticity ( $190.7 \pm 246.6$  1/s) than KO ( $100.6 \pm 169.3$  dyn/cm<sup>2</sup>;  $1893 \pm 2804$  1/s) and WT ( $165.8 \pm 267.1$  dyn/cm<sup>2</sup>;  $2244 \pm 3045$  1/s) ( $p < 0.0001$ ).

**Conclusions:** At Day 21, lower vorticity in OE suggested that the velocity streamlines in OE were smoother than in KO and WT, and lower WSS in OE suggested that WSS was attempting to return to the pre-surgery baseline. Both are characteristics of favored hemodynamics remodeling. We are continuing to refine CFD protocols and increase animal numbers for future studies.

## SA-PO013

### Comparison of Local Hemodynamics in Rat Arteriovenous Fistula With and Without Accessory Vein

Britney Chen,<sup>1</sup> Brayden Fairbourn,<sup>1</sup> Hannah M. Northrup,<sup>1</sup> Timmy C. Lee,<sup>2</sup> Yan-Ting E. Shiu.<sup>1</sup> <sup>1</sup>The University of Utah, Salt Lake City, UT; <sup>2</sup>The University of Alabama at Birmingham, Birmingham, AL.

**Background:** Arteriovenous fistula (AVF) maturation failure is a major clinical problem. AVF hemodynamics are a significant factor in regulating AVF remodeling and maturation, but our understanding of the precise hemodynamics in the AVF is not yet complete. The presence of accessory veins (i.e., vein branches from the primary venous limb of an AVF) may decrease blood flow through the fistula and consequently contribute to AVF maturation failure. Therefore, in patients, accessory veins may be ligated at the time of AVF creation. Here we investigate the effects of accessory veins on AVF hemodynamics in a rat model.

**Methods:** Femoral AVFs were created in 12 to 16-week-old male Sprague-Dawley mice. MRI scans taken 21 days after AVF creation were used to create reconstructions of the AVF lumen with and without an accessory vein (n = 3). The reconstructions were then used, together with MRI-measured velocities, in computational fluid dynamic (CFD) simulations. Hemodynamic parameters (velocity, wall shear stress (WSS), vorticity, and oscillatory shear index (OSI)) were calculated for the AVF vein segment starting from the anastomosis and ending at the location immediately prior to the vein branch and an equivalent proximal artery segment.

**Results:** The AVF vein WSS result with and without an accessory vein was similar ( $247.1 \pm 291.8$  vs.  $190.0 \pm 195.1$  dynes/cm<sup>2</sup>;  $p > 0.05$ ). The AVF vein OSI result with and without the accessory vein was also similar ( $0.06 \pm 0.06$  vs.  $0.08 \pm 0.06$ ;  $p > 0.05$ ). However, the AVF vein vorticity with and without an accessory vein ( $3569.9 \pm 4381.9$  vs.  $2711.5 \pm 3145.4$  1/s) and AVF vein velocity with and without an accessory vein ( $65.9 \pm 64.1$  vs.  $53.6 \pm 50.6$  cm/s) were significantly different ( $p < 0.05$ ). The proximal artery WSS, OSI, vorticity, and velocity were similar between the AVFs with and without an accessory vein ( $p > 0.05$ ).

**Conclusions:** Except for vorticity and velocity in the AVF vein, the hemodynamics between AVFs with and without accessory veins were largely similar. Including accessory veins when analyzing AVF hemodynamics in CFD simulations may result in some different hemodynamic parameters. Future research will investigate whether these differences are associated with AVF maturation failure.

## SA-PO014

### Renal Autoregulation Assessment in Conscious Rats Using Deep Learning Networks

Geoffrey A. Williamson,<sup>1</sup> Purva R. Chopde,<sup>1</sup> Sebastian Anand A. Alphonse,<sup>4</sup> Aaron J. Polichnowski,<sup>2</sup> Karen A. Griffin.<sup>3,5</sup> <sup>1</sup>Illinois Institute of Technology, Chicago, IL; <sup>2</sup>East Tennessee State University, Johnson City, TN; <sup>3</sup>Loyola University Chicago Stritch School of Medicine, Maywood, IL; <sup>4</sup>Livanova, Houston, TX; <sup>5</sup>Edward Hines Junior VA Hospital, Hines, IL.

**Background:** Renal autoregulation (AR) maintains constant GFR and prevents glomerular transmission of systemic pressure. AR assessment informs about susceptibility to hypertensive renal injury and thus may influence management of patients with chronic kidney disease (CKD). In rats, AR assessment has typically involved measuring the recovery of renal blood flow (RBF) after acute step blood pressure (BP) changes under anesthesia, via AR indices quantifying fractional changes in RBF relative to BP. We developed a Short Segment AR Index (SSARI) methodology for AR assessment in conscious animals (Bidani et al., JASN 31(2):324-336, 2020). This method locates adjacent short segments (0.5 to 20 s) in the BP/RBF record where mean BP changes by  $> 5$  mmHg and averages the AR index for those segment pairs over all pairs. Here, we develop and train a Deep Neural Network (DNN) to effect a similar AR assessment and compare its performance with that of SSARI. Our DNN design leverages our earlier work applying DNNs to differentiate intact and impaired AR (Alphonse et al., 2020 28th EUSIPCO, 1165-1169, 2021).

**Methods:** The DNN input employs a one min. long BP/RBF record sampled at 200 Hz. The DNN architecture includes four convolutional layers followed by two dense layers, each with leaky Relu activation, and max pooling after convolutional layers. The output is a scalar produced with linear activation. Using 2960 30-min. BP/RBF recordings, we trained the DNN to match the average SSARI score (using 2.5 s. segments) for the full 30 min. data set. The DNN was tested using a separate set of 3413 30-min. BP/RBF recordings.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Results:** With the test data, we achieved a mean-square error of 0.0555 between the average DNN score using all 30 1-min. segments and the average SSARI value for the full 30 min. Furthermore, averaged DNN scores had 1/10 the variability of the averaged SSARI values.

**Conclusions:** The DNN can distinguish between intact AR and impaired AR (e.g. via calcium channel blockade or renal mass reduction or both), just as does SSARI as we have reported. The DNN, however, provides equivalent accuracy in doing this with only 1/10 the data length. Further refinement of this methodology will allow us to leverage its use in the clinical setting as DNN will inform AR impairment and susceptibility to hypertensive renal injury in patients with CKD.

**Funding:** NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

## SA-PO015

### Differences in Early Hemodynamics Between Arteriovenous Fistulas and Grafts in Porcine Models

Samantha Vranes,<sup>1</sup> Brayden Fairbourn,<sup>1</sup> Hannah M. Northrup,<sup>1</sup> Yong He,<sup>2</sup> Scott A. Berceci,<sup>2,3</sup> Alfred K. Cheung,<sup>1,4</sup> Yan-Ting E. Shiu.<sup>1,4</sup> <sup>1</sup>The University of Utah, Salt Lake City, UT; <sup>2</sup>University of Florida, Gainesville, FL; <sup>3</sup>VA Medical Center Malcom Randall, Gainesville, FL; <sup>4</sup>VA Salt Lake City Health Care System, Salt Lake City, UT.

**Background:** The formation of neointimal hyperplasia (NH) leads to shortened patency rates for long-term hemodialysis vascular accesses – the arteriovenous fistula (AVF) and the arteriovenous graft (AVG). NH is more severe in AVG than AVF in patients, though the reasons are not yet completely understood and may be multifactorial. Blood flow parameters (e.g., wall shear stress (WSS)) are linked to NH formation. Here we investigated and compared hemodynamics and NH in porcine AVF and AVG models. We hypothesized that a higher WSS value leads to less NH formation and better vascular access outcomes. Therefore, we compared early flow hemodynamics to late NH formation.

**Methods:** Carotid-jugular fistulas and grafts were created in young pigs (n=3 each). They were scanned by magnetic resonance imaging (MRI) 1 week after surgery. Black-blood and phase-contrast velocity MRI scans were used to calculate cross-sectional area (CSA) and perform computational fluid dynamics to analyze hemodynamic parameters, including flow rate, velocity, WSS, and oscillatory shear index (OSI). Since NH formation occurs near the venous anastomosis, we focused on the proximal venous segments closer to the anastomosis. Early hemodynamics were obtained at week 1. NH was visualized at weeks 4-6 by histology.

**Results:** The venous CSA in the AVFs (mean±SD, 14.87±7.38 mm<sup>2</sup>) and the AVGs (19.58±5.63 mm<sup>2</sup>) were similar (p=0.06) at week 1. However, the AVF venous flow rate (532.24±87.27 mL/min), velocity (67.70±20.02 cm/s), and WSS (196.68±91.12 dyn/cm<sup>2</sup>) were significantly larger than the AVG (346.49±127.92 mL/min, 31.80±15.65 cm/s, 73.59±51.53 dyn/cm<sup>2</sup>) (p=0.01 – 0.02) at week 1. OSI in the AVF and AVG were similar (0.031±0.029 vs. 0.027±0.03 rotation/s; p=0.07). Histology showed that the AVG had more NH than the AVF at weeks 4-6.

**Conclusions:** Our results reveal differences between the AVF and AVG in early hemodynamics and late NH formation. Specifically, AVFs had less NH than AVGs in our porcine models, similar to human. Our results suggest that higher WSS values in AVF may prevent NH formation and lead to better vascular access outcomes. Future research can consider hemodynamic parameters at later time points, in other regions of the vessel (i.e. the arterial anastomosis), and fluid-structure interactions.

**Funding:** NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

## SA-PO016

### Differential Hemodynamics Between Arteriovenous Fistulas With or Without Intervention Before Successful Use

Hannah M. Northrup,<sup>1</sup> Yong He,<sup>2</sup> Ha D. Le,<sup>1</sup> Scott A. Berceci,<sup>2,3</sup> Alfred K. Cheung,<sup>1,4</sup> Yan-Ting E. Shiu.<sup>1,4</sup> <sup>1</sup>University of Utah, Salt Lake City, UT; <sup>2</sup>University of Florida, Gainesville, FL; <sup>3</sup>Malcolm Randall Veterans Affairs Medical Center, Gainesville, FL; <sup>4</sup>VA Salt Lake City Health Care System, Salt Lake City, UT.

**Background:** A significant number of arteriovenous fistulas (AVFs) fail to mature for dialysis. Although interventions promote maturation, functional primary patency loss is higher for AVFs with interventions (assisted maturation) than AVFs without interventions (unassisted maturation). Blood flow-associated hemodynamics are proposed to affect AVF remodeling. However, the optimal hemodynamic parameters for unassisted maturation are unclear.

**Methods:** Patients (n=6) underwent magnetic resonance imaging (MRI) at 1 day, 6 weeks, and 6 months after AVF creation surgery. Before successful use for hemodialysis, 3 AVFs required intervention and 3 did not. MRI of the AVFs were used to calculate lumen cross-sectional area (CSA) and perform computational fluid dynamics to analyze hemodynamics, i.e. velocity, wall shear stress (WSS), and vorticity.

**Results:** The no-intervention group and intervention group had similar pre-surgery vein diameter and 1-day post-surgery venous CSA. The no-intervention group had significantly larger 1-day venous velocity (0.97±0.67 m/s; mean±SD), WSS (333±336 dyne/cm<sup>2</sup>) and vorticity (1709±1290 1/s) than the intervention group (velocity=0.23±0.10 m/s; WSS=49±40 dyne/cm<sup>2</sup>; vorticity=493.1±227 1/s) (P<0.05). At 6 months, the no-intervention group had significantly larger venous CSA (43.5±27.4 mm<sup>2</sup>) than the intervention group (15.1±6.2 mm<sup>2</sup>) (P<0.05). No-intervention AVF arteries followed the same trend.

**Conclusions:** Lumen area and hemodynamic parameters differ between intervention and non-intervention AVF groups. Larger venous velocity, WSS, and vorticity immediately after AVF creation surgery may be important for later lumen enlargement and AVF maturation.

**Funding:** NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

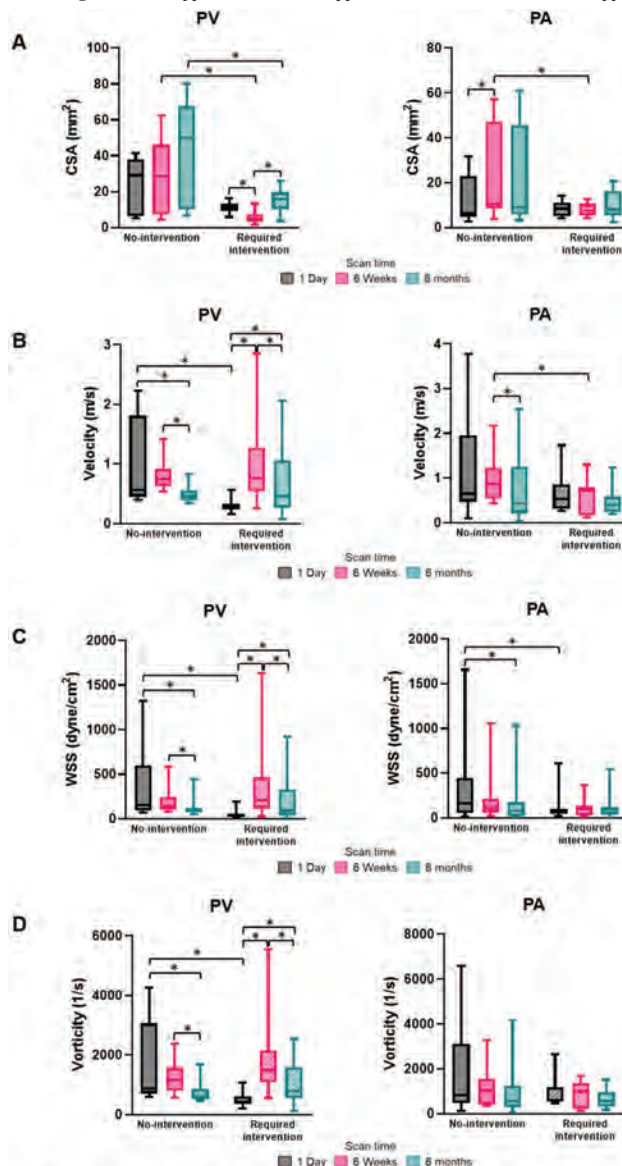

Figure 1: Proximal vein (PV) and proximal artery (PA) results of "no intervention" and "required intervention" groups at 1 day, 6 weeks, and 6 months. (A) cross-sectional area (CSA), (B) velocity, (C) wall shear stress (WSS), and (D) vorticity. Graphs show 25<sup>th</sup> to 75<sup>th</sup> percentiles within the box, with the line in the middle of the box as the median and whiskers extending to the minimum and maximum values. \*P<0.05, n=3.

## SA-PO017

### Formulating Customizable Extracellular Matrix Scaffolds From Decellularized Mouse Kidneys

Nina Cintron Pregosin, Sandeep K. Mallipattu. *Stony Brook Medicine, Stony Brook, NY.*

**Background:** Current cell culture methods are not adequate for recapitulating the physiology of mature, differentiated kidney cells in vivo. Podocytes plated on plastic tissue culture dishes differ from podocytes within the glomerulus due to their lack of foot processes or slit diaphragms, making human podocytopathies difficult to accurately study in this system. Several researchers have shown that growing podocytes in 2D culture systems that better resemble their native environment, the glomerular basement membrane, can help promote their differentiation. Rather than using expensive commercially available products, here we formulate a cell culture matrix derived from decellularized mouse kidneys. By removing the cellular content from mouse kidneys while leaving the extracellular matrix intact, we create a customizable, non-immunogenic scaffold for cell growth in-house.

**Methods:** Wild-type C57BL/6 mice were initially perfused with D-PBS and kidneys were dissected and sliced into 300µm sections then washed in D-PBS on a shaker overnight. The slices were decellularized by washing in 1% TritonX-100 for 5 hours, then 0.1% SDS for 1 hour. SDS was washed off in D-PBS overnight and kidneys were sterilized by washing in 1% normal saline. The tissue was then lyophilized, crushed, and digested in 3M urea for 36 hours. The decellularized solution was then diluted to a final concentration of 1-3% in Geltrex for coating cell culture plates or mixed with GelMA bioink for 3D bioprinting applications.

**Results:** Decellularized kidney slices had an 89% reduction in DNA content compared to control slices with preserved histological structure. Loss of cellular content was also observed after counting DAPI+ cells in ImageJ. Both glomerular endothelial cells and iPSCs showed adhesion, proliferation, and expression of mature differentiation markers on the decellularized extracellular matrix scaffold as compared to no matrix or commercially available matrix under differentiating conditions.

**Conclusions:** We generated a more accessible, sustainable, and reproducible protocol for generating decellularized extracellular matrix scaffolds in-house. Future work includes measuring the viability of various cells, such as renal epithelial cells and podocytes, and their ability to differentiate on these scaffolds.

**Funding:** NIDDK Support, Other NIH Support - NIH T32, Veterans Affairs Support
