**Methods:** We purified endogenous LRP2 from mouse kidney by isolating proximal tubule apical membrane, solubilizing in detergent, and purifying LRP2 from solubilized membrane using ion exchange chromatography and gel filtration. Protein was frozen in vitreous ice and then imaged with a Titan Krios microscope. Data was processed to yield cryo electron microscopy (cryo-EM) maps with resolutions of 2.8Å and 3.0Å for LRP2 at extracellular and endosomal pH, respectively.

**Results:** At each pH, LRP2 adopts a homodimeric assembly stabilized by pH-dependent interfaces (Figure). A significant change in tertiary structure between the two structures is mediated by pH-sensitive Ca<sup>2+</sup>-coordinating sites. At endosomal pH, Ca<sup>2+</sup> dissociates from multiple sites including both homodimer and intramolecular interfaces, enabling large-scale domain rearrangements that bury ligand-binding sites. A subset of human Donnai-Barrow loss of function missense mutations appear to impair homodimer assembly of LRP2 by perturbing pH-sensitive interfaces.

**Conclusions:** This work lays the foundation for further understanding the function and mechanism of the critical proximal tubule endocytic receptor, LRP2. In particular, our structural data highlights the central importance of pH-sensitive Ca<sup>2+</sup> switches in LRP2's structural transitions during cellular trafficking. Based on analysis of our structures and published genetic data, we unexpectedly find that LRP2 homodimerization appears conserved, necessitating a re-evaluation of the structural biology of related receptors, including LRP1 and LDLR.

### HMGB1 and Antiphospholipid Antibodies Are Involved in the Pathogenesis of Systemic Lupus Erythematosus

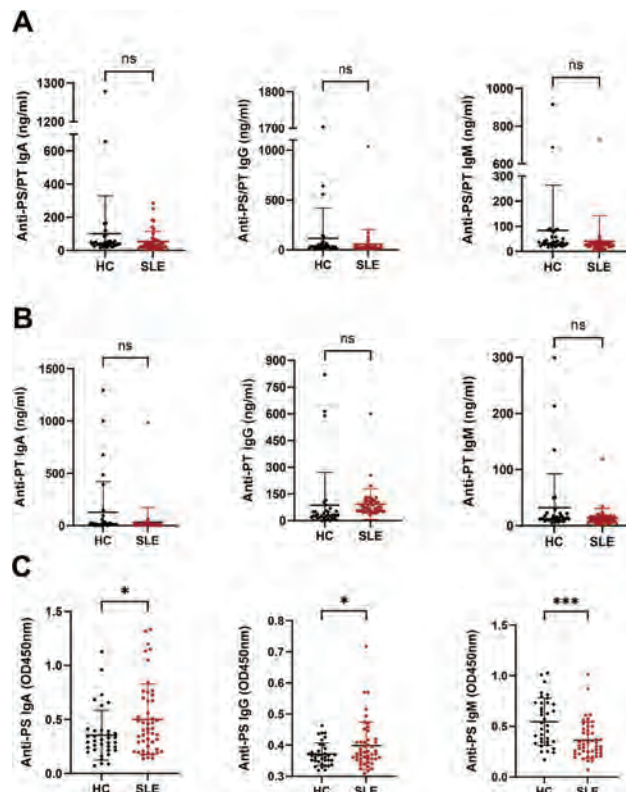

Hui Guan, Xiaohua Wang, Chun Tang, Keping Wu, Jiasi Chen, Zhihua Zheng. Department of Nephrology, Center of Kidney and Urology, The Seventh Affiliated Hospital, Sun Yat-Sen University, Shenzhen, China.

**Background:** Antiphospholipid antibodies (aPLs) are involved in the multiorgan damage of systemic lupus erythematosus (SLE). High Mobility Group Protein 1 (HMGB1) can promote the secretion of antinucleosomes in SLE. The study aims to explore the role of HMGB1 and aPLs in the pathogenesis of lupus nephritis.

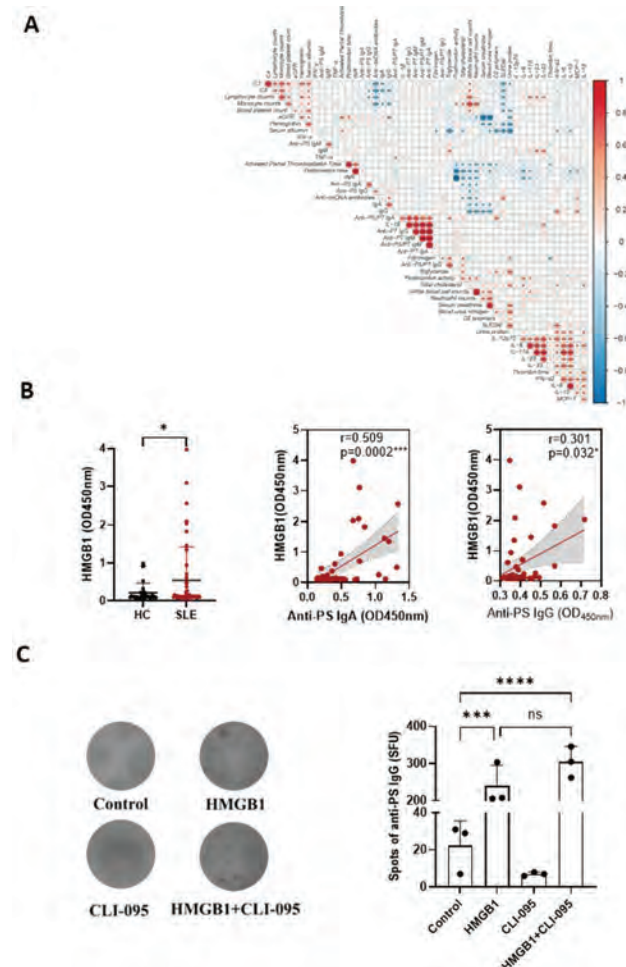

**Methods:** Antiphospholipid antibodies and HMGB1 levels were detected by enzyme-linked immunosorbent assays. Enzyme-linked immunospot assay was used to detect the ability of B cells to secrete antibodies.

**Results:** Anti-phosphatidylserine (PS) antibodies were significantly different between the SLE and control groups, while anti-phosphatidylserine/prothrombin (PS/PT) and anti-prothrombin (PT) were not. Anti-PS IgG antibodies were positively correlated to disease activity in SLE patients, while others were not. HMGB1 of SLE patients was correlated with anti-PS antibodies. HMGB1 protein stimulated peritoneal B-1a cells of C57 mice to secrete anti-PS IgG antibodies, which could not be blocked by TLR4 inhibitors (CLI-095).

**Conclusions:** Anti-PS antibodies and HMGB1 are involved in the pathogenesis of SLE.

Comparison of antiphospholipid antibodies between healthy controls and SLE patients.

Antiphospholipid antibodies and HMGB1 were involved in the pathogenesis of SLE.

**Auto-Inhibitory Domain of HIPK2 Is a Novel Inhibitor of NF- $\kappa$ B Signaling in Kidney Cells**

Ye Feng, Kyung Lee, John C. He. *Icahn School of Medicine at Mount Sinai, New York, NY.*

**Background:** We previously identified HIPK2 as a key protein kinase that regulates pro-apoptotic (p53), pro-fibrotic (TGF- $\beta$ ) and pro-inflammatory (NF- $\kappa$ B) pathways in renal tubular cells (RTEC) and diseased kidneys. As HIPK2 has multiple functional domains, mapping the individual domains required for distinct downstream pathway activation may be an optimal approach towards targeting specific HIPK2-dependent pathway. In this study, we have elucidated a novel function and mechanism of auto-inhibitory domain (AID) of HIPK2 (HIPK2-AID) in regulation of renal inflammation and fibrosis.

**Methods:** Plasmids encoding different functional domains of HIPK2 were constructed. To determine the functional role of HIPK2-AID in RTEC, we used HK2 cells. In vivo, we generated a mouse model in which expression of HIPK2-AID is induced specifically in RTECs. In this model, we examined the effects of HIPK2-AID on renal inflammation and fibrosis after creation of unilateral ureteral obstruction (UUO).

**Results:** We identified that HIPK2-AID fragment was released after Caspase 6-mediated cleavage of HIPK2. Interestingly, HIPK2-AID could act as a dominant negative to suppress TNF $\alpha$ -induced NF- $\kappa$ B (p65) transcriptional activation in HK2 cells. Mechanistically, HIPK2-AID's interaction with p65 resulted in its cytoplasmic sequestration, thereby reducing its transcriptional activity: Co-localization of p65 and HIPK2-AID in cytosol was confirmed by confocal microscopic analysis. In TNF $\alpha$ -stimulated cells, HIPK2-AID attenuated I $\kappa$ B- $\alpha$  phosphorylation and blocked p65 nuclear translocation, resulting in NF- $\kappa$ B pathway inactivation. Consistently, overexpression of HIPK2-AID specifically in RTECs attenuated p65 nuclear translocation in tubular cells and reduced macrophage infiltration in the kidney of UUO mice. The levels of p65 and I $\kappa$ B- $\alpha$  phosphorylation in the UUO kidneys were also downregulated with HIPK2-AID overexpression.

**Conclusions:** Collectively, our findings suggest that HIPK2-AID functions as a potential inhibitor of NF- $\kappa$ B signaling and HIPK2-AID or its analogues could be developed as anti-inflammatory agents to treat kidney disease.

**Diagnostic Performance of a Unique Fragment of Human Fetuin-A for Patients Undergoing Native Kidney Biopsy**

Ming-Tsun Tsai,<sup>1</sup> Wei-Cheng Tseng,<sup>1</sup> Tzu-Ling Tseng,<sup>2</sup> *<sup>1</sup>Taipei Veterans General Hospital, Taipei, Taiwan; <sup>2</sup>Bio Preventive Medicine Corp., Hsinchu, Taiwan.*

**Background:** Fetuin-A is a hepatokine secreted into the systemic circulation and regulates many biological processes. The relationship between fetuin-A and progression of chronic kidney disease (CKD) has been studied intensively, but its role in CKD and its complications remains to be clarified. Several types of post-translational modifications (PTMs) on fetuin-A are identified in patients with CKD, implying the possible effects of these modifications on renal structure and function.

**Methods:** A commercial immunoassay, DNlite-IVD103 supplied by Bio Preventive Medicine Corp., was used to measure urine levels of a unique PTM fetuin-A (uPTM-Fet-A) in a cohort of patients undergoing native kidney biopsies. Relationships between uPTM-Fet-A, clinical characteristics, and tubulointerstitial damage were analyzed with logistic regression. Furthermore, the accuracy of the uPTM-Fet-A in predicting the severity of tubulointerstitial fibrosis was evaluated by constructing receiver operating characteristic curves.

**Results:** To analyze the relationship between uPTM-Fet-A and clinical features, we divided the patients into two groups according to median levels of uPTM-Fet-A (65.6 ng/mg). The high-level group had a larger percentage of elderly male patients and patients with decreased renal function, higher levels of proteinuria, and severe renal fibrosis than the low-level group. After multivariate adjustment, renal impairment, hypoalbuminemia, and high-grade proteinuria were independently correlated with elevated levels of uPTM-Fet-A. Moreover, compared with the urine protein-to-creatinine ratio (uPCR), uPTM-Fet-A had a better performance in the diagnosis of different extents of renal fibrosis.

**Conclusions:** Our results suggested that uPTM-Fet-A may be a potential diagnostic biomarker for patients with CKD.

**Funding:** Government Support - Non-U.S.

ROC curve analyses comparing the predictability in distinguishing the different grades of IFTA of the uPTM-Fet-A/Cr (ng/mg) with uPCR (mg/mg). The area under the curve (AUC) represents the probability to discriminate the presence of > 10% (A), > 25% (B), or > 50% (C) IFTA in the tissue samples.

## TH-PO548

**Afferent but Not Efferent Vagus Nerve Stimulation Reduces Endotoxin-Induced Acute Lung Injury via Vagosympathetic Communication**

Nabin Poudel, Shuhei Kuwabara, Shinji Tanaka, Eibhlín S. Goggins, Mark D. Okusa. *UVA Health, Charlottesville, VA.*

**Background:** Vagus nerve stimulation (VNS) has a potent anti-inflammatory effect during inflammatory conditions such as acute kidney injury (AKI), arthritis, and experimental sepsis. Sepsis is an acute life-threatening condition that results from hyperactivation of the immune system as a response to infection and involves injury to multiple organs such as kidneys and lungs. We previously showed that VNS is protective in ischemia reperfusion injury induced AKI. We hypothesized that VNS protects mice from sepsis induced acute lung injury (ALI).

**Methods:** VNS was performed by exposing the left cervical vagus nerve (VN) and stimulating either electrically (eVNS) in C57BL/6 mice or optogenetically (optoVNS) in transgenic mice expressing channelrhodopsin-2 specifically in either afferent or efferent VN. Unidirectional selective VNS was performed by applying bupivacaine to one end of VN followed by VNS. Local sympathetic denervation was achieved by intranasal instillation of 6-hydroxydopamine. Hypothalamo-pituitary-adrenocortical (HPA) axis was blocked using mifepristone. 24 hours after VNS, animals were instilled with lipopolysaccharide intranasally to induce ALI followed by analysis of bronchoalveolar lavage (BAL) and lung tissues at 6 hours. Flow cytometry was performed to quantify immune cell infiltration. Luminex was performed to quantify cytokine levels. H&E staining was performed to evaluate extent of lung injury.

**Results:** We observed a significant reduction in immune cell infiltration in the alveolar space after eVNS. Selective central eVNS to stimulate afferent VN also reduced LPS induced leukocyte counts in the BAL, while selective distal eVNS failed to exert this effect. Moreover, optoVNS of anterograde afferent VN ameliorated lung injury which was abrogated by local sympathetic denervation of the lung and airway. Blocking the HPA axis did not alter the protective effect of VNS. Cytokine analysis showed that afferent VNS decreased pro-inflammatory cytokines Cxcl1, Cxcl10, RANTES, and Vegfa.

**Conclusions:** Our previous and current data collectively suggest that VNS can be an effective therapeutic approach for acute inflammatory conditions such as AKI and ALI. This phenotype is mediated by reduced cytokine production and an overall reduction in inflammatory cells recruitment in the target organ.

## TH-PO549

**Hirudin Alleviates Renal Fibrosis by Regulating PDGFB Pathway Based on Bioinformatics**

Ying Li, Weijian Xiong. *Chongqing Hospital of Traditional Chinese Medicine, Chongqing, China.*

**Background:** RIF is the final pathological manifestation of most patients with CKD and a precursor of end-stage renal disease. In recent years, many reports have confirmed the therapeutic effect of hirudin in renal disease. Our study was committed to revealing the hirudin's reduction to renal fibrosis (RF) as well as the molecular mechanism.

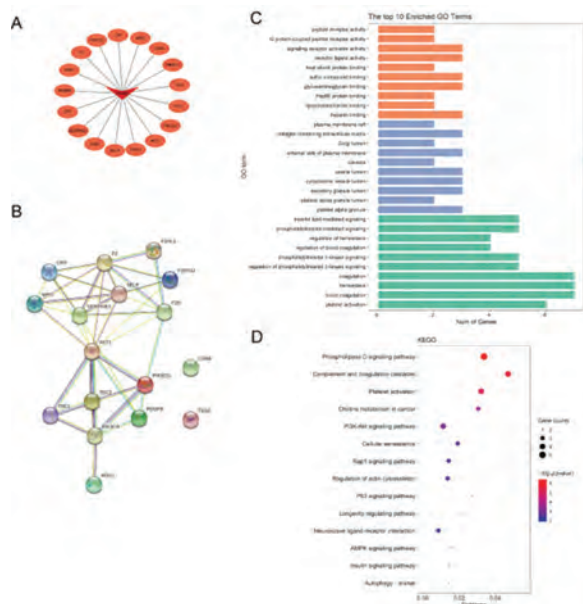

**Methods:** To begin with, we commenced both the identification and the determination to the hirudin targeted proteins and its down-stream signaling pathways with the methods of bioinformatics, molecular docking and coprecipitation. After that, we validated hirudin's interaction with PDGFB with the assays of molecular docking and immunoprecipitation.

**Results:** With the help of CTD database, 10 target proteins of hirudin were obtained, and N proteins were screened by mass spectrometry analysis. 5 proteins were screened out and 5 flag-target overexpressed plasmid vectors were constructed respectively, which were verified by immunoprecipitation in NRK-52E cells. We found that only PDGF-BB is capable of binding to hirudin. Subsequently, we confirmed that hirudin inhibits the EMT caused by PI3K-AKT by reducing the phosphorylation of PDGFR $\beta$  in vitro.

**Conclusions:** Hirudin reduces the phosphorylation level of PDGFR $\beta$  by binding to PDGF-BB.

**Funding:** Government Support - Non-U.S.

**Results:** Most of the biomarkers were significantly increased within the ESRD group compared to normal plasma. Annexin V (23.64%,  $p < 0.001$ ), L-FABP (1983%,  $p < 0.0001$ ), D-dimer (650.53%,  $p < 0.0001$ ), TNF-alpha (35.87%,  $p < 0.0001$ ), IL-6 (317.21%,  $p < 0.0001$ ), CRP (2214.43%,  $p < 0.0001$ ), NO (151.74%,  $p < 0.0001$ ), vWF (183.03%,  $p < 0.0001$ ), and MCP-1 (67.49%,  $p < 0.0001$ ) showed significant increase when compared to normal volunteers. Varying levels of correlations were noted within some of these biomarkers. Other measured biomarkers did not demonstrate any significant differences between the ESRD and control groups.

**Conclusions:** This study suggests that thrombo-inflammatory biomarkers may be helpful in the diagnosis of CRS in ESRD patients. This multi-parametric profiling may be helpful in risk stratification and prediction of adverse outcomes within ESRD patients and the development of CRS.

### Upregulation of IRF4 Correlates With Renal Damage in Systemic Lupus Erythematosus

Yu Liu,<sup>1</sup> Chun Tang,<sup>1</sup> Xiaohua Wang,<sup>1</sup> Yan Lei,<sup>1</sup> Li Na,<sup>1</sup> Enyi Zhu,<sup>1</sup> Hui Guan,<sup>1</sup> Xiaoping Liu,<sup>2</sup> Zhihua Zheng.<sup>1</sup> <sup>1</sup>The seventh Affiliated Hospital of Sun Yat-Sen University, Shenzhen, China; <sup>2</sup>Guangzhou Women and Children's Medical Center Institute of Pediatrics, Guangzhou, China.

**Background:** Transcription factor interferon regulatory factor 4 (IRF4) plays an essential role in driving maturation and differentiation of Ab secreting plasma cells. Our study aims to investigate the expression and localization of IRF4 in systemic lupus erythematosus (SLE) and its correlation with clinical characteristics.

**Methods:** The expression of IRF4 in PBMCs from 31 SLE patients and 17 healthy controls (HC) were checked by qPCR and Western blotting. Meanwhile, the relationship between the IRF4 mRNA level and clinical manifestations were analyzed. Furthermore, the distribution patterns of IRF4 and plasma cells were identified in kidneys of MRL/lpr mice and C57BL/6 mice by immunofluorescence staining.

**Results:** Among patients with active disease but not in remission, the mRNA and protein expression of IRF4 in PBMCs were remarkably increased compared to that in HC group. The mRNA level of IRF4 was positively correlated with frequency of peripheral blood B cells and serum IgA level in SLE patients. Moreover, patients with increased IRF4 mRNA level have a significantly higher frequency of renal damage. Consistently, elevated mRNA and protein expression patterns of IRF4 were observed in kidneys from MRL/lpr mice compared to that from C57BL/6 mice. Besides, IRF4 was found mainly expressed in plasma cells in spleens of MRL/lpr mice, which was notably higher than that of C57BL/6 mice. Also, IRF4 significantly co-localized with CD138<sup>+</sup> plasma cells among kidneys from MRL/lpr mice.

**Conclusions:** Upregulated IRF4 may be clinically involved in renal damage in SLE.

**Funding:** Other NIH Support - Shenzhen Municipal Science and Technology Innovation Commission (Project-ID JCYJ20120324123414040), and Guangdong Basic and Applied Basic Research Foundation (Project-ID 2019A1515110488 and 2020A1515110306)

**Figure 1. IRF4 is upregulated in SLE patients and MRL/lpr mice.** (A) RT-qPCR for IRF4 mRNA levels in PBMCs of healthy controls (HC; n=17), SLE in active period (SLE-AP, n=13) and remission period (SLE-RP, n=18); (B) Western blotting for IRF4 protein levels in healthy controls and SLE patients; (C) Flow cytometry analysis for MF1 of IRF4 in plasma cells in spleens of C57BL/6 mice and MRL/lpr mice; (D) Double staining of IRF4 with CD138 by immunofluorescence staining in kidneys of C57BL/6 mice and MRL/lpr mice.

## TH-PO552

### Association Between Ongoing Antithrombotic Agents and Renal Biopsy Bleeding Complication

Ryumon Miyashita,<sup>1,2</sup> Keita Hirano,<sup>1,2</sup> Ichiro Ohkido,<sup>2</sup> Nobuo Tsuboi,<sup>2</sup> Takashi Yokoo,<sup>2</sup> Ashikaga Sekijuki Byoin, Ashikaga, Japan; <sup>2</sup>Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan.

**Background:** Numbers of kidney disease patients with prescribed antithrombotics have been growing because of their increased cardiovascular risk. Stopping them prior to renal biopsy can lead to delays in diagnosis and treatment, and increase the likelihood of ischemic events. Since there have been few studies examining bleeding complications due to continued antithrombotics up to the time of renal biopsy, we aimed to retrospectively examine this risk of bleeding in our historical cohort of renal biopsy.

## TH-PO550

**Thrombo-Inflammatory Biomarkers of Cardiorenal Syndrome in ESRD**  
Vinod K. Bansal, Pranathi Karumanchi, Fakiha Siddiqui, Mark Jaradeh, Debra Hoppensteadt, Jawed Fareed. Loyola University Health System, Maywood, IL.

**Background:** Cardiovascular complications commonly occur in patients with end-stage renal disease (ESRD) and lead to a 20-fold increase in mortality relative to the general population. The strong interdependence between ESRD and cardiovascular complications may be explained through cardiorenal syndrome (CRS). CRS comprises a spectrum of disorders involving both the heart and kidneys in which acute or chronic dysfunction in one organ may induce consequential pathogenesis in the other organ. Previous studies have demonstrated that inflammation and thrombosis are integral to CRS development and key cardiac and renal biomarkers are elevated in CRS patients. This study aims to profile thrombo-inflammatory biomarkers in ESRD patients to establish relevance to CRS.

**Methods:** Plasma samples were collected from 95 ESRD patients following approval by an IRB at Loyola University Medical Center. Control group was comprised of plasma samples (N=50), obtained from a commercial source (George King Biomedical, USA). Thrombo-inflammatory biomarkers, including Annexin V, MPO, Troponin, L-FABP, VEGF, D-dimer, TNF-alpha, IL-6, CRP, eNOS, Nitrotyrosine, MDA, NEFA, NO, vWF and MCP-1 were measured using commercially available ELISA methods. Results were compiled as group means±SEM and analyzed using GraphPad software.

**Methods:** Patients undergoing ultrasound-guided renal biopsy at our hospital between 2013 and 2021 were enrolled. Observation period was one week before and after renal biopsy. Exposure was any antithrombotics continued during the observation period. Control was no antithrombotics during this period. Primary outcome was change in hemoglobin levels from the day of biopsy to one day after. Secondary outcome was any macroscopic hematuria within 7 days after biopsy. Matching with 1:1 ratio on the basis of derived propensity scores for the treatment with antithrombotic agents was used to balance baseline characteristics between exposure and control.

**Results:** Among enrolled 1392 patients, 156 patients in antithrombotic group (antiplatelet 117 [75.0%], anticoagulant 33 [21.2%], both of them 6 [3.8%]) were matched. The top two most commonly prescribed antiplatelet and anticoagulant agents were Acetylsalicylic acid and Clopidogrel, and Warfarin and Apixaban, respectively. Difference in change of hemoglobin levels between antithrombotic and control groups was not significant (mean -0.14 g/dl, standard error 0.12, 95% confidence interval [CI] -0.37 to 0.10, P=0.243). The risk of macroscopic hematuria after renal biopsy in antithrombotic group was not significant compared to control (odds ratio 0.85, 95% CI 0.45 to 1.62, P=0.623).

**Conclusions:** Our retrospective single center study has demonstrated that continuing antithrombotic agents at the time of renal biopsy was not significantly associated with increased risk of bleeding.

TH-PO553

**Factors Associated With Excessive Glomerular Hypertrophy in Patients With CKD: Renal Biopsy-Based Study**  
Ryo Zamami, Kentaro Kohagura, Yusuke Ohya. *Ryukyu Daigaku, Nakagami-gun, Japan.*

**Background:** Loss of nephrons leads to compensatory hypertrophy of the residual glomeruli, and glomerular hypertrophy beyond the compensatory range due to impaired renal autoregulation triggers progressive renal dysfunction. Various factors have been reported to as a cause of glomerular hypertrophy, but it is unclear which factors are most associated with excessive glomerular hypertrophy. In this study, we used renal biopsy specimens to determine which factors are most associated with excessive glomerular hypertrophy.

**Methods:** Subjects were 104 patients who underwent renal biopsy at the University of the Ryukyus Hospital from 2016 to 2017, excluding those with less than 5 glomeruli collected. Predicted maximum glomerular diameter was determined by simple regression analysis using the glomerular density and maximum glomerular diameter of each specimen, and the difference between the measured and predicted maximum glomerular diameter was defined as the glomerular hypertrophy index (GHI). Multiple regression analysis was used to determine the most relevant factors for the GHI using following factors associated with impaired renal autoregulation as variables: age, gender, systolic blood pressure, body mass index (BMI), creatinine clearance, serum uric acid level (SUA), HbA1c, protein intake, and use of renin-angiotensin-aldosterone system inhibitors. The fourth quartile of GHI was defined as the excessive glomerular hypertrophy group, and multiple logistic analysis was performed using the same variables.

**Results:** The median age of the subjects was 49 years, and the median eGFR was 67 ml/min/1.73 m2. In simple regression analysis, BMI, HbA1c, and SUA were significantly associated with GHI. In multiple regression analysis, BMI and HbA1c were significantly associated with GHI independently of other factors, with standardized partial regression coefficients of 0.325 and 0.249, respectively. In multiple logistic analysis, only BMI was associated with excessive glomerular hypertrophy.

**Conclusions:** BMI may lead to excessive glomerular hypertrophy in patients with chronic kidney disease.

TH-PO554

**Daily Variability of Urinary Extracellular Vesicles in Healthy Patients**  
Margaret Selesky,<sup>1</sup> Samantha G. Upson,<sup>2</sup> Luca Musante,<sup>3</sup> Hayrettin Yavuz,<sup>4</sup> Michael A. Harding,<sup>4</sup> Uta Erdbruegger.<sup>4</sup> *<sup>1</sup>University of Virginia School of Medicine, Charlottesville, VA; <sup>2</sup>University of Virginia, Charlottesville, VA; <sup>3</sup>University of Pennsylvania, Philadelphia, PA; <sup>4</sup>UVA Health, Charlottesville, VA.*

**Background:** Urinary extracellular vesicles (uEVs) have been shown to parallel physiologic and pathologic processes in the kidney, but minimal literature exists studying the daily variability of EV secretion in healthy patients. In this pilot study, we used Nanoparticle Tracking Analysis (NTA) to study particle and EV secretion in urine throughout a 24-hour collection in 9 healthy individuals.

**Methods:** We collected every void during a 24-hour period for 9 healthy individuals starting with the second morning void and ending with the first of the following day for a total of 61 samples and an average of 6.8 voids per individual. We created a 24-hour collection sample by combining 20% of each void and quantitated creatinine concentration in each void using the picrate alkaline colorimetric assay. EVs were separated from urine with differential centrifugation at 4,600g and 21,500g to remove cells and debris and to pellet EV respectively. The uEV pellet was washed 3 times with a low ionic strength buffer and centrifuged at 25,000g serially to collect uEVs. We performed particle count and sizing on each final pellet using an NTA instrument (ZetaView PMX-120; Particle Metrix). Nanoparticle concentration was normalized to creatinine concentration for each void to account for hydration status. Paired t-test was used to evaluate whether any individual void was significantly different from the 24-hour collection, defined as p<0.05.

**Results:** Neither median diameter nor nanoparticle concentration were significantly different between any individual void and the 24-hour sample on paired t-test (Figure 1), although the difference between median diameter of the second morning void and 24-hour sample were closest to significantly different (p=0.09).

**Conclusions:** We found no difference in uEV concentration or median diameter between any individual void in a 24-hour collection and the 24-hour sample. Further studies are needed to dissect the mechanisms of uEV size differences and variability of uEV markers like AQP2.

TH-PO555

**Aging Aggravates Oxidation Processes and Collagen Accumulation in the Experimental AKI-to-CKD Transition**  
Laura Marquez-Exposito,<sup>1,2</sup> Lucia Tejedor,<sup>1,2</sup> Floris Valentijn,<sup>3</sup> Vanessa Marchant,<sup>1,2</sup> Roel Goldschmeding,<sup>3</sup> Marta Ruiz-Ortega.<sup>1,2</sup> *<sup>1</sup>Universidad Autonoma de Madrid, IIS-FJD, Madrid, Spain; <sup>2</sup>REDinREN, Madrid, Spain; <sup>3</sup>University Medical Center Utrecht, Utrecht, Netherlands.*

**Background:** Chronic kidney disease (CKD) is very frequent in aged patients, being associated to a high mortality. Our group has previously described a dysfunctional redox-regulated mechanisms and an early activation of cellular senescence in 1 year old C57BL6 mice. Moreover, in folic acid (FA)-induced Acute Kidney Injury (AKI) in these mice, exacerbation of tubular injury, necroinflammation and cellular senescence was observed. However, mechanisms leading to AKI-to-CKD transition in the aging are completely unknown.

**Methods:** A single low-dose of FA (125mg/kg) were injected to young (3 months) and aged (12 months) mice and kidneys were studied after 10 days.

**Results:** First, a Kaplan-Meier curve showed a 91% of survival in the FA-young group, whereas only a 46% of FA-aged group survived. The higher mortality in aging mice was observed at day 8 corresponding to the AKI-to-CKD transition phase. The PAS staining in survival mice showed higher inflammatory infiltrating cells in FA-aged mice compared to FA-young mice, but tubular dilatation and renal dysfunction were similar between groups. The assessment of cellular senescence mechanisms through the activation of DNA-Damage Responses, such as phosphorylation of H2AX histone and the cycline-dependent kinase inhibitors, such as p21cip1 and p16ink4a, demonstrated not significant differences between FA-damaged groups. On the contrary, gene expression levels of several Senescence-Associated Secretory Phenotype, such as *Ccn2*, and the proinflammatory factors *Tnfa* and *Ccl5*, were found augmented in FA-aged mice. Collagen accumulation, evaluated by a picrosirius red staining, showed higher deposition in FA-aged mice. Moreover, LOX and LOXL2 protein levels were significantly increased in FA-aged mice. On the other hand, NRF2 antioxidant protein evaluation and total protein nitration by 3-nitrotyrosine, showed an increase in the FA-aged mice, demonstrating a deregulation in the cellular oxidation and antioxidant response associated to aging in these mice.

**Conclusions:** Our study showed that AKI-to-CKD transition in aging mice is characterized by increased mortality, inflammatory cell infiltration and kidney fibrosis. The mechanisms involved in increased susceptibility to CKD progression might be mediated by deregulation of redox processes and sustained inflammation.

**Funding:** Government Support - Non-U.S.

TH-PO556

**Detrimental Role of Hypoxia-Inducible Factor Asparaginyl Hydroxylase (FIH) in CKD**  
Anna Faivre,<sup>1</sup> Romain Dissard,<sup>1</sup> Willy Kuo,<sup>2</sup> Thomas Verissimo,<sup>1</sup> David Legouis,<sup>1</sup> Gregoire Arnoux,<sup>1</sup> Maja Lindenmeyer,<sup>3</sup> Solange Moll,<sup>4</sup> Carsten C. Scholz,<sup>2</sup> Vartan Kurtcuoglu,<sup>2</sup> Sophie M. De Seigneux.<sup>1</sup> *<sup>1</sup>Universite de Geneve Departement de physiologie cellulaire et metabolisme, Geneve, Switzerland; <sup>2</sup>Universitat Zurich Physiologisches Institut, Zurich, Switzerland; <sup>3</sup>Universitätsklinikum Hamburg-Eppendorf Zentrum für Innere Medizin, Hamburg, Germany; <sup>4</sup>Hopitaux Universitaires Geneve, Geneve, Switzerland.*

**Background:** The roles of hypoxia and hypoxia inducible factor (HIF) during chronic kidney disease (CKD) are much debated. Interventional studies with HIF-α activation in rodents yielded contradictory results. The HIF pathway is regulated by three prolyl and one asparaginyl hydroxylases; while prolyl hydroxylase inhibition is a well-known method to stabilize HIF-α, little is known about the effect of the inhibition of the asparaginyl hydroxylase Factor Inhibiting HIF (FIH).

**Methods:** We used a model of progressive proteinuric CKD and a model of obstructive nephropathy with unilateral fibrosis. In these models, we assessed hypoxia with pimonidazole and vascularization with high-definition three-dimensional micro-CT

imaging. We analyzed a database of 217 CKD biopsies from stage 1 to 5 for transcription and we randomly collected 15 CKD biopsies from various severity degrees to assess FIH expression. Finally, we modulated FIH activity *in vitro* and *in vivo* using a pharmacologic approach, to assess its relevance in CKD.

**Results:** In our model of proteinuric CKD, we show that early CKD stages are not characterized by hypoxia or HIF activation. At late CKD stages, some areas of hypoxia are observed, but interestingly these are not colocalizing with fibrosis. In mice and in humans, we observed a downregulation of the HIF pathway, together with an increased FIH expression in CKD, according to its severity. Modulating FIH *in vitro* affects cellular metabolism, as described previously. *In vivo*, pharmacologic FIH inhibition increases the glomerular filtration rate of control and CKD animals and is associated with a reduced development of fibrosis.

**Conclusions:** The causative role of hypoxia and HIF activation in CKD progression is questioned. A pharmacological approach of FIH downregulation seem promising in proteinuric kidney disease.

Renal Pathology Global Practice Variation

Joseph Gaut,<sup>1</sup> Joris Roelofs,<sup>2</sup> Surya V. Seshan,<sup>3</sup> Joel M. Henderson,<sup>4</sup> Shreeram Akilesh,<sup>5</sup> Swarnalata Gowrishankar,<sup>6</sup> Thorsten Wiech,<sup>7</sup> Luiz A. Moura.<sup>8</sup>  
<sup>1</sup>Washington University in St Louis School of Medicine, St Louis, MO; <sup>2</sup>Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; <sup>3</sup>Weill Cornell Medicine, New York, NY; <sup>4</sup>Boston University, Boston, MA; <sup>5</sup>University of Washington, Seattle, WA; <sup>6</sup>Apollo Hospitals, Hyderabad, India; <sup>7</sup>Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; <sup>8</sup>Universidade de Sao Paulo, Sao Paulo, Brazil.

**Background:** Renal pathology relies on special histologic stains and ancillary techniques. Global practice variation is not well documented. This study aims to examine global renal biopsy pre-analytic and analytic variability in the current era.

**Methods:** The Renal Pathology Society membership was surveyed between Aug 24, 2021 - Oct 22, 2021 with 66 questions. 126 members responded.

**Results:** Respondents represented 47% North America, 26% Asia, 19% Europe, 4% South America, 3% Central America, 1% Australia, and 1% Africa. Most have a practice processing 500 - 1000 biopsies annually, most being native kidney biopsies. The survey consisted of questions regarding general practice variables, tissue preparation, and processing for light, immunofluorescence, and electron microscopy. The most variable survey responses are summarized in Table 1. The remaining responses that were more consistent were not shown.

**Conclusions:** There is significant variation in renal biopsy processing and extent of pathological evaluation across the globe. Paraffin immunofluorescence is not widely available nor are THSD7A, collagen IV isoform, and DNAJB9 immunostains. EM is only used routinely in ~50% of biopsies. Morphometric measurement of fibril thickness varies in practice. Despite the wide range of resources available in differing global settings, most pathologists have access to many ancillary tests. Improved access to adequate resources is needed to standardize global renal biopsy practice. These data reveal many potential sources of variability across all processing phases and microscopic techniques. Further study is needed to understand the impact on renal pathology practice.

Table 1

Question	Response (%)
Where are renal biopsies divided for LM, IF, EM?	Bedside/procedure (32); lab (56); nephrologists/radiologists (42)
Who divides the biopsy?	Pathologist (44); trainee (16); tech (56); surgeon (6); nephrologist (33); radiologist (16)
Total # slides prepared for 1 biopsy	4-5 (18); 6-8 (30); 9-10 (21); >10 (30)
# H&E slides for 1 biopsy	1 (16); 2 (37); 3 (32); 4 (15)
# PAS slides for 1 biopsy	1 (34); 2 (27); 3 (28); 4 (10)
# Silver slides for 1 biopsy	0 (2); 1 (53); 2 (25); 3 (16); 4 (4)
Section thickness for Congo Red	<5 µm (12); 5 µm (18); 7 µm (24); >7 µm (44); do not use (2)
Do you offer paraffin IF?	Yes (49); No (51)
PLA2R immunostaining	Yes IF (26); Yes IHC (32); Yes sendout (17); No (26)
DNAJB9 immunostaining	Yes IF (4); Yes IHC (23); Yes sendout (23); No (50)
THSD7A immunostaining	Yes IF (5); Yes IHC (13); Yes sendout (19); No (63)
Collagen IV isoforms staining	Yes IF (27); Yes IHC (33); Yes sendout (22); No (48)
Morphometric fibril thickness - how many measurements?	<10 (26); 10-20 (34); 20-50 (10); >50 (3); minimum (13); No (25)

TH-PO558

The Cleveland Clinic Kidney Biopsy Epidemiology Project

Gilda M. Portalandin,<sup>1</sup> Hanny Sawaf,<sup>2</sup> Shruti Shettigar,<sup>1</sup> Astrid I. Carrión Rodríguez,<sup>1</sup> Leal C. Herlitz,<sup>2</sup> Surafel K. Gebreselassie,<sup>1</sup> Shane A. Bobart.<sup>1</sup>  
<sup>1</sup>Cleveland Clinic Florida, Weston, FL; <sup>2</sup>Cleveland Clinic, Cleveland, OH.

**Background:** The kidney biopsy is the gold standard for diagnosing kidney disease. Large-scale, epidemiological studies describing the prevalence of biopsy proven kidney diseases are lacking. We aimed to determine the spectrum and prevalence of biopsy proven kidney disease across the Cleveland Clinic.

**Methods:** We identified all patients who had a native kidney biopsy performed/ reviewed at the Cleveland Clinic from January 2015 to September 2021. Clinical and demographic characteristics were obtained by retrospective chart review. Results were stratified by age, race and state to assess any epidemiological trends in kidney disease.

**Results:** Over 9600 patients were identified. After excluding transplant/donor biopsies and unavailable records, we had 4148 patients with native biopsy data. The mean age at biopsy was 57 years old, with 46% female. There were 3256 patients in Ohio and 349 patients in Florida. Self-reported racial demographics were 72.9% white (5.1% Hispanic), 21.7% black, 3.1% multi-racial, and 1.6% Asian. Diagnoses identified were: FSGS (15.2%), diabetic kidney disease (DKD) (14.6%), IgA nephropathy (7.7%), lupus nephritis (7.0%), pauci-immune glomerulonephritis (6.6%), membranous nephropathy (5.1%), acute interstitial nephritis (AIN) (3.0%), and amyloidosis (2.7%). When stratified by age groups 0-18, 19-64, 65-85 and over 85 years old, AIN and pauci-immune glomerulonephritis were more prevalent in those >85 years. Among those <65 years old, lupus nephritis, IgA nephropathy and minimal change disease was more prevalent. In Ohio, there was a higher percentage of black (23.4% vs 17%) and non-Hispanics (96.3% vs 79.2%) vs Florida with more white (74.8% vs 71.8%) and Hispanics (20.8% vs 3.7%). Pauci-immune glomerulonephritis was more commonly seen in whites, while DKD, FSGS and lupus nephritis were more prevalent in black patients. Notably, the prevalence of membranous nephropathy, a disease that primarily affects whites, was similar between white and black patients in our cohort (5.0 vs 5.2%).

**Conclusions:** Our study catalogues the spectrum of biopsy proven kidney disease across the US Cleveland Clinic enterprise. Key demographic and geographical trends have been identified. Future studies include an in depth look at clinical outcomes and clinic trails for specific glomerular diseases at our Florida and Ohio campuses.

TH-PO559

Baseline Characteristics of Renal Biopsy Cohort of Patients With CKDu in Nicaragua

Cristian J. Urey,<sup>1</sup> Nelson B. Garcia Salazar,<sup>1</sup> Biruh Workeneh,<sup>2</sup> Alexei V. Mikhailov,<sup>3</sup> Michael H. Carstens,<sup>3</sup> Sreedhar A. Mandayam.<sup>2</sup>  
<sup>1</sup>MINSA, Chinandega, Nicaragua; <sup>2</sup>The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>3</sup>Wake Forest Baptist Medical Center, Winston-Salem, NC.

**Background:** CKDu represents a devastating form of kidney disease in young adults in Central America with no traditional risk factors for CKD. Renal biopsy studies of patients with CKDu have been rare. We report the baseline characteristics of a cohort of patients with CKDu that underwent renal biopsy in Leon and Chinandega, Nicaragua

**Methods:** Study was approved by local IRB and MINSA, Nicaragua. After signing informed consent, patients with CKDu were identified by treating nephrologists and admitted to Hospital Escuela Oscar Danilo Rosales Argüello for renal biopsy. Ultrasound guided percutaneous renal biopsy was performed under conscious sedation and local anesthesia. 2-3 cores were sampled in each patient and verified for adequacy

**Results:** 32 patients were screened for kidney biopsy for CKDu with baseline CBC, BP and Coagulation panel 24 hours pre biopsy. 3 patients were not biopsied for safety concerns (small kidney size, uncontrolled HTN). 14 were female, Mean age of patients was 34 years. Mean serum creatinine at biopsy was 1.4mg/dl. All patients had post biopsy ultrasound to r/o bleeding complications and labs at 24 hours to confirm absence of significant bleeding or other complications

**Conclusions:** Ultrasound guided percutaneous renal biopsy can be safely conducted in resource poor settings to help diagnose and manage patients with CKDu.

TH-PO560

Survey of Utility of Renal Pathology Society-Sponsored Existing Classifications

Suman Setty,<sup>1</sup> Shreeram Akilesh,<sup>4</sup> Marjan Afrouzian,<sup>3</sup> Volker Nicleleit,<sup>5</sup> Joseph Gaut.<sup>2</sup> Research and Scientific Committee, Renal Pathology Society  
<sup>1</sup>University of Illinois Chicago UI Health, Chicago, IL; <sup>2</sup>Washington University in St Louis School of Medicine, St Louis, MO; <sup>3</sup>The University of Texas Medical Branch at Galveston, Galveston, TX; <sup>4</sup>University of Washington School of Medicine, Seattle, WA; <sup>5</sup>University of North Carolina System, Chapel Hill, NC.

**Background:** The Renal Pathology Society with an international membership has sponsored many classifications over the years. We revisit these classifications with the intent to examine their impact on pathology practice and impressions of their relevance to patient care.

**Methods:** A survey was constructed and released to the renal pathologist community on March 12, 2022. The survey closed on April 21, 2022 with 266 respondents. Of these 247 completed surveys were analyzed.

**Results:** Forty % of respondents practice solely renal pathology and 60% in part. Of the 60%, 65% (102/157) practice at least 25% renal pathology. Of the 259 respondents, 132 (51%) were from North America, 62 (24%) from Asia, 48 (19%) Europe, 10 (4%) South America, <2% from Australia and <1% from Africa. Survey responses are summarized in Table 1. Between 15 and 30% of the pathologists who report the classifications as written, use a synoptic version. Also, of those surveyed, 169/198 (85%) find templates to be useful for their reporting purposes.

**Conclusions:** We surveyed members for their impression of Renal Pathology Society -Sponsored classifications of renal diseases. Responses were received from mainly N. America, Europe and Asia of whom the majority have a substantial renal pathology practice. A majority of those surveyed were familiar with all the publications and use the recommended definitions and terminology as outlined in the publication or use most of the descriptive elements in their reports. The principal reason for not using classifications is the belief that they do not have clinical utility or that clinicians do not use information derived from the classifications e. g. 31% for IgA nephropathy vs 91% for diabetic nephropathy. Also, at best 30% of the pathologists who report the classification as written, use a synoptic version.

Table 1. Analysis of Questionnaire

	Lupus Nephritis (Bojarski et al, 2018)	IgA Nephropathy (Trimathi et al, 2017)	Diabetic Nephropathy (Fernandez et al, 2016)	Glomerulonephritis (Sethi et al, 2015)	Standard Reporting (Chang et al, 2012)
Familiarity with classifications	233/247 (94%)	228/247 (92%)	206/247 (83%)	182/247 (74%)	154/247 (62%)
Pathologists using the recommended definitions and terminology as outlined in the publications or using most of the descriptive elements in their reports (such that the classification can be retrospectively assigned)	214/217 (99%)	202/208 (97%)	159/157 (101%)	153/204 (75%)	128/199 (64%)
Of the pathologists who report the classification as written, the following use a synoptic version	55/185 (29%)	57/188 (30%)	15/94 (16%)	15/73 (21%)	10/67 (15%)
Pathologists who believe that clinicians use the information derived from the classification	167/185 (90%)	157/193 (81%)	54/95 (57%)	68/75 (91%)	58/50/70 (84%)
Of those who do not use the classification, those not seeing a clinical utility or who think that clinicians do not make use of the information in the report	16/42 (38%)	12/43 (28%)	144/155 (93%)	50/134 (44%)	41/137 (29%)
Pathologists who would like to see an update including description of utility of the various elements	132/210 (63%)	143/208 (69%)	156/233 (67%)	130/201 (65%)	131/196 (67%)

TH-PO561

**A Novel Activity and Chronicity Index for Histologic Assessment of Renal Biopsies in ANCA-Associated Vasculitis**  
Bogdan Obrisca,<sup>1</sup> Alexandru F. Procop,<sup>1</sup> George Terinte-Balcan,<sup>2</sup> Roxana A. Jurubita,<sup>1</sup> Alexandra Vornicu,<sup>1</sup> Mihaela Gherghiceanu,<sup>2</sup> Gener Ismail.<sup>1</sup>  
<sup>1</sup>Fundeni Clinical Institute, Bucharest, Romania; <sup>2</sup>Victor Babes National Institute of Pathology, Bucharest, Romania.

**Background:** Prediction of renal outcome in ANCA-associated vasculitis (AAV) remains a major challenge. We aimed to evaluate a novel score for histologic assessment of renal biopsies in AAV.

**Methods:** A semiquantitative activity (AI) and chronicity (CI) index were assessed in relation to achievement of remission or ESRD. The AI consisted of the percentage of normal glomeruli, cellular/fibrocellular crescents, fibrinoid necrosis, neutrophil infiltration, the severity of interstitial inflammation, the presence of tertiary lymphoid organs, arteritis and TMA. The CI consisted of a total glomerulosclerosis score, the percentage of glomeruli with fibrous crescents, the severity of IFTA and the presence of arteriosclerosis.

**Results:** 27 patients with AAV were included in the study. Their mean age was 60±10 years, 70% were females and 74% had a pANCA-vasculitis. The baseline eGFR was 21±16 ml/min, while 70.4% of patients achieved a remission and 22.5% progressed to ESRD. The baseline eGFR significantly correlated with AI ( $r=-0.53$ ;  $p=0.005$ ), CI ( $r=-0.37$ ;  $p=0.05$ ) and individual components, cellular/fibrocellular crescent score ( $r=-0.44$ ;  $p=0.02$ ), interstitial inflammation score ( $r=-0.5$ ;  $p=0.009$ ) and tubular atrophy score ( $r=-0.38$ ;  $p=0.04$ ) (Figure 1). Non-responders had higher median AI [11.5 (IQR:6.5-16.25)], CI [8.5 (IQR:5.7-10)] and cellular/fibrocellular crescent score [6 (IQR:2.5-6)] compared to responders [8 (IQR:5-12); 6 (IQR:5-8) and 2 (IQR:2-4), respectively]. Patients that progressed to ESRD had higher AI [11 (IQR:6-13.2)] and fibrinoid necrosis score [3 (IQR:1.5-4.5)] compared to non-progressors [8 (IQR:5.5-14) and 0 (IQR:0-4)].

**Conclusions:** This novel histologic score correlated with the baseline severity of renal involvement in AAV and may be useful for predicting the renal outcome.

Figure 1. Variables correlation.

**Development of a Multiple Convolutional Neural Network Facilitated Immunofluorescence Assessment of Glomerular Diseases**  
Peng Xia,<sup>1</sup> Xueyuan Zhang,<sup>2</sup> Yubing Wen,<sup>1</sup> Baichuan Zhang,<sup>2</sup> Xuesong Zhao,<sup>1</sup> Fei Ren,<sup>3</sup> Limeng Chen.<sup>1</sup> <sup>1</sup>Peking Union Medical College Hospital, Beijing, China; <sup>2</sup>Beijing Zhijian Life Technology Co. LTD, Beijing, China; <sup>3</sup>Institute of Computing Technology Chinese Academy of Sciences, Beijing, China.

**Background:** Immunofluorescence (IF) tests of renal tissue are important in diagnosing glomerular diseases. We developed a multiple CNN facilitated program to generate suggested IF diagnosis of glomerular diseases.

**Methods:** A dataset of 2747 IF images of glomerulus, including IgA Nephropathy (IgAN, n=759), Idiopathic Membranous Nephropathy (IMN, n=1050), anti-glomerular basement membrane antibody disease (anti-GBM disease, n=64), Mesangial Proliferative Glomerular Nephritis (MPGN, n=63), Poststreptococcal Glomerulonephritis (PSGN, n=83) and other glomerular diseases (n=728) including Lupus Nephritis, Diabetic Nephropathy and Secondary MN from Peking Union Medical College Hospital were used for training and validation datasets. Another 869 images from 183 patients were used as test dataset. The program included a CNN trained as glomeruli location module and a CNN trained as deposition appearance and location classifier (Figure 1). The performance of the program was evaluated by sensitivity, specificity and F1 score. F1 was computed as  $2 \times \text{True Positive} / (2 \times \text{True Positive} + \text{False Positive} + \text{False Negative})$ .

**Results:** The program was accurate common glomerular diseases. The sensitivity of diagnosing suspected IgAN and IMN were 95.9% and 91.1%, and the specificity were 99.1% and 97.1%. The corresponding F1 score were 0.972 and 0.911. The program showed specific diagnostic performance for uncommon glomerular diseases. The specificity of diagnosing suspected anti-GBM disease, MPGN, PSGN and C3 glomerulonephritis were 100%, 100%, 100%, and 98.9% (Table 1).

**Conclusions:** This multiple CNN facilitated diagnostic program were useful in IF assessment of glomerular diseases.

Figure 1 Overview of the CNN trained for deposition appearance and location classification

## TH-PO563

## Feasibility and Utility of Intraoperative Kidney Biopsy Specimen Adequacy Verification With a Portable Digital Microscope

Ali Shueib, Pedro J. Martinez Pitre, Muner Mohamed, Juan Carlos Q. Velez. Ochsner Nephrology Ochsner Medical Center, New Orleans, LA.

**Background:** Retrieval of optimal tissue specimens during a percutaneous kidney biopsy (PKB) is critical for establishing diagnoses. Lack of widespread availability of a pathologist during the procedure or of a regular light microscope in the procedural room are barriers that may result in submission of inadequate specimens, often agglomerular, impairing the ability to make a diagnosis. We examined the feasibility and utility of using a portable digital microscope (pDigMICRO) for intraoperative verification of kidney tissue biopsy specimen adequacy.

**Methods:** We reviewed cases at Ochsner Medical Center in which a PKB was performed by a nephrologist and a pocket-size battery-operated pDigMICRO was used for verification of specimen adequacy immediately upon each tissue core retrieval. Images obtained at 50X and 1000X magnification were wirelessly captured in a smartphone and transferred to a secure server for storage. Demographics, clinical data, and pathology reports were collected. Based on total number of retrieved glomeruli examined under light microscopy, immunofluorescence, and electron microscopy, optimal PKB was defined as  $\geq 15$ .

**Results:** A total of 20 patients were included, median age 58 (31-70), 40% women, 40% self-identified black, median BMI 28 (25-38). Median serum creatinine at the time of PKB 1.5 (0.7-5.2) mg/dL. Indications for PKB were proteinuria (90%), AKI (30%) and hematuria (20%). All PKBs were performed with a 16 g needle. An average of 2.6 cores were obtained after an average of 3.8 needle passes. Glomeruli were visualized with pDigMICRO in all cases (100%). A pathological diagnosis was achieved in all cases (100%). Nineteen (95%) cases were optimal for diagnosis, none (0%) were agglomerular. Median number of glomeruli retrieved per biopsy was 26 (6-53). No patient required an intervention or blood transfusion. One patient developed gross hematuria that resolved spontaneously.

**Conclusions:** Use of pDigMICRO allowed for verification of tissue adequacy in a similar manner to that previously reported utilizing standard methods of adequacy verification. This approach may be a viable tool to improve performance of PKB in centers without access to a pathologist or a regular light microscope, such as in those performed by interventional radiologists.

## TH-PO564

## Safety and Adequacy of Kidney Biopsy Procedure in Patients With Obesity

Long Qian,<sup>1</sup> Jason N. Weinstein,<sup>1</sup> Hannah C. Melchinger,<sup>1</sup> David G. Hu,<sup>2</sup> Steven Menez,<sup>2</sup> Heather Thiessen Philbrook,<sup>2</sup> Randy L. Luciano,<sup>1</sup> Mark A. Perazella,<sup>1</sup> Melissa M. Shaw,<sup>1</sup> Chirag R. Parikh,<sup>2</sup> Francis P. Wilson,<sup>1</sup> Dennis G. Moledina.<sup>1</sup> <sup>1</sup>Yale University, New Haven, CT; <sup>2</sup>Johns Hopkins University, Baltimore, MD.

**Background:** Obesity is considered a risk factor for kidney biopsy-related complications. Here we compared the safety and adequacy of kidney biopsy procedures between obese and non-obese patients.

**Methods:** We included patients from the Yale kidney biopsy cohort enrolled between 2015-2017. Using linear regression analysis, we tested the association of class 2 obesity (body mass index  $\geq 35\text{kg/m}^2$ ) with post-biopsy drop in hematocrit (hct) and number of glomeruli sampled, adjusting for pre-biopsy risk factors and needle gauge. We conducted a supplementary analysis using data from the Johns Hopkins University (JHU).

**Results:** Of the 337 patients at Yale, 76 (23%) had obesity. Obese patients were more likely to undergo biopsy using 18- (vs 16-) gauge needle (48 (66%) vs 113 (45%),  $P=0.002$ ). Obese patients had a lesser drop in hct from pre- to post-biopsy in univariable analysis (2.1% vs 3.0%; unadjusted difference -0.95% (95% CI -0.14, -1.75); adjusted for pre-biopsy risk factors -0.92 (-1.73, -0.11)%. Obesity was not associated with hct drop after further adjusting for needle gauge [-0.78 (-1.59, 0.03)%. However, fewer glomeruli were sampled from obese patients [-2.6 (-4.6, -0.7) glomeruli]. At JHU (N=78, 12 obese), where all biopsies were performed using 18G needle, obesity was not associated with hct drop (0.40 (-1.26, 2.05)%). Meta-analysis of the two cohorts found no association of obesity with hct drop [-0.48 (-1.74, 0.78)%].

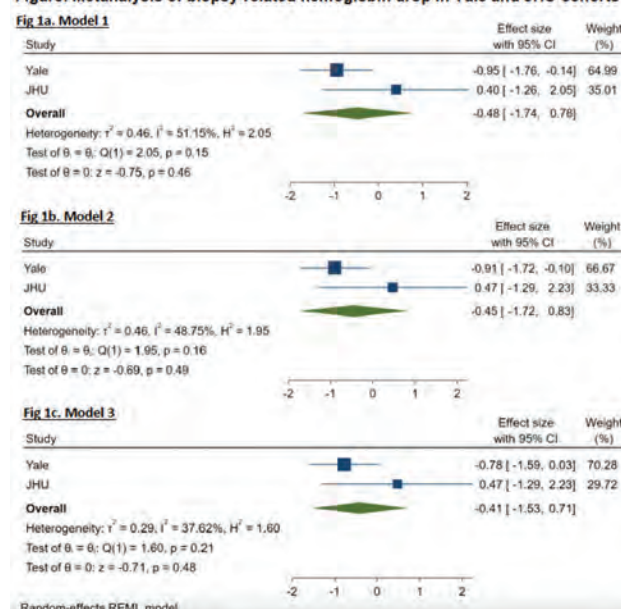

**Conclusions:** Obese patients did not have a greater risk of post-biopsy hematocrit drop than those without obesity but tended to have fewer glomeruli available for diagnosis. Future studies could examine techniques to improve diagnostic yield of kidney biopsy for obese patients.

**Table. Association of obesity with kidney biopsy-related hematocrit drop**

Site	Difference in drop in hematocrit between obese vs. non-obese (95% CI)		
	Model 1	Model 2	Model 3
Yale (n=337)	-0.95 (-1.76, -0.14)	-0.91 (-1.72, -0.10)	-0.78 (-1.59, 0.03)
JHU (n=78)	0.40 (-1.26, 2.05)	0.47 (-1.29, 2.23)	0.47 (-1.29, 2.23)
Combined	-0.48 (-1.74, 0.78)	-0.45 (-1.72, 0.83)	-0.41 (-1.53, 0.71)

Footnote: Linear regression analysis showing association of class 2 obesity with hematocrit drop after kidney biopsy. Beta coefficient and 95% confidence intervals shown. A negative coefficient indicates that there was lesser drop in hematocrit among those with obesity. Model 1 is univariable. Model 2 controls for platelet count, international normalized ratio, and blood urea nitrogen. Model 3 additionally controls for needle gauge (16 vs. 18)

**Figure. Metanalysis of biopsy-related hemoglobin drop in Yale and JHU cohorts**

## TH-PO565

## Stain-Independent Segmentation and Quantification of Kidney Histopathology Using Deep Learning

Peter Boor,<sup>1</sup> David Laurin Hölscher,<sup>1</sup> Barbara M. Klinkhammer,<sup>1</sup> Roman D. Bülow,<sup>1</sup> Johannes Lotz,<sup>2</sup> Nick Weiss,<sup>2</sup> Christoph Daniel,<sup>3</sup> Kerstin U. Amann,<sup>3</sup> Nassim Bouteldja.<sup>1</sup> <sup>1</sup>Universitätsklinikum Aachen, Aachen, Germany; <sup>2</sup>Fraunhofer-Institut für Digitale Medizin MEVIS, Bremen, Germany; <sup>3</sup>Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany.

**Background:** In digital pathology, many image analysis tasks are challenged by the need for exhaustive and time-consuming data annotations to tackle various sources of variability in the image domain. Thus, there is a great need for methods addressing data variation without the manual overhead. E.g., in clinical routine and preclinical research, different tissue stainings are used that show differently colored and textured tissue. Deep learning (DL) models however are typically trained and thus limited to a single stain.

**Methods:** In this work, we deal with this inter-stain variation and propose a methodological concept based on stain augmentation to make DL models stain independent. We comprehensively compare this approach with two state-of-the-art methodologies including stain translation and image registration. Our aim was to make a pretrained and stain-specific DL segmentation model applicable to various other stains without the need for data annotations. We employed our previously published DL model that segments six major kidney structures from PAS-stained histopathology in different species.

**Results:** Validation on various immunohistochemical stainings in mice and humans showed that the proposed stain augmentation significantly outperformed both baseline approaches in all stains. It provided high segmentation accuracies in all structures and stains, even in held-out stains not seen during training. We used the stain-augmented model to facilitate compartment-specific morphometrical analysis of immunostainings in animal models and patient biopsies for the efficient analysis of inflammation and fibrosis.

**Conclusions:** This benchmark study suggests that stain augmentation is a highly effective approach to yield stain independence in DL models without manual overhead. This opens new possibilities for efficient and exhaustive computational immunohistomorphometry.

**Funding:** Government Support - Non-U.S.

TH-PO566

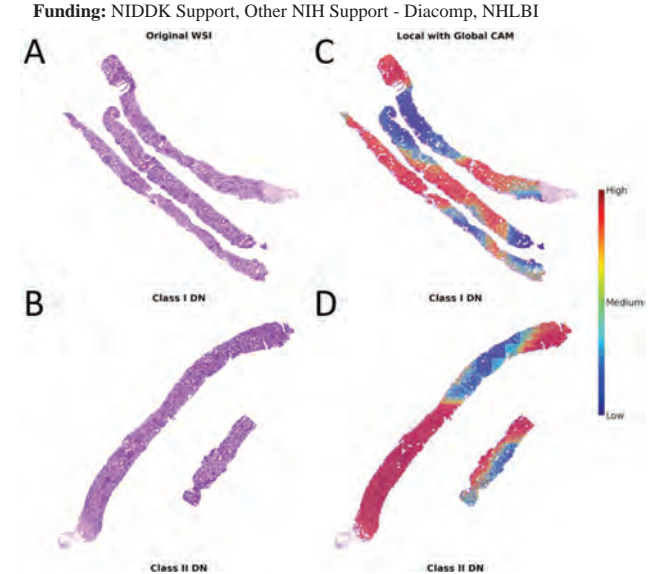

**Computational Assessment of Early Diabetic Nephropathy**  
Lindsey Claus,<sup>1</sup> Yichi Zhang,<sup>1</sup> Yi Zheng,<sup>1</sup> Tejus Surendran,<sup>1</sup> Vipul C. Chitalia,<sup>1</sup> Patrick D. Walker,<sup>2</sup> Clarissa A. Cassol,<sup>2</sup> Vijaya B. Kolachalama.<sup>1</sup> <sup>1</sup>*Boston University, Boston, MA;* <sup>2</sup>*Arkana Laboratories, Little Rock, AR.*

**Background:** Patients with diabetic nephropathy (DN) often have glomerular, tubular, interstitial, and vascular lesions on biopsy, though a recently proposed DN classification focuses on glomerular features. While it is important to quantify the extent of these histopathological manifestations across all stages of DN, we sought to investigate whether these findings can be identified in early DN patients.

**Methods:** A deep learning framework known as a feature pyramid network (FPN) was implemented to classify digitized renal biopsies as class I or II DN. PAS-stained whole slide images (WSIs) of cases with class I (n=23) or class II (n=77) DN were divided into training, validation, and test sets in 3:1:1 ratio. This process was repeated five times to achieve a 5-fold cross validation. The FPN expected two inputs, 224x224-pixel patches cropped from WSIs and 16x downsampled WSIs, to learn and combine features at two levels of magnification. Class activation maps (CAMs) were generated to visualize informative regions on the WSIs.

**Results:** Our FPN model achieved an accuracy of 0.8 and an F1 score of 0.6. On a representative set of test images, we found the majority (~84%) of patches identified by CAMs as highly informative for model prediction contained tubules or interstitium, not just glomerular regions (Fig. 1).

**Conclusions:** Our study identified several regions on the biopsy images as informative for prediction of class I vs II DN. Further analysis can elucidate the importance of various histopathological features of early stage DN.

(A and B) Whole slide images and their class labels (Class I & II DN). (C and D) Class activation maps generated on the images, indicating the regions highly associated with the corresponding label. The warmer the color, the higher the probability of a region contributing to the DN class prediction.

TH-PO567

**Machine-Learning-Quantified Lupus Nephritis Histological Features Correlate With NIH Activity and Chronicity Index Subscores**  
Solange Moll,<sup>1</sup> Cary D. Austin,<sup>3</sup> Balazs Toth,<sup>3</sup> Filip Kos,<sup>2</sup> Stephanie Hennek,<sup>2</sup> Christina Jayson,<sup>2</sup> Brian H. Baker,<sup>2</sup> Benjamin Trotter,<sup>2</sup> Webster U. Lincoln,<sup>3</sup> Jacqueline A. Brosnan-Cashman,<sup>2</sup> Thomas Schindler,<sup>4</sup> Murray Resnick,<sup>2</sup> Anthony Chang,<sup>5</sup> Ilan Wapinski,<sup>2</sup> Michael Montalto,<sup>2</sup> Jay P. Garg,<sup>3</sup> Wei Tew,<sup>3</sup> Marco Prunotto,<sup>4</sup> <sup>1</sup>*Universite de Geneve, Geneve, Switzerland;* <sup>2</sup>*PathAI, Boston, MA;* <sup>3</sup>*Genentech Inc, South San Francisco, CA;* <sup>4</sup>*F Hoffmann-La Roche AG, Basel, Switzerland;* <sup>5</sup>*University of Chicago Pritzker School of Medicine, Chicago, IL.*

**Background:** Histologic evaluation of renal biopsies is necessary for lupus nephritis (LN) diagnosis and treatment decisions; however, interobserver variability and poor quantitation limit the utility of histology-based metrics for precision medicine. To mitigate these challenges, we developed ML-based models to quantify histologic features in LN.

**Methods:** 374 hematoxylin and eosin (H&E)-stained whole-slide images (WSI) of non-LN kidney and LN biopsies were obtained, mainly from a LN cohort at the University of Geneva and a clinical trial of obinutuzumab (OBZ) in proliferative LN (NCT02550652). WSI were split into training (286; 76%) and validation (88; 24%) sets. Expert pathologist annotations trained deep convolutional neural networks, yielding two distinct segmentation models covering anatomic regions and histopathological features. Model performance was tested on a held-out set of 94 WSI. For each model, 20-30 image frames were annotated by 3-5 pathologists to derive ground truth consensus. Whole slide

predictions on 73 baseline cases from the OBZ trial were correlated to manual revised NIH LN activity and chronicity index (CI) subscores and kidney function metrics using Spearman method.

**Results:** The model performed comparably to pathologists on both WSI and frames identifying tissue regions (e.g. cortex,  $F1_{model}=0.78$ ;  $F1_{pathologist}=0.75$ ) and tissue features (e.g. interstitial inflammation,  $F1_{model}=0.68$ ;  $F1_{pathologist}=0.60$ ). ML-quantified interstitial inflammation and sclerotic glomeruli regions correlated with the NIH activity index interstitial inflammation ( $r=0.638$ ;  $p<0.0001$ ) and CI glomerulosclerosis subscores ( $r=0.702$ ;  $p<0.0001$ ), respectively, as well as with eGFR, creatinine, and UPCR ( $r=0.32 - 0.47$ ;  $p<0.01$ ).

**Conclusions:** We developed ML models that quantify histologic features on LN H&E biopsies, revealing significant correlations with NIH disease index subscores and kidney function metrics. The findings demonstrate the feasibility of ML for quantifying LN histologic features. The utility of this approach in predicting treatment response is being evaluated.

TH-PO568

**Accurate and Regional Assessment of Tubular Diameter Predicts Progressive CKD After Radical Nephrectomy**  
Aleksandar Denic,<sup>1</sup> Amr Moustafa,<sup>1</sup> Mrunanjali Gaddam,<sup>1</sup> Aidan F. Mullan,<sup>1</sup> Anthony C. Luehrs,<sup>1</sup> Laura Barisoni,<sup>2</sup> Andrew D. Rule.<sup>1</sup> <sup>1</sup>*Mayo Foundation for Medical Education and Research, Rochester, MN;* <sup>2</sup>*Duke University, Durham, NC.*

**Background:** Manual morphometry of near to normal adult kidneys demonstrated that larger glomerular volume but not cross-sectional tubular area predicts progressive CKD. We hypothesized that a more accurate and regional assessment of enlarged tubular size may be prognostic for progressive CKD.

**Methods:** Periodic Acid Schiff-stained sections from benign parenchyma from 1453 radical nephrectomies were scanned into whole slide images. The mean true diameter of circular or oval shaped (minor axis) tubules was determined separately for proximal and distal tubular profiles in the superficial, middle, and deep cortical regions. Cox models assessed the risk of CKD progression (defined as dialysis, kidney transplantation, or a 40% decline from postnephrectomy baseline eGFR) with proximal and distal tubular diameters at different depths. Cox models were unadjusted, and adjusted for age, sex, body mass index, hypertension, diabetes, eGFR, and proteinuria.

**Results:** Among 1453 patients (mean age, 64 years; postnephrectomy baseline eGFR, 50.9 ml/min per 1.73 m<sup>2</sup>), 114 progressive CKD events, and 272 non-cancer deaths occurred during a median 3.4 years. As shown in the Table, larger proximal tubular diameter predicted CKD progression only in the superficial cortex; while larger distal tubular diameter predicted CKD progression in all cortical regions, though, more strongly in the superficial cortex. None of the tubular measures predicted non-cancer mortality.

**Conclusions:** Measurement of average proximal and distal tubular diameters separately at different depths was predictive of progressive CKD. Tubular hypertrophy of more distal nephron segments in the superficial cortex appears to be more prognostic of progressive CKD than deeper tubules and more proximal segments.

**Funding:** NIDDK Support

Tubular measures as predictors of CKD progression from 4 months following a radical nephrectomy.

N=1453, 114 CKD events	Unadjusted		Adjusted for clinical characteristics*	
	HR (95% CI)	P value	HR (95% CI)	P value
<b>Superficial</b>				
Mean proximal tubular diameter	1.33 (1.12, 1.59)	0.001	1.28 (1.05, 1.56)	0.01
Mean distal tubular diameter	1.59 (1.34, 1.88)	<0.0001	1.52 (1.26, 1.84)	<0.0001
<b>Middle</b>

## Computationally Derived “Functional” Tubule Density Is Prognostic of Outcome in Glomerular Diseases

Fan Fan,<sup>1</sup> Bangchen Wang,<sup>2</sup> Takaya Ozeki,<sup>3</sup> Jeremy Rubin,<sup>4</sup> Yijiang Chen,<sup>1</sup> Jeffrey B. Hodgin,<sup>3</sup> Laura H. Mariani,<sup>3</sup> Lawrence B. Holzman,<sup>5</sup> Kyle Lafata,<sup>6</sup> Anant Madabhushi,<sup>1,7</sup> Laura Barisoni,<sup>2</sup> Jarcy Zee,<sup>4</sup> Andrew Janowczyk.<sup>1,8</sup>  
<sup>1</sup>Case Western Reserve University Department of Biomedical Engineering, Cleveland, OH; <sup>2</sup>Duke University Department of Pathology, Durham, NC; <sup>3</sup>University of Michigan Department of Internal Medicine, Ann Arbor, MI; <sup>4</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>5</sup>University of Pennsylvania Department of Medicine, Philadelphia, PA; <sup>6</sup>Duke University Department of Radiation Oncology, Durham, NC; <sup>7</sup>VA Northeast Ohio Healthcare System, Cleveland, OH; <sup>8</sup>Precision Oncology Center, Lausanne University Hospital, Lausanne, Switzerland.

**Background:** While tubular atrophy (TA) is associated with a decrease of functional tubules (FT) and disease progression in kidney diseases, reproducible visual quantification of TA remains challenging. In our study, the value of computationally derived FT density (FT pixel area per cortical pixel area) was explored.

**Methods:** N=239 PAS-stained whole slide images from the NEPTUNE digital pathology repository were studied (135 FSGS, 51 MCD, and 53 MCD-like). The kidney cortex was manually annotated by pathologists and a validated deep learning (DL) model was used to segment cortical FTs (Fig.1). Cortical FT density was subsequently computed for each biopsy. Spearman's correlation coefficient was used to measure the correlation between the FT density and visually scored TA. Kaplan-Meier curves were estimated, and a log-rank test was used to assess the association between FT density measured in quartiles and the composite disease progression outcome of time from biopsy to 40% eGFR decline or kidney failure.

**Results:** The FT density decreased from MCD to MCD-like and to FSGS biopsies (Fig.2). There was a strong negative association between FT density and TA ( $\rho=-0.75$ ,  $p<0.001$ ). There was a significant difference in disease progression for subjects within different quartiles of FT; those with FT density  $<0.39$  having worse outcomes. Each 0.1 increase in FT density ( $<0.49$ ) was associated with 46% decreased hazards of disease progression, but when FT density was  $>0.49$ , the association was not significant.

**Conclusions:** DL-derived FT density is a robust and feasible approach to measuring the status of the tubulointerstitium and a biomarker of clinical outcome, with potential predictive value in assessing the risk of progression.

## A Computational Pipeline for Segmentation and Classification of Tubules

Pinaki Sarder,<sup>1</sup> Brandon Ginley,<sup>1</sup> Nicholas Lucarelli,<sup>1</sup> Yijiang Chen,<sup>6</sup> Jeffrey B. Hodgin,<sup>2</sup> Avi Z. Rosenberg,<sup>3</sup> Charles E. Alpers,<sup>5</sup> Anant Madabhushi,<sup>6</sup> Laura Barisoni,<sup>4</sup> Ulysses G. Balis.<sup>2</sup> KPMP <sup>1</sup>University of Buffalo, Buffalo, NY; <sup>2</sup>University of Michigan, Ann Arbor, MI; <sup>3</sup>Johns Hopkins University, Baltimore, MD; <sup>4</sup>Duke Medicine, Durham, NC; <sup>5</sup>University of Washington, Seattle, WA; <sup>6</sup>Case Western Reserve University, Cleveland, OH.

**Background:** The highly repetitive kidney structure is well-suited for high-throughput segmentation using unsupervised methods. Herein, we combined image-based, machine learning (ML) tools to realize a computational pipeline for image curation, segmentation, and classification.

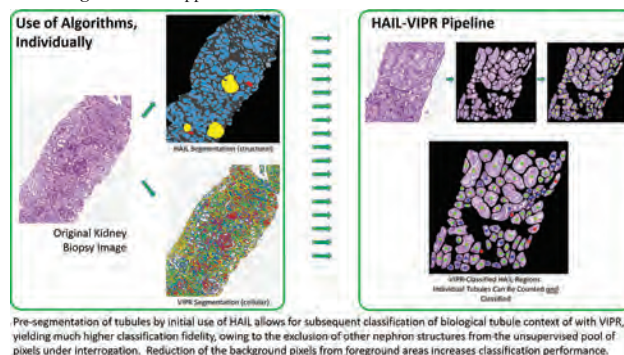

**Methods:** 25 chronic kidney disease and 10 healthy reference tissue were first curated using HistoQC, an open source tool for qualification of whole slide images (WSIs), for histology and imaging artifacts in WSIs that would interfere with ML techniques. WSIs

were then processed by the Human-AI-Loop pipeline, a deep-learning-based supervised image segmentation tool, to generate binary masks of all tubules. Segmented tubules were then extracted and processed at the pixel level by the spatially invariant vector quantization (SIVQ) algorithm, which is prepackaged as the validated identification of pre-qualified regions algorithm (VIPR). SIVQ mines a composite vector of biological content inherent in single pixel domains by extracting local kernel goodness-of-fit to a library of pre-selected Fourier signatures of histological primitives. Renal pathologists manually labeled each segmented tubules as normal and abnormal proximal, normal and abnormal distal, and abnormal indeterminate.

**Results:** 3 machine learning-based tubular classes (1-3) were identified by VIPR. There was  $>95\%$  correlation between manual scoring of proximal tubules (normal and abnormal) and class 1, manual scoring of distal tubules (normal and abnormal) vs. class 2, and for normal vs. abnormal tubular morphology.

**Conclusions:** Our tools will enable development of large scale feature extraction and statistical quantification of different sub-classes of tubules from giga-pixel size kidney WSIs. This pipeline unleashes the power of artificial intelligence in precision nephrology with the promise of deriving novel digital image biomarkers that can potentially inform disease progression or alignment with molecular markers for therapeutic discoveries.

## TH-PO571

## A Novel Pipeline for the Tissue Transformation, 3D Imaging, and

## Visualisation in Virtual Space of Optically Cleared Human Renal Tissue

Keith Siew, Zhongwang Li, Stephen B. Walsh. University College London, London, United Kingdom.

**Background:** Kidney biopsies have been the gold standard for diagnosis of pathological kidney diseases for almost 70 years. However, due to the small volume of tissue obtained from a needle biopsy traditional histopathological examinations are limited by the number of sections that can be obtained, with no two sections capturing the exact same histological features, sometimes necessitating multiple biopsies to be taken to ensure there is enough material to work with & that an accurate representation of the kidney histology is obtained. Developing a non-destructive 3D histopathology would allow for 60+ stains to be colocalised within their intact anatomical context, therefore reducing the risk of missing pathologies & need to re-biopsy patients.

**Methods:** Human renal biopsies & transplant rejected tissue routinely donated for research at the Royal Free Hospital were used for this study. These samples were fixed in formaldehyde, before undergoing tissue transformation following the SHIELD protocol (Park et al., 2018, doi:10.1038/nbt.4281). These were then delipidated & stained using the LifeCavas Technologies platforms, & optically cleared by refractive index matching prior to rapid 3D fluorescent lightsheet microscopy. These data were then preprocessed using imageJ & Imaris, before being imported into Syglass for 3D virtual reality visualisation using Oculus Quest 2 headsets.

**Results:** In less than 24h were able to take fresh tissue, rapidly transform, multiplex stain and image immune cell infiltration (CD3), antibodies (IgA, IgM, IgG), complement (C1q), endothelium (CD31), Interstitium (Collagen IV), Nuclei (Histone H3), cytosol (Eosin) or tubule segment markers (Tomato Lectin - DCT/TAL marker (green); see figure 1). We were able to visualise these data with a histopathologist in virtual 3D space, where it was possible to toggle between the different markers, reorientate and resection the sample with ease.

**Conclusions:** See virtual reality headset demo at presentation.

## TH-PO572

**Integration of Spatial Transcriptomics and Morphology in Assessing Atubular vs. Connected Glomeruli**

Haichun Yang,<sup>1</sup> Ruining Deng,<sup>2</sup> Jianyong Zhong,<sup>1</sup> Yuankai Huo,<sup>2</sup> Agnes B. Fogo,<sup>1</sup> <sup>1</sup>*Vanderbilt University Medical Center, Nashville, TN;* <sup>2</sup>*Vanderbilt University, Nashville, TN.*

**Background:** We previously found that atubular glomeruli increased in mice with proximal tubule-specific injury compared to normal mice. We have developed AI algorithms to identify such atubular glomeruli from serial whole slide images (WSI) and also found subvisual morphologic features in 2D slides that could be detected by 3D AI. Using spatial transcriptomics, we aimed to assess the topography of gene expression and any correlation with morphologic alterations quantified by AI.

**Methods:** Wild-type (WT) and transgenic mice with tubular cell expression of the diphtheria toxin (DT) receptor were studied. All mice were injected with DT at week 0 and week 1 and sacrificed 6 weeks later. 19 serial sections from paraffin block tissue were cut, and all except the middle section were scanned for atubular glomeruli assessment by AI. The middle section was then used for spatial transcriptome. The morphologic features in the resulting 3D reconstructed atubular vs connected glomeruli were quantified by AI.

**Results:** Atubular glomerular were increased in DT vs WT mice (19.2% vs. 5.8%). The glomerular volume was increased, and the ratio of columnar to flat parietal epithelial cells (PECs) ratio was significantly decreased in atubular compared to connected glomeruli. Using spatial transcriptomic analysis, 412 differentially expressed genes were detected in atubular glomeruli in WT vs DT mice, while 6795 genes were differentially expressed comparing the connected glomeruli in WT vs DT mice. By comparing transcriptomics in atubular vs connected glomeruli in the same mouse, 170 differentially expressed genes were detected. Among them, genes related to extracellular matrix organization (such as *DAG1*, *TIMP2*), or related to cell migration (such as *FLNA*, *MYLK*) were upregulated.

**Conclusions:** Spatial transcriptomic sequencing complemented AI-assisted morphology assessment, uncovering potential mechanisms driving extracellular matrix organization, regulation of cell migration and PEC alterations in the pathogenesis of atubular glomeruli.

## TH-PO573

**Automated Tools for Renal Biopsy Diagnosis**

Zhongwang Li, Stephen B. Walsh, Keith Siew. *University College London, London, United Kingdom.*

**Background:** Histological examination of the glomeruli in renal biopsies is essential for diagnosing many kidney diseases. However, manual identification and characterisation of glomeruli in biopsies requires trained histopathologists and can be tedious time-consuming task. Thus, development of automatic tools to help accelerate diagnostic workflow and improve detection accuracy is an unmet need. Such tools should have the ability to detect and count glomeruli of various sizes, shapes, and disease status across whole slide image (WSI) biopsies, annotate these in the image. Advanced functionality could then be developed to classify glomeruli based on disease features (e.g. fibrosis, mesangial expansion) and generate preliminary biopsy reports for review by the histopathologist.

**Methods:** Routine renal biopsies collected at Royal Free Hospital with patients' consent for research were used for this study (n=300). 2-5um biopsy sections were acquired as 8-bit RGB WSI using an Axio Scan Z.1 (20x/0.8NA). To ensure the general applicability of the model, multiple common histochemical stains (H&E, PAS, Silver stain) were imaged and included in the training dataset. These digitised slides were then manually annotated by histopathologists and nephrologists using QuPath (version 0.3.2) on Wacom Cintiq Pro 32 interfaces to capture the features described in the matching to biopsy reports. "You only look once" (YOLO) is a real-time object detection system that has previously been used to identify glomeruli in PASM stained section. For our work, we decided to adapt this approach using the latest version of YOLO that can function under multiple conditions (e.g. different stains and magnifications), and a Convolutional Neural Network (CNN) model may then be used to classify various glomerular diseases.

**Results:** Using the location information given by YOLO, the glomerular images could be cropped from the original image and tabularised alongside morphometric and histopathological readouts from our U-NET model that could segment the identified glomeruli from the background tissue and quantify features (e.g. % area of fibrosis).

**Conclusions:** This work shows that an automated image analysis pipeline can identify, quantify and characterize glomeruli in 2D slides in seconds, with obvious utility for pathologists and clinicians. Further work to expand the functionality of this model and to validate it further in larger datasets is warranted.

## TH-PO574

**Modulation of Linear Ranges in Immunohistochemistry and Immunofluorescence Assays**

Michael J. Ferkowicz,<sup>1</sup> Seshi R. Sompuram,<sup>2</sup> Daria Barwinska,<sup>1</sup> Tarek M. El-Achkar,<sup>1</sup> Steve Bogen.<sup>2</sup> KPMP <sup>1</sup>*Indiana University School of Medicine, Indianapolis, IN;* <sup>2</sup>*Boston Cell Standards, Boston, MA.*

**Background:** Assays for the detection of specific proteins in tissue sections are usually performed by immunohistochemistry (IHC) or immunofluorescence (IF). These are qualitative assays, indicating whether the protein is detectable or undetectable. Attempts have been reported to express relative quantification of protein analytes (in IHC or IF) by describing the staining as weak, moderate, strong, or as percent of positive cells.

However, the actual linear range of these assessments has not been determined. The ability to determine the quality of an antibody or lot over time is crucial. Connecting the presence of staining to cellular protein concentrations has never been possible. We hypothesize that using IHC/IF calibrators, newly developed by our group, it will be feasible to characterize linear ranges of IHC and IF assays. By adjusting the reagents or staining protocol, it is possible to adjust the linear ranges for greater or lesser analytic sensitivity.

**Methods:** Four calibrator targets (analytes), developed for the Kidney Precision Medicine Project (KPMP) - Aquaporin-1 (AQP1), Uromodulin (UMOD), Myeloperoxidase (MPO) and CD3 were covalently attached to glass microbeads across a range of concentrations simulating different cellular expression levels. The cell-sized microbeads were then adhered to microscope slides, stained, and imaged by confocal microscopy. Mean fluorescence intensity of microbeads across ten concentrations was measured.

**Results:** Assessment of mean fluorescent intensity revealed that all four assays have a linear range of detection when measured by either IF or IHC. Furthermore, we observed that IF can demonstrate a broader linear range due to the inherent ability to tune the confocal microscope.

**Conclusions:** IHC/IF calibrators are a useful tool for assessing antibody quality, lot to lot consistency, and degradation over time. These data also establish a foundation for using IHC and IF assays for quantifying cellular expression levels of proteins in tissue sections.

**Funding:** NIDDK Support

## TH-PO575

**Development of a Computational Modeling Tool for Automated Detection of Urinary Casts and Acanthocytes**

Josean O. Flores Santiago, Juan Carlos Q. Velez. *Ochsner Nephrology Ochsner Health Network LLC, New Orleans, LA.*

**Background:** Microscopic examination of the urinary sediment (MicrExUrSed) is a tool of proven clinical utility. However, it requires training and expertise for proper identification of urinary casts. Incorrect cast identification may lead to flawed clinical-decision making. We hypothesized that a machine learning approach could be used to create a tool for automated real-time identification of urinary casts.

**Methods:** We accessed a database of MicrExUrSed images routinely obtained and stored as part of a prospective research cohort. Images were captured with a smartphone camera adapted to the microscope eyepiece. Images were categorized and labeled by trained observers and divided into datasets for classification and object detection tasks. Input contained annotations about illumination, staining, and magnification. Bounding boxes for 3 major structures: casts, cells, and crystals were fed into the model. We performed preliminary experimentation on a subset of images (308 images containing 572 casts and 107 acanthocytes) to train a YOLOv5 object detection model to identify acanthocytes and 4 types of clinically relevant urinary casts: muddy brown-granular, granular, waxy casts, and cellular casts. Images were preprocessed using YOLOv5 data augmentation technique. The model was trained with empty weights and on pre-trained models, with image sizes of 640 and 1280, batches of 6 and 16, and 300 epochs.

**Results:** After model development and training, performance was tested in 75 additional images containing acanthocytes and casts. The best performance was obtained with YOLOv5m with 640 image size, a batch of 6, and 300 epochs. It achieved a mean average precision (mAP) of 0.7618, which is above the performance of benchmark databases. The model performed equally accurately for acanthocytes and casts.

**Conclusions:** To our knowledge, this is the first implementation of computational model/machine learning for real-time automated identification of findings from MicrExUrSed. In this dataset, the different illumination techniques, degree of magnification, high-resolution images, and staining techniques served as different backgrounds that increased the model performance even with a small number of training data. More work is needed to expand the capability of the tool to other unique structures.

## TH-PO576

**Cumulative Smoking Dose Is a Risk Factor for Renal Arteriolar Hyalinization and Glomerular Sclerosis in Individuals Without CKD: A Cross-Sectional Study**

Eri Ataka,<sup>1</sup> Yuta Matsukuma,<sup>1</sup> Kenji Ueki,<sup>1</sup> Akihiro Tsuchimoto,<sup>1</sup> Yasuhiro Okabe,<sup>1</sup> Kosuke Masutani,<sup>2</sup> Toshiaki Nakano,<sup>1</sup> Takanari Kitazono.<sup>1</sup> <sup>1</sup>*Kyushu Daigaku, Fukuoka, Japan;* <sup>2</sup>*Fukuoka Daigaku, Fukuoka, Japan.*

**Background:** Cigarette smoking is an established risk factor for the development of chronic kidney disease (CKD). However, the renal pathological lesions related to smoking have not been clearly elucidated in healthy participants. In this study, we investigated the relationship between cumulative smoking dose and renal microstructural features in participants without CKD.

**Methods:** We evaluated the time-zero biopsy specimen of 547 living kidney donors. Renal arteriolar hyalinization, intimal thickening of small-medium arteries, glomerular sclerosis and interstitial fibrosis and tubular atrophy (IF/TA) were investigated.

**Results:** In total, 199 patients (36.4%) had smoking history, 92 (16.8%) of them were with <20 pack-years and 107 (19.6%) were with ≥20 pack-years. Increase in cumulative smoking dose was significantly associated with the prevalence of arteriolar hyalinization in multivariable logistic analysis. Odds ratio (OR) (95% confidence interval [CI]) for arteriolar hyalinization per 20 pack-years increase was 1.52 (1.18-1.95) and those of the group with <20 pack-years and with ≥20 pack-years vs. non-smokers were 1.73 (1.01-2.94) and 2.38 (1.43-3.97), respectively. Increase in smoking dose was also related to the prevalence of >10% global glomerular sclerosis. OR (95% CI) for >10% global glomerular sclerosis per 20 pack-years increase was 1.25 (0.98-1.58) and those

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

of the group with <20 pack-years and with ≥20 pack-years vs non-smokers were 1.39 (0.77-2.52) and 1.93 (1.11-3.35), respectively. Intimal thickening of small- to medium-sized arteries and IF/TA were not associated with smoking dose.

**Conclusions:** Cumulative smoking dose was an independent risk factor for renal arteriolar hyalinization and abnormal glomerulosclerosis in individuals without chronic kidney disease.

## TH-PO577

### Urine Biomarkers of Systemic Lupus Erythematosus Identified Using Liquid and Gas Chromatography/Mass Spectrometry (LC-QTOF-MS and GC-QTOF-MS)

Gustavo Aroca Martínez,<sup>1</sup> Lisandro Pacheco,<sup>1</sup> Alejandra R. Sánchez,<sup>1</sup> Ada L. Carmona Martes,<sup>2</sup> Elkin Navarro.<sup>1</sup> <sup>1</sup>Universidad Simon Bolivar, Barranquilla, Colombia; <sup>2</sup>Universidad del Atlantico, Barranquilla, Colombia.

**Background:** Systemic lupus erythematosus (SLE or lupus) is a chronic autoimmune disease, and kidney involvement with SLE, lupus nephritis (LN), is a frequent and severe complication of SLE that increases patient morbidity and mortality. The current gold standard for classifying LN progression is a renal biopsy, an invasive procedure with potential risks. Undergoing a series of biopsies for monitoring disease progression and treatments is unlikely suitable for patients with LN. Thus, there is an urgent need for non-invasive alternative biomarkers that can facilitate LN class diagnosis. Such biomarkers will be very useful in guiding intervention strategies to mitigate or treat patients with LN. The current study aims to explore new biomarker candidates for non-invasive diagnosis of LN and explore the pathogenic mechanisms that contribute to renal injury.

**Methods:** A metabolomics approach using LC-QTOF-MS in both positive and negative electrospray ionization (ESI) modes and GC-QTOF-MS was developed for comparison of urine metabolic profile of 23 LN patients, 16 SLE patients, and 10 healthy controls (HCs). Differential metabolites were evaluated with univariate (UVA) and multivariate (MVA) analysis using a nonparametric *t* test, principal component analysis (PCA) and orthogonal partial least squares regression (OPLS-DA).

**Results:** Both UVA and MVA showed a clear discrimination in the urinary metabolome between LN, SLE and HCs. The significant altered metabolites between LN and SLE correspond mainly to fatty acyls, amino acids, bile acids in particular methylglutamic acid, monopalmitin methyl-L-proline, 3-oxo-4-pentenoic acid, glutaric acid, 3-hydroxyglutaric acid, citraconic acid, glutamine, glycocholic acid and ureidoisobutyric acid. Analysis of metabolic pathways shows disturbances in biosynthesis of alanine, aspartate and glutamate metabolism, citrate cycle (TCA cycle) and glutamine and glutamate metabolism.

**Conclusions:** The urinary metabolome of SLE and LN patients made it possible to determine metabolic alterations and discriminate LN patients from SLE patients. If confirmed in larger studies, these urine metabolites may serve as biomarkers to help discriminate between SLE with and without renal involvement.

## TH-PO578

### A Clinical Tool for Prediction of Bleeding Complications After Percutaneous Renal Biopsy

Nicolas Bergeron, Stephanie Lord, Sébastien Dion, David Philibert, Simon Desmeules, Mohsen Agharazii. *CHU de Quebec-Universite Laval, Quebec, QC, Canada.*

**Background:** Kidney biopsy is a diagnostic procedure which may result in bleeding-related complications. Developing a tool for risk stratification could help predict such risk and would benefit shared decision-making. The aim of the present study was to derive and verify such a tool from training and validation cohorts.

**Methods:** This is a single-center study of 1450 ultrasound-guided native kidney biopsies performed for diagnosis of kidney disease between 2007 and 2020 at a tertiary academic hospital in Quebec, Canada. Major bleeds were defined by hematoma/hematuria with 1 g/dL drop in hemoglobin (Hb) and requiring transfusion, bleeding requiring hospitalization or transfer to ICU, hemorrhagic shock, angioembolization, nephrectomy, or death. Two thirds of the cohort was randomly selected and used as the training set (n=987) for the identification of the determinants of major bleeds, using univariate and multivariate logistic regression analysis, and the rest was used as validation cohort.

**Results:** In the training cohort (59% male) the mean age, weight, Hb and platelet counts were 55±17 years, 79±20 kg, 11.4± 2.5 g/dL, and 243± 100 × 10<sup>9</sup>/L, respectively, while the median eGFR was of 33 mL/min/1.73m<sup>2</sup> (IQR: 12-62). In this group, major bleeding occurred in 57 patients (5.8%). Major bleeding was higher with younger age, lower pre-biopsy Hb, the use of anticoagulant within the week prior to the biopsy (defined as the use of direct-acting oral anticoagulants, warfarin, i.v. heparin, therapeutic doses of low molecular weight heparin), and higher INR at the time of kidney biopsy. The probability of risk was defined by the following equation: Probability of bleeding =  $e^{(-2.426054 - 0.017820 \times \text{Age} + 0.910106 \times \text{Anti\_Coag} - 0.026364 \times \text{Hb} + 3.142164 \times \text{INR})}$  /  $(1 + e^{(-2.426054 - 0.017820 \times \text{Age} + 0.910106 \times \text{Anti\_Coag} - 0.026364 \times \text{Hb} + 3.142164 \times \text{INR})})$  The AUC of the equation was 0.741 (Min-Max: 0.740 - 0.742) in the training cohort. In our validation cohort, with similar characteristics, major bleedings occurred in 18 patients (3.9%). The AUC of the equation predicted well the risk in the validation cohort (AUC of 0.733 (Min-Max: 0.711 - 0.747)).

**Conclusions:** This study proposes an equation for the estimation of the probability of major bleeding after percutaneous renal biopsy.

## TH-PO579

### Urine Sediment Examination: Comparison Between Laboratory-Performed vs. Nephrologist-Performed Microscopy

Remy Fadel, Jonathan J. Talierto, Susana Arrigain, Jesse D. Schold, James F. Simon, Ali Mehdi, Georges Nakhoul. *Cleveland Clinic, Cleveland, OH.*

**Background:** Urine microscopy is a standard component of the urinalysis and one of the oldest tests in medicine. In more recent years, it is increasingly performed by automated analyzers rather than clinicians. However, we believe that urine sediment evaluation by a nephrologist continues to serve a critical role in the assessment of patients with kidney disease.

**Methods:** Using our Electronic Medical Records, we identified 387 adult patients with acute kidney injury that had urine microscopy with sediment analysis performed both by the laboratory and by a nephrologist within 72 hours of each other. We collected data to determine the following: number of RBCs (≤ 5 or > 5 HPF), number of WBCs (≤ 5 or > 5 HPF), presence of casts (<1 or ≥ 1 LPF), type of casts (hyaline, fine granular, coarse granular, muddy brown, WBC and RBC casts), and presence of dysmorphic RBCs. We used Kappa statistics to evaluate agreement between automated urine microscopy versus nephrology review.

**Results:** The reported agreement was moderate for RBCs with 75% of samples in agreement (Kappa 0.46 – 95% CI: 0.37, 0.55), none to slight for WBCs with 72% of samples in agreement (Kappa 0.36 – 95% CI: 0.27, 0.45), and there was no agreement for casts (Kappa 0). Nephrologists detected 12 dysmorphic RBC's (Kappa 0) while the laboratory did not detect any. Additionally, the laboratory only detected hyaline and fine granular casts, whereas nephrologists reported coarse granular / muddy brown, RBC and WBC casts.

**Conclusions:** Urine microscopy can provide important diagnostic information about underlying kidney disease. In our study, we report a disagreement between automated vs. nephrologist performed analysis. A nephrologist is more likely to recognize the presence of coarse granular, muddy brown, WBC and RBC casts, and dysmorphic red blood cells in urine. Nephrologist-performed UA is superior to laboratory-performed UA as correct identification of these casts carries important diagnostic and prognostic value when evaluating kidney disease.

#### Type of casts agreement

Frequency	Cast Group Sediment					Total
	1 No	2 Hyaline or FG	3 CG or MBC	4 WBC	5 RBC	
1 No	67	61	74	5	5	212
2 Hyaline or FG	47	49	62	3	9	170

## TH-PO580

### Isolated Penile Calciphylaxis in ESRD

Kelly Ingram,<sup>1</sup> Raj Jessica Thomas,<sup>3</sup> Nathan Johnson,<sup>4</sup> Douglas J. Grider.<sup>1,2</sup> <sup>1</sup>Virginia Tech Carilion School of Medicine, Roanoke, VA; <sup>2</sup>Dominion Pathology Associates, Roanoke, VA; <sup>3</sup>Cleveland Clinic, Cleveland, OH; <sup>4</sup>Advanced Dermatology and Skin Cancer Center, PLLC, Fayetteville, AR.

**Introduction:** Calciphylaxis is a vascular occlusive disease associated with ESRD. The pathophysiology is not well understood, but it is considered a manifestation of severely dysregulated calcium-phosphorus metabolism. Blood vessel lumens undergo progressive medial calcification and intimal fibrosis resulting in thrombosis, ischemia, and tissue death. It commonly involves the lower extremities, but penile involvement is rare.

**Case Description:** A 75-year-old male presented to the ED with a 3-week history of progressive pain with focal erythematous macules/patches on the glans penis. Past medical history included ESRD with peritoneal dialysis and anuria. The rash consisted of necrotic crust at the urethral meatus (Fig. 1A) and white circinate and hemorrhagic purpuric patches on the proximal glans (Fig. 1B). Wound culture was positive, but histopathology also revealed fibrointimal hyperplasia (bracket), calcified thrombus (solid arrow), and calcification of a vessel (dotted arrow) (Fig. 2A). von Kossa staining indicated calcium deposition, confirming the diagnosis of calciphylaxis (Fig. 2B). The patient declined additional treatment and died 1 month later.

**Discussion:** Calciphylaxis develops rapidly and has a poor prognosis with a mortality rate of 40-80%; therefore, early diagnosis and intervention are critical. Calciphylaxis is an important differential in ESRD patients and special stains, such as the von Kossa, are essential to avoid overlooking subtle calcifications. Calciphylaxis requires a multidisciplinary approach involving nephrology, urology, surgery, and palliative care. Treatment includes sodium thiosulfate, hemodialysis, wound care, pain management, and tissue debridement or amputation.

## Lab Results

Test	Results (Reference Range)
Calcium	7.9 mg/dL (8.5-10.7 mg/dL)
Phosphorous	8.0 mg/dL (2.5-4.6 mg/dL)
BUN	51 mg/dL (6-30 mg/dL)
GFR	5 mL/min/1.73m <sup>2</sup> (>60 mL/min/1.73m <sup>2</sup> )
Creatinine	8.6 mg/dL (0.5-1.4 mg/dL)
PTH	852.4 pg/mL (18.4-88.0 pg/mL)
Wound Culture	4+ Gram Negative Rods and Gram Positive Cocci

Fig. 1

Fig. 2

## TH-PO581

## Effects of Obesity on Pheresis Outcomes

Aniesh Bobba,<sup>1</sup> Karthik Gangu,<sup>2</sup> Ellil O. Krishnaraju,<sup>1</sup> Christina Mariyam joy,<sup>2</sup>  
<sup>1</sup>John H Stroger Jr Hospital of Cook County, Chicago, IL; <sup>2</sup>Medical College of Wisconsin, Milwaukee, WI; <sup>3</sup>University of Missouri, Columbia, MO.

**Background:** The prevalence of obesity is on the uptrend in the United States. The degree of obesity can affect the estimation of plasma volume calculations while performing pheresis. In this study, we investigate the effect of Body Mass Index (BMI) on post-pheresis hospital outcomes.

**Methods:** We performed a retrospective study by utilizing the 2016 to 2018 National inpatient sample, and we included patients aged 18 or older who underwent pheresis for any cause during hospitalization. Patients were subdivided based on BMI. Categorical variables were compared using the Chi-square test. A multivariate logistic regression model was used for all-cause mortality and intubation rates.

**Results:** Of the 77,170 patients who had pheresis 50,222 patients were obese (BMI>30), a total of 23,922 were in the extreme obesity (BMI>40) category. The mean age in extreme obesity group was 49 years and women formed 66.15% of the group. Extreme Obesity was associated with increased odds of intubation and in-hospital mortality. The in-hospital mortality rate adjusted Odds ratio(aOR) was 1.32(1.02-1.72, p = 0.03) and need for mechanical ventilation 1.68 (1.42-2.01, p <0.001). Patients with BMI< 25 had increased odds of mechanical ventilation(aOR = 1.54, p<0.001) and trend towards increased mortality(aOR = 1.28, p=0.059).

**Conclusions:** Pheresis in extreme obesity is associated with an increased risk of mechanical ventilation and in-hospital mortality. Further investigations into interventions and protocols to improve outcomes should be undertaken.

## TH-PO582

**Transdermal Estrogen Provides Comparable Effectiveness With Desmopressin in Preventing Uremic Bleeding in CKD Patients Undergoing Kidney Biopsy: A Pilot Randomized, Double-Blinded Controlled Trial**  
 Ascharya Wipattanakitcharoen, Paweena Susantitaphong, Pisut Katavetin, Kearkiat Praditpornsilpa, Somchai Eiam-Ong, Kullaya Takkavatakarn. *King Chulalongkorn Memorial Hospital, Bangkok, Thailand.*

**Background:** In CKD patients, impairment of renal function and accumulation of uremic toxins increase the risk of post-biopsy bleeding due to platelet dysfunction. A previous study revealed that estrogen could shorten the prolonged bleeding time. We conducted this study to compare the effectiveness of transdermal estrogen and desmopressin, the most common agent used in uremic patients, in preventing post-biopsy bleeding complications.

**Methods:** This non-inferiority, randomized, double-blinded, placebo-controlled trial enrolled patients with eGFR of less than 60 mL/min/1.73m<sup>2</sup> undergoing kidney biopsy. Participants were randomly assigned to receive either transdermal estrogen patches (50 mcg/day) for 7 days or intravenous desmopressin (0.4 mcg/kg). The primary outcome

was the incidence of post-biopsy bleeding complications (hematoma or gross hematuria). The secondary outcomes were hematoma size, changes in hemoglobin levels, platelet function assay by PFA-200, and adverse events.

**Results:** Twenty-one CKD patients underwent randomization to transdermal estrogen (n=10) or desmopressin (n=11) treatment. Transdermal estrogen provided comparable post-biopsy bleeding event to desmopressin (60% and 45.5%; p=0.67). There were no significant differences in hematoma size (7.44±8.4 cm<sup>2</sup> and 7.31±11.9 cm<sup>2</sup>; p=0.98) and hemoglobin change (-0.63±1.1 g/dL and -1.2±1.3 g/dL; p=0.31) between transdermal estrogen and desmopressin respectively. A significant improvement of platelet function represented by a decrease in closure times of PFA-200 assay with collagen and epinephrine (Col/EPI) was observed in desmopressin compared with transdermal estrogen (-50±32.6 sec and 20.3±36.4 sec; p<0.001). Sodium levels significantly decreased in patients receiving desmopressin (-6.0±4.3 mmol/L; p<0.05). There was no thromboembolism event observed.

**Conclusions:** In CKD patients, transdermal estrogen provided comparable effectiveness to desmopressin in preventing post-biopsy bleeding complications, hematoma size, and hemoglobin change without increased risk of thromboembolism and hyponatremia.

**Funding:** Other NIH Support - The Kidney Foundation of Thailand

## TH-PO583

## CKD Disrupts the Intestinal Mucosal Barrier by Altering Occludin Expression

Georgia Andriana Georgopoulou,<sup>1</sup> Pinelopi Bosgana,<sup>2</sup> Marios Papatotiriou,<sup>1</sup> Anne-Lise de Lastic,<sup>3</sup> Evangelos Papachristou,<sup>1</sup> Dimitrios S. Goumenos,<sup>1</sup> Vasiliki Zolota,<sup>2</sup> Stelios F. Assimakopoulos.<sup>4</sup> <sup>1</sup>Division of Nephrology, Department of Internal Medicine, University of Patras Medical School, Patras, Greece; <sup>2</sup>Department of Pathology, University of Patras Medical School, Patra, Greece; <sup>3</sup>Division of Hematology, Department of Internal Medicine, University of Patras Medical School, Patra, Greece; <sup>4</sup>Division of Infectious Diseases, Department of Internal Medicine, University of Patras Medical School, Patra, Greece.

**Background:** The gut barrier function is compromised in chronic kidney disease (CKD) resulting in increased gut permeability. However, little is known on the potential implicated mechanism(s). This study was undertaken to investigate intestinal occludin expression (a molecular component of epithelial tight junctions) in patients with CKD of various stages.

**Methods:** Thirty-three patients with CKD stage I-IV (n=17) or end-stage kidney disease (ESKD) (n=16) and 11 healthy controls were subjected to duodenal biopsy. Specimens were examined histologically and the villous height/crypt depth ratio and apoptotic body count (by morphology) in the cryptal epithelium was recorded. The expression of occludin in the intestinal epithelium was evaluated by immunohistochemistry. Circulating endotoxin concentration was evaluated by enzyme-linked immunosorbent assay.

**Results:** Patients with CKD stage I-IV or ESKD presented significantly higher serum endotoxin concentrations as compared to controls (P<0.001, respectively). There was an increase of cryptal apoptotic body count in CKD and ESKD patients (P<0.001 vs. controls) and a trend towards decreased villous height/crypt depth ratio. Occludin expression was significantly decreased in CKD and ESKD patients as compared to controls (P<0.001) (Table 1). Interestingly, a gradient of occludin expression from the crypt to the tip of the villi was recorded; occludin expression was retained in crypts, it was reduced in the middle part of the villi, while greater loss of its expression was observed at the upper part.

**Conclusions:** Decreased intestinal occludin expression, observed mainly at the upper third of the villi and increased crypt epithelial apoptosis might represent important mechanisms for intestinal barrier dysfunction and hyperpermeability in patients with CKD or ESKD.

TABLE 1: Occludin immunohistochemical expression: (%) of positive enterocytes (mean±SD)

	CKD stage I to IV (n=17)	ESKD (n=16)	CKD (total) (n=33)	Healthy controls (n=11)
Total occludin (%) of enterocytes	75.3±6.2*	77.2±9.6*	76.3±8*	90.9±9.4
Tip of villi (%)	44.7±25*	50.6±29*	47.7±27*	86.4±13.6
Middle of villi (%)	84.7±6.2*	85.2±9*	84.9±7*	97.3±4.7
Crypt (%)	97±5.9	93.3±10.9	95.1±8.9	99±3

## Renal Biopsy in Systemic Infections: Expect the Unexpected

Bangchen Wang, Alexandra Grand, Micah Schub, Harpreet K. Singh, David I. Ortiz Melo, David N. Howell. *Duke University Health System, Durham, NC.*

**Introduction:** Infection-related glomerulonephritis is well recognized and often included in the differential diagnosis in patients with ongoing infections. It can be missed, however, if the infection is unusual or undetected. We present three cases where the renal biopsy findings prompted the identification or treatment of systemic infections.

**Case Description:** Case 1: A 84-year-old male presented with acute kidney injury (AKI) and a new purpuric rash. Clinically, IgA nephropathy was suspected. A renal biopsy showed active glomerulonephritis with abundant neutrophils, focal segmental tuft necrosis, and one cellular crescent. Predominantly mesangial immune complex deposits containing IgA and IgG were seen. The findings suggested IgA-rich

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

infection-associated glomerulonephritis. Infectious workup was positive for COVID-19, suggesting exacerbation of IgA nephropathy by recent COVID-19 infection. Case 2: A 31-year-old female status post kidney transplant for granulomatosis with polyangiitis (GPA) had recent pregnancy with preterm delivery, disseminated herpes simplex virus (HSV) infection with HSV hepatitis, and AKI. Urine culture was positive for *E. coli*. The differential diagnosis included HSV nephritis, drug reaction, rejection, recurrent GPA, thrombotic microangiopathy (TMA), and pyelonephritis. A renal biopsy showed proliferative glomerulonephritis with subendothelial and mesangial immune complex deposits containing IgG and C3. The findings were most consistent with infection-related immune complex glomerulonephritis, most likely related to the HSV infection. Case 3: A 78-year-old female presented with AKI, proteinuria, hematuria, and positive p-ANCA. Clinically, ANCA vasculitis was suspected, and the renal biopsy did show focal, segmental, necrotizing glomerulonephritis. However, immunofluorescence and electron microscopy showed IgM-rich immune complex deposits in the mesangium. The unusual presentation of ANCA glomerulonephritis was suggestive of an underlying infection. Bartonella antibody panel showed very high titers; the patient was treated with antibiotics for Bartonella endocarditis.

**Discussion:** Infection-related glomerulonephritis has a wide variety of presentations histologically and clinically. The three cases we present here emphasize the importance of recognizing these entities to help guide treatment and improve patient care.

## TH-PO585

### Renal Involvement in Sarcoidosis-Lymphoma Syndrome: A Report of Two Cases

Siarhei Dziedzic,<sup>1</sup> Ilya Glezerman,<sup>2</sup> Hye-Ran Park,<sup>3</sup> Steven Salvatore,<sup>4</sup> Surya V. Seshan.<sup>4</sup> <sup>1</sup>New York-Presbyterian Hospital, New York, NY; <sup>2</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>3</sup>Kidney Care Specialists-Medical Associates of Drexel Hill, Drexel Hill, PA; <sup>4</sup>Weill Cornell Medicine, New York, NY.

**Introduction:** Sarcoidosis-lymphoma syndrome (S-LS) is a condition characterized by the development of sarcoidosis and lymphoma in the same patient. Chronic inflammation is a putative mediator of this risk. Documented locations affected by sarcoidosis are lymph nodes, lung, bone marrow and spleen. Clinically significant renal involvement by sarcoidosis has not been reported in S-LS.

**Case Description:** Patient #1: 52-year-old male with small lymphocytic lymphoma (SLL) treated with steroids and rituximab (2018), sarcoidosis (2018) and chronic kidney disease (2019). In November 2021 he developed acute kidney injury, refractory hypercalcemia and lung nodules. Complete blood count (CBC) - hemoglobin 8.8 g/dL, WBC 6.2. Serum findings - creatinine 4.5 mg/dL (baseline 2.1 mg/dL), glucose 103 mg/dL, albumin 3.4 g/dL, calcium 13.2 mg/dL, ACE level 71 (normal <40). Patient #2: 58-year-old female with TP53-mutated chronic lymphocytic leukemia (CLL) treated with fludarabine, bendamustine and rituximab (2002). In 2019 patient started ibrutinib with good response. One year later she developed anterior uveitis, lymphadenopathy, fever and night sweats. Lymph node biopsy confirmed sarcoidosis. Steroid course was initiated with resolution of the symptoms. In November 2021, one month before kidney biopsy, PET-CT showed CLL progression. CBC - hemoglobin 13.2 g/dL, WBC 4.77. Serum findings - creatinine 1.9 mg/dL (baseline 1.0 mg/dL), glucose 67 mg/dL, albumin 3.9 g/dL, calcium 9.4 mg/dL, ACE level 42. In both cases there was no hematuria or proteinuria on urinalysis. Kidney biopsies demonstrated diffuse interstitial nephritis with non-caseating granulomatous inflammation and widespread tubular atrophy with interstitial fibrosis suggestive of sarcoidosis. No other infections or medications could be implicated. No evidence of SLL/CLL was identified.

**Discussion:** The differential diagnosis of impaired kidney function in patients with hematologic malignancies is broad. Infections, drug toxicity and direct or indirect involvement by the malignancy should be considered. Renal biopsy remains a definitive modality for an accurate diagnosis. These cases represent the first reported description of renal sarcoidosis as a part of S-LS. Renal pathologists and nephrologists should be aware of this association for potential accurate diagnosis of both entities and appropriate treatment.

## TH-PO586

### Potential Factors for Specimen Adequacy and Bleeding Complications of Ultrasound-Guided Renal Biopsy

Kanin Thammavaranu<sup>1</sup>, Ittikorn Spanuchart,<sup>2</sup> <sup>1</sup>Chakri Naruebodin Medical Institute, Bang Phli, Thailand; <sup>2</sup>Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.

**Background:** A kidney biopsy is indicated for establishing a definite diagnosis and guiding the treatment of various kidney diseases. While obtaining adequate tissue is important, procedure-related risks, particularly bleeding, need to be minimized. The angle and depth of the biopsy needle trajectory have been studied for the safety outcome however the data on tissue adequacy associated with these factors is little. We aimed to evaluate potential factors, including the needle cortical tangential angle and the needle-distance ratio, for tissue adequacy and complications in native kidney biopsy.

**Methods:** A retrospective study was conducted on adult patients who underwent ultrasound-guided native kidney biopsy by interventional radiologists at Ramathibodi Hospital between January 1<sup>st</sup>, 2016, and December 31<sup>st</sup>, 2020. Clinical, imaging and technical parameters were collected for analysis.

**Results:** Of 124 kidney biopsies, the demographic data includes the mean age of 51.5 years, male sex of 57.3%, BMI of 27.2 kg/m<sup>2</sup>, kidney size of 4.9x9.9 cm, the parenchymal thickness of 1.3 cm, increased echogenicity 73.4%, and loss of

corticomedullary differentiation 44.4%. The parenchymal thickness of the adequate group was higher than the suboptimal/inadequate groups (p=0.056). Loss of corticomedullary differentiation was higher in the suboptimal/inadequate group (p=0.045). The needle cortical tangential angle in the range of 30-60° yielded tissue adequacy of 64% compared to 16% with the angle out of range (p<0.01). The mean needle-distance ratios of the adequate, suboptimal, and inadequate groups were 0.64, 0.74, and 0.79 cm, respectively (p=0.01). Major bleeding occurred at 13.7%. In multivariable analysis, needle cortical tangential angle was statistically significant for the tissue adequacy outcome.

**Conclusions:** Our study showed the cortical tangential approach with the angle between 30°-60° had higher tissue adequacy than the angle out of 30°-60°. The needle-distance ratio toward one, loss of corticomedullary differentiation, and decreased parenchymal thickness showed a tendency of having suboptimal or inadequate tissue.

## TH-PO587

### Tenofovir Associated Hyaline Arteriosclerosis

Jee Hoon Kim, Maxwell L. Smith, Leslie F. Thomas. Mayo Clinic Arizona, Scottsdale, AZ.

**Introduction:** Tenofovir Disoproxil Fumarate (TDF) is associated with various patterns of kidney injury. We present a case of hyaline arteriosclerosis (HA) associated with TDF.

**Case Description:** A 40-year-old Caucasian male with a history of epilepsy on Lacosamide and Brivaracetam, hepatitis C (HCV) treated with Sofosbuvir/Velpatasvir (SV), cutaneous sarcoid on Hydroxychloroquine, pre-exposure prophylaxis on Emtricitabine and TDF for seven years presented to nephrology clinic with asymptomatic elevation in creatinine (CR). Patient was diagnosed with HCV and started on SV one year prior to presentation. One month after starting treatment, patient's CR was elevated to 1.38 mg/dL from a baseline of 1.03 mg/dL. Near the end of HCV treatment, the patient developed a rash that was eventually biopsy proven to be cutaneous sarcoid. Additional workup for the rash also showed a positive p-ANCA/MPO without evidence of vasculitis and a persistently elevated CR of 1.56 mg/dL. Negative studies included HCV, HIV, sedimentation rate, A1c. Urine studies were also unremarkable. Blood pressures were normal and the only known potential nephrotoxic agents were TDF and Omeprazole. Patient's CR continued to rise and peaked at 1.85 mg/dL. A kidney biopsy was pursued. Kidney biopsy revealed HA. The renal cortex was intact with normal glomeruli. Immunofluorescence was negative. HA was thought to be due to TDF exposure. Fortunately, patient's CR stabilized at around 1.5 mg/dL without any intervention.

**Discussion:** TDF is a known potential nephrotoxin. Commonly described nephrotoxic patterns associated with TDF include proximal tubular dysfunction, acute and chronic kidney damage, nephrogenic diabetes insipidus and distal tubular acidosis. Small vessel disease, such as HA, due to TDF has never been described. HA is mainly seen in the elderly, patients with diabetes or hypertension or patients on calcineurin inhibitors. Our patient was taking 300 mg of TDF daily without any side-effects. The sudden increase in CR coincided with the start of SV. The concomitant use of TDF and SV increases the TDF concentration in the serum and may worsen renal function, as seen in our patient. Moreover, the twelve weeks of increased TDF exposure may have led to microvascular changes that ultimately resulted in HA. To our knowledge, this is the first case of HA associated with TDF in a young patient without any known risk factors.

## TH-PO588

### SeqStain Based Spatialomic Profiling of Human Kidney Tissues Identifies Cellular Neighborhoods

Ishwarya Venkatesh, Disha Varma, Kwi Hye Koh, Billy Nguyen, Vineet Gupta, David J. Cimbalku. Team SeqStain Rush University Medical Center; Chicago, IL.

**Background:** An improved understanding of the underlying cellular heterogeneity of human kidney tissue is essential for providing an accurate disease diagnosis, rate of progression and potential therapeutic avenues for a variety of chronic kidney disease pathologies. Newer multiplex imaging based methods are providing such tools for implementation in the clinical setting in the future. We recently developed a novel tissue imaging method, termed SeqStain, for immunofluorescence based multiplexed tissue imaging and analyses. Here, we describe utility of this approach for improving our understanding of kidney tissue samples from healthy subjects and patients with various glomerular diseases.

**Methods:** SeqStain utilizes fluorescent DNA-tagged antibodies and antibody-fragments for analyzing tens of kidney-specific analytes in a single tissue section. We designed and optimized SeqStain multiplex panels with sets of antibodies to probe different histological regions relevant to the kidney and used conventional fluorescence microscopy set-up for imaging and analyses.

**Results:** We show that SeqStain is an efficient method for multiplex imaging of both paraffin-fixed and frozen tissue sections. Image acquisition using off-the-shelf components, and confocal microscopes that are widely available in laboratories, were able to accurately image tens of antigens on single tissue specimens for healthy subjects, and from patients with lupus nephritis (LN) or diabetic nephropathy (DN). Automated analysis of the aligned tissue images showed enrichment of specific cellular clusters into distinct neighborhoods.

**Conclusions:** This newly developed imaging method, SeqStain, provides an easy to use and robust platform for deep profiling of kidney tissue specimen. The generated spatial maps will provide important new insights about the disease pathobiology and improve future diagnostics and therapeutics for LN and DN.

## TH-PO589

# Temporal Trends in Prevalence of Blood Pressure Screening and Hypertension After Introduction of Clinical Practice Guidelines on Hypertension in Canadian Children: A Time-Series Analysis

Michael Wu,<sup>1</sup> Allison Dart,<sup>2</sup> Leanne Kosowan,<sup>2</sup> Smita Roychoudhury,<sup>1</sup> Alexander Singer,<sup>2</sup> Rahul Chanchlani.<sup>1</sup> <sup>1</sup>McMaster University, Hamilton, ON, Canada; <sup>2</sup>University of Manitoba, Winnipeg, MB, Canada.

**Background:** In 2016 & 2017 respectively, new Canadian & American guidelines for assessing pediatric hypertension (HTN) were introduced. It is unknown whether these guidelines have impacted blood pressure (BP) screening & HTN prevalence in primary care settings.

**Methods:** The study included 438,297 children (3-18 years) from seven Canadian provinces with 1+ encounter in the Canadian Primary Care Sentinel Surveillance Network (CPCSSN) database between January 1, 2011 & December 31, 2019. The study cohort had 3 phases: Jan 1, 2011-Dec 31, 2015 (era 1), Jan 1, 2016 – Dec 31, 2017 (wash out) & Jan 1, 2018- Dec 31, 2019 (era 2). HTN was defined by NHLBI guideline up to December 31, 2017 & AAP 2017 guideline thereafter. We performed an interrupted time series analysis to assess impact of the guideline recommendations on BP screening and HTN prevalence.

**Results:** 264,635 children in era 1 & 193,654 children in era 2 were evaluated. In era 1 and 2, there were 66,653 (25.2%) & 45,050 (23.3%) children, respectively with at least 1 BP measurement. Annual BP screening generally increased each year from 13.3% in 2011 to 20.2% in 2019. In Era 1, a total of 1.1% of children met HTN criteria with a mean onset age of 12.6 years (SD 4.1). In Era 2, a total of 2.0% of children met HTN criteria with a mean onset age of 14.1 years (SD 4.1). Time series analysis revealed a significant increase in BP screening and HTN after the guidelines' introduction ( $p=0.04$  and  $p<0.0001$  respectively).

**Conclusions:** BP screening and HTN prevalence generally increased between 2011 and 2019, with a significant increase in post-guideline BP documentation and children meeting HTN criteria following guideline implementation.

Proportion of children who received BP screening or who met HTN criteria from Jan 1, 2011 to Dec 31, 2019

## TH-PO590

# Low Birth Weight and Hypertension Severity in Youth Referred for Hypertension Disorders: A SUPERHERO Interim Analysis

Rachel A. Carrasquillo,<sup>1</sup> Victoria Giammattei,<sup>1</sup> Caroline Lucas,<sup>1</sup> Christine B. Sethna,<sup>3</sup> Carol Vincent,<sup>1</sup> Irina Viviano,<sup>1</sup> Donald J. Weaver,<sup>2</sup> Andrew M. South.<sup>1</sup> <sup>1</sup>Wake Forest University School of Medicine, Winston-Salem, NC; <sup>2</sup>Levine Children's Hospital, Charlotte, NC; <sup>3</sup>Cohen Children's Medical Center, Queens, NY.

**Background:** Pediatric hypertension (HTN) has short and long-term adverse health effects. While children with low birth weight (LBW, <2500 g) have an increased risk of HTN, it is unknown whether LBW is associated with more severe HTN once diagnosed. Our objective is to evaluate if youth referred for HTN disorders who had LBW are more likely to have worse blood pressure (BP).

**Methods:** Cross-sectional analysis of preliminary baseline data from The Study of the Epidemiology of Pediatric Hypertension (SUPERHERO) Registry, an ongoing multicenter retrospective cohort using bioinformatics to obtain electronic health record data from youth referred to subspecialty clinics for HTN disorders. Inclusion criteria were <19 years of age, initial visit 1/01/2016 to 12/31/2021 (index date), and ICD-10 diagnostic codes for HTN disorders. Exclusion criteria were pregnancy, kidney failure on dialysis, or kidney transplantation by ICD-10 codes. BP severity was based on the average of all BP measurements obtained on the index date. We classified BP based on age, sex, and

height per pediatric guidelines. We further defined high BP as elevated BP or any stage of HTN. LBW of any severity was based on ICD-10 diagnostic codes at the index date. We estimated  $\beta$ , RR, and OR with 95% CL using unadjusted generalized linear models.

**Results:** Of the 3295 participants, 29% identified as Black/African American, 17% Hispanic, 37% were female, and the median age was 14.2 years (IQR 10.5, 16.4); 52% had obesity. Only 1% ( $n=18$ ) had an ICD-10 code for LBW, and 60% of the cohort had stage 1 or stage 2 HTN. LBW ICD-10 codes were associated with an 18% higher risk of high BP (RR 1.18, 95% CL 1.04 to 1.33) and 46% higher risk of HTN (RR 1.46, 95% CL 1.21 to 1.77).

**Conclusions:** Youth referred for HTN disorders who had ICD-10 codes for LBW had higher risk of more severe BP classification compared to those without these codes. It is likely that LBW status is not being heavily documented, hence it is unlikely that there is only 1% prevalence. Our findings could aid health care providers in HTN clinics to be more alert of a possible risk factor that needs to be taken into consideration. Ongoing analyses in this population include obtaining actual birth weight and investigating the association with target organ damage.

**Funding:** NIDDK Support, Other NIH Support - NHLBI K23-HL148394, L40-HL148910 (South), NCTAS UL1-TR001420 (WFUSM)

## TH-PO591

# Childhood Systolic Blood Pressure Predicts Hypertension in Young Adults: A 10-Year Follow-Up Study of Icelandic Children

Asdis H. Sigurdardottir,<sup>1</sup> Olafur S. Indridason,<sup>1,2</sup> Thordis J. Hrafnkelsdottir,<sup>1,3</sup> Sigurdur S. Stephensen,<sup>1,4</sup> Vidar O. Edvardsson.<sup>1,4</sup> <sup>1</sup>Faculty of Medicine, School of Health Sciences, University of Iceland, Reykjavik, Iceland; <sup>2</sup>Division of Nephrology, Landspítali-The National University Hospital of Iceland, Reykjavik, Iceland; <sup>3</sup>Division of Cardiology, Internal Medicine Services, Landspítali-The National University Hospital of Iceland, Reykjavik, Iceland; <sup>4</sup>Children's Medical Center, Landspítali-The National University Hospital of Iceland, Reykjavik, Iceland.

**Background:** Although there is significant evidence for an association between childhood and adult clinic blood pressure (BP), data on the association of childhood BP and ambulatory BP (ABP) and hypertension in young adults are missing. The aim of this study was to examine the predictive value of childhood BP for ambulatory HTN in young adults.

**Methods:** Subjects were recruited from a cohort of 970 adults aged 20-22-years who participated in a population-based study of BP in 9-10-year-old Icelandic children. All participants underwent 4 resting BP measurements in childhood and the follow-up study included both clinic and ABP measurements. The 2017 AHA guideline was used to define HTN at follow-up and the fourth report on the diagnosis, evaluation, and treatment of high blood pressure in children and adolescents was used to define childhood BP percentiles. Logistic regression analysis was used to examine the relationship between childhood BP and HTN at follow-up.

**Results:** A total of 163 individuals, 66 (40%) men, participated in the follow-up study. At follow-up a total of 40 (24%) participants had HTN, of those 37 (23%) had ambulatory HTN, 11 had both clinic and ambulatory HTN and 3 had white-coat HTN only. There was an independent association between HTN at follow-up and absolute childhood systolic BP (SBP) (OR 1.08, CI95% [1.02 – 1.15]). Men were more likely to have HTN than women at follow-up (OR 3.00, CI95% [1.4 – 6.6],  $p<0.001$ ). Men were also more likely than women to have ambulatory HTN at follow-up (OR 2.39, CI95% [1.12 – 5.25],  $p<0.05$ ). One mm Hg increase in SBP at the age of 9-10 years was associated with a 10% rise in the probability of ambulatory HTN at age 20-22 years (OR 1.10, CI95% [1.01 – 1.21],  $p<0.05$ ). Individuals with SBP >90<sup>th</sup> percentile were three times more likely to have ambulatory HTN (OR 3.4, CI95% [1.5 – 7.68],  $p<0.001$ ) at follow-up. Diastolic BP (DBP) and body mass index (BMI) percentiles at the age of 9-10 years predicts neither clinic nor ambulatory HTN at the age of 20-22 years.

**Conclusions:** Male sex and SBP indices at the age of 9-10 years predicts both clinic and ambulatory HTN in young adults.

## TH-PO592

# Anxiety Disorders and Hypertension in Children: Interim Analysis of the Study of the Epidemiology of Pediatric Hypertension (SUPERHERO) Registry

Christine B. Sethna,<sup>1</sup> Shupri Biswas,<sup>1</sup> Victoria Giammattei,<sup>2</sup> Caroline Lucas,<sup>2</sup> Carol Vincent,<sup>2</sup> Irina Viviano,<sup>2</sup> Donald J. Weaver,<sup>3</sup> Andrew M. South.<sup>2</sup> <sup>1</sup>Cohen Children's Medical Center, Queens, NY; <sup>2</sup>Wake Forest University School of Medicine, Winston-Salem, NC; <sup>3</sup>Levine Children's Hospital, Charlotte, NC.

**Background:** Studies in adults have linked anxiety disorders with hypertension, however not much is known about this relationship in children. The study aimed to assess the association of anxiety disorders with blood pressure classification and initial evaluation/management among youth referred for subspecialty evaluation of hypertension.

**Methods:** Interim analysis of baseline data from the SUPERHERO Registry, a multicenter retrospective cohort of youth referred for hypertension disorders, was conducted. Data were collected via standardized electronic health record queries. Inclusion criteria were initial visit to a subspecialty clinic for hypertension disorders identified by ICD-10 codes from 1/1/2016–12/31/2021 and age <19 years. Exclusion criteria were kidney failure on dialysis, kidney transplantation, or pregnancy by ICD-10 codes. The primary exposure was anxiety disorders identified by ICD-10 codes “other

anxiety disorder”, “reaction to severe stress, and adjustment disorders”, and “emotional disorders with onset specific to childhood”. Outcomes were blood pressure classification and orders for antihypertensive medication, echocardiogram, and urine protein/albumin. Associations were estimated using unadjusted generalized linear models.

**Results:** Of 3295 participants, median age was 14.2 years [10.5, 16.4], 63% were male, 29% identified as Black or African American, and 52% had obesity. There were 36 anxiety disorder diagnosis codes identified among 26 participants. Blood pressure classification included elevated blood pressure 17%, stage 1 hypertension 34%, and stage 2 hypertension 26%. Participants with anxiety disorders were more likely to identify as White and less likely to be prescribed anti-hypertensive medication ( $p < 0.05$ ). In regression analysis, participants with anxiety disorders were more likely to have orders placed for urine albumin (RR 1.26, CL 1.02 to 1.55).

**Conclusions:** In a large multicenter cohort of youth referred for subspecialty evaluation of hypertension disorders, patients with anxiety diagnoses were more likely to have urine tests ordered. It is very probable that anxiety disorders are underreported by ICD-10 codes in the electronic health record in this population.

## TH-PO593

### Social Determinants of Health and Blood Pressure in Children: Interim Analysis of the Study of the Epidemiology of Pediatric Hypertension (SUPERHERO) Registry

Christine B. Sethna,<sup>1</sup> Shupri Biswas,<sup>1</sup> Victoria Giammattei,<sup>2</sup> Caroline Lucas,<sup>2</sup> Carol Vincent,<sup>2</sup> Irina Viviano,<sup>3</sup> Donald J. Weaver,<sup>3</sup> Andrew M. South,<sup>2</sup> <sup>1</sup>Cohen Children's Medical Center, Queens, NY; <sup>2</sup>Wake Forest University School of Medicine, Winston-Salem, NC; <sup>3</sup>Levine Children's Hospital, Charlotte, NC.

**Background:** Social determinants of health (SDoH) are known to impact chronic health conditions, however the relationship between SDoH and hypertension (HTN) in children has not been well-studied. The objective was to determine the association of unmet social needs (USN) with blood pressure (BP) classification and initial evaluation/management among youth referred for HTN.

**Methods:** Interim analysis of baseline data from the SUPERHERO Registry, a multicenter retrospective cohort of youth referred for HTN disorders, was conducted. Data were collected via standardized electronic health record queries. Inclusion criteria were initial visit to a subspecialty clinic for HTN disorders by ICD-10 codes from 1/1/2016–12/31/2021 and age <19 years. Exclusion criteria were dialysis, kidney transplantation, or pregnancy by ICD-10 codes. USN exposures included problems related to housing/economic circumstances, social environment, upbringing, and other psychosocial circumstances by ICD-10 codes. Unadjusted generalized linear models estimated the association of USN with outcomes of BP and orders for antihypertensive medication, echocardiogram, and urine protein.

**Results:** Of 3295 participants, median age was 14.2 years [10.5, 16.4], 63% were male, 29% identified as Black, and 52% had obesity. There were 16 USN diagnosis codes identified among 10 participants: 13 housing/economic, 1 social environment, 1 upbringing, and 1 other psychosocial circumstance. BP classification included elevated BP 17%, stage 1 HTN 34%, and stage 2 HTN 26%. Participants with USN were more likely to have obesity and, among age  $\geq 13$  years, higher diastolic BP,  $p < 0.05$ . Having USN was associated with HTN (RR 1.45, CL 1.18–1.78), greater systolic BP ( $\geq 13$  years only,  $\beta$  13.0 mmHg, CL 0.7–25.2), and greater diastolic BP ( $\geq 13$  years only,  $\beta$  12.4 mmHg, CL 3.0–21.8). Those with USN were also more likely to have orders placed for antihypertensive medications (RR 1.93, CL 1.03–3.59).

**Conclusions:** In a large multicenter cohort of youth referred for evaluation of HTN disorders, patients with USN were more likely to have HTN, greater BP and were more likely to be prescribed antihypertensive medications. Ongoing steps include multivariable analysis to further investigate SDoH in youth with HTN.

## TH-PO594

### CKD Stage/Duration and Cardiovascular (CV) Risk Factors in Children With Proteinuric Glomerulopathies (GD)

Christine B. Sethna,<sup>1</sup> Kevin E. Meyers,<sup>2</sup> Tarak Srivastava,<sup>3</sup> Susan F. Massengill,<sup>4</sup> Donald J. Weaver,<sup>4</sup> Keisha L. Gibson,<sup>5</sup> Katherine R. Tuttle,<sup>6</sup> Katherine M. Dell,<sup>7</sup> Debbie Gipson,<sup>8</sup> Cheryl L. Tran,<sup>9</sup> Howard Trachtman,<sup>8</sup> Elizabeth C. Mitchell.<sup>1</sup> <sup>1</sup>Cohen Children's Medical Center, Queens, NY; <sup>2</sup>The Children's Hospital of Philadelphia, Philadelphia, PA; <sup>3</sup>Children's Mercy Hospitals and Clinics, Kansas City, MO; <sup>4</sup>Levine Children's Hospital, Charlotte, NC; <sup>5</sup>The University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>6</sup>Providence St Joseph Health, Renton, WA; <sup>7</sup>Case Western Reserve University, Cleveland, OH; <sup>8</sup>University of Michigan, Ann Arbor, MI; <sup>9</sup>Mayo Clinic Minnesota, Rochester, MN.

**Background:** Children with GD are at increased risk for CV disease, however the impact of CKD stage and disease duration has not been well studied.

**Methods:** Ambulatory blood pressure monitoring (N=90), echocardiography (N=119), pulse wave velocity (PWV) (N=44) and lipids (N=96) were performed in a cross-sectional study of children <21 yr with GD from 10 sites within Nephrotic Syndrome Study Network (NEPTUNE) and Cure Glomerulonephropathy Network (CureGN). Data were also obtained from children with GD in the Chronic Kidney Disease in Children (CKiD) study. Blood pressures (BP) were indexed to the 95%ile.

Left ventricular hypertrophy (LVH) was defined as >95%ile and >51 g/m<sup>2.7</sup>. The bedside Schwartz formula was used to estimate glomerular filtration rate (eGFR) and stage CKD. Disease duration was categorized as 0–<2, 2–<5, 5–<10 and >10 yrs. Analysis included Kruskal Wallis and chi-square tests.

**Results:** Of 144 children (age 14 [10.7–17] yr, 59% M), hypertension (HTN), isolated nocturnal HTN, LVH 95%ile and LVH>51 were present in 38.9%, 20.9%, 28.6% and 10.1%, respectively. There was a higher proportion of HTN and LVH with higher CKD stages. Office BP, BP loads and triglycerides were also greater in higher CKD stages (Table). PWV was higher in those with disease duration 2–<5 years compared to other durations (6.15 vs. 4.5–5.26 m/s,  $p=0.03$ ). No other measures were significantly different by disease duration.

**Conclusions:** CV risk factors are more prevalent in advanced CKD stages despite similar disease duration in children with GD. Longitudinal studies are needed to examine the effect of CKD stage/duration on CV risk factors in this high risk group.

**Funding:** Private Foundation Support

## TH-PO595

### Gaisbock Syndrome: A Rare Etiology of Secondary Hypertension Taylor Greene. The University of Oklahoma - Tulsa, Tulsa, OK.

**Introduction:** Gaisbock syndrome is an unusual clinical disorder first described in 1905 by Dr. Felix Gaisbock as hypertension in males attributed to elevated hematocrit levels without splenomegaly or abnormal leukocyte counts. The underlying pathophysiology for this syndrome was explained as psychiatric disorders that result in chronic stress, extracellular volume depletion due to diuresis, and hypoxemia due to obstructive sleep apnea as these conditions lead to relative and absolute polycythemia.

**Case Description:** 17-year-old Caucasian male without significant medical history was referred to nephrology clinic for new onset of hypertension with associated headache. He was initially seen by his family physician and evaluation revealed polycythemia with hemoglobin (Hb) of 20 g/dl, hematocrit of 57%, and hypertensive urgency with blood pressure of 160/110 mmHg. Physical exam was within normal limits with normal BMI. Secondary etiologies for hypertension evaluating for renal artery stenosis, Coarctation of the aorta, hyperaldosteronism, and Pheochromocytoma were all unrevealed. Hematological evaluation revealed negative JAK2 mutation and further genetic testing revealed a P50 mutation consistent with familial polycythemia. With other secondary causes ruled out, the patient's hypertension was attributed to Gaisbock syndrome due to familial polycythemia. The patient was initially treated with an Ace-inhibitor and Calcium channel blocker to control hypertension. Eventually one year after starting serial phlebotomy and attaining Hb of 15–16 g/dl, the patient was able to come off antihypertensive medications and remained normotensive while continuing phlebotomy.

**Discussion:** While rare, Gaisbock syndrome is a known phenomenon due to increased intravascular pressure from relative and absolute polycythemia. It can be difficult to differentiate, if hypertension is a consequence or its own diagnosis in some cases. It is important to consider other causes of secondary hypertension especially in patients with atypical presentations, such as this patient who was only 17 years old at onset of hypertension. Notably, Gaisbock syndrome does not have one singular etiology and thus treatment strategies may vary from patient to patient. In our patient, phlebotomy has proven to be an effective treatment in controlling hypertension. It is important to control hypertension as hyper viscosity poses an increased risk for thromboembolic complications.

## TH-PO596

**Primary Hypertension in Patients With Sickle Cell: Observations From an Adult Sickle Cell Kidney Disease Clinic**  
Jonathan Keyes, Oyintayo Ajiboye, Pooja Kalantri, Pooja D. Amarapurkar. Emory University School of Medicine, Atlanta, GA.

**Background:** Patients with Sickle Cell Disease (SCD) have lower blood pressures (BP). Relative hypertension (HTN) increases the risk for stroke, pulmonary HTN, and kidney dysfunction in SCD patients. Limited data exists about the prevalence of HTN in SCD population. We describe our observations from an adult SCD kidney clinic.

**Methods:** We performed a retrospective chart review of patients seen in the SCD kidney clinic at the Georgia Comprehensive Center between January 2021 to December 2021. Demographics, clinical characteristics, albuminuria, estimated glomerular filtration rate (eGFR), BP trends, number of antihypertensive medications, correlation of BP with albuminuria, eGFR and hyperkalemia were noted. Data analyses were generated using R-statistical software.

**Results:** During the study period 44 African American patients, 28 (64%) females and 16 (36%) males, with SCD were enrolled. The median age was 45 years. The sickle cell phenotypes were predominantly SS 38 (86%) [SC 4 (9.1%), hemoglobin S/high fetal hemoglobin 1 (2.3%), and sickle cell beta thalassemia 1 (2.3%)]. HTN was present in 23 (52%) patients. Median albumin to creatinine ratio (ACR) was 330 mg/g creatinine (IQR 75-941). ACR>300 was present in 14 (61%) patients with HTN and 9 (43%) without ( $p=0.23$ ). The median eGFR at initial visit was 59 mL/min/1.73m<sup>2</sup> (IQR 38-106). eGFR<60 mL/min was present in 12 (52%) with HTN and 4 (19%) without. Hyperkalemia (>5.5 mg/dL) was present in 8 (35%) with HTN and 6 (29%) without HTN. The systolic BP range was 114-185. The diastolic BP range was 65-110. Of those with HTN, 16 (70%) were on angiotensin converting enzyme inhibitors (ACEI) or angiotensin receptor blockers (ARB), 7 (30%) on diuretics, 9 (39%) on calcium channel blockers, 10 (43%) on a combination of 2 medications.

**Conclusions:** Our study is unique in that 52% of our SCD patients had HTN on presentation. We observed a correlation between HTN, albuminuria, and decreased eGFR. Optimal HTN management is crucial but challenging. Diuretics can increase the risk of sickle crisis while ACEI/ARB may contribute to hyperkalemia. Further studies are needed to assess the epidemiology of HTN and determine optimal BP regimens for patients with SCD.

## TH-PO597

### Blood Pressure Sensitivity to Sodium Is Accompanied by Distinct Microcirculatory Changes in CKD and Healthy Controls

Jetta J. Oppelaar,<sup>1</sup> Emanuele Favaron,<sup>2,3</sup> Emma H. van Schijndel,<sup>1</sup> Wim Jan V. Boven,<sup>3</sup> Can Ince,<sup>2</sup> Liffert Vogt.<sup>1</sup> <sup>1</sup>Department of Nephrology, Amsterdam University Medical Center, Amsterdam, Netherlands; <sup>2</sup>Department of Intensive Care, Erasmus MC, Rotterdam, Netherlands; <sup>3</sup>Department of Cardiothoracic Surgery, Amsterdam University Medical Center, Amsterdam, Netherlands.

**Background:** In CKD, blood pressure (BP) is closely related to sodium (Na<sup>+</sup>) intake. CKD is characterized by microcirculatory alterations, which are thought to contribute to impaired Na<sup>+</sup> and water excretion leading to Na<sup>+</sup>-sensitive BP response. We investigated whether high Na<sup>+</sup> induces similar microcirculatory changes in CKD as compared to Na<sup>+</sup>-sensitive healthy volunteers.

**Methods:** We performed a randomized cross-over study in healthy controls (HC) and CKD patients (stage 2a-3, proteinuria >500 mg/d). All subjects followed both an 8-day low Na<sup>+</sup> diet (LSD, <50 mmol/d) and high Na<sup>+</sup> diet (HSD, >200 mmol/d). IfMAP increased after HSD, subjects were considered as Na<sup>+</sup>-sensitive (SS-HC). Microcirculation was assessed by using an angiopoietin-2 (Ang2) ELISA and sublingual incident dark field (IDF) imaging with and without nitro-glycerine (NTG).

**Results:** We included 9 SS-HC (median age 29) and 6 CKD patients (median age 49, mean proteinuria 1.2 g/d). The mean Na<sup>+</sup>-sensitive MAP increase was 4.8 in SS-HC and 9.8 mmHg in CKD. Ang2 levels increased after Na<sup>+</sup> loading in SS-HC, but not in CKD (Fig 1A). After LSD, no differences could be observed in microcirculatory parameters between SS-HC and CKD. In SS-HC, HSD did not influence vessel density or perfusion. In CKD, HSD resulted in lower total vessel density after NTG (Fig 1B). After NTG supplementation, total red blood cell perfusion was higher after LSD in CKD compared to SS-HC (57.52 and 46.00 mm/mm<sup>2</sup>,  $p=0.02$ ) but diminished in this group whereas an increase in SS-HC was observed after switching to HSD.

**Conclusions:** We show that BP sensitivity to Na<sup>+</sup> is accompanied by distinct microcirculatory changes in CKD as compared to SS-HC. In SS-HC Na<sup>+</sup> loading affects the vascular permeability, yet no differences could be observed in total amount of vessels. However, in CKD Na<sup>+</sup> loading decreases the amount and perfusion of small blood vessels, indicating that Na<sup>+</sup> affects the capacity to adequately perfuse tissues in CKD. Authors 1 and 2 contributed equally to this abstract

**A.** Na<sup>+</sup> loading resulted in an increase in Ang2 in SS-HC (23.17 vs 29.95,  $p=0.04$ ). But not in CKD (27.07 vs 27.8,  $p=0.65$ ). **B.** After NTG, total vessel density (TVD) was not affected by Na<sup>+</sup> loading in SS-HC. But, the amount of functional vessels significantly decreased in CKD (22.27 vs 25.06,  $p<0.01$ ).

## TH-PO598

### Gender Disparity on the Association Between Dietary Sodium Intake and Blood Pressure: Analysis of the NHANES 2017-2018

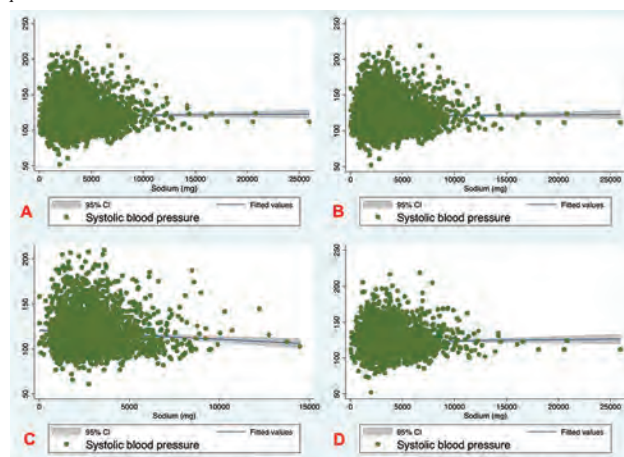

Ekamol Tantisattamo,<sup>1,2</sup> Phuwwadith Wattanachayakul,<sup>3</sup> Watsachon Pangkanon,<sup>4</sup> Chawin Lopimpisuth,<sup>5</sup> Pakin Lalitnithi,<sup>5</sup> Chanattha Thimphithaya,<sup>6</sup> Chalothorn Wannaphut,<sup>7</sup> Nattanicha Chairimaneepan.<sup>8</sup> <sup>1</sup>Division of Nephrology, Hypertension and Kidney Transplantation, University of California Irvine School of Medicine, Orange, CA; <sup>2</sup>Nephrology Section, Tibor Rubin Veterans Affairs Medical Center, Veterans Affairs Long Beach Healthcare System, Long Beach, CA; <sup>3</sup>Department of Microbiology, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; <sup>4</sup>Faculty of Medicine, Srinakharinwirot University, Bangkok, Thailand; <sup>5</sup>Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand; <sup>6</sup>Bangkok Metropolitan Administration General Hospital, Bangkok, Thailand; <sup>7</sup>Department of Medicine, Siriraj Piyamaharajkarun Hospital, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; <sup>8</sup>Institute of Dermatology, Ministry of Public Health, Bangkok, Bangkok, Thailand.

**Background:** Women have greater blood pressure (BP) lowering response to low dietary sodium intake (DSI). Whether this gender disparity between DSI and BP remains unclear.

**Methods:** A cross-sectional study using data from the NHANES from 2017 to 2018 included participants  $\geq 18$  years old. Association between DSI and systolic blood pressure (SBP) was examined by multiple linear regression.

**Results:** Of 9,254 participants, mean $\pm$ SD age was 34 $\pm$ 26 and 51% were female. Up to 34% was White followed by Black and Mexican American. Body mass index was 25.8 kg/m<sup>2</sup> (IQR 20.4, 31.3). Median DSI was 2,816 mg/day (IQR 1920, 4028) and SBP was 117 mmHg (IQR 106, 131). Every 1,000 mg increase in DSI was associated with increase in 0.99 mmHg SBP ( $\beta$  0.000099,  $P$  0.480, 95%CI -0.000176, 0.000373). After stratifying by gender, higher DSI of 1,000 mg/day was associated with significantly decreased SBP of 1 mmHg in women; while SBP was 0.16 mmHg increase but non-significant in men ( $\beta_{\text{women}}$  -0.001007,  $P$  <0.0001, 95%CI -0.001516, -0.000497 and  $\beta_{\text{men}}$  0.000161,  $P$  0.326, 95%CI -0.000160, 0.000481). After adjusting for age, gender, race, body mass index, and interaction term between gender and DSI, SBP was 0.036 mmHg increase for every 1,000 mg higher DSI ( $\beta$  0.000364,  $P$  0.012, 95%CI 0.000080, 0.000649). With the same amount of DSI, SBP was 0.78 mmHg lower in women compared to men for every 1,000 mg incremental DSI ( $\beta_{\text{interaction}}$  -0.000779,  $P$  0.002, 95%CI -0.001261, -0.000297; Figure 1A-D).

**Conclusions:** Higher DSI is inversely associated with SBP levels in women, but not in men. This disparity and paradoxical relationship may explain better BP response to low dietary sodium intervention in women compared to men, although longitudinal studies are required to elucidate the mechanism.

**Figure 1:** Scatter plot between dietary sodium intake and systolic blood pressure in the crude model (A), in the fully adjusted model (B), female (C), and men (D).

## TH-PO599

### Adherence to Guidelines for Management of Hypertensive Emergency

Lama Ghazi, James Nugent, Angela M. Victoria Castro, Francis P. Wilson. Yale University, New Haven, CT.

**Background:** Hypertensive emergencies, severe blood pressure (BP) elevation >180/120 associated with end organ damage, are associated with increased mortality. Rates of hospitalization for hypertensive emergencies have increased over the past 10 years especially among Black adults. We assessed the adherence to BP reduction goals for hypertensive emergency and the rates by race.

**Methods:** This is a retrospective study of patients admitted for hypertensive emergency from 2016-2018 within the Yale New Haven Health System. We used International Classification of Diseases codes, labs and manual chart review to assess end organ damage.

We then calculated percent adherence to BP reduction goals set by 2017 American College of Cardiology/American Heart Association guidelines in all patients and by race.

**Results:** We identified 596 patients admitted for hypertensive emergency. Patients were  $65 \pm 16$  years, 50% male, 43% Black with median BP on admission of 207 [193, 226]/110 [94, 126] mmHg. Most patients were admitted with ischemic stroke followed by pulmonary edema (Table 1). BP reduction goals were not achieved among most patients at 6 hours and 24 hours regardless of end organ damage type. Black adults are less likely to achieve BP reduction for patients with hypertensive emergency and acute coronary syndrome (ACS) or hemorrhagic stroke (Figure 1).

**Conclusions:** Adherence to BP guidelines in treatment of patients admitted for hypertensive emergency was found to be suboptimal. Black patients with ACS and ischemic stroke had lower rates of BP control. Future efforts should focus on understanding the reasons behind the lack of guideline adherence and racial inequities in treatment.

Table 1. Achieved blood pressure reduction according to 2017 ACC/AHA guidelines

	AAA n= 18 (2.3%)	Pulmonary Edema n= 217 (19.5%)	ACS n= 116 (18.6%)	AKI n= 133 (7.4%)	Ischemic Stroke n= 94 (36.4%)	Hemorrhagic stroke n= 44 (15.8%)
<b>Guideline Recommendations</b>						
BP reduction $\geq 25\%$ during the 1 <sup>st</sup> hour	11 (79)					
BP reduction by $\geq 25\%$ over the 1 <sup>st</sup> hour		139 (63)	77 (66)	77 (69)		
BP reduction to $<160/100$ over 2-6 hours		100 (46)	50 (43)	25 (23)		
BP reduction to $<140/90$ over 24-48 hours		53 (24)	28 (22)	17 (15)		
BP reduced $\geq 35\%$ over 24 hours (SBP $\geq 220$ or DBP $\geq 120$ )					Out of 54 patients 35 (65)	
BP reduced to 140-150 over 1 hour						38 (86)
Harmful BP reduced $<140$ over 1 hour						0 (0)

### Clinical Pharmacists Are Underutilized in the Management of Hypertension

Ahmad A. Masry,<sup>1</sup> Meenakshi Sambharia,<sup>1</sup> Linder Wendt,<sup>2</sup> Samantha E. Shaffer,<sup>4</sup> Melissa L. Swee,<sup>1</sup> Patrick Ten Eyck,<sup>2</sup> Korey Kennelty,<sup>4</sup> Heather Reisinger,<sup>2,3</sup> Diana I. Jalal.<sup>1,3</sup> <sup>1</sup>University of Iowa Carver College of Medicine, Iowa City, IA, United States, Iowa, IA; <sup>2</sup>Institute for Clinical and Translational Science, University of Iowa, Iowa City, IA, United States, Iowa, IA; <sup>3</sup>Center for Access & Delivery Research and Evaluation, Iowa City VAMC, Iowa City, IA, United States, Iowa, IA; <sup>4</sup>College of Pharmacy, University of Iowa, Iowa City, IA, United States, Iowa, IA.

**Background:** Previous studies have shown pharmacist-based interventions improve blood pressure (BP) control in individuals with hypertension. We evaluated provider attitudes towards clinical pharmacist support in the management of hypertension.

**Methods:** We surveyed primary care providers, internal medicine residents, nephrologists, cardiologists, nephrology and cardiology fellows, and nurse practitioners at the University of Iowa Hospitals and Clinics and the Iowa City VA Medical Center to determine the attitudes of providers towards clinical pharmacist management of high BP. Continuous data were summarized with medians and interquartile ranges and compared across strata using Wilcoxon rank sum tests. Categorical data were summarized with counts and percentages and compared across strata using Fisher's Exact Tests.

**Results:** 153 out of 413 providers completed the survey. We observed high confidence in the diagnosis and treatment of hypertension among all surveyed groups. Almost half (48%) indicated that they had never referred patients to the clinical pharmacist for management of BP medications and only 32% indicated they rarely did. Pharmacist utilization varied only slightly based on pharmacist availability. 70% agree that clinical pharmacists support clinical decision-making for the management of BP medications, improves the safety of treatment plans for patients taking BP medications, and reduces the burden on providers. Learners and primary care providers were less likely than non-learners and specialists, respectively to refer patients to a pharmacist for management of hypertension. Despite the conflicting evidence regarding home BP monitoring, 90% of the providers indicated that they ask their patients to monitor home BP and that they titrate medications according to home BP readings.

**Conclusions:** Clinical pharmacists are underutilized in our practice although providers expressed favorable perception of clinical pharmacists' roles in the management of hypertension. Interventions are needed to improve pharmacist utilization in the management of hypertension.

### Prevalence and Overlap of Cardio-Renal-Metabolic Conditions in US Adults, 2015-2018

John W. Ostrowski,<sup>1,2</sup> Suzanne V. Arnold,<sup>3</sup> Javed Butler,<sup>4</sup> Gregg C. Fonarow,<sup>5</sup> Jamie S. Hirsch,<sup>6</sup> Swetha R. Palli,<sup>7</sup> Bonnie M. Donato,<sup>7</sup> Christina Parrinello,<sup>8</sup> Eric B. Collins,<sup>9</sup> Tom O'Connell,<sup>10</sup> Mikhail Kosiborod,<sup>3</sup> Muthiah Vaduganathan,<sup>1,2</sup> <sup>1</sup>Brigham and Women's Hospital Carl J and Ruth Shapiro Cardiovascular Center, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>Saint Luke's Mid America Heart Institute, Kansas City, MO; <sup>4</sup>Baylor Scott & White Health, Dallas, TX; <sup>5</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; <sup>6</sup>Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; <sup>7</sup>Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT; <sup>8</sup>Pine Mountain Consulting, Redding, CT; <sup>9</sup>Medicus Economics, LLC, Philadelphia, PA; <sup>10</sup>Medicus Economics, LLC, Boston, MA.

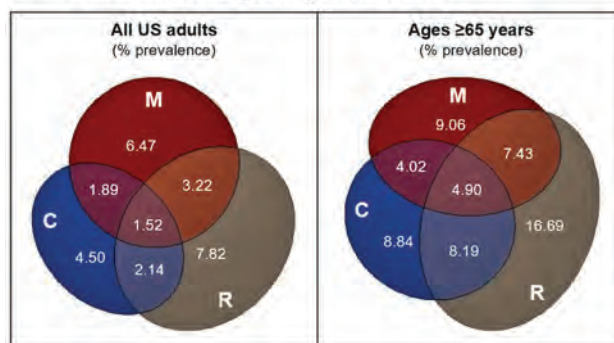

**Background:** Cardio-renal-metabolic (CRM) conditions are leading causes of death, disability, and economic burden. Individually, CRM conditions are prevalent in the US population, but the frequency with which CRM conditions coexist has not been comprehensively characterized.

**Methods:** Nationally representative, cross-sectional data on nonpregnant US adults aged  $\geq 20$  years from the 2015-2018 NHANES were evaluated. We calculated the proportion of participants with CRM conditions - overall and stratified by age - defined as cardiovascular disease (CVD; atherosclerotic CVD or heart failure), chronic kidney disease (CKD), or type 2 diabetes (T2D). CRM risk factors were also examined by CRM status.

**Results:** Of 9113 US adults included in the analysis (mean age 48.3 y [SD 0.44]; 51.0% women), 27.6% (~70 million adults using population weights) had  $\geq 1$  CRM condition, 8.7% had  $\geq 2$  CRM conditions, and 1.5% had all 3 CRM conditions (Figure). Individually, CVD was observed in 10.1% of participants, CKD in 14.7%, and T2D in 13.1%. CKD+T2D was the most common CRM dyad (3.2%), followed by CVD+CKD (2.1%) and CVD+T2D (1.9%). Among participants aged  $\geq 65$  years, 59.1% had  $\geq 1$  CRM condition, 24.5% had  $\geq 2$ , and 4.9% had 3 CRM conditions. In this group, CVD+CKD (8.2%) was most common, followed by CKD+T2D (7.4%) and CVD+T2D (4.0%). Higher CRM comorbidity burden was associated with more severe CKD stage, additive CVD conditions, older age, male sex, Black race, greater prevalence of key CRM risk factors, and adverse socioeconomic characteristics. Among those with all 3 CRM conditions, 67%, 64%, 4%, and 3% of participants were on a statin, ACEi/ARB, GLP1-RA, or SGLT2i, respectively.

**Conclusions:** CRM conditions commonly intersect in the contemporary US population, with more than a quarter having  $\geq 1$  CRM condition. Use of disease-modifying evidence-based CRM therapies remains suboptimal.

Figure. Prevalence of cardio-renal-metabolic (CRM) conditions in all US adults vs. ages  $\geq 65$  years, 2015-2018

## TH-PO602

### Newer Guideline-Directed Medical Therapies Are Underutilized in 2021-2022 in Patients With Heart Failure and CKD

Mario Enrico Canonico,<sup>1,2</sup> Judith Hsia,<sup>2</sup> Christopher P. Cannon,<sup>3</sup> Marc P. Bonaca.<sup>1,2</sup> <sup>1</sup>CPC Clinical Research, Aurora, CO; <sup>2</sup>University of Colorado Denver School of Medicine, Aurora, CO; <sup>3</sup>Brigham and Women's Hospital Department of Medicine, Boston, MA.

**Background:** Chronic kidney disease (CKD) is a common comorbidity in patients with heart failure (HF). In 2021 and 2022, HF guidelines endorsed newer therapies such as angiotensin receptor-neprilysin inhibitors (ARNI) and sodium-glucose cotransporter-2 inhibitors (SGLT2i) as first-line medications to improve clinical outcomes in HF patients with or without CKD.

**Methods:** Patients with HF encounters from May 2021 to April 2022 were extracted from the University of Colorado health system TriNetX database. Use of guideline-directed medical therapy (GDMT) was compared by chi square and p for trend calculated across CKD stages. CKD stages were defined by eGFR; dialysis patients were excluded.

**Results:** Among 17990 patients with HF encounters, 51% had reduced (HFrEF) and 49% preserved ejection fraction (HFpEF). Mild CKD was more common among patients with HFrEF than HFpEF (Stage G1 25% vs 20%,  $p<0.0001$ ; G2 40% vs 38%,  $p<0.05$ ) while more severe CKD was more common in patients with HFpEF (G3 32% vs

37%,  $p < 0.0001$ ; G4 4% vs 5%,  $p = 0.0005$ ). Prevalence of hypertension, diabetes (DM), hyperlipidemia, prior myocardial infarction and peripheral artery disease increased with CKD stage (all  $p < 0.0001$ ). Older GDMT (B-blockers, ACE inhibitors, ARB) were widely prescribed (Figure). Use of mineralocorticoid receptor antagonists was intermediate, whereas use of newer GDMT (ARNI and SGLT2i) was less frequent. Among patients with HFrEF or HFpEF, those with DM were more likely to receive SGLT2i than those without T2D ( $p < 0.0001$  for each CKD stage).

**Conclusions:** ARNI and SGLT2i use even in 2021-2 was infrequent among patients with HF irrespective of CKD stage; SGLT2i use was particularly low in those without DM.

**Funding:** Commercial Support - Lexicon Pharmaceuticals, The Woodlands, TX, USA

Use of GDMT in HFrEF (upper panel) and in HFpEF (lower panel) by CKD stage.

## TH-PO603

### Association Between ACEI/ARB Use With Mortality, Heart Failure Admissions, and Kidney Failure Outcomes Among Patients Admitted for Acute Heart Failure Requiring Invasive Hemodynamic Monitoring

Marcelle Tuttle,<sup>1</sup> Hocine Tighiouart,<sup>1,3</sup> Jake Gillberg,<sup>1</sup> Run Banlengchit,<sup>1</sup> Tatsufumi Oka,<sup>1</sup> Jeffrey M. Testani,<sup>2</sup> Michael S. Kiernan,<sup>1</sup> Mark J. Sarnak,<sup>1</sup> Wendy I. McCallum.<sup>1</sup> <sup>1</sup>Tufts Medical Center, Boston, MA; <sup>2</sup>Yale School of Medicine, New Haven, CT; <sup>3</sup>Tufts Medical Center Institute for Clinical Research and Health Policy Studies, Boston, MA.

**Background:** Angiotensin-converting enzyme inhibitors or angiotensin II receptor blockers (ACEI/ARB) are recommended for patients with heart failure. However, frequently ACEI/ARBs are discontinued or never started during hospitalizations for acute heart failure (AHF), despite evidence of their cardio- and renal-protective benefit.

**Methods:** Records for patients admitted to a quaternary academic center for AHF from 2015-2021 requiring hemodynamic monitoring were reviewed. Definitions included those who continued (ACEI/ARB on the admission and discharge list), started (ACEI/ARB on discharge list only), discontinued (ACEI/ARB on admission list only), or never started. Multivariable Cox regression models were used to examine the association of ACEI/ARB use with a composite outcome of death or AHF readmission and kidney failure (KF) requiring renal replacement therapy.

**Results:** We identified 727 patients admitted for AHF requiring hemodynamic monitoring and surviving to discharge. Mean (SD) age was 61 (14) years and eGFR was 57 (27) mL/min/1.73m<sup>2</sup>. 32% continued, 10% started, 20% discontinued and 38% never started ACEI/ARBs. Over a median follow-up of 5.7 months, compared to patients who continued on ACEI/ARBs, those who either stopped or never started ACEI/ARBs had higher risk of death or AHF hospitalization (Table). KF event numbers were small (n=54) but with similar trends not reaching statistical significance.

**Conclusions:** Among patients admitted for AHF requiring invasive hemodynamic monitoring, patients who were discontinued or never started on ACEI/ARB had an increased risk of death and heart failure hospitalization. Either this supports the importance

of ACEI/ARB benefit in this high acuity AHF cohort, or the inability to tolerate RAAS inhibition is a powerful prognostic factor.

**Funding:** Other NIH Support - NCATS

**Table.** Hazard ratios for composite of death and heart failure hospitalizations and kidney failure during follow-up based on ACEI/ARB use at admission and discharge for acute heart failure hospitalization

Composite of Death and Heart Failure Readmission				
	Continued	Started	Discontinued	Never Started
N	231	73	150	273

### Patiomer for Hyperkalemia Management in Patients Receiving Renin-Angiotensin-Aldosterone System Inhibitors for Heart Failure (DIAMOND): Prespecified Analysis of Patients With or Without Diabetes

Gerasimos Filippatos. On behalf of the DIAMOND Executive Committee National and Kapodistrian University of Athens, Athens, Greece.

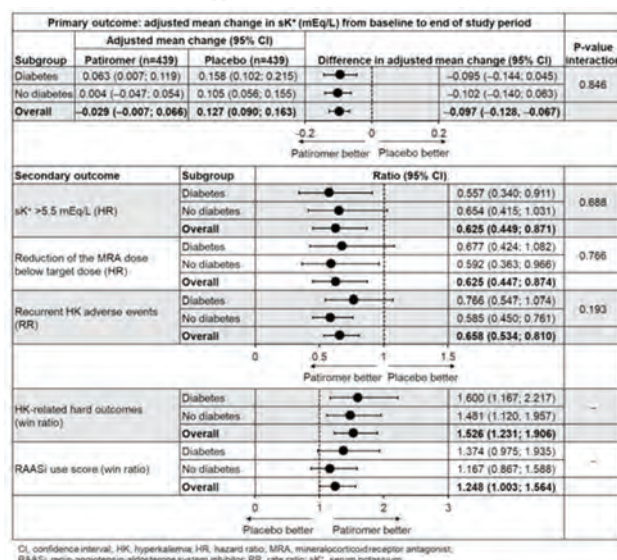

**Background:** Renin-angiotensin-aldosterone system inhibitors (RAASi) are the cornerstone of treatment for heart failure with reduced ejection fraction (HFrEF) and chronic kidney disease; hyperkalemia (HK) can result in suboptimal RAASi use. The DIAMOND trial showed that treatment with patiomer, a novel potassium binder, maintained lower serum potassium (sK<sup>+</sup>) vs placebo, and facilitated optimal RAASi therapy, including mineralocorticoid receptor antagonists (MRAs), in patients with HFrEF. This prespecified analysis of the trial assessed patient subgroups with or without diabetes.

**Methods:** Patients with HFrEF with current or history of HK entered a single-blinded run-in phase of up to 12 weeks in which patiomer and RAASi were optimized. Patients were then randomized (1:1) to receive either double-blind continued patiomer or placebo (patiomer withdrawal). The primary endpoint was the mean change in sK<sup>+</sup> from baseline to the end of the trial. Secondary endpoints included sK<sup>+</sup> >5.5 mEq/L, durable enablement of MRA at target dose, investigator-reported adverse events of HK, HK-related hard outcome endpoints, and a win ratio of novel RAASi use score based on the sequence of all-cause mortality, cardiovascular hospitalization, and RAASi use. This prespecified analysis was performed in patients with or without diabetes.

**Results:** Of 1195 patients entering the run-in phase, 878 were randomized, of whom 356 (41%) had diabetes. Patiomer's treatment effect vs placebo was consistent in patients both with and without diabetes (Figure).

**Conclusions:** Patiomer can effectively control sK<sup>+</sup> and facilitate optimization of MRAs in patients with HFrEF irrespective of diabetes.

**Funding:** Commercial Support - Vifor Pharma

were significantly higher for hypertension (OR 7.43) and dyslipidemia (OR 1.45) in the extremely high-risk group than in the low-risk group.

**Conclusions:** Patients with non-dialysis-dependent CKD demonstrate an increased cardiovascular risk factor burden with CKD progression. Extremely high-risk CKD is associated with difficulty in managing cardiovascular risk factors.

## TH-PO609

### Sex Hormone and Risk of Cardiovascular Disease and Mortality in Men and Women With CKD: A Systematic Review and Meta-Analysis

Ester Oh,<sup>1</sup> Courtney Steele,<sup>1</sup> Zhiying You,<sup>1</sup> Kristen L. Nowak,<sup>1</sup> Anna Jovanovich.<sup>1,2</sup> <sup>1</sup>University of Colorado - Anschutz Medical Campus, Aurora, CO; <sup>2</sup>VA Eastern Colorado Health Care System, Aurora, CO.

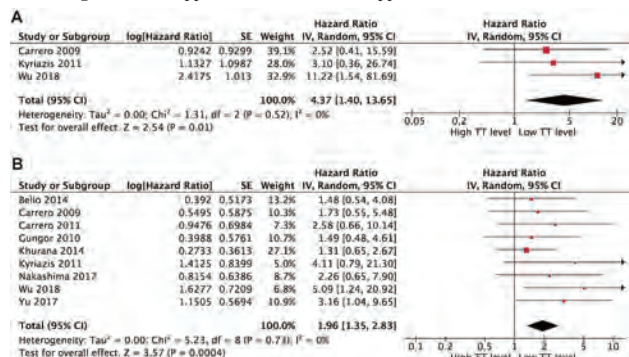

**Background:** Patients with chronic kidney disease (CKD) commonly experience sex hormone disturbances, which may be associated with risk of cardiovascular disease (CVD) and mortality. A few studies examined the association of sex hormone levels with the risk of cardiovascular outcomes and mortality in a CKD population; however, no studies to date have systematically evaluated current evidence on the association of sex hormone levels with the risk of CVD events and CVD and all-cause death in male and female patients.

**Methods:** Articles were systematically searched in CINAHL, Cochrane, and PubMed from February 1955 through October 2021. A total of 1,698 articles were independently screened by two reviewers, and 17 prospective cohort studies were included. The sex hormones studied were testosterone, estradiol, prolactin, dehydroepiandrosterone sulfate, and relaxin. A random-effects model was used to generate a pooled hazard ratio (HR) to evaluate the association of testosterone levels with the risk of CVD and all-cause death.

**Results:** The sample size ranged from 111-2,419 and the mean age of subjects ranged from 52-72 years. The clinical conditions of the patients included those with non-dialysis CKD (mean/median eGFR between 15–51 mL/min/1.73 m<sup>2</sup>) and dialysis CKD (mean/median vintage between 6–125 months). The majority of the studies examined testosterone levels (11 out of 17 studies) and studied only male patients (12 out of 17 studies). A lower testosterone level was associated with a higher risk of CVD death [HR 4.37 (1.40-13.65), P=0.01] (Fig. 1A) and all-cause death [HR 1.96 (1.35-2.83), P=0.0004] (Fig. 1B) in men with CKD.

**Conclusions:** A lower testosterone level was associated with a higher risk of CVD and all-cause death. There is a strong need for additional studies examining the association of female sex hormones with the cardiovascular and mortality risk.

**Funding:** NIDDK Support, Veterans Affairs Support

HR for CVD death (A) and all-cause death (B) comparing highest vs. lowest tertile of testosterone level in men with CKD

## TH-PO610

### Testosterone and Endothelial Function in Females With CKD

Nabilah Gulamhusein, Marriisa S. Buchan, Sofia B. Ahmed, Todd J. Anderson, Darlene Y. Sola, Milada Pajevic, Sandi M. Dumanski. *University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

**Background:** Cardiovascular disease is the leading cause of death in females with chronic kidney disease (CKD). Elevated testosterone has been associated with increased cardiovascular risk in postmenopausal women and premenopausal women with polycystic ovarian syndrome in the general population, but whether testosterone levels are associated with cardiovascular risk in this high-risk population is unknown. The goal of this study was to determine the association between testosterone levels and endothelial function, a validated measure of cardiovascular risk, in females with CKD.

**Methods:** A cross-sectional study was performed in premenopausal-aged females with CKD (18-51 years). Demographic and metabolic measurements were collected, alongside measurement of total testosterone. Standardized protocols were utilized to measure endothelial function, including right brachial artery flow-mediated dilation (FMD) and hyperemic velocity time integral (VTI). The associations between total testosterone and each outcome (FMD and VTI) were examined using multivariate linear regression analyses.

**Results:** 52 females with non-dialysis-dependent CKD (mean estimated glomerular filtration rate 84 ± 30 mL/min/1.73m<sup>2</sup>, range: 13 - 138 mL/min/1.73m<sup>2</sup>) and 9 females treated with dialysis (89% hemodialysis, 11% peritoneal dialysis) were enrolled, with a

mean age of 37 ± 8 years. Total testosterone levels ranged from <0.2nmol/L to 3.4nmol/L (mean testosterone 0.73 ± 0.63 nmol/L). No association was observed between estimated glomerular filtration rate and testosterone or body mass index and testosterone. There was a trend towards a negative relationship between age and testosterone (p=0.06). After adjusting for age and mean arterial pressure, testosterone was positively associated with VTI (R<sup>2</sup>=0.19, p<0.01), but not FMD (R<sup>2</sup>=0.05, p=0.43).

**Conclusions:** Reduced testosterone levels are associated with impaired microvascular endothelial function in young females with CKD, and may be an important marker of future cardiovascular risk. Given the high cardiovascular risk in the CKD population, further investigation into this risk factor is warranted.

**Funding:** Government Support - Non-U.S.

## TH-PO611

### Glomerular Hyperfiltration as Risk Factor of Major Adverse Cardiovascular Events After Acute Myocardial Infarction

Jin sug Kim, Kyung hwan Jeong, Hyeon Seok Hwang. *Division of Nephrology, Department of Internal Medicine, Kyung Hee University, Seoul, Republic of Korea.*

**Background:** A reduced glomerular filtration rate (GFR) is a definite risk factor for major adverse cardiovascular event (MACE) in patients with acute myocardial infarction (AMI). While glomerular hyperfiltration (GHF) is associated with early phases of kidney disease, it is unclear whether GHF is associated with higher risk of MACE.

**Methods:** We enrolled total 9,644 AMI patients with estimated GFR ≥60 mL/min/1.73 m<sup>2</sup> from prospective population-based national cohort between November 2011 and December 2015. GHF was defined as GFR > 90th percentile after adjustment for age, sex, lean body mass and history of diabetes and hypertension, systolic blood pressure, left ventricular ejection fraction (LVEF) and use of angiotensin converting enzyme inhibitor or receptor blocker. The primary endpoint was a combination of 3-year major MACEs after AMI occurrence.

**Results:** The GFR in 964 patients with GHF was 113.0 ± 13.1 and it was significantly higher than those in patients with normal GFR (87.7 ± 13.8; P < 0.001). The cumulative event rate of MACEs was significantly higher in patients with GHF (P = 0.033). In multivariable Cox-regression analysis, compared to patients with normal GFR, GHF increased the 1.39-fold risk of MACE (95% confidence interval [CI] 1.15-1.67). Patients with GHF had significantly higher risk of all-cause mortality (hazard ratio [HR] 1.70; 95% CI 1.30-2.23), cardiac death (HR 1.84; 95% CI 1.30-2.60) and ischemic stroke (HR 1.53; 95% CI 1.01-2.33). However, the risk of recurrent MI and rehospitalization for heart failure was not significantly increased.

**Conclusions:** The GHF was independently associated with increased risk of MACE after AMI and the hazardous effects of GHF was pronounced in all-cause mortality, cardiac death and ischemic stroke.

## TH-PO612

### The Association of Ejection Fraction With Cardiac Arrest and Myocardial Infarction Differed by eGFR

Katherine S. Ravi,<sup>1,2</sup> Thomas Mavrakas,<sup>3</sup> Aisha Khattak,<sup>7</sup> Karandeep Singh,<sup>6</sup> David M. Charytan,<sup>4,5</sup> Finnian R. McCausland,<sup>1,2</sup> *'Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>McGill University, Montreal, QC, Canada; <sup>4</sup>New York University School of Medicine, New York, NY; <sup>5</sup>NYU Langone Medical Center, New York, NY; <sup>6</sup>University of Michigan Medical School, Ann Arbor, MI; <sup>7</sup>The University of Texas Health Science Center at Houston, Houston, TX.*

**Background:** Advanced chronic kidney disease (CKD) and left ventricular (LV) systolic dysfunction are potent risk factors for cardiovascular events. Here we explore if the association of LV ejection fraction (EF) with cardiac arrest, myocardial infarction (MI), ischemic stroke, and all-cause mortality differs by eGFR across earlier stages of CKD.

**Methods:** Using registry data from 2004-2014 from five Mass General Brigham hospitals, we performed an observational cohort study of 17,962 patients with eGFR 30-90mL/min/1.73m<sup>2</sup>. Cardiovascular outcomes were ascertained from ICD-9 codes. Cox regression models, incorporating an interaction term for continuous eGFR and LVEF, were fit and adjusted for age, sex, race, hypertension, diabetes mellitus, coronary artery disease, and left ventricular mass index.

**Results:** Mean age was 67 years, and 51% were male. The mean eGFR was 66±16 mL/min/1.73m<sup>2</sup> and LVEF 54±13%. Over a median of 0.96 (0.14-4.84) years there were 437 cardiac arrests, 4,634 MIs, 1,549 ischemic strokes, and 6,282 deaths. The association of LVEF with cardiac arrest differed according to eGFR (P-interaction <0.01). While there was no evidence of association of LVEF with cardiac arrest in the lowest quartile of eGFR (adjusted hazard ratio (aHR) 1.02; 95% CI 0.92-1.13), for each 5% increase in LVEF there was a 21% lower risk of cardiac arrest in the highest quartile of eGFR (aHR 0.79; 95% CI 0.66-0.94; Table). The association of LVEF with MI also decreased as eGFR declined (Table). There was no evidence of effect modification of LVEF by eGFR for ischemic stroke or mortality (P-interaction >0.3 for both).

**Conclusions:** Among patients with eGFR 30-90mL/min/1.73m<sup>2</sup>, the association of LVEF with cardiac arrest disappears at lower (vs. higher) levels of kidney function and is less pronounced for MI at lower (vs. higher) levels of kidney function. Further research is required to elucidate what factors beyond LVEF drive these outcomes in the setting of more advanced kidney disease.

**Funding:** NIDDK Support

### Risk of cardiac arrest and myocardial infarction per each increase in left ventricular ejection fraction of 5% according to eGFR quartile

Outcome	eGFR (CKD-EPI, ml/min/1.73 m <sup>2</sup> ) aHR (95% CI)				P-Interaction
	Quartile 1 (30-54) N=4,598	Quartile 2 (55-68) N=4,400	Quartile 3 (69-80) N=4,671	Quartile 4 (81-90) N=4,293	
Cardiac Arrest	1.02 (0.92-1.13) P=0.72	0.97 (0.86-1.10) P=0.64	0.76 (0.63-0.92) P<0.01	0.79 (0.66-0.94) P=0.01	<0.01
Myocardial Infarction	0.94 (0.91-0.98) P<0.01	0.91 (0.87-0.95) P<0.001	0.90 (0.86-0.95) P<0.001	0.83 (0.79-0.88) P<0.001	<0.01

Abbreviations. eGFR: estimated glomerular filtration rate, CKD-EPI: Chronic Kidney Disease Epidemiology Collaboration, aHR: adjusted hazard ratio, CI: confidence interval, N: number.

P-Interaction reported for eGFR quartile.

### TH-PO613

#### Rapid Resting Heart Rate Is Associated With ESRD Independent of CVD Risk Factors

Chi pang Wen, Min Kuang Tsai. *National Health Research Institutes, Zhunan, Taiwan.*

**Background:** Rapid resting heart rate (RHR) has been associated with kidney diseases among individuals with cardiovascular diseases (CVD) but whether such an association exists among those without CVD, including ESRD, is unclear.

**Methods:** Data from a cohort comprising 442,714 adults who participated in a private medical screening program between 1996 and 2017 in Taiwan were analyzed. Participants' IDs were linked and identified 2,212 individuals undergoing dialysis or kidney transplant, with a median follow-up of 13 years. RHR was extracted from reading EKG performed in a supine position after rest. We grouped participants by RHR into 40-59, 60-69, 70-79, 80-89, and  $\geq 90$  beats/min. Cox proportional hazard model was used to develop hazard ratios (HRs) with 95% confidence intervals.

**Results:** Approximately one-fifth (22.2%) of the participants had rapid RHR at  $\geq 80$ /min, and one-third (32.6%) had normal RHR (60-69/min). Rapid RHR had a higher CKD proportion than those with normal RHR. RHR at 80-89/min was associated with a 24% increased ESRD (HR: 1.24, 95% CI: 1.09, 1.42), and, at  $\geq 90$ /min, with a 64% increased ESRD (HR: 1.64, 95% CI: 1.42, 1.90). Starting at 60/min, ESRD risk increased by 14% per 10 beats/min increase (HR: 1.14, 95% CI: 1.10, 1.19). By excluding participants with anyone with any of 4 CVD risks, such as smoking, hypertension, diabetes, or obesity, the significant increase remained in this new CVD risk-free sub-cohort.

**Conclusions:** Rapid resting heart rate ( $\geq 80$ /min) is associated with increased ESRD risks, independent of CVD risks. Rapid RHR should be considered as a risk factor for kidney-related diseases.

### TH-PO614

#### High-Density Lipoprotein Particle Size and Function Predict Cardiovascular Events in Patients With CKD

Anna V. Mathew, Yun Han, Vetalise K. Chefor, Yanhong Guo, Y. Eugene Chen, Brenda W. Gillespie, Rajiv Saran, Subramaniam Pennathur. *University of Michigan, Ann Arbor, MI.*

**Background:** Chronic Kidney Disease (CKD) is a risk factor for cardiovascular disease (CVD) and 40% of patients with CKD exhibit clinical CVD with greater than 10-fold mortality compared to healthy subjects. Lipoprotein particle size profiles measured with nuclear magnetic resonance spectroscopy and cholesterol efflux capacity (CEC), a metric of high-density lipoprotein (HDL) function predict CVD in the general population. CEC also predicts incident CV events in patients with CKD, but the association of lipoprotein particle size with incident CV events and its link with CEC in CKD patients is unknown.

**Methods:** We quantified the CEC and lipoprotein particle profile of 325 subjects with stage 3-4 CKD (median follow-up of 2.5 years). To assess the association of lipoprotein particle size with incident CV events, we created Cox regression models controlled for various clinical factors, including age, gender, race, history of CVD, diabetes, systolic blood pressure, C reactive protein, renal function, urine protein, and total cholesterol.

**Results:** CEC [HR=1.46, p=0.03] was associated with CV events after adjustment for clinical factors. Increased HDL particle size [HR=2.56, p=0.002], Large HDL particles [HR=1.41, p=0.001], and HDL-cholesterol levels [HR=1.04, p=0.001] associate with decreased time to CV events, while a decrease in small VLDL particles [HR=0.97, p=0.02] particles increased the risk of CV events after adjusting for clinical factors.

**Conclusions:** CEC, HDL cholesterol, and particle size paradoxically were associated with incident CV events in the CKD population adding evidence to the altered HDL metabolism in patients with CKD-associated CVD.

#### Association of DNA Methylation Signatures With Premature Aging and Cardiovascular Death in Patients With ESKD: A Pilot Study

Keiichi Sumida,<sup>1</sup> Khyobeni Mozhui,<sup>1</sup> Xiaoyu Liang,<sup>1</sup> Zhongji Han,<sup>1</sup> Yamini Mallisetty,<sup>1</sup> Csaba P. Kovacs,<sup>1,2</sup> <sup>1</sup>The University of Tennessee Health Science Center, Memphis, TN; <sup>2</sup>VA Memphis Medical Center, Memphis, TN.

**Background:** Patients with ESKD display features of premature aging, with extremely high cardiovascular (CV) mortality at a younger age. There is strong evidence that changes in DNA methylation (DNAm) contribute to age-related pathologies; however, little is known about their association with premature aging and CV death in patients with ESKD.

**Methods:** We assayed genome-wide DNAm in a pilot case-control study of 30 hemodialysis (HD) patients who died of CV events as cases and 30 matched HD controls who remained alive during follow-up of 2.0 years. DNAm was profiled on the Illumina EPIC BeadChip. Four established DNAm clocks (i.e., Horvath-, Hannum-, Pheno-, and GrimAge) were used to estimate epigenetic age (DNAmAge), and epigenetic age acceleration (EAA) were derived as the residuals of regressing DNAmAge on chronological age (cAge). An epigenome-wide association study (EWAS) was performed to identify differentially methylated CpGs associated with CV death, adjusted for cAge, sex, race, and top 5 principal components.

**Results:** Patient characteristics were similar between cases and controls, with a mean age of 63 years, 48% male, and 54% African American in both groups. All clocks performed well at predicting cAge (correlation between DNAmAge and cAge of  $r=0.76-0.89$ ). GrimAge had the largest absolute deviation from chroAge (mean, +21.3 years) (**Figure**). There was no significant difference in EAA between groups. For EWAS, a CpG (cg22305782) in *FBXL19* had the strongest association with CV death with significantly lower DNAm in cases vs. controls ( $P_{FDR}=2.0 \times 10^{-6}$ ). *FBXL19* is involved in inflammation, apoptosis, and cell migration.

**Conclusions:** Overall, we observed more accelerated aging in patient with ESKD, although there was no difference in EAA between groups. EWAS suggests a potential novel DNAm biomarker for premature CV death in ESKD.

Correlation between cAge and GrimAge in 60 HD patients

#### Circulating Small Non-Coding RNA Profiles for Premature Cardiovascular Death in Hemodialysis Patients

Keiichi Sumida,<sup>1</sup> Surabhi Naik,<sup>1</sup> Zhongji Han,<sup>1</sup> Yamini Mallisetty,<sup>1</sup> Cem Kuscu,<sup>1</sup> Csaba P. Kovacs,<sup>1,2</sup> Canan Kuscu.<sup>1</sup> <sup>1</sup>The University of Tennessee Health Science Center, Memphis, TN; <sup>2</sup>VA Memphis Medical Center, Memphis, TN.

**Background:** Patients with ESKD suffer from disproportionately high cardiovascular disease (CVD) burden. Circulating small non-coding RNAs (c-sncRNAs) have emerged as novel epigenetic regulators and are suggested as novel biomarkers and therapeutic targets for CVD; however, little is known about the associations of c-sncRNAs with premature CV death in ESKD.

**Methods:** Using plasma samples of 50 hemodialysis (HD) patients who died of CV events (cases) and of 50 HD controls who remained alive during a median follow-up of 2.0 years, matched by age, sex, race, and dialysis vintage, we performed c-sncRNAs profile using next-generation sequencing to identify differentially expressed microRNAs (miRNAs) between cases and controls. The association of differentially expressed miRNAs with CV mortality were examined using multivariable conditional logistic regression.

**Results:** Patient characteristics were similar between cases and controls, with a mean age of 63 years, 48% male, and 54% African American in both groups. Among 613 miRNAs detected in the plasma, five miRNAs (i.e., miR-129-1-5p, miR-500b-3p, miR-125b-1-3p, miR-3648-2-5p, and miR-3150b-3p) were identified to be significantly differentially expressed between cases and controls with cut-offs of  $p < 0.01$  and  $\log_2$  fold-change ( $\log_2FC$ )  $> 1$ . When using more stringent cut-offs of  $p$ -adjusted  $< 0.05$  and  $\log_2FC > 1$ , only miR-129-1-5p, which is involved in oxidative stress, inflammation, and cardiovascular pathophysiology, remained significant with higher levels of miR-129-1-5p

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

in cases than in controls (**Figure A**). The expression levels of miR-129-1-5p were significantly associated with risk of CV death (adjusted ORs [95%CI], 1.03 [1.00-1.06] for 1 increase in DESeq2 normalized counts), independent of matched variables, diabetes, history of CVD, and serum albumin and phosphorus levels (**Figure B**).

**Conclusions:** Circulating miR-129-1-5p may serve as a novel biomarker for premature CV death in ESKD.

(A) MiR129-1-5p normalized counts in plasma of cases and controls; and (B) Odds ratios and 95% confidence interval for cardiovascular death associated with circulating miR-129-1-5p

### Dysregulation of Fatty Acid Binding Protein and Its Relationship With Inflammatory Biomarkers in Atrial Fibrillation and Renal Dysfunction

**Vinod K. Bansal,** Emily Bontekoe, Mark Jaradeh, Madeline T. Allen, Debra Hoppensteadt, Fakiha Siddiqui, Omer M. Iqbal, Jawed Fareed, Mushabbar Syed. *Loyola University Health System, Maywood, IL.*

**Background:** Atrial Fibrillation (AF) represents a complex multi-factorial syndrome and is associated with renal compromise. Thrombo-inflammation plays an important role in the pathogenesis of cardiorenal syndrome associated with AF. Fatty acid binding proteins (FABPs) regulate transport of fatty acids and other lipophilic mediators including eicosanoids. While upregulation of FABPs have been reported in AF and their relationship with inflammatory biomarkers is not fully understood. Liver fatty acid binding protein (L-FABP) also known as FABP-1 is a 14kDa protein expressed in the liver and tubular kidney cells. Kidney damage and other pathologic conditions secondary to AF result in the marked upregulation of this protein. This study was aimed to investigate the association of FABP with inflammatory biomarkers in the AF patient population and renal compromise.

**Methods:** Citrated blood samples from 70 AF patients with confirmed clinical diagnosis of atrial fibrillation were enrolled in this study. For comparison purposes normal human plasma collected from 50 normal healthy male and female individuals were used. Plasma prepared from these patients and normal individuals were analyzed for FABP-1 and such inflammatory biomarkers as IL-6, TNF $\alpha$  and inflammasome, using commercially available ELISA methods. All results were compiled and correlation analysis between FABP-1 levels and biomarkers of inflammation were carried out using GraphPad prism software.

**Results:** The AF patients showed a marked increase in FABP levels ( $13.1 \pm 1.1$  ng/ml) with a broad range ( $2.1 \pm 37.2$ ) in comparison to normal ( $5.1 \pm 0.2$  ng/ml SEM) with a range of ( $3.4 - 9.2$  ng/ml). Marked increases in IL-6, TNF $\alpha$  and inflammasome were also noted (2 - 4 fold). FABP-1 showed varying degrees of positive correlation with inflammatory biomarkers.

**Conclusions:** These studies suggest that baseline plasma levels of FABP-1 is markedly increased in AF patients with renal compromise. Other biomarkers of inflammation are also upregulated and demonstrate varying degrees of correlation suggesting inter-relationship between FABP-1 and inflammatory processes. These results also suggest that atrial fibrillation and secondary damage to the kidneys contribute to the marked increase in FABP-1 and AF patients.

### The Risks and Benefits of Aspirin for Primary and Secondary Prevention of Mortality, Cardiovascular Disease, and Kidney Failure

**Jonathan J. Taliercio,**<sup>1</sup> Georges Nakhoul,<sup>1</sup> Ali Mehdi,<sup>1</sup> Daohang Sha,<sup>3</sup> Jesse D. Schold,<sup>1</sup> Matthew R. Weir,<sup>2</sup> Scott E. Kasner,<sup>3</sup> Mohamed Hassanein,<sup>4</sup> Sankar D. Navaneethan,<sup>5</sup> Alan S. Go,<sup>6</sup> Claudia M. Lora,<sup>7</sup> Bernard G. Jaar,<sup>8</sup> Teresa K. Chen,<sup>8</sup> Jing Chen,<sup>9</sup> Jiang He,<sup>9</sup> Mahboob Rahman.<sup>10</sup> <sup>1</sup>Cleveland Clinic, Cleveland, OH; <sup>2</sup>University of Maryland Baltimore, Baltimore, MD; <sup>3</sup>University of Pennsylvania, Philadelphia, PA; <sup>4</sup>The University of Mississippi Medical Center, Jackson, MS; <sup>5</sup>Baylor College of Medicine, Houston, TX; <sup>6</sup>University of California San Francisco School of Medicine, San Francisco, CA; <sup>7</sup>University of Illinois Chicago, Chicago, IL; <sup>8</sup>Johns Hopkins University, Baltimore, MD; <sup>9</sup>Tulane University, New Orleans, LA; <sup>10</sup>Case Western Reserve University, Cleveland, OH.

**Background:** CKD is a risk-enhancing factor for cardiovascular disease (CVD) and mortality. The role of aspirin use is unclear in this population since many clinical studies exclude or underrepresent CKD patients. We investigated the risks and benefits of aspirin use in primary and secondary prevention of CVD in the Chronic Renal Insufficiency Cohort (CRIC) Study.

**Methods:** We identified and analyzed 3,664 CRIC subjects based on absence or presence of pre-existing CVD between 2003 -2018. We performed an intention-to-treat analysis and used multivariable Cox proportional hazards model to examine associations of time varying aspirin use with mortality, a composite of CVD events (myocardial infarction, stroke, and peripheral arterial disease), kidney failure (including dialysis and transplant), and major bleeding.

**Results:** The overall cohort included 3,664 subjects, including 2,578 (70.3%) individuals in the primary prevention group. Mean age was 57 (+/- 11) years, 46% women, 42% black, 47% diabetic, and 86% hypertensive. The mean estimated Glomerular Filtration Rate (eGFR) was 45 ml/min/1.73 m<sup>2</sup> and median 24-hour urine protein was 0.2 grams/day. Median follow up was 11.5 (IQR: 7.4-13) years. Aspirin was not protective in all-cause mortality in those without pre-existing CVD (HR 0.89; 95% CI, 0.75 to 1.05, p=0.15) or those with CVD (HR 1.02; 95% CI, 0.91 to 1.14, p=0.74). Aspirin was not associated with a reduction of the CVD composite in primary prevention (HR 0.97; 95% CI, 0.77 to 1.23, p=0.79) and in secondary prevention (HR 1.08; 95% CI, 0.89 to 1.31, p=0.46). Aspirin use was not associated with kidney failure (HR 0.95; 95% CI, 0.8 to 1.13, p=0.55) or major bleeding (HR 0.84; 95% CI, 0.61 to 1.15, p=0.27) in primary prevention.

**Conclusions:** Aspirin use in CKD patients was not associated with reduction in primary or secondary CVD events, progression to kidney failure, or major bleeding. More clinical studies are needed to assess the use of aspirin in primary and secondary prevention in the CKD population.

Outcome	Aspirin Users		Secondary Prevention	
	Primary Prevention		Hazard Ratio (95% CI)	p-value
Death	0.89(0.75-1.05)	0.16	1.02(0.91-1.14)	0.74
CVD Death	1.1(0.78-1.54)	0.59	1.11(0.91-1.34)	0.30
CVD Composite	0.94(0.74-1.19)	0.59	1.12(0.95-1.32)	0.16
Kidney Failure	0.96(0.81-1.15)	0.66	0.99(0.87-1.12)	0.83
Major Bleeding	0.85(0.63-1.15)	0.29	0.82(0.66-1.03)	0.08

## TH-PO619

### Early Discontinuation of Aspirin Among Patients With CKD Undergoing Percutaneous Coronary Intervention With a Drug Eluting Stent: A Meta-Analysis

**Maria Carolina Festa,** Sathiepan Rasasingam, Abhinav Sharma, Thomas Mavrakas. *McGill University Health Centre, Montreal, QC, Canada.*

**Background:** Conflicting evidence exists to support whether short duration of dual antiplatelet therapy (DAPT) followed by P2Y12 inhibitor monotherapy reduces bleeding complications after coronary artery drug-eluting stent (DES) insertion, compared with standard 12-month DAPT, particularly among patients with CKD who are at increased risk of bleeding.

**Methods:** A Medline search identified randomized trials comparing up to 3 months of DAPT followed by P2Y12 inhibitor monotherapy versus twelve months of DAPT after insertion of a DES for any indication. Trials were included if they reported ischemic or bleeding outcomes among patients with CKD (eGFR < 60). The primary outcome was a composite of all-cause mortality, cardiac or cerebrovascular events, stent thrombosis (MACCE), and major bleeding events. Secondary outcomes were the individual components of the primary outcome, and clinically significant bleeding. The relative risk (RR) was estimated using a random-effects model.

**Results:** Six randomized trials were included for a total of 4,996 patients with CKD (14% of the trial population). Early discontinuation of aspirin was associated with a similar incidence of the primary outcome among patients with CKD compared with twelve-month DAPT (RR 0.97; 95% confidence interval [95% CI] 0.73-1.30). The relative risk of MACCE was also similar between the two arms (RR 1.02; 95% CI 0.85-1.23). The risk of clinically significant bleeding was significantly lower with early discontinuation of aspirin (RR 0.60; 95% CI 0.46-0.78).

**Conclusions:** P2Y12 inhibitor monotherapy after a shortened course of DAPT is associated with a similar risk of ischemic events and a lower risk of bleeding events after DES insertion among patients with CKD compared with 12-month DAPT.

**Funding:** Government Support - Non-U.S.

Relative risk of MACCE and of clinically significant bleeding with P2Y12 inhibitor monotherapy after shortened DAPT (P2Y12 monotherapy) versus 12-month DAPT (DAPT).

## TH-PO620

## A Deep Learning System for Retinal Vessel Calibre Improves Cardiovascular Risk Prediction in Asians With CKD

Cynthia C. Lim,<sup>1</sup> Crystal Chong,<sup>2</sup> Gavin Tan,<sup>2,3</sup> Ching-Yu Cheng,<sup>2</sup> Charumathi Sabanayagam,<sup>2,3</sup> <sup>1</sup>Singapore General Hospital, Singapore, Singapore; <sup>2</sup>Singapore Eye Research Institute, Singapore, Singapore; <sup>3</sup>Duke-NUS Medical School, Singapore, Singapore.

**Background:** Cardiovascular disease (CVD) and mortality is elevated in chronic kidney disease (CKD). Retinal vessel calibre in retinal photographs is associated with CVD risk and automated measurements from retinal photographs by a deep learning system (DLS) may aid CVD risk prediction.

**Methods:** Retrospective cohort study of 838 Chinese, Malay and Indian participants aged 40-80 years with CKD (estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m<sup>2</sup>) at the baseline visit (2004-2011) of the population-based Singapore Epidemiology of Eye Diseases Study. Retinal vessel calibre measurements were generated by DLS: central retinal arteriolar equivalent and central retinal venular equivalent at Zone<sub>B</sub> and Zone<sub>C</sub> (CRAE<sub>B</sub>, CRAE<sub>C</sub> and CRVE<sub>B</sub>, CRVE<sub>C</sub>, respectively). Incidence of CVD (defined as non-fatal acute myocardial infarction (AMI) and stroke, and death due to AMI, stroke and heart failure) in those who were free of CVD at baseline was ascertained until 31st December 2018. Risk factors (traditional and retinal-DLS measures) were examined using Cox proportional hazards regression models. Improvement in risk prediction by addition of retinal vascular parameters was assessed by net reclassification improvement (NRI).

**Results:** Baseline mean age was 67.8 (SD 8.8) years and eGFR 47.3 (11.8) ml/min/1.73 m<sup>2</sup>. Incidence of CVD was 30.3%. Multivariable regression models adjusting for traditional risk factors showed that eGFR and retinal parameters independently predicted 10-year CVD risk (Table 1). Addition of eGFR, retinal arteriolar calibre and retinopathy improved overall reclassification of incident CVD beyond traditional risk factors with NRI of 38.2% for Zone<sub>B</sub> and 44.9% for Zone<sub>C</sub> (p<0.001 for both).

**Conclusions:** Addition of kidney function and retinal vessel calibre measurements by DLS improved CVD risk prediction among Asians with CKD.

Table 1. Multivariable regression models for incident cardiovascular disease among Asians with chronic kidney disease

	Model 1	Model 2	Model 3	Model 4
	HR (95% CI)	HR (95% CI)	HR (95% CI)	HR (95% CI)

CRVE <sub>B</sub> , per 50 decrease in vessel calibre			1.15 (0.96-1.39)	
CRAE <sub>C</sub> , per 50 decrease in vessel calibre				1.44 (1.18-1.79)
CRVE <sub>C</sub> , per 50 decrease in vessel calibre				1.25 (0.99-1.48)

HR = hazard ratio; CI = confidence interval; HDL = high-density lipoprotein; LDL = low-density lipoprotein; eGFR = estimated glomerular filtration rate; CRAE = central retinal arteriolar equivalent; CRVE = central retinal venular equivalent; CRAE<sub>B</sub> = central retinal arteriolar equivalent at Zone B; CRVE<sub>B</sub> = central retinal venular equivalent at Zone B; CRAE<sub>C</sub> = central retinal arteriolar equivalent at Zone C; CRVE<sub>C</sub> = central retinal venular equivalent at Zone C.

Model 1: Traditional risk factors (age, sex, ethnicity, total cholesterol, HDL cholesterol, current smoking, systolic blood pressure, diastolic blood pressure). Model 2: Model 1 + eGFR. Model 3: Model 1 + eGFR + retinopathy. Model 4: Model 1 + eGFR + CRAE<sub>B</sub> + CRVE<sub>B</sub> + CRAE<sub>C</sub> + CRVE<sub>C</sub>.

## TH-PO621

## Associations Between Blood Pressure (BP) and Risk of CKD: A Clinically Adjudicated Study of 0.5 Million Chinese Adults

Sarah Y. Ng,<sup>1</sup> Rebecca J. Sardin,<sup>1</sup> Peiling Chen,<sup>2</sup> Guang Chen,<sup>2</sup> Jingjing Wang,<sup>2</sup> Shuiqin Cheng,<sup>2</sup> Wenjing Fan,<sup>2</sup> Xia Liu,<sup>2</sup> Zhengming Chen,<sup>1</sup> Zhihong Liu,<sup>2</sup> Yiping Chen,<sup>1</sup> Colin Baigent,<sup>1</sup> Natalie Staplin,<sup>1</sup> William G. Herrington.<sup>1</sup> <sup>1</sup>MRC Clinical Trial Service Unit and Epidemiological Studies Unit, Oxford, United Kingdom; <sup>2</sup>National Clinical Research Center for Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.

**Background:** Observational studies from China show a positive, log-linear relationship between high BP with CKD, but have not adjudicated outcomes.

**Methods:** The China Kadoorie Biobank is a cohort of 0.5 million adults from 5 urban and 5 rural areas of China aged 30-79 years at recruitment between 2004-2008. Hospitalized kidney outcomes were ascertained by prospective linkage to health insurance databases with medical notes reviewed by nephrologist adjudicators. Cox models estimated associations between long-term average (i.e. "usual") BP with risk of CKD. Analyses were performed by time since recruitment and by kidney diagnosis.

**Results:** During a median of 11.1 years follow-up, 3,337 participants were hospitalized with CKD. Mean (SD) eGFR of adjudicator-confirmed CKD was 37.6 (27.0) ml/min/1.73m<sup>2</sup>. Each 10 mmHg higher usual SBP and 5 mmHg higher DBP were associated with a 28% (HR 1.28, 95% CI 1.25-1.32) and 24% higher risk (1.24, 1.21-1.28) of incident CKD (Fig 1). BP-CKD associations were unmodified by time since recruitment but the strengths of associations differed by kidney diagnosis. HRs for diabetic kidney disease, hypertensive nephropathy and glomerulonephritis per 10 mmHg higher SBP were 1.24 (1.14-1.35), 1.65 (1.52-1.78) and 1.18 (1.06-1.32) respectively (Fig 2).

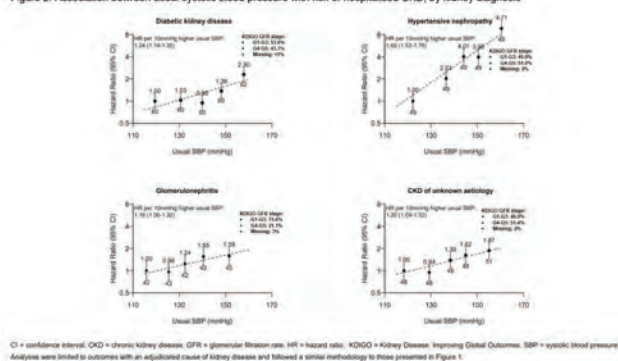

**Conclusions:** Higher BP is linked to a range of kidney diseases with stronger associations in hypertensive nephropathy. Randomized data are needed to confirm causality.

Figure 1. Association between usual systolic blood pressure and diastolic blood pressure with risk of hospitalized CKD

BP = blood pressure; CI = confidence interval; CKD = chronic kidney disease; DBP = diastolic blood pressure; eGFR = estimated glomerular filtration rate; HR = hazard ratio; SBP = systolic blood pressure; uACR = urine albumin:creatinine ratio. Analyses were done in 482,884 participants, using unadjusted CKD outcomes identified from health insurance data and by adjudication of kidney outcomes. Participants with self-reported prior chronic disease (including CKD) or extremely high/low values of BP were excluded. HRs were adjusted for age, sex, region, income, education, adiposity, smoking status, alcohol intake and diabetes status. The area of each square is inversely proportional to the variance of the category-specific log risk. Corresponding 95% CIs are plotted as lines. HRs were shown above each square and the numbers of events below. Hospitalized CKD outcomes were a composite defined as health insurance-linked CKD-10 coded CKD or glomerular

Figure 2. Association between usual systolic blood pressure with risk of hospitalised CKD, by kidney diagnosis

CI = confidence interval; CKD = chronic kidney disease; eGFR = glomerular filtration rate; HR = hazard ratio; KDIGO = Kidney Disease: Improving Global Outcomes; SBP = systolic blood pressure. Analyses were limited to outcomes with an adjudicated cause of kidney disease and followed a similar methodology to those presented in Figure 1.

## TH-PO622

## Association of Isolated Diastolic Hypertension With Risk of Renal and Cardiovascular Outcomes in CKD: A Report From the Chronic Renal Insufficiency Cohort (CRIC) Study

Saud A. Alsaleh, Mirela A. Dobre, Sarah Delozier, Mahboob Rahman, Nishigandha Pradhan. University Hospitals, Cleveland, OH.

**Background:** Isolated Diastolic Hypertension (IDH) has drawn increased interest after the new definition of hypertension proposed by the 2017 ACC/AHA guidelines. Our analysis examined the prevalence of IDH, and the association of IDH with adverse renal and CV outcomes in patients with CKD

**Methods:** Participants in the CRIC Study; a multicenter observational cohort of ethnically diverse patients with CKD aged 21-74 years. IDH was defined as Systolic BP ≤ 130 and DBP > 80. Outcomes were composite kidney events (50% decline in eGFR or onset of ESKD), composite CV events (MI, CHF, stroke, PAD) and all-cause mortality. Cox proportional hazards models adjusted for demographic and clinical covariates

**Results:** The cohort included 5621 participants with a mean age of 59 years; 44% were females and 43% were Black. 51% had diabetes. IDH was present in 6.1% of participants at baseline. After median follow up of 17 years, there was no statistically significant association between IDH and composite kidney outcome (Hazard ratio (HR) 1.17 95% CI 0.93-1.47, p 0.18). The findings were consistent in subgroups by age ≤ 60 years or > 60 years (HR 1.14 95% CI 0.88-1.48, p=0.31 and HR 1.55 95% CI 0.84-2.83, p 0.16 respectively). No association was found between presence of IDH and risk of composite CV events (HR 0.91 (95% CI 0.65-1.27, p=0.58) or all-cause mortality (HR 0.82, 95% CI 0.57-1.19, p 0.30)

**Conclusions:** The Prevalence of IDH in this cohort of participants with CKD patients is 6.1%, similar to that in non-CKD populations. IDH is not associated with risk of adverse kidney and CV events irrespective of age

Association between IDH and clinical outcomes, compared to participants with normal systolic and diastolic BP

	Hazard Ratio (95% CI)	
	Unadjusted	Adjusted
Composite of MI, Stroke, CHF, PAD		
Isolated Diastolic hypertension	.55 (.41, .73), p < .001*	.91 (.65, 1.27), p = .576
Isolated Systolic hypertension	1.71 (1.52, 1.93), p < .001*	1.20 (1.03, 1.39), p = .022*
Systolic Diastolic hypertension	1.46 (1.26, 1.69), p < .001*	1.41 (1.17, 1.71), p < .001*
All-cause mortality		
Isolated Diastolic hypertension	.42 (.30, .58), p < .001*	.82 (.57, 1.19), p = .304
Isolated Systolic hypertension	1.58 (1.38, 1.80), p < .001*	1.11 (.94, 1.30), p = .221
Systolic Diastolic hypertension	1.23 (1.04, 1.45), p = .017*	1.42 (1.16, 1.74), p < .001*

## TH-PO623

# Comparison of Cardiovascular Event Predictability Between the 2009 CKD-EPI Equation and the New 2021 CKD-EPI Equations in a Korean CKD Cohort: From the KNOW-CKD Study

Ji Hye Kim, Kook-Hwan Oh. *Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

**Background:** 2009 CKD-EPI creatinine (Cr) equation is commonly used for estimated glomerular filtration rate (eGFR). However, it contains race component which is not a biological factor and may cause biased racism. Therefore, 2021 CKD-EPI Cr and creatinine-cystatin C (Cr-Cys) equations omitting race factor were introduced. This study evaluated if new 2021 equations have better predictability for cardiovascular events (CVE) and all-cause mortality in Korean chronic kidney disease (CKD) cohort.

**Methods:** This study included 2207 CKD patients enrolled in KoreaN Cohort Study for Outcome in Patients With Chronic Kidney Disease (KNOW-CKD). eGFR was calculated using 2009 Cr (eGFR<sub>Cr</sub>), 2021 Cr and Cr-Cys (eGFR<sub>Cr-Cys</sub>) equations. Receiver operating characteristic (ROC) and net reclassification improvement (NRI) were used to compare predictability of each CKD-EPI equation for CVE and CVE and all-cause mortality combined.

**Results:** Overall prevalence of CVE and all-cause mortality were 9% and 7%. For CVE predictability, 10 mL/min/1.73m<sup>2</sup> increase in eGFR was associated with lower odds only in unadjusted model in all three equations (2009 eGFR<sub>Cr</sub>: HR 0.90, 95% CI [0.86, 0.95], 2021 eGFR<sub>Cr</sub>: HR 0.91, 95% CI [0.87, 0.96], 2021 eGFR<sub>Cr-Cys</sub>: HR 0.90, 95% CI [0.85, 0.95]). For CVE and all-cause mortality combined, 10 mL/min/1.73m<sup>2</sup> increase in eGFR was associated with lower odds in all three equations including multivariable model (2009 eGFR<sub>Cr</sub>: HR 0.93, 95% CI [0.89, 0.98], 2021 eGFR<sub>Cr</sub>: HR 0.94, 95% CI [0.89, 0.98], 2021 eGFR<sub>Cr-Cys</sub>: HR 0.92, 95% CI [0.87, 0.96]). Area under curves of ROC for both CVE (0.715, 0.716, 0.716) and CVE and all-cause mortality combined (0.747, 0.747, 0.751) did not show significant differences among the three equations. Compared to 2009 equation, both 2021 Cr (NRI 0.013, 95% CI [-0.002, 0.028], *p*=0.09) and Cr-Cys (NRI -0.001, 95% CI [-0.031, 0.029], *p*=0.94) equations did not show improved CVE predictability. Similar findings were observed for CVE and all-cause mortality combined for both 2021 Cr (NRI -0.019, 95% CI [-0.039, 0], *p*=0.06) and Cr-Cys (NRI -0.002, 95% CI [-0.023, 0.018], *p*=0.82).

**Conclusions:** Neither 2021 CKD-EPI Cr, nor Cr-Cys equations showed significant improvement in predicting CVE and all-cause mortality in Korean CKD patients compared to 2009 CKD-EPI Cr equation.

## TH-PO624

# Structural Equation Modeling of Kidney Function Biomarkers Improves Incident Cardiovascular Risk Estimation

Ryosuke Fujii,<sup>1,2</sup> Roberto Melotti,<sup>1</sup> Martin Gögele,<sup>1</sup> Laura Barin,<sup>1</sup> Dariush Ghasemi-Semeskandeh,<sup>1</sup> Giulia Barbieri,<sup>1</sup> Peter Paul Pramstaller,<sup>1</sup> Cristian Pattaro,<sup>1</sup> <sup>1</sup>Eurac Research, Bolzano, Italy; <sup>2</sup>Fujita Health University, Toyoake, Japan.

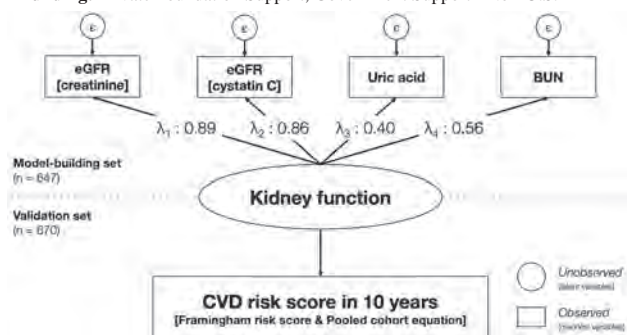

**Background:** While there is no biochemical trait that alone can represent the true kidney function of an individual, formulas have been developed to obtain the estimated glomerular filtration rate (eGFR) based on serum creatinine (eGFR<sub>crea</sub>) or cystatin C (eGFR<sub>cys</sub>) or their combination (eGFR<sub>crea-cys</sub>). However, a more general method that takes advantage of kidney function-related changes observed in other biomarkers is lacking.

**Methods:** In the Microisolates in South Tyrol (MICROS) study, we applied structural equation modeling (SEM) to derive a latent kidney function biomarkers based on serum creatinine, cystatin C, eGFR<sub>crea</sub>, and eGFR<sub>cys</sub> estimated with the CKD-Epi equations, uric acid (UA), and blood urea nitrogen (BUN), and accounting for sex and age (*n*=647). In an independent longitudinal dataset (*n*=670), we assessed the ability of the identified latent trait to predict increased risk of cardiovascular disease (CVD) over 10 years.

**Results:** Based on standard goodness-of-fit statistics, the best model was selected that included eGFR<sub>crea</sub>, eGFR<sub>cys</sub>, UA, and BUN. The corresponding latent trait showed a C-statistics [95% CI] of 0.70 [0.65–0.74] for a 10-year prediction of a Framingham risk score of ≥5%. The corresponding C-statistics for CKD-EPI eGFR<sub>crea</sub>, eGFR<sub>cys</sub>, and eGFR<sub>crea-cys</sub> were of 0.63 [0.58–0.68], 0.69 [0.65–0.74], and 0.66 [0.62–0.71], respectively.

**Conclusions:** The SEM-derived latent kidney trait showed better performance in 10-year CVD risk prediction over conventional eGFR estimation methods.

# Association Between Homocysteinemia and Mortality in CKD: A Propensity-Score Matched Analysis Using NHANES-National Death Index

Jinsuk Bae,<sup>1,2</sup> Jehun Song,<sup>1,2</sup> Hyuk Huh,<sup>3</sup> Eunjin Bae,<sup>3</sup> Jeonghwan Lee,<sup>4,6</sup> Jung Pyo Lee,<sup>4,6</sup> Jong Soo Lee,<sup>1,2</sup> Kyung Don Yoo.<sup>1,2</sup> <sup>1</sup>University of Ulsan College of Medicine, Songpa-gu, Seoul, Republic of Korea; <sup>2</sup>Ulsan University Hospital, Ulsan, Dong-gu, Republic of Korea; <sup>3</sup>Gyeongsang National University Graduate School of Medicine, Jinju, Gyeongsangnam-do, Republic of Korea; <sup>4</sup>Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; <sup>5</sup>Inje University Busan Paik Hospital, Busan, Republic of Korea; <sup>6</sup>Seoul National University College of Medicine, Seoul, Republic of Korea.

**Background:** Hyperhomocysteinemia (HHcy) is considered a risk factor for cardiovascular disease (CVD) including chronic kidney disease (CKD). In this study, we investigated the association between serum homocysteine (Hcy) level and mortality according to the presence of CKD.

**Methods:** Our study included data of 9,895 participants from the 1999–2016 National Health and Nutrition Examination Surveys (NHANES). Multivariable-adjusted Cox proportional hazards models using propensity-score were used to examine dose-response associations between Hcy level and mortality.

**Results:** Of 9,895 participants, 1032 (21.2%) participants were diagnosed with CKD. In a multivariate Cox regression analysis including all participants, Hcy level was associated with all-cause mortality, compared with the 1<sup>st</sup> quartile in the fully adjusted model (2<sup>nd</sup> quartile: hazard ratio (HR) 1.751, 95% confidence interval (CI) 1.348–2.274, *p*<0.001; 3<sup>rd</sup> quartile: HR 2.220, 95% CI 1.726–2.855, *p*<0.001; 4<sup>th</sup> quartile: HR 3.776, 95% CI 2.952–4.830, *p*<0.001). In the non-CKD group, there was a significant association with all-cause mortality; however, this finding was not observed in the CKD group. The observed pattern was similar after propensity score matching. In the non-CKD group, overall mortality increased in proportion to Hcy concentration (2<sup>nd</sup> quartile: HR 2.195, 95% CI 1.299–3.709, *p* = 0.003; 3<sup>rd</sup> quartile: HR 2.607, 95% CI 1.570–4.332, *p*<0.001; 4<sup>th</sup> quartile: HR 3.720, 95% CI 2.254–6.139, *p*<0.001). However, the risk of all-cause mortality according to the quartile of Hcy level did not increase in the CKD group.

**Conclusions:** This study found a correlation between the Hcy level and mortality rate only in the non-CKD group. These altered risk factor patterns may be attributed to protein-energy wasting or chronic inflammation status that is accompanied by CKD.

## TH-PO626

# Calcification of Branches Is Superior to Abdominal Aortic Calcification in Predicting Mortality of Hemodialysis Patients

Wen Shi, Xiaoliang Zhang. *Southeast University, Nanjing, China.*

**Background:** Vascular calcification (VC) is considered to be an important risk factor of cardiovascular events, which contributes to the leading cause of death in hemodialysis (HD) patients. Inspired by an extreme example of VC in dialysis patients, calciphylaxis, we hypothesized VC of branches was a better predictor of mortality than abdominal aortic calcification (AAC).

**Methods:** A cohort study was established including 237 HD patients. The calcification volume of abdominal aorta and its branches in CT were quantitatively evaluated through software 3DSlicer4.11. Patients were followed up to death or September 2020, and were randomly divided into training set and testing set in a ratio of 7:3. Lasso regression analysis, Cox regression and nomograms were used to construct a predictive model.

**Results:** The prevalence of total VC is 95.36%. AAC is the most prevalent (88.61%), followed by calcification of internal iliac artery (85.65%). AUC of Time-dependent ROC by internal iliac artery and mesenteric artery calcification for predicting mortality is significantly higher than the others. Internal iliac artery calcification (IIAC) was screened out as the most valuable predictor for all-cause death among the arteries. IIAC (HR=1.503, *P*<0.001), serum albumin (HR=0.911, *P*<0.001) and the history of cardio-cerebrovascular diseases (HR=1.735, *P*=0.017) were independent factors of mortality in HD patients. The nomogram based on Cox regression model is shown in Figure 1. The clinical decision curve shows the model's high value of clinical application. (Figure 2).

**Conclusions:** Calcification of branches, especially IIAC, is a better predictor for mortality of HD patients than AAC. Our concern with calcification of large arteries in HD patients needs to be shifted to smaller branches.

Decision curves of Cox regression model from training dataset(A) and testing dataset(B).

## TH-PO627

### Cardiorenal Syndrome and Kidney Disease Progression in Patients With Heart Failure or CKD: Is the Heart Leading the Way?

Carla Alexandra R. Santos Araujo,<sup>3,1</sup> Luís C. Mendonça,<sup>3</sup> Daniel Seabra,<sup>2</sup> Filipa Bernardo,<sup>4</sup> Marisa Pardal,<sup>4</sup> João Couceiro,<sup>4</sup> Hugo M. Martinho,<sup>4</sup> Daniel Dias,<sup>5</sup> Ricardo J. Dinis-Oliveira,<sup>6,7</sup> Cristina Gavina,<sup>2</sup> Tiago Taveira Gomes.<sup>5</sup>  
<sup>1</sup>Nephrology Department, Pedro Hispano Hospital, Matosinhos, Portugal; <sup>2</sup>Cardiology Department, Pedro Hispano Hospital, Matosinhos, Portugal; <sup>3</sup>UnIC@RISE, Department of Surgery and Physiology, Faculty of Medicine of the University of Porto, Porto, Portugal; <sup>4</sup>Medical Department, AstraZeneca, Lisbon, Portugal; <sup>5</sup>Department of Community Medicine, Information and Decision in Health, Faculty of Medicine, University of Porto, Porto, Portugal; <sup>6</sup>TOXRUN – Toxicology Research Unit, University Institute of Health Sciences, Advanced Polytechnic and University Cooperative (CESPU), CRL, Gandra, Portugal; <sup>7</sup>Department of Public Health and Forensic Sciences, and Medical Education, Faculty of Medicine, University of Porto, Porto, Portugal.

**Background:** Simultaneous occurrence of heart failure (HF) and chronic kidney disease (CKD) is known as cardiorenal syndrome (CRS). This study aims to assess CKD progression and estimate 1-year risk of end-stage renal disease (ESRD) in patients with HF, CKD and CRS.

**Methods:** Retrospective analysis of an integrated healthcare institution database from 2008-2019 was performed. We defined 4 incident cohorts: **Control** - 75 years old; **HF** - HF patients without CKD; **CKD** - CKD patients without HF; **CRS** - patients with HF and CKD. HF was defined as either: i) ejection fraction (EF)  $\leq 40\%$  and NT-proBNP  $\geq 200$ pg/mL OR BNP  $\geq 100$ pg/mL; ii) EF  $> 40\%$  in the presence of structural cardiac abnormalities. CKD was defined as eGFR  $\leq 60$ mL/min (EPI-CKD). Kidney disease progression was evaluated by eGFR drop of  $\geq 50\%$  from baseline and ESRD defined by eGFR  $< 15$ mL/min or any ICD-9/10 codes for dialysis. Hazard ratios and 95% confidence intervals were estimated using Cox regression models adjusted for age, sex, hypertension, myocardial infarction, stroke, peripheral artery disease and type 2 diabetes.

**Results:** We identified 3973 patients with HF, 13990 with CKD, 6784 with CRS and 16182 controls. Patients were 75-77 years old, mostly female and well treated with CV drugs. eGFR drop  $\geq 50\%$  from baseline was observed early at 60 days (7% in CKD, 9% in HF and 13% in CRS) and maintained throughout the observation period. ESRD risk was 4.0 in HF patients (3.1-5.3) and 4.1 in CKD patients (3.3-5.1). CRS was associated with the highest risk of ESRD development: 9.9 (7.9-12.4) (Figure 1).

**Conclusions:** Kidney disease progression was frequent in cardiorenal disease patients and occurred early in disease development. CRS establishment added a significant risk of early and fast ESRD. Although HF patients begin with higher eGFR, overall ESRD risk is similar which deserves future analysis.

### Cardiorenal Syndrome and Death Risk in Heart Failure or CKD Patients: An Urgent Call for Action

Carla Alexandra R. Santos Araujo,<sup>1,2</sup> Luís C. Mendonça,<sup>1</sup> Daniel Seabra,<sup>5</sup> Filipa Bernardo,<sup>3</sup> Marisa Pardal,<sup>3</sup> João Couceiro,<sup>3</sup> Hugo M. Martinho,<sup>3</sup> Daniel Dias,<sup>4</sup> Ricardo J. Dinis-Oliveira,<sup>6,7</sup> Cristina Gavina,<sup>5</sup> Tiago Taveira Gomes.<sup>4</sup>  
<sup>1</sup>UnIC@RISE, Department of Surgery and Physiology, Faculty of Medicine of the University of Porto, Portugal, Porto, Portugal; <sup>2</sup>Nephrology Department, Pedro Hispano Hospital, Matosinhos, Portugal, Matosinhos, Portugal; <sup>3</sup>Medical Department, AstraZeneca, Lisbon, Portugal, Lisbon, Portugal; <sup>4</sup>Department of Community Medicine, Information and Decision in Health, Faculty of Medicine, University of Porto, Portugal, Porto, Portugal; <sup>5</sup>Cardiology Department, Pedro Hispano Hospital, Matosinhos, Portugal, Matosinhos, Portugal; <sup>6</sup>TOXRUN – Toxicology Research Unit, University Institute of Health Sciences, Advanced Polytechnic and University Cooperative (CESPU), CRL, Portugal, Gandra, Portugal; <sup>7</sup>Department of Public Health and Forensic Sciences, and Medical Education, Faculty of Medicine, University of Porto, Porto, Portugal, Porto, Portugal.

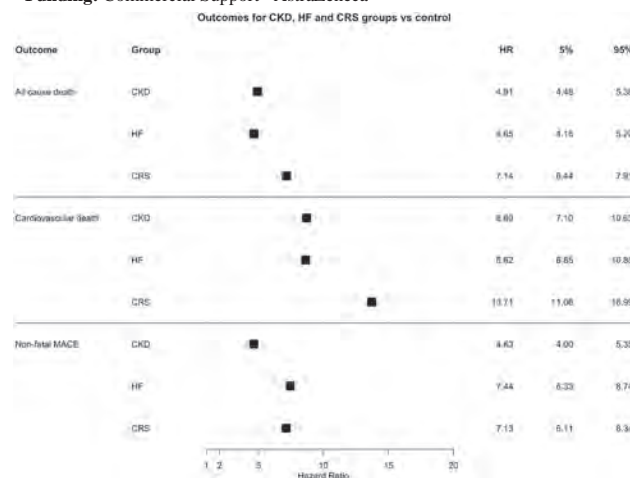

**Background:** Simultaneous occurrence of heart failure (HF) and chronic kidney disease (CKD) is known as cardiorenal syndrome (CRS). This study aims to estimate 1-year CRS risk in HF or CKD patients and 1-year risk of all-cause death, cardiovascular (CV) death and non-fatal major CV events (MACE) in HF, CKD and CRS patients.

**Methods:** Retrospective analysis of integrated healthcare institution database from 2008-2019. We defined 4 cohorts: **Control** - 75 years old; **HF** - HF patients without CKD; **CKD** - CKD patients without HF; **CRS** - HF and CKD patients. HF was defined as: i) ejection fraction (EF)  $\leq 40\%$  and NT-proBNP  $\geq 200$ pg/mL OR BNP  $\geq 100$ pg/mL; ii) EF  $> 40\%$  in the presence of structural cardiac abnormalities. CKD was defined as eGFR  $\leq 60$ mL/min (EPI-CKD). Hazard ratios and 95% confidence intervals were estimated by Cox regression models adjusted for age, sex, hypertension, myocardial infarction, stroke, peripheral artery disease and type 2 diabetes.

**Results:** We identified 3973 HF patients, 13990 with CKD, 6784 with CRS and 16182 controls. Patients were 75-77 years old, mostly female and well treated with CV drugs. On follow-up 1293 CKD patients (9.2%) and 593 HF patients (14.9%) developed CRS. All-cause death risk was 4.7 (4.1-5.2) for HF and 4.9 (4.5-5.4) for CKD. CV death risk was 8.6 (6.8-10.8) for HF and 8.7 (7.1-10.6) for CKD. Non-fatal MACE risk was 7.4 (6.3-8.7) for HF, 4.6 (4.0-5.3) for CKD, and 7.1 (6.1-8.3) for CRS. CRS was associated with the highest risk of all-cause and CV death: 7.1 (6.4-7.9) and 13.7 (11.7-17.0), respectively (Figure 1). Most events occurred in first 90 days.

**Conclusions:** Cardiorenal disease was associated with very high short-term risk of CRS or death, with highest risk in CRS patients. These results support an urgent need for improved prevention of cardiorenal disease and CRS.

## TH-PO629

### Cardiac Biomarkers and Kidney Function: A Bidirectional Mendelian Randomization Study

Cassianne Robinson-Cohen,<sup>1</sup> Nicholas Vartanian,<sup>1</sup> Elvis A. Akwo,<sup>1</sup> Adriana Hung,<sup>1</sup> Talat Alp Ikizler,<sup>1</sup> Nisha Bansal.<sup>2</sup>  
<sup>1</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>2</sup>University of Washington, Seattle, WA.

**Background:** Observational studies report strong associations between circulating cardiac biomarkers and kidney function. However, this evidence is vulnerable to bias from confounding and reverse causation. The aim of this study was to explore the causal direction of the relationship between kidney function and cardiac biomarkers using a bidirectional Mendelian Randomization (MR) approach.

**Methods:** Four cardiac biomarkers were studied, including NT-proBNP (N-terminal pro-B-type natriuretic peptide), galectin-3, growth differentiation factor-15 (GDF-15) and soluble ST2. Two-sample MR was used to estimate the causal effect of eGFR on these

biomarkers and then performed in the opposite direction. We used as instruments genetic variants associated with creatinine-based eGFR in a large trans-ethnic genome-wide association study (GWAS) among individuals from the Chronic Kidney Disease Genetics Consortium (CKDGen, n=765,348) and UK Biobank (UKB, n=436,581), explaining up to 8.9% of the variance in eGFR, and GWAS of cardiac biomarkers from the SCALLOP consortium (n=21,757).

**Results:** Genetically predicted lower levels of eGFR were associated with higher levels of galectin-3 ( $p=2.3\times10^{-9}$ ) and GDF-15 ( $p=3.9\times10^{-4}$ ), but not NT-proBNP or soluble ST2 (Figure 1). In the other direction, there was evidence of a causal relationship between higher soluble ST2 and lower eGFR ( $p=0.0032$ ), but not for any of the other biomarkers (Figure 2).

**Conclusions:** This MR study suggests that elevated galectin-3 and GDF-15, but not NT-proBNP or soluble ST2, are a consequence rather than a cause of reduced eGFR. Our findings also support a role for ST2 as a risk factor for reduced eGFR. Future work is needed to understand the mechanisms underlying these relationships and potential clinical utility of these biomarkers.

TH-PO630

Association Between CKD Progression and Heart Failure: A Retrospective Cohort Study

Silvia J. Leon Mantilla,<sup>1</sup> Reid Whitlock,<sup>1</sup> Clara Bohm,<sup>2</sup> Paul Komenda,<sup>2</sup> Claudio Rigatto,<sup>2</sup> Navdeep Tangri.<sup>2</sup> <sup>1</sup>Seven Oaks General Hospital, Winnipeg, MB, Canada; <sup>2</sup>University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada.

**Background:** Heart failure (HF) and chronic kidney disease (CKD) are strongly interlinked through multifaceted inter-organ cross-talk that increase the risk of the co-existence of both conditions. HF and CKD separately and in combination, are associated with high symptom burden, mortality risk and increased healthcare costs. We sought to determine if heart failure is a risk factor for adverse renal outcomes and death in patients with CKD and to quantify the magnitude of its effect.

**Methods:** We conducted a retrospective cohort study using administrative health data from Manitoba, Canada. We included all adults ( $\geq 18$  years) with prevalent CKD (as defined by KDIGO using CDK-EPI eGFR  $<60$  mL/min/1.73 m<sup>2</sup> and/or proteinuria for over 3 months) between January 1st, 2007, and Jan 1st, 2018. We identified a subgroup of patients with HF at baseline. We examined the association of interim HF event (as time-dependent exposure) with study outcomes using time-dependent Cox models adjusted for demographics, comorbidities, eGFR, UACR, and medications (e.g., RAASi, beta blockers). The primary composite outcome was  $\geq 40\%$  decline in estimated glomerular filtration rate (eGFR), renal replacement therapy (chronic dialysis or kidney transplant), or all-cause mortality; DD40 events.

**Results:** Of the 18,880 prevalent CKD, 3,650 (19%) had history of HF at baseline. The mean eGFR was  $51 \pm 26$  mL/min/1.73m<sup>2</sup> and the median UACR was 6.20 mg/mmol (IQR: 1.4 - 32.4). There were 4,546 (24%) patients with at least 1 interim HF event, with a median time to first interim HF event of 1.9 years. In time-dependent analysis, those with HF at baseline had a higher risk of DD40 events as well as its components after an interim HF event compared to those without interim HF events adjusted HR for DD40 (aHR): 1.98; 95%CI: 1.81-2.17. Similarly, in those without HF at baseline, interim HF hospitalization was associated with higher risk of DD40 events compared to those without interim HF events (aHR: 1.59; 95%CI: 1.50-1.69).

**Conclusions:** Interim heart failure is associated with an increased risk of a composite outcome of all-cause mortality, ESKD, and  $\geq 40\%$  decline in eGFR in patients with CKD irrespective of history of HF. These findings strongly support efforts to optimize treatment for primary and secondary prevention of heart failure hospitalizations in patients with CKD.

TH-PO631

Race-Free KDIGO Risk Categories and CVD Mortality Among Black US Adults, 1999-2019

Juanly N. Rodriguez, Yelena Drexler, Richard Barrios, Neda Shahoori, Farid Isaac, Gabriel Contreras, Tali Elfassy. Filtering 305 University of Miami School of Medicine, Miami, FL.

**Background:** Mortality from cardiovascular disease (CVD) is high among those with CKD. Remarkable racial disparities in CVD risk and progression to ESKD exist between Black and non-Black adults. Elimination of the race coefficient to estimate GFR, while helping to mitigate these disparities, results in higher prevalence estimates for CKD among Blacks. In this study, we describe CVD mortality rates among Black US adults by KDIGO risk category using a race-free eGFR equation.

**Methods:** The National Health and Nutrition Examination Survey is a representative sample of US adults. We included 10,658 Black adult participants (1999-2018) with mortality data through 2019 linked from the National Death Index. Using serum creatinine, eGFR was calculated using the 2009 CKD-EPI and 2021 race-free CKD-EPI equations. Albumin-to-creatinine ratio (ACR in mg/g) was measured from spot urine samples. Participants were classified into four KDIGO risk categories (low, intermediate, high, or very high risk) based on ACR and eGFR. CVD mortality (CVD-M) was defined through ICD-10 codes as diseases of the heart or cerebrovascular disease. We used age adjusted Poisson regression models to estimate incidence densities (ID) per 1,000 person years (PY) and ID ratios (IDRs) for CVD-M.

**Results:** The population was comprised of 55.6% women with a mean age of 43 years. After an average follow-up of 9.9 years, 1,348 (11.5%) died of any cause and 438 (3.8%) died of CVD. Rates of CVD-M were not significantly different when using the 2009 CKD-EPI or 2021 race-free CKD-EPI equation to classify KDIGO risk. After removing the race coefficient, compared to the lowest KDIGO risk (ID: 2.3/1,000PY, 95% CI: 1.9, 2.8), CVD-M was 115% greater (IDR: 2.15, 95% CI: 1.69, 2.73) with intermediate KDIGO risk (ID: 5.0/1,000 PY, 95% CI: 4.2, 6.1), 200% greater (IDR: 3.00, 95% CI: 2.20, 4.09) with high KDIGO risk (ID: 7.0/1,000PY, 95% CI: 5.4, 9.1), and 428% greater (IDR: 5.28, 95% CI: 3.59, 7.78) with very high KDIGO risk (ID: 12.4/1,000PY, 95% CI: 9.3, 16.5).

**Conclusions:** Among Black US adults, CVD-M rates were similar using the 2009 CKD-EPI or 2021 race-free CKD-EPI equation. CVD-M rates were substantially higher with greater KDIGO risk, independently of the use of a race coefficient.

TH-PO632

Deep Learning Retinal Image Analysis for the Detection of CKD and Cardiovascular Risk Factors in the General Population

Donal J. Sexton,<sup>1,4</sup> Roman Romero-Ortuno,<sup>2,4</sup> Silvín P. Knight,<sup>2</sup> Rozenn Dahyot,<sup>3,5</sup> Rose Anne M. Kenny,<sup>1,4</sup> Ali Karaali.<sup>1,5</sup> <sup>1</sup>Irish Longitudinal Study on Ageing (TILDA), Trinity College Dublin, Dublin, Ireland; <sup>2</sup>FRAILMatics group, TILDA, Trinity College Dublin., Dublin, Ireland; <sup>3</sup>Maynooth University, Maynooth, Ireland; <sup>4</sup>St James's Hospital, Dublin, Ireland; <sup>5</sup>ADAPT Research Centre, Dublin, Ireland.

**Background:** Retinal blood vessel patterns provide an opportunity to personalize an individuals risk assessment for CKD and cardiovascular risk factors (CVRF). In this study we propose a deep learning (DL) based prediction tool that uses retinal images from the Irish Longitudinal Study on Ageing (TILDA) to detect the existence of CKD in community dwelling individuals aged 50 years and over.

**Methods:** TILDA is a stratified random sample of the general population of Ireland. N=4569 participants underwent a detailed health assessment including retinal photography. We developed a convolutional neural network architecture inputting a single retinal image per participant for the prediction of CKD & CVRF. Binary cross entropy was used as a loss function. Analyses were conducted on the FRAILMatics HPC "Tinney".

**Results:** See Table 1 & Image 1 for results.

**Conclusions:** A DL retinal image algorithm has good discrimination for CKD, eGFR and CVRF in community dwelling individuals. The prediction emphasis of our DL algorithm focuses on slightly different structures within the retinal image to predict serum creatinine versus serum cystatin.

Results of Deep Learning Retinal Image Analysis for CKD

Classification Neural Network (Image only)	AUC
CKD by Serum Creatinine	0.68
CKD by Serum Cystatin C	0.71
Regression Neural Network (image only)	MAE
Age	0.84 yrs
Systolic BP	16.55 mmHg
eGFR CKDEPI Creatinine	13.9 mL/min
eGFR CKDEPI Cystatin C	14.8 mL/min

Attention Map demonstrating where within the retinal image the algorithm is focusing to predict CKD by Cystatin C. Red-Yellow-Blue in descending order of importance.

TH-PO633

ESKD as a Risk Factor for Acute Coronary Syndrome in Younger Patients

Millan L. Whittier, Meloney Oliveira, Augustine Manadan. Rush University Medical Center, Chicago, IL.

**Background:** End-stage kidney disease (ESKD) is a known risk factor for cardiovascular (CV) disease including acute coronary syndrome (ACS), arrhythmias and congestive heart failure. ESKD patients are at higher risk of CV related mortality compared to the general population. There is presently a paucity of population-based studies of ESKD as a risk factor for ACS in young patients. We aimed to compare the presence of ACS in hospitalized patients aged 18-40 to patients >40 years with and without ESKD while controlling for traditional CV risk factors.

**Methods:** Data was extracted from the 2016-2019 US National Inpatient Sample (NIS) database. Hospitalizations of adult patients with ACS as the principal diagnosis, with and without ESKD as the secondary diagnosis were evaluated. Age was divided categorically into 2 groups: adults 18-40 and >40 years. The primary outcome was the development of ACS. MV logistic regression analysis was used to adjust for confounders.

**Results:** There were 121,099,120 adult hospital discharges in 2016-2018 NIS database. Of those, 74,225 between 18-40 and 2,626,129 >40 years were hospitalized with a principal diagnosis of ACS. Traditional CV risk factors were associated with ACS hospitalizations in both age groups. In MV analysis of the 18-40 age group, the odds ratio (OR) for ESKD was 1.24 (P<0.001) (Table 1). Above the age 40, the OR for ESKD was 0.95 (P<0.001) (Table 1).

**Conclusions:** In younger patients, ESKD was strongly associated with ACS hospitalization in addition to the traditional CV risk factors. In the older group, traditional CV risk factors predominated in the association with ACS.

Multivariate Analysis of CV Risk Factors

Variables	ACS between ages 18 to 40			ACS in greater than age 40		
	Odds Ratio	P-Value	95% Confidence Interval	Odds Ratio	P-value	95% Confidence Interval
Diabetes	1.22	<0.001	1.166-1.287	1.17	<0.001	1.159-1.177
Hypertension	2.33	<0.001	2.256-2.435	0.95	<0.001	0.942-0.957

Heart Failure: A Risk Factor for Progression to ESKD

Sydney E. Hartsell,<sup>1,2</sup> Xiangyang Ye,<sup>1,2</sup> Amara Sarwal,<sup>1,2</sup> Robert E. Boucher,<sup>1,2</sup> Adhish Agarwal,<sup>1</sup> Guo Wei,<sup>1,2</sup> Srinivasan Beddhu.<sup>1,2</sup> <sup>1</sup>The University of Utah School of Medicine, Salt Lake City, UT; <sup>2</sup>VA Salt Lake City Health Care System, Salt Lake City, UT.

**Background:** Despite much interest in cardiorenal syndrome, there is a paucity of data on whether heart failure (HF) is a risk factor for progression to end-stage kidney disease (ESKD).

**Methods:** We used the VA Informatics and Computing Infrastructure (VINCI) platform to identify a national cohort of veterans (N=993,929) with CKD stages 3A, 3B or 4 (two or more outpatient CKD-EPI eGFR 15 to <60 ml/min/1.73m<sup>2</sup> taken 60 days apart) from January 2010 to December 2015. Index date was defined as the date of second outpatient creatinine with follow-up through June 30, 2018. ICD9/10 codes defined baseline comorbidities and prevalent HF. We identified ESKD by linkage to the US Renal Data System, and mortality from VA CDW data. In separate multivariate Cox regression models, we related baseline HF with time to ESKD alone and a composite of ESKD/ death adjusted for demographics, comorbidities and baseline blood pressure.

**Results:** 19.4% had HF at baseline. The distribution of CKD 3A, 3B and 4 were 68.3%, 25.3% and 6.4% respectively. There were 21,706 ESKD events over 4.7 million person-years of follow-up, 409,539 deaths over 4.6 million person-years and 420,505 ESKD/death events over 4.6 million person-years of follow up. In the entire CKD cohort, HF was significantly associated with higher hazard of ESKD (HR1.27, 95% CI 1.23-1.31) and ESKD/death (HR1.90, 95% CI 1.89-1.92). Compared to those without HF and with stage 3A CKD, those with HF and more advanced CKD had higher risk of ESKD and ESKD/death (Fig 1 and Table).

**Conclusions:** HF is an independent risk factor for ESKD progression in CKD. Interventions that target HF might slow CKD progression to ESKD.

**Funding:** NIDDK Support, Other NIH Support - R01 DK118219 – NIDDK; R01 AG074592 – NIA; R01 DK128640 – NIDDK, Veterans Affairs Support

Adjusted Hazard of ESKD or Composite ESKD/Death

CKD Stage & Baseline HF Status	HR of ESKD	95% CI	HR of Composite	95% CI
3A & No HF	1 (reference)	—	1 (reference)	—
3A & HF	1.62	1.51-1.73	2.02	2.00-2.04
3B & No HF	4.11	3.95-4.28	1.40	1.39-1.41
3B & HF	5.45	5.15-5.76	2.62	2.59-2.65
4 & No HF	19.92	19.12-20.75	2.35	2.32-2.38

Association of Microscopic Hematuria With Long-Term Mortality in Patients With Hypertensive Crisis

Saeyoung Jeong,<sup>1</sup> Mi-yeon Yu,<sup>1</sup> Jeong-Hun Shin,<sup>2</sup> Byung Sik Kim.<sup>2</sup> <sup>1</sup>Division of Nephrology, Department of Internal Medicine, Hanyang University College of Medicine, Hanyang University Guri Hospital, Guri, Republic of Korea; <sup>2</sup>Division of Cardiology, Department of Internal Medicine, Hanyang University College of Medicine, Hanyang University Guri Hospital, Guri, Republic of Korea.

**Background:** Microscopic hematuria is associated with an increased risk of chronic kidney disease and death in the general population. However, there are no data on the long-term mortality risk associated with microscopic hematuria among patients with hypertensive crisis. We hypothesized that microscopic hematuria at initial presentation in patients with hypertensive crisis would be associated with higher long-term mortality.

**Methods:** This retrospective study included patients admitted to the emergency department between 2016 and 2019 for hypertensive crisis (systolic blood pressure ≥180 mmHg or diastolic blood pressure ≥110 mmHg). Microscopic hematuria was defined as ≥3 red blood cells per high-power field on microscopic evaluation of urine.

**Results:** Among the 3,595 patients, 1,359 (37.8%) had microscopic hematuria. The 3-year all-cause mortality in patients with and without microscopic hematuria were 25.5% and 16.3%, respectively. After adjusting for confounding variables, patients with microscopic hematuria (adjusted HR, 1.30; 95% CI, 1.10–1.54) showed a significantly higher risk of 3-year all-cause mortality than patients without microscopic hematuria. In a subgroup analysis according to presence of proteinuria, microscopic hematuria was a significant predictor of all-cause mortality in patients without proteinuria (adjusted HR, 1.61; 95% CI, 1.28–2.03), but not in patients with proteinuria.

**Conclusions:** Microscopic hematuria was a significant predictor of all-cause mortality in patients with hypertensive crisis. Our study suggests that microscopic hematuria can serve as a useful prognostic marker and permit early detection of patients with an increased risk of death. Clinicians in the emergency department should consider screening for kidney function using urine analysis during the initial assessment of patients with hypertensive crisis.

### Renal B-Cell Activating Factor Correlates With Worsened Allograft Pathology and Inflammation in a Rat Model of Antibody-Mediated Rejection

Sarah E. Panzer, Nancy A. Wilson. *University of Wisconsin-Madison, Madison, WI.*

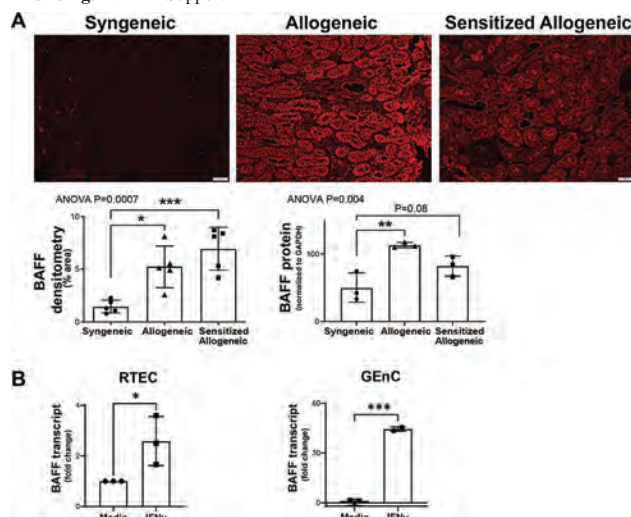

**Background:** B-cell activating factor (BAFF) promotes B cell maturation and correlates with renal disease activity in lupus nephritis. We hypothesized renal allograft BAFF levels are increased in chronic-active antibody-mediated rejection (AMR).

**Methods:** A minor mismatch rat kidney transplant model was utilized, with experimental groups of syngeneic, allogeneic, and sensitized allogeneic (donor blood transfusion 21 days pre-transplant) recipients. Allograft pathology and donor-specific antibody levels (DSA) were assessed 6 months post-transplant. Renal tubular epithelial cell (RTEC) and glomerular endothelial cell (GEnC) BAFF gene expression was determined, *in vitro*.

**Results:** Allogeneic and sensitized allogeneic recipients had chronic-active AMR and elevated renal BAFF levels compared to syngeneic recipients (Figure 1A). Renal BAFF correlated with glomerulitis ( $R^2=0.39$ ,  $P=0.01$ ), peritubular capillaritis ( $R^2=0.60$ ,  $P=0.0007$ ), microvascular inflammation ( $R^2=0.64$ ,  $P=0.0003$ ), C4d ( $R^2=0.43$ ,  $P=0.008$ ), intragraft macrophages ( $R^2=0.48$ ,  $P=0.004$ ), vimentin ( $R^2=0.46$ ,  $P=0.006$ ), and IgG DSA ( $R^2=0.69$ ,  $P=0.0001$ ). RTEC and GEnC generated BAFF transcript in response to IFN $\gamma$  stimulation, *in vitro* (Figure 1B).

**Conclusions:** Renal BAFF levels were elevated in chronic-active AMR and correlated with allograft inflammation (microvascular inflammation, intragraft macrophages, and C4d) and epithelial de-differentiation (vimentin). Thus, renal BAFF contributes to allograft inflammation and resident renal cells are a source of BAFF. As anti-BAFF therapeutics are now clinically available, further studies are needed of the effects BAFF has on renal tissues and its therapeutic effectiveness in AMR.

**Funding:** NIDDK Support

**Figure 1. A)** BAFF (red) was increased in allogeneic and sensitized allogeneic recipients compared to syngeneic recipients. **B)** RTEC and GEnC stimulated with IFN $\gamma$  generated BAFF transcript.

### Normothermic Ex Vivo Kidney Perfusion Preserves ATP Generation and Graft Function After Warm Ischemia, Which Is Further Enhanced With Pharmacologic Mitochondrial Protection

Masataka Kawamura,<sup>1,2</sup> Catherine Parmentier,<sup>1,3</sup> Samrat Ray,<sup>1,3</sup> Sergi Clotet Freixas,<sup>1,3</sup> Emmanuel Nogueira,<sup>1,3</sup> Yuki Noguchi,<sup>1,3</sup> Bhranavi Arulratnam,<sup>1,3</sup> Sujani Ganesh,<sup>1,3</sup> Ana Konvalinka,<sup>1,3</sup> Markus Selzner,<sup>1,3</sup> Lisa Robinson.<sup>2,4</sup>  
<sup>1</sup>Toronto General Hospital, Toronto, ON, Canada; <sup>2</sup>The Hospital for Sick Children, Toronto, ON, Canada; <sup>3</sup>University Health Network, Toronto, ON, Canada; <sup>4</sup>University of Toronto, Toronto, ON, Canada.

**Background:** Normothermic Ex-vivo kidney machine perfusion (NEVKP) is a novel preservation technique. We recently determined that NEVKP preserves the expression of proteins involved in mitochondrial biogenesis in kidneys. We hypothesize that ex vivo machine perfusion will replenish energy levels in mitochondria, thereby restoring mitochondrial function and reducing injury in kidney grafts. AP39, a mitochondria-

targeted hydrogen sulfide donor, has been shown to stimulate mitochondrial electron transport and improve cellular bioenergetic function. Here, we investigated whether administering AP39 during NEVKP protects mitochondrial function and protects renal grafts from ischemia reperfusion injury.

**Methods:** Porcine kidneys were subjected to either 0 or 60 minutes of warm ischemia (WI) followed by 5 hours of static cold storage (SCS) or NEVKP. The warm ischemia grafts were subsequently divided into three groups: SCS group, NEVKP group, and a group in which AP39 was additionally administered during NEVKP (NEVKP + AP39) (Fig. 2.). After contralateral nephrectomy, grafts were auto-transplanted and animals were followed for 3 days. Renal function and ATP levels were assessed.

**Results:** All animals (n=5-6 in each group) survived the follow-up period. Grafts preserved with NEVKP had lower serum creatinine (SrCr) on postoperative day 3 compared to the SCS group (Fig. 1). Treatment with NEVKP + AP39 further reduced SrCr when compared to the NEVKP group (HB vs SCS vs NEVKP vs NEVKP + AP39:  $1.7\pm0.3$  vs  $12.7\pm1.1$  vs  $7.6\pm2.8$  vs  $3.5\pm1.1$  mg/dl, mean $\pm$ SD). We measured ATP in biopsy-derived cell suspensions from grafts stored using SCS, NEVKP, and NEVKP + AP39. ATP levels were increased in the NEVKP group compared with SCS group at the time of pre-implantation and this level was further increased when AP39 was administered. (SCS vs NEVKP vs NEVKP + AP39:  $21.9\pm11.4$  vs  $73.6\pm9.3$  vs  $121.6\pm36.3$  nM/1000cells).

**Conclusions:** For grafts subjected to warm ischemia, NEVKP has the potential to preserve ATP generation and graft function, which is further enhanced with mitochondria-targeted hydrogen sulfide donor, AP39.

### HIF1 $\alpha$ and Succinate Pathway: Role in Deceased Kidney Donors Inflammation

Jordi Vilardell. *Fundacio Puigvert, Barcelona, Spain.*

**Background:** The type of donor has an impact on the renal prognosis of the recipient. It has been observed that the decline of renal function is higher in deceased donor (DD). These could be related with the pre-implantation inflammation state of the donor and the development of fibrotic processes. Own data indicate that complex succinate dehydrogenase (SDH) has a lower gene expression in DD kidneys and is associated with inflammatory markers, macrophages, and purinergic receptors and a worse renal function graft. The aim of this study is to determine that in renal DD, ischemia/hypoxia can increase renal succinate levels, inducing infiltration of inflammatory cells.

**Methods:** Pre-implantational kidneys biopsies from 47 DD and 19 LD, were collected. 159 genes from these samples were analysed by qRT-PCR. Relative quantification of gene expression was performed with 3 internal controls. Genes with high positive correlation with HIF1 $\alpha$  have been grouped in clusters using STRING database. Succinate levels were measured in serum from 27 renal DD and in 10 healthy volunteers with the EnzyChrom<sup>TM</sup> Succinate Assay Kit. All statistical data was analyzed using GraphPad Prism 5.

**Results:** To determine the hypoxia status of kidney donors, transcription levels of HIF1 $\alpha$  and HIF2 $\alpha$  were determined from renal tissue samples. A significant increase in HIF1 $\alpha$  gene expression is observed in DD compared to LD ( $p<0.001$ ). From the expression of the 159 genes analyzed, 24 of them are expressed exclusively in DD samples and have a high correlation with HIF1 $\alpha$  ( $Rho > 0.5$ ). These genes have been grouped in 3 different clusters: Transcription factors and metalloproteinases, ECM proteins and integrins and Inflammatory and Macrophages Markers. We also found reduced mRNA expression of all the SDH subunits ( $p<0.001$ ) in DD samples. As a consequence, succinate cannot be converted to fumarate in concordance with the greater succinate levels ( $p=0.002$ ) observed in sera of DD.

**Conclusions:** These results indicate that kidneys from DD undergo a greater hypoxia compared with LD, demonstrated by the increased transcription rate of HIF1 $\alpha$ . Hypoxia not only increases HIF1 $\alpha$  but also may affect the energetic metabolism of the cell, reducing the expression of SDH. As a consequence extracellular levels of succinate increase, maintaining HIF1 $\alpha$  levels, that could take part in a sustained inflammatory/anti-inflammatory process in kidney from DD.

### Changes in Urinary Proteome in Living Kidney Donors After Kidney Donation

Sachin M. Naik, Kajal Kamboj, Jaskiran Kaur, Joyita Bharati, Ashok K. Yadav, Vivek Kumar. *Post Graduate Institute of Medical Education and Research, Chandigarh, India.*

**Background:** Recent concerns about long term effects of living kidney donation have generated interest in adaptive mechanisms post kidney donation. We present initial data on changes in urinary proteome over 6 months after living kidney donation.

**Methods:** Prospective living kidney donors, scheduled for living donor kidney transplantation, were enrolled. Participants were followed up at 6 months after surgery. Urine samples for proteomics were collected before surgery and at 6 months after surgery. Urinary proteomic profiling was done by liquid chromatography and mass spectrometry (LC-MS/MS) using Thermo Scientific<sup>TM</sup> Orbitrap Fusion<sup>TM</sup> Tribrid<sup>TM</sup> mass spectrometer.

**Results:** 25 participants have been enrolled till date. We present data of 15 participants who have completed follow up. The mean age was  $43.2\pm7.62$  years. Serum creatinine increased while hemoglobin and serum inorganic phosphorus decreased at 6 months after living kidney donation. Proteomic analyses showed 257 differentially expressed proteins (DEPs) (115 downregulated, 142 upregulated, figure 1). Gene ontology enrichment analysis suggest upregulation of insulin like growth factor pathway, growth factor activity, cell junction organization and cell activation, and downregulation of generation of precursor metabolites and energy, various solute transporters, cell cycle, cell adhesion

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

molecule binding, MAPK family signaling pathway. The protein-protein interactions and pathway relatedness suggest linkage to Erb1 downstream pathway, Rho GTPase effectors, PDGFRB pathway etc.

**Conclusions:** This study provides clues to possible biological processes and pathways involved in kidney adaptation. However, these need more evaluation and validation.

**Funding:** Government Support - Non-U.S.

UPREGULATED PROTEINS		
Accession No	Protein name	Function
P01344	Insulin-like growth factor II	positive regulation of organ growth
P98172	Ephrin-B1	Angiogenesis, cell adhesion; cell-cell signaling
P55285	Cadherin-6	Wnt signaling, adherens junction organization, proximal tubular development
P05413	Fatty acid-binding protein, heart	positive regulation of lipid metabolism
P02760	Protein AMBP	cell adhesion, heme catabolic process
P25311	Zinc-alpha-2-glycoprotein	Cell adhesion, negative regulation of cell population proliferation
Q9GZX9	Twisted gastrulation protein homolog 1	upregulation of BMP signaling, TGF beta receptor signaling pathway
Q6P986	MTOR-associated protein MEAK7	mTOR pathway, regulation of cell population proliferation
P13987	CD59 glycoprotein	negative regulation of activation of MAC and complement activation, complement-dependent cytotoxicity
P41222	Prostaglandin-H2 D-isomerase (PGD2 synthase)	prostaglandin biosynthetic process
DOWNREGULATED PROTEINS		
Q9Y696	Chloride intracellular channel protein 4	angiogenesis; branching morphogenesis of an epithelial tube; cell differentiation, chloride transport
P13866	Sodium/glucose cotransporter 1	Sodium and glucose transport
P04085	Platelet-derived growth factor subunit A	actin cytoskeleton organization; angiogenesis; signaling
A0PJK1	Sodium/glucose cotransporter 5	hexose transmembrane transport; sodium ion transport
P55017	Solute carrier family 12 member 3 (Na-Cl cotransporter)	Chloride, sodium and potassium ion homeostasis
Q15109	Advanced glycosylation end product-specific receptor	positive regulation of ERK1 and ERK2, MAPK, NFkB signaling
Q69577	Sodium-dependent neutral amino acid transporter B	Sodium and amino acid transport
Q13214	Semaphorin 3B	cell-cell signaling, positive regulation of cell migration

**Metabolic Profiling of Kidney Grafts: A Novel Approach for Allograft Monitoring in Transplantation**

Sergi Clotet Freixas,<sup>1,2</sup> Caitríona M. McEvoy,<sup>1,2</sup> Masataka Kawamura,<sup>3,4</sup> Max Kotlyar,<sup>5,6</sup> Alexander Boshart,<sup>1,2</sup> Aninda D. Saha,<sup>1,2</sup> Joseph Kim,<sup>1,7</sup> Rohan John,<sup>1,8</sup> Lisa Robinson,<sup>3,9</sup> Ana Konvalinka.<sup>1,2</sup> <sup>1</sup>Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada; <sup>2</sup>Soham and Shaila Ajmera Family Transplant Centre, University Health Network, Toronto, ON, Canada; <sup>3</sup>Division of Nephrology, The Hospital for Sick Children, Toronto, ON, Canada; <sup>4</sup>Division of General Surgery, University Health Network, Toronto, ON, Canada; <sup>5</sup>Osteoarthritis Research Program, Division of Orthopedic Surgery, Schroeder Arthritis Institute, University Health Network, Toronto, ON, Canada; <sup>6</sup>Krembil Research Institute, University Health Network, Toronto, ON, Canada; <sup>7</sup>Division of Nephrology, Department of Medicine, University Health Network, Toronto, ON, Canada; <sup>8</sup>Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada; <sup>9</sup>Program in Cell Biology, The Hospital for Sick Children Research Institute, Toronto, ON, Canada.

**Background:** Kidney transplantation is the optimal treatment for end-stage kidney disease, but kidney grafts are often lost prematurely. In transplanted organs, ischemia reperfusion injury (IRI) predisposes to inferior graft outcomes. Delayed graft function (DGF) is the manifestation of severe IRI in kidney transplantation. DGF is manifested as acute tubular necrosis (ATN), and injury to the peritubular and glomerular vasculature, features of acute kidney injury (AKI). Increasing evidence suggests that altered metabolism in the graft mediates AKI and is the major cause of DGF. Deciphering the metabolic underpinnings of IRI will improve our capacity to diagnose, prevent, and treat AKI.

**Methods:** We studied the tubulointerstitial and glomerular proteome of kidney transplant patients that developed ATN (n=12) and compared them to cases with antibody-mediated rejection (n=7) or acute cellular rejection (n=11). In addition to kidney graft proteome, we studied metabolic function of biopsy-derived kidney cell suspensions, and the urinary excretion of lactate, in a pig kidney auto-transplantation model.

**Results:** Patients with ATN showed increased expression of 8 glycolytic enzymes in the tubulointerstitium (ALDOA, ALDOC, GPI, LDHA, PFKF, PGM2, PKM, and TALDO1) and 5 in the glomeruli (ALDOA, G6PD, HK1, LDHA, and TALDO1), at the time of rejection. ATN was also linked to altered levels of mitochondrial proteins (P<0.05). In our pig model, ischemia followed by cold storage led to significantly reduced mitochondrial respiration in cells derived from the kidney graft, in comparison to the 'healthy' contralateral kidney. Functional changes after cold storage were linked to significantly reduced levels of kidney mitochondrial proteins (e.g., CPT2, ETFB; n=10; P<0.05), and significantly increased lactate levels in urine (n=10; P<0.05).

**Conclusions:** Our work shows that increased glycolysis and reduced mitochondrial function may contribute to post-transplant AKI and solidifies the importance of monitoring metabolism in kidney transplantation. Our next goal is to delineate a glycolytic signature that identifies 'high risk allografts', facilitating early diagnosis of DGF in kidney transplantation. Such signature could facilitate future clinical interventions targeting the highest risk grafts.

TH-PO641

**Cellular and Molecular Landscape of AKI Post-Renal Transplant**

Jennifer M. McDaniels,<sup>1</sup> Amol C. Shetty,<sup>1</sup> Thomas Rousselle,<sup>1</sup> Elissa Bardhi,<sup>1</sup> Daniel G. Maluf,<sup>1</sup> Enver Akalin,<sup>2</sup> Valeria R. Mas.<sup>1</sup> <sup>1</sup>University of Maryland Baltimore, Baltimore, MD; <sup>2</sup>Albert Einstein College of Medicine, Bronx, NY.

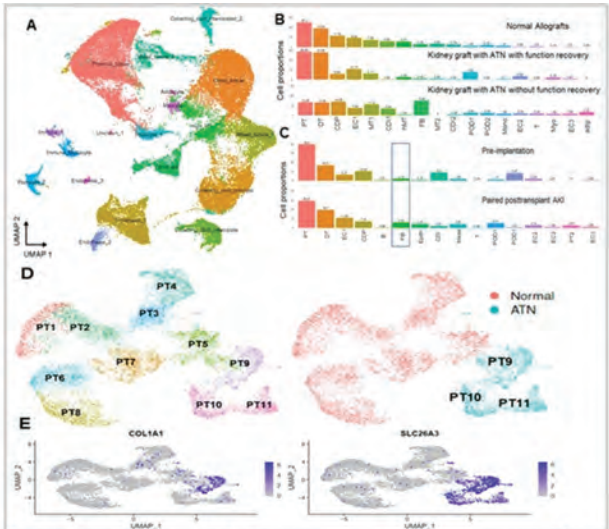

**Background:** Acute kidney injury (AKI) is a risk factor for chronic kidney disease. Delayed graft function (DGF) post kidney transplantation (KT) is common due to ischemia/reperfusion injury and acute tubular necrosis (ATN). The pathophysiology of AKI post-KT and acute-to-chronic transition is unknown.

**Methods:** Kidney grafts with DGF <6 weeks post-KT (AKI graft with ATN (n=4); no evidence of acute/chronic Banff injury scores) and normal allografts (NA, n=4) (normal function/histology) were tested using single nuclei (sn)RNA-seq (10X Genomic Chromium Platform). Analysis was done with Cell Ranger. DEGs (FDR≤0.05) identified enriched GO terms and pathways.

**Results:** 31,803 nuclei UMAP showed 19 main clusters (**Fig 1A**). AKI KT patients were divided as with (WGFr; n=2) and without graft function recovery (WoGFr; n=2). ATN WoGFr showed lower proximal tubule epithelial cells (PTEC) and increased fibroblasts (FB). Also, monocytes and T cells were increased in ATN WoGFr. FBs were higher (**Fig 1B**) and more transcriptionally active in AKI WoGFr compared to NA and AKI WGFr. A paired pre-implantation biopsy for an AKI WoGFr patient presented a temporal increase in FB with AKI onset (**Fig 1C**). PTECs showed high heterogeneity between NA and AKI grafts (**Fig 1D**). PTEC clusters 9-11 were mainly present in AKI grafts and enriched in myofibroblast markers (*COL1A1*, *COL1A2*, *SLC26A3*) (**Fig 1E**), marked metabolic dysfunction, and produced ECM. PTEC DEGs in AKI WoGFr were enriched in epithelial cell differentiation and tubule morphogenesis, suggesting a transitional cellular state.

**Conclusions:** Different immune and PTEC clusters were identified based on condition (NA vs ATN) and graft outcome (WGFr vs WoGFr), showing cell-type specific transcriptional profiles and pathways associated with impaired repair in AKI post-KT.

**Funding:** NIDDK Support

**Fig 1. A.** UMAP cell clusters. **B.** Cell proportions among different conditions. **C.** Cell proportions between paired biopsies at two-time points. **D.** UMAP showing all PTEC subclusters (left) and per condition (right). **E.** Expression of myofibroblast markers.

TH-PO642

**Discrepant Toxicity Profiles of Cyclosporine A and Tacrolimus Beyond Calcineurin Inhibition**

Duygu E. Yilmaz,<sup>1</sup> Karin M. Kirschner,<sup>1</sup> Hasan Demirci,<sup>1</sup> Nina Himmerkus,<sup>2</sup> Sebastian Bachmann,<sup>1</sup> Kerim Mutig.<sup>1</sup> <sup>1</sup>Charite Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>Christian-Albrechts-Universität zu Kiel, Kiel, Germany.

**Background:** Calcineurin inhibitors (CNI), cyclosporine A (CsA) or tacrolimus (Tac), belong to the first-line immunosuppressive strategies after solid organ transplantation. However, both CNI exert pronounced nephrotoxicity, which is typically stronger in patients receiving CsA. Calcineurin inhibition by CsA occurs via building complexes with cyclophilins, whereas Tac recruits FKBP12 instead. We hypothesized that suppression of cyclophilin chaperone function by CsA may induce endoplasmic reticulum (ER) stress and pro-apoptotic unfolded protein response (UPR) in kidney epithelia.

**Methods:** Effects of CsA vs. Tac (10  $\mu$ M for 6 h) on the UPR signaling were compared in cultured human embryonic kidney cells (HEK293), human renal proximal tubular (PT) epithelial cells (HRPTEpC), and freshly isolated rat PTs using quantitative PCR, immunoblotting, and immunofluorescence staining. An established ER stress inducer, thapsigargin (Tg) served as a positive control.

**Results:** CsA and Tg, but not Tac, induced ER stress and pro-apoptotic UPR in HEK293 cells, as reflected by increased levels of key UPR products (BiP, CHOP, spliced XBP1, and phosphorylated IRE1 $\alpha$ ) and cleaved caspase-3 (cCas-3). Similar effects were observed in HRPTEpC cells and isolated rat PTs. Knockdown of cyclophilin A or B isoforms in HEK293 cells using siRNA aggravated CHOP and cCas-3 suggesting relevance of cyclophilin activity for intact proteostasis. Application of chemical chaperones, TUDCA or 4-PBA, alleviated the CsA-induced UPR suggesting that improved protein folding may have protective effects against CsA cytotoxicity. Along the same line, genetic suppression of UPR in HEK293 cells by CRISPR/Cas9-mediated deletion of the key ER stress sensors, PERK or ATF6, blunted the pro-apoptotic UPR in response to CsA.

**Conclusions:** In summary, these results suggest that nephrotoxic effects of CsA may be aggravated by suppression of cyclophilins, ER stress, and pro-apoptotic UPR. Pharmacological or genetic modulation of UPR bears the potential to alleviate CsA nephrotoxicity.

### Towards the Use of Immortalized Perfusate-Isolated Human Endothelial Cells for the Screening of Non-human Leukocyte Antigen (Non-HLA) Antibodies in Kidney Transplant Recipients

Dania Altulea,<sup>1</sup> Rosa G. Lammerts,<sup>1</sup> Wendy Dam,<sup>1</sup> Jacob van den Born,<sup>1</sup> Jan-Stephan Sanders,<sup>1</sup> Constanca Figueiredo,<sup>2</sup> Stefan P. Berger.<sup>1</sup> <sup>1</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>2</sup>Medizinische Hochschule Hannover, Hannover, Germany.

**Background:** Endothelial cells (ECs) are important target cells for both cellular and antibody mediated rejection in transplanted kidneys. Non-HLA antibodies may play an important role in immunity to the allograft, yet screening for non-HLA antibodies is not routinely performed prior to transplantation due to uncertainty about the clinical relevance and the lack of validated detection assays. Recently, cell-based crossmatching assays have been described for the screening of non-HLA antibodies using either primary ECs such as human umbilical vein endothelial cells (HUVECs), Tie-2+ endothelial precursor cells, or cell lines such as the conditionally immortalized human glomerular endothelial cells (CiGeNCs) as the target cells. However, despite the promising results of these assays, HUVECs and Tie-2+ ECs are not organ specific, and CiGeNCs, despite being kidney-specific, are derived from a single donor and thus lack heterogeneity in protein expression. Therefore, the development of an ideal EC crossmatching assay with organ and donor specificity is warranted. We aimed to establish a cell bank of kidney-derived ECs covering a broad array of HLA and non-HLA targets, upon which, an EC-based crossmatch assays will be developed using ECs isolated from the liquid of machine-perfused kidneys.

**Methods:** Human cells were collected and cultured from the perfusate after post-mortem kidney donation and perfusion, then, ECs were isolated based on the expression of CD31. Transduction of the ECs was performed utilizing a lentiviral vector encoding for the SV40 large T antigen and mCherry as reporter gene.

**Results:** To assess the success of the transduction, the expression of the reporter gene was assessed using fluorescence microscopy. The positive cells were cultured for a period of 5-8 weeks until a suitable expansion level, then checked for the expression of EC markers including CD31, CD34, VEGFR-2, ET-1, and vWF with flow cytometry.

**Conclusions:** Our results showed that the transformed cells expressed the selected common ECs markers even after a long period of culturing, confirming their endothelial characteristics. Additional flow cytometry analysis for a broad array of EC markers, as well as single-clone expansion and HLA-silencing is planned in the near future.

**Funding:** Government Support - Non-U.S.

### Machine Perfusion Affects Endothelium of Porcine Kidneys Irrespective of Haematocrit of Perfusion Fluid

Cor van 't Hof, Tobias M. Huijink, Anita Meter, Jacob van den Born, Stefan P. Berger, Henri Leuvenink. *Universitair Medisch Centrum Groningen, Groningen, Netherlands.*

**Background:** In transplanted kidneys, ischemia-reperfusion injury (IRI) is a major cause of renal failure and eventual allograft loss. In the pathological mechanisms of IRI, renal endothelium plays a key role. In this project, the effects of different haematocrits during kidney machine perfusion on the endothelium were investigated by assessing phenotypic alterations in renal endothelial cells in porcine kidneys.

**Methods:** Two experimental groups of porcine kidneys (n=6 per group), obtained from a local abattoir, were subjected to 35 minutes of warm ischemia and flushed with 1L saline. Thereafter, kidneys underwent 3 hours of hypothermic and 4 hours of normothermic machine perfusion (NMP). During NMP experimental groups were perfused with either a 24% or 36% haematocrit. Post-nephrectomy and post-normothermic machine perfusion biopsies of two groups were obtained and stained for endothelial markers vascular endothelial growth factor receptor 2 (VEGFR-2) and endocan. The stained sections were scanned and quantified digitally. A p-value of <0.05 was considered significant. P-values were calculated using a paired T-test, in the case of a normal distribution, or a Wilcoxon Signed Rank test, in the case of a non-normal distribution.

**Results:** Since no significant differences were found between 24% and 36% haematocrit groups, both groups were combined. The expression of endocan and VEGFR-2 was significantly reduced from post-nephrectomy to post-normothermic machine perfusion in both groups. Endocan expression was mainly decreased in the glomerular capillaries compared to peritubular capillaries (P=0.012 and P=0.596). VEGFR-2 expression both in glomerular and peritubular capillaries was largely lost after normothermic machine perfusion, P=0.002 and P=0.003 respectively.

**Conclusions:** These data show that machine perfusion, irrespective of the haematocrit of the perfusion solution, strongly affects the endothelium of the perfused kidneys. Additional analysis will be performed to explore when this decline in expression occurs.

### Nephrotoxic Side Effects of the Calcineurin Inhibitors Cyclosporin A and Tacrolimus Affect Glomeruli and Tubulointerstitium Differentially in Chronic Experimental Settings

Hasan Demirci,<sup>1</sup> Suncica Popovic,<sup>1</sup> Duygu E. Yilmaz,<sup>1</sup> David H. Ellison,<sup>2</sup> Kerim Mutig,<sup>1</sup> Sebastian Bachmann.<sup>1</sup> <sup>1</sup>Charite Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>Division of Nephrology & Hypertension, Oregon Health & Science University, Portland, OR.

**Background:** Chronic calcineurin inhibitor (CNI) nephrotoxicity is a major drawback in current immunosuppressive regimens. Pathology includes vascular/glomerular and tubulointerstitial alterations. Although still commonly in use, cyclosporine A (CsA) is increasingly replaced by tacrolimus (Tac) for a more favorable clinical outcome. Data on their differential pathogenetic effects in the kidney are still scarce. We hypothesized that the major renal compartments are differentially affected by the two drugs. Histological, ultrastructural and gene expression changes were registered to achieve mechanistic perspectives in controlling CNI nephrotoxicity.

**Methods:** CsA and Tac were administered chronically in wt rats and mice with a megalin-related endocytosis defect. Clinical parameters were controlled. Animals were prepared for high-end morphological analysis, elective immunostaining, and high-throughput technology.

**Results:** In rats, CsA and Tac produced distinct alterations in glomeruli and tubulointerstitium. Both drugs caused a-SMA-positive fibrotic foci with sclerotic glomeruli and damaged tubules to similar extent. With CsA, glomerular damage was milder than with Tac. Proximal tubules showed increases in dysmorphic lysosomes along with high apoptosis rate and diminished albumin uptake. Megalin-dependent endocytosis was causally involved in the changes. Lysosomal exocytosis was stimulated at the apical cell pole. KIM1 signal was moderate. With Tac, these changes were far less pronounced, but focal tubular necrosis along with KIM-1 signal was enhanced. High throughput analysis showed differential changes between CsA and Tac with almost no overlap between the respective spectra. CsA caused upregulation of components of the unfolded protein response and apoptosis, whereas Tac showed a disproportionately sharp induction of the RAS and vascular structural deterioration.

**Conclusions:** In sum, CNI nephrotoxicity presented with fundamentally different effects caused by CsA vs. Tac. While CsA mostly affected proximal tubular integrity, Tac was primarily acting on vascular components. Results may serve to better adjust immunosuppressive treatment combinations in transplant patients.

## TH-PO646

### Polygenic Burden for Hypertension, Stroke, and Intracranial Aneurysm in Deceased Kidney Donors

Kane E. Collins,<sup>1</sup> Edmund H. Gilbert,<sup>1</sup> Katherine A. Benson,<sup>1</sup> Elhussein A. Elhassan,<sup>2</sup> Graham M. Lord,<sup>3</sup> Gianpiero Cavalleri,<sup>1</sup> Peter J. Conlon.<sup>2,1</sup> <sup>1</sup>Royal College of Surgeons in Ireland, Dublin, Ireland; <sup>2</sup>Beaumont Hospital, Dublin, Ireland; <sup>3</sup>King's College London, London, United Kingdom.

**Background:** Intracranial Haemorrhage (ICH) and stroke are common causes of death among kidney donors, but the genetic factors involved are poorly understood. Polygenic burden for a trait can be calculated by generating a Polygenic Risk Score (PRS) which estimates the cumulative effect of common genetic variation on an individual's disease status. Previous studies have found that PRS for ischemic stroke offer predictive performance similar to clinical risk factors. Here we investigate the role of polygenic burden in determining donor cause and age of death.

**Methods:** We utilised 2122 genotyped kidney transplant donor-recipient pairs from across the UK and Ireland. We calculated PRSs for stroke, Intracranial Aneurysm (IA) and hypertension using large published GWASs of European ancestry. We compared PRSs between the donors who died of intracranial haemorrhage (DDICH) (1,303 individuals) and controls, as well as donors who did not die of ICH. We investigated whether kidneys that came from individuals with high polygenic risk (defined as top 20% of distribution) performed differently from lower risk kidneys (bottom 80%) when transplanted into recipients.

**Results:** DDICH had significantly higher PRSs for hypertension, stroke, and IA than controls (p-values 1.0e-13, 1.2e-11, and 0.028 respectively), but also than the donors who did not die of ICH (p-values 2.9e-9, 2.3e-4, and 0.41). The risk of death from ICH was 9% greater in individuals with high polygenic risk for hypertension (OR: 1.09, p: 0.015). Similarly, for donor age of death, polygenic risk for hypertension had an Odds Ratio (OR) of 12.2 (p-value 0.002). Polygenic risk for each trait in donor kidneys did not have a statistically significant impact on graft survival.

**Conclusions:** These observations support the hypothesis that DDICH carry an increased burden for traits related to stroke. This results in a greater risk of death from ICH and a younger age of death. These PRSs are similarly predictive to established clinical risk factors. Kidneys that come from donors with high polygenic risk for all traits do not have different graft function or survival from low risk kidneys. PRSs can distinguish DDICH from the general population. These findings could have utility in testing relatives of DDICH to determine if they share the same risk for ICH.

**Funding:** Government Support - Non-U.S.

TH-PO647

Recipient Polygenic Burden as a Predictor of Kidney Transplant Outcome

Kane E. Collins,<sup>1</sup> Edmund H. Gilbert,<sup>1</sup> Katherine A. Benson,<sup>1</sup> Elhussen A. Elhassan,<sup>2</sup> Graham M. Lord,<sup>3</sup> Peter J. Conlon,<sup>2,1</sup> Gianpiero Cavalleri.<sup>1</sup>  
<sup>1</sup>Royal College of Surgeons in Ireland, Dublin, Ireland; <sup>2</sup>Beaumont Hospital, Dublin, Ireland; <sup>3</sup>King's College London, London, United Kingdom.

**Background:** The clinical predictors of transplant outcome have been well established and include HLA mismatch, donor age, era of transplantation, immunosuppressive regimen, and recipient blood pressure. Polygenic burden can be quantified using a Polygenic Risk Score (PRS), which estimates the cumulative effect of common genetic variation on an individual's disease status. Polygenic burden has been demonstrated to have an impact on kidney function, but the impact of polygenic burden on kidney graft function is less clear. It has also been shown that polygenic burden can predict certain transplant outcomes including the development of Non Melanoma Skin Cancer. Here, we investigate the role of polygenic burden in kidney transplant recipients on transplant outcome.

**Methods:** We utilised 2,122 genotyped donor-recipient pairs from across the UK and Ireland and 5,519 ancestry matched controls. We calculated PRSs for eGFR, albuminuria, and hypertension from large, publicly available summary statistics from populations of European ancestry. We compared PRSs between recipients and the healthy controls. We also investigated the differences in transplant outcome between the individuals with high polygenic burden (defined as top 20% of distribution) for each trait and those with low polygenic burden (bottom 80%).

**Results:** Recipients had lower polygenic burden for reduced eGFR (p-value: 7.9e-4) than healthy controls. There was no statistically significant difference in graft survival or graft function at 1-year post-transplant between individuals with high and low polygenic burden. However, there was a significant difference in graft function at 5 years' post-transplant between the high and low polygenic burden individuals (Odds Ratio: 16.2, p-value: 0.048).

**Conclusions:** Polygenic burden for eGFR has an impact on graft function at 5 years' post-transplant, but other traits do not appear to have a significant effect. This is in line with what previous studies have found.

**Funding:** Government Support - Non-U.S.

TH-PO648

Comparison Between Nuclear Medicine Studies, Creatinine Clearance, and Estimated Glomerular Filtration Rate

Ana C. Acosta Peña, Mario Alamilla Sanchez. Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Mexico City, Mexico.

**Background:** Measurement and estimation of glomerular filtration rate (GFR) are associated with systematic error, leading to differences in measured GFR, estimated GFR, and creatinine clearance. eGFR or CrCl within 30% of a mGFR is appropriate.

**Methods:** Comparative study between mGFR DTPA by renal scintigraphy, CrCl in 24-hour urine, and eGFR CKD-EPI/MDRD. Means were compared, with a 95% CI calculation. Bias and precision are assessed, providing a standard margin of  $\pm 30\%$  relative to mGFR DTPA.

**Results:** 40 donors were studied, 50% women, aged 42 years [20 – 67 years], weight 72.9  $\pm$  13.2 kg, serum creatinine 0.74  $\pm$  0.15 mg/dL. The mGFR DTPA measurement was on average 128.4  $\pm$  23 mL/min; higher in men [136.1 vs. 120.7 mL/min; p = 0.03]. The eGFR were: CKD-EPI 107.6  $\pm$  17.2 mL/min, MDRD 105.3  $\pm$  20 mL/min; no differences between men and women [p = 0.84]; CrCl was 113.1  $\pm$  32.6 mL/min; significantly higher in men [p = 0.006]. Differences were found between mGFR DTPA vs CrCl [128 vs 113 mL/min; p = 0.01] vs. CKD-EPI [128 vs. 107 mL/min; p < 0.001] vs. MDRD [128 vs. 105 mL/min; p < 0.001]. No differences when comparing CrCl and CKD-EPI [113 vs 108 mL/min, diff. = 4.3mL/min; p = 0.49] or MDRD [113 vs. 107 mL/min; p = 0.39]; neither between CKD-EPI and MDRD [107 vs 105 mL/min; p = 0.13]. When estimating the precision at 30% (p < 30) regarding mGFR DTPA between the methods, CrCl had less bias and GFR CKD-EPI better precision.

**Conclusions:** The use of mGFR DTPA is the best tool to establish GFR, however, among the methods used, CrCl has the least bias and GFR CKD-EPI has the best precision within 30% compared to mGFR DTPA.

**Funding:** Government Support - Non-U.S.

Comparison of measurement GFR DTPA vs estimation of GFR CKD-EPI/MDRD vs CrCl

Method	ml/min	Difference in ml/min vs mGFR DTPA [bias/precision %]	p [IC 95%]
mGFR DTPA	128.4 $\pm$ 23	Ref.	Ref.
CrCl	113.1 $\pm$ 32.6	15.6 [12 / 80]	0.01 [3.2 – 28]
eGFR CKD-EPI	107.6 $\pm$ 17.2	20.8 [16 / 85]	< 0.001 [12.9 – 28.6]
eGFR MDRD	105.3 $\pm$ 20	23.1 [18 / 80]	< 0.001 [14.8 – 31.3]

TH-PO649

Blood-Brain-Barrier Biomarkers in Patients Before and After Kidney Transplantation

Leah N. Hernandez, Liam J. Ward, Samsul Arefin, Peter F. Barany, Peter Stenvinkel, Karolina Kublickiene. Department of Clinical Science, Intervention and Technology (CLINTEC), Division of Renal Medicine Karolinska Institutet, Stockholm, Sweden.

**Background:** The uremic milieu affects the blood-brain barrier by altering the levels of brain-specific biomarkers in the peripheral circulation, which may be due to increased BBB leakage. Renal replacement therapy such as kidney transplantation in ESKD patients may improve neurologic status and may be reflected by the altered levels of circulating BBB-specific biomarkers. The aim of this study is to compare the levels of the circulating BBB-specific biomarkers such as neuron-specific enolase (NSE), neurofilament light chain (NFL), and brain-derived neurotrophic factor (BDNF) in living-donor kidney transplant patients and non-CKD controls.

**Methods:** Serum from non-CKD control (n=80) and plasma from living-donor renal transplant patients (LD-RTx, n=69) were used to measure NSE, NFL, and BDNF using commercially available enzyme-linked immunosorbent assay (ELISA). Circulating levels of the NSE, NFL, and BDNF in kidney transplant recipients were compared at baseline, and one and two years follow-up.

**Results:** LD-RTx patients showed lower levels of NSE at 1 year, 2-year post-transplantation when compared to baseline and non-CKD controls (p < 0.05). BDNF and NFL levels were higher in LD-RTx patients at 1 year and 2-year follow-up compared to baseline and non-CKD controls (p < 0.05). Sex divided analysis showed significant difference in NFL levels only at 1 year follow up, with males having higher NFL levels compared to females.

**Conclusions:** Varying levels of BBB biomarkers suggest that kidney transplantation may have a beneficial effect on the BBB integrity. This is supported by the altered circulating levels of NSE, BDNF and NFL in the peripheral circulation. Further studies are ongoing to understand implications of sex differences and associations with clinical and biochemical parameters related to the maintenance of BBB and neurological status.

TH-PO650

DNA of Urinary Extracellular Vesicles Reflects Kidney Allograft Injury

Ivana Sedej,<sup>1,2</sup> Maja Stalekar,<sup>3</sup> Magda Tusek Znidaric,<sup>3</sup> Katja Goricar,<sup>2</sup> Nika Koje,<sup>4</sup> Polona Kogovšek,<sup>3</sup> Vita Dolzan,<sup>2</sup> Metka Lenassi,<sup>2</sup> Miha Arnol.<sup>1</sup>  
<sup>1</sup>Department of Nephrology, Division of Internal Medicine, University Medical Center Ljubljana, Ljubljana, Slovenia; <sup>2</sup>Institute of Biochemistry and Molecular Genetics, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; <sup>3</sup>Department of Biotechnology and Systems Biology, National Institute of Biology, Ljubljana, Slovenia; <sup>4</sup>Institute of Pathology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia.

**Background:** When allograft injury (AI) occurs, levels of donor-derived cell-free DNA (dd-cfDNA) increase in kidney transplant (TX) recipients' body fluids, including urine. Within this are extracellular vesicles (uEVs), membranous particles released by virtually all cell types carrying biomolecules reflecting the state of the original cell. DNA is an important, unexplored uEV cargo (evDNA) that may be a relevant noninvasive biomarker for AI. The rationale of our study was to investigate the evDNA characteristics of kidney TX recipients to reveal possible association with AI and finally to evaluate the biomarker potential of dd-evDNA.

**Methods:** We isolated uEVs, ev-, and cfDNA from 2nd morning spot urine of 41 kidney TX recipients undergoing protocol or for-cause biopsy. We used Nanoparticle Tracking Analysis to determine the size and concentration of uEVs. We measured DNA yield, copy number, integrity index, and dd-fraction using fluorometry, donor-recipient genotyping and digital droplet PCR, respectively. We associated DNA characteristics to histological phenotype, by comparing data from normal histology (NH), rejection injury (RI; combination of antibody- (ABMR) and T-cell mediated rejection (TCMR)) and non-rejection injury (NRI) group.

**Results:** The uEVs concentration was similar in all patient groups, whereas uEVs were significantly larger in the RI and NRI groups (mean  $P=0.045$ ; median  $P=0.031$ ). We detected higher evDNA yields and higher evDNA copy number in the RI and NRI groups than in the NH group ( $P=0.018$  and  $P=0.007$ , respectively). In particular, the number of dd-evDNA copies was significantly increased in ABMR patients (Figure 1). In addition, we report significantly lesser fragmentation of dd-evDNA vs. dd-cfDNA ( $P<0.001$ ). evDNA characteristics were related to the degree of interstitial inflammation, microvascular inflammation, and inflammation in the areas of fibrosis (all  $P<0.050$ ).

**Conclusions:** evDNA reflects AI, particularly allograft rejection and could be used as a biomarker for monitoring kidney allograft injury status.

## TH-PO651

### Roles of Endothelial and Mesangial Cells in the Progression of Transplant Glomerulopathy

Pongpratch Puapatanakul, Samir Husami, Jeffrey H. Miner, Sanjay Jain, Tarek Alhamad, Hani Suleiman. *Washington University in St Louis School of Medicine, St Louis, MO.*

**Background:** Transplant glomerulopathy (TG) is a morphologic diagnosis characterized by reduplication of the glomerular basement membrane (GBM) on kidney allografts. Changes to the GBM and adjacent structures as TG develops and progresses have not been studied extensively at a molecular level.

**Methods:** Archived paraffin-embedded kidney biopsies from 9 TG patients (2 and 7 patients with Banff score cg1a and cg1b or higher [1b+], respectively), and 10 nephrectomy controls were imaged by Airyscan confocal microscopy. Immunofluorescence staining was performed using antibodies against collagen  $\alpha1\alpha2(IV)$ , collagen  $\alpha3\alpha4\alpha5(IV)$ , laminin  $\alpha5$  (LG domain), and agrin as markers of GBM; CD34 as a marker of endothelial cells; vimentin as a marker of endothelial activation; and integrin  $\alpha8$  and  $\alpha$ -smooth muscle actin ( $\alpha$ -SMA) as markers of mesangial cells.

**Results:** There were significant increases in thickness and intensity of most GBM proteins, namely collagen  $\alpha1\alpha2(IV)$ , laminin  $\alpha5$ , and agrin at all stages of TG. Collagen  $\alpha3\alpha4\alpha5(IV)$  was unchanged, suggesting that podocytes did not contribute much to GBM thickening. Laminin  $\alpha5$  appeared as two leaflets correlating with visible GBM reduplication by light microscopy in Banff cg1b+ TG. CD34 staining extending from capillary lumina into the thickened GBM, suggesting protrusions of endothelial cells, was observed more prominently in Banff cg1b+ TG. TG endothelial cells expressed vimentin consistently at all stages, whereas controls did not. We also observed integrin  $\alpha8$  and  $\alpha$ -SMA in the reduplicated GBM in Banff cg1b+ TG, which could represent mesangial interposition as the GBM thickened at later stages.

**Conclusions:** We demonstrate that endothelial activation occurs early, followed by endothelial protrusion into the GBM and expansion of collagen  $\alpha1\alpha2(IV)$ , highlighting the importance of endothelial injury in TG. The presence of mesangial markers in the thickened GBM later in the course of disease suggests a role for mesangial cells in TG progression. Whether these successive changes yield prognostic values requires future prospective studies.

## TH-PO652

### Identification of Complement Regulatory Proteins in ABO-Incompatible and HLA-Incompatible Kidney Transplantation

Kavita Jintanapramote,<sup>1</sup> Thansita Bhunyakarnjanarat,<sup>2</sup> Jeerath Phannajit,<sup>1</sup> Jerasit Surintrspanont,<sup>3</sup> Asada Leelahavanichkul,<sup>1,2</sup> Yingyos Avihingsanon,<sup>1</sup> Somchai Eiam-Ong,<sup>1</sup> Natavudh Townamchai.<sup>1</sup> <sup>1</sup>Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; <sup>2</sup>Chulalongkorn University Department of Microbiology, Bangkok, Thailand; <sup>3</sup>Chulalongkorn University, Bangkok, Thailand.

**Background:** ABO incompatible kidney transplantation (ABOi KT) provides better allograft outcomes compared to HLA incompatible KT (HLAi KT), especially a lower incidence of antibody-mediated rejection (ABMR). The findings in ABMR generally consist of the presence of serum anti-donor antibody, C4d staining, and inflammation in the allograft. Despite the positivity of C4d, there is no evidence of inflammation found in ABOi KT, indicating that there must be some mechanisms preventing the allograft from complement mediated injury. We hypothesize that the complement regulatory proteins may play roles in this process.

**Methods:** This observational, retrospective study was conducted at King Chulalongkorn Memorial Hospital. All living donor KT patients were divided into 4 groups according to pre-transplant antibody: 1) ABOi, 2) HLAi, 3) combined ABOi and HLAi, which considered as high-immunologic risk groups and 4) compatible KT, which served as the control group. The expression of complement regulatory proteins including CD59, CD55, CD46, and CD35 was measured from allograft tissue within 1 year after KT using RNA isolation and quantitative reverse transcription-PCR (qRT-PCR).

**Results:** There were 87 patients enrolled of which 12 were ABOi KT, 22 were HLAi KT, 6 were combined ABOi and HLAi KT and 47 were compatible KT group. There was no differences in CD59, CD55, CD46, and CD35 expression between all groups. However, CD46 expression was significantly higher in ABOi KT patients with C4d positive (accommodation) who have a high ABO titer ( $\geq 1:32$ ) compared to a low ABO titer ( $<1:32$ ) ( $p = 0.006$ ). In addition, CD 59 was upregulated in high-immunologic risk patients compared with the control group ( $p = 0.018$ ).

**Conclusions:** This study found no evidence of increased CD59, CD55, CD46, or CD35 expression in ABOi KT compared with other types of transplantation. However, CD46 expression increased in association with the ABO titer. All types of incompatible KT revealed higher CD59 expression, which may play roles protection of the allograft against preformed antibodies.

## TH-PO653

### Universal Antigen Specific CD8 Treg to Suppress Alloreactive T Cells

Anis J. Saad,<sup>1,3</sup> John Y. Choi,<sup>1,3</sup> Hye-jung Kim,<sup>2,3</sup> Nour K. Younis,<sup>1,3</sup> Hengcheng Zhang,<sup>1,3</sup> Christa A. Deban,<sup>1,3</sup> Zhabiz Solhjoui,<sup>1,3</sup> Ahmad Halawi,<sup>1,3</sup> Harvey Cantor,<sup>2,3</sup> Jamil R. Azzi.<sup>1,3</sup> <sup>1</sup>Brigham and Women's Hospital Department of Medicine, Boston, MA; <sup>2</sup>Dana Farber Cancer Institute, Boston, MA; <sup>3</sup>Harvard Medical School, Boston, MA.

**Background:** We have previously shown that alloreactive T cells upregulate their expression of Qa-1(HLA-E in human)-FL9 peptide complex, making them susceptible to killing by Qa1 restricted CD8 Treg. Mobilization and activation of CD8 Treg in vivo by immunization with an engineered FL9 peptide superagonist, dampens Tfh-dependent Ab mediated injury and prolongs allograft survival. Therefore, we hypothesized that adoptively transferred FL9-antigen specific CD8 Treg may preferentially suppress the alloimmune response, and delay allograft rejection, opening new horizons for the use of CD8 Treg in cellular therapies.

**Methods:** We generated FL9-Qa-1 TCR Transgenic mice (FL9-Tg). We then transplanted B6 hosts with BALB/c skin allografts with or without vaccinating with FL9 superagonist AND with or without adoptively transferring CD8 T cells isolated from FL9 TCR Tg mice. One group of skin allograft recipient was subsequently transplanted with BALB/c hearts. Allograft survival was monitored and CD8 Treg migration was tracked in allograft and lymphoid organs. Mechanistic analysis was performed in the spleen, LN and allograft.

**Results:** FL9 specific CD8 Tregs significantly suppressed Tfh, GC B cell differentiation and DSA production, prolonging skin and heart allograft survivals compared to FL-9 superagonist alone or untreated recipients ( $p<0.05$ ). Furthermore, the superagonist vaccine and CD8 Treg adoptive transfer group showed a synergistic effect ( $p<0.05$ ), prolonging mean survival time of heart allografts from 4 to up to 15 days in a stringent sensitized transplant model.

**Conclusions:** Implementation of Tg CD8 Treg in cellular therapies has provided proof of concept data for the role of CD8 Treg in allo-immune response with high translational potential.

## TH-PO654

### Single Cell RNAseq Analysis of Kidney Transplant Biopsies Demonstrates a Role for Endothelial Cell CCL23 in Antibody Mediated Rejection

Andrew F. Malone, Aidan Leckie-Harre. *Washington University in St Louis, St Louis, MO.*

**Background:** Antibody mediated rejection (AMR) remains one of the major causes of allograft failure and our understanding of this disease process is poor. Macrophages are thought to play an important role in the alloimmune reaction including AMR. We performed single cell RNAseq on biopsies from transplant patients to examine the effects of endothelial cell ligand expression on macrophages in AMR.

**Methods:** The 10X Genomics platform was used to make libraries which were sequenced to a depth of ~50k reads/cell. Gene-cell matrices were obtained from Cell Ranger and the downstream analysis were done using R and Seurat. The effect of ligand expression on target cells was analyzed using nichenetr. nichenetr predicts ligand-receptor interaction based on known target cell gene activity in response to ligand activity. This study had IRB approval.

**Results:** 15375 cells in total from 5 kidney transplant biopsy samples (3 AMR and 2 non-AMR) were included in the final integrated analysis using UMAP. All major kidney cell types were identified including macrophages. Endothelial cells (EC) were subclustered into 4 subgroups, IFNg\_EC, PTC\_EC, GEC\_EC, and angiogenic\_EC. The ligand with the greatest prediction score (0.958) for target cell (macrophage) gene activity in the rejection niche was CCL23 acting through CCR1 receptor. CCL23 was differentially expressed in IFNg\_EC cells in AMR (compared to other ECs and non-rejecting ECs).

**Conclusions:** A target gene activity approach to ligand-receptor analysis using single cell RNAseq of human kidney transplant biopsies suggests CCL23 expression from endothelial cells interacts with macrophages in AMR. Therefore, CCL23 may mediate macrophage recruitment to the kidney allograft in AMR.

**Funding:** NIDDK Support

## TH-PO655

### Immune-epithelial Niches Are Dose-Dependent in Calcineurin Inhibitor Nephrotoxicity

Seth Winfree,<sup>1</sup> Kyle Mcandrews,<sup>1</sup> Krysten Vance,<sup>1</sup> Gregory S. Kubik,<sup>1</sup> Anna A. Zmijewska,<sup>2</sup> James Eudy,<sup>1</sup> Roslyn B. Mannon.<sup>1</sup> <sup>1</sup>University of Nebraska Medical Center, Omaha, NE; <sup>2</sup>University of Alabama, Birmingham, AL.

**Background:** While mainstay immunosuppressive agents in kidney transplantation, calcineurin inhibitors (CNIs) are limited by their intrinsic nephrotoxicity. Understanding the mechanisms of injury following chronic CNI exposure is critical to developing strategies to ameliorate this toxicity. There is growing evidence the interplay between the renal tubular epithelium and immune cells plays a critical role in renal injury and disease. We used spatial transcriptomics (ST) to elucidate this interaction and the role immune-epithelial niches may play in CNI nephrotoxicity.

**Methods:** 8-10 week old mice on a low-salt diet were treated with 90 or 120 mg/kg Cyclosporine A (CsA) daily for two weeks and kidneys were harvested and frozen. Frozen kidneys were embedded in optimal cutting temperature media prior to sectioning. High quality tissue sections (RIN 6-8) were processed for use on the 10x Visium platform including imaging and library generation followed by next-generation sequencing. FASTQ and TIFF file processing were performed with Cell Ranger. Expression matrices and images were imported into Seurat (v4.0) for analysis. Cell-type distributions within Visium spots were determined by deconvolution with SPOTLight (v0.1.7) using a scRNASeq reference library generated from mouse kidneys.

**Results:** Cortical and medullary markers of the murine kidney were identified by ST and spatially correlated with histologically defined regions of the kidney. Following treatment with CsA, kidney injury markers, *Havcr1* and *Lcn2*, increased. At the higher dose of CsA, there was a differential upregulation of immune markers, cytokine/chemokines and profibrotic genes. After Visium spot deconvolution, epithelial cell signatures were identified and localized to expected regions of the kidney. Further, signatures of immune cells were associated with specific tubular subsegments (cortical vs. medullary-thick ascending limb) in a CsA dose dependent manner.

**Conclusions:** Our data demonstrates ST can uncover molecular profiles and cellular niches of CNI nephrotoxicity. Furthermore, our data provide initial observations of a shift in the transcriptional state of the kidney and the cellular niches of toxicity with increasing doses of CsA. This suggests multiple mechanisms of injury in nephrotoxicity may be at play as a function of CNI dose.

**Funding:** Veterans Affairs Support

## TH-PO656

### Paracrine FGF23 Signaling Suppresses Erythropoiesis in Iron Deficiency Anemia

Guillaume Courbon, Jadeah J. Spindler, John C. Von Drasek, Aline Martin, Valentin David. Northwestern University Feinberg School of Medicine, Chicago, IL.

**Background:** Iron deficiency anemia (IDA) stimulates fibroblast growth factor 23 (FGF23) production in osteocytes and erythroid cells, leading to excess circulating FGF23 derived fragments but only slightly elevated intact (iFGF23). Recent studies have suggested that rising iFGF23 in IDA negatively regulates erythropoiesis. However, the contribution of osteocytic and/or erythroid iFGF23 production to anemia remains to be determined.

**Methods:** We generated conditional *Fgf23* knockout mice by deleting *Fgf23* under the control of dentin matrix protein 1 (*Dmp1*) in osteocytes (*Fgf23<sup>Dmp1-cKO</sup>*) or hemoglobin Beta (*HbB*) in erythroid cells (*Fgf23<sup>HbB-cKO</sup>*). Next, we induced IDA in mutant and wild-type (WT) mice, by feeding animals a control (Ctr) or a low-iron diet (ID) from 3 to 6 weeks of age. In all mice, we analyzed serum biochemical parameters of iron metabolism, hematological parameters and bone marrow erythroid differentiation by flow cytometry and PCR. In parallel, we investigated the effects of FGF23 signaling in erythroid cell cultures, in presence of recombinant FGF23 and FGF receptors inhibitors.

**Results:** Compared to WT-Ctr mice, WT-ID mice developed IDA, marked by decreased serum iron, Hb content, increased erythroid progenitors, and a reduction in erythroblasts and reticulocytes number ( $p < 0.05$ ). WT-ID mice also showed a mild but significant increase in serum iFGF23 levels. Deletion of *Fgf23* in osteocytes completely rescued iFGF23 levels in *Fgf23<sup>Dmp1-cKO</sup>*-ID mice. In sharp contrast, deletion of *Fgf23* in erythroid cells only minimally decreased circulating iFGF23 levels. Intriguingly, suppression of *Fgf23* in erythroid cells corrected the reductions in Hb in ID mice, whereas suppression of *Fgf23* in bone did not. In addition, *Fgf23<sup>HbB-cKO</sup>*-ID mice showed a ~30% increase in erythroblasts and reticulocytes number compared to WT-ID mice. In line with these findings, erythroid progenitors treated with escalating doses of iFGF23 dose dependently blocked erythroid differentiation at precursor stage and reduced reticulocyte number. These effects were fully suppressed by co-treatment with FGFR1 inhibitor.

**Conclusions:** In aggregate, our results show that erythroid-produced iFGF23, but not circulating iFGF23, is a negative regulator of erythropoiesis and contributes to anemia via FGFR1 activation in erythroid precursors.

## TH-PO657

### Inflammation-Induced Alterations in Erythropoiesis at the Single Cell Level

Jane J. Thomas, Guillaume Courbon, Aline Martin, Valentin David. Northwestern University Feinberg School of Medicine, Chicago, IL.

**Background:** Inflammation is a common determinant of anemia in patients with chronic kidney disease (CKD). Inflammation restricts bone marrow (BM) erythropoiesis, due to hepcidin-mediated hypoferremia, and increases erythrophagocytosis. In addition, pro-inflammatory cytokines act on erythroid cells to suppress erythroid differentiation. Splenic hematopoiesis helps maintain erythroid homeostasis in inflammation, but the exact mechanisms are poorly understood.

**Methods:** To investigate the immediate effects of inflammation on BM and on the spleen (SP), we injected 6 week-old mice with a single dose of saline (Ctr) or 250 ng/g IL-1 $\beta$  (IF) and performed single cell RNA sequencing on BM and SP cells from Ctr and IF mice collected 4 hours post-injection. We examined the hematopoietic progenitors and terminally differentiated cells response to IF using differentiation-specific molecular markers.

**Results:** Compared to Ctr, IF rapidly led to an increased recruitment of precursors to myeloid progenitors in BM. In addition, IF increased the number of lymphoid and megakaryocytic progenitors at the expense of the erythroid lineage in BM. In contrast, IF increased the number of terminally differentiated cells detected in SP. Indeed, while the number of lymphoid progenitors and precursors increased in BM, the number of terminally differentiated B, T and NK cells increased in SP in response to IF. A similar effect was seen in the megakaryocytic lineage resulting in an increased number of megakaryocytes in SP during IF. Interestingly, we further found that SP-differentiated erythroid cells were identical to BM erythroblasts, suggesting that trafficking of BM erythroid progenitors to the SP, rather than de novo recruitment of splenic precursors, maintains extramedullary erythropoiesis. However, in addition to mature reticulocytes, we found an alternate cluster of cells differentiating from orthochromatic erythroblasts in SP that was quasi-absent in BM. This cluster increased in response to IF, and shows a reduction in apoptotic markers and an increase in mature reticulocyte markers compared to steady state reticulocytes.

**Conclusions:** In aggregate, our results suggest that IF leads to increased trafficking of erythroid progenitors from the BM to the SP. Further maturing of erythroid progenitors in the SP results in reticulocytes that might be functionally distinct from BM cells.

### Rates of Major Events in Untreated Patients Diagnosed With Anemia of CKD in France

Gema Requena,<sup>1</sup> Benedicte Stengel,<sup>2</sup> Oriane Lambert,<sup>2</sup> Ziad Massy,<sup>2,3</sup> Anne-Charlotte M. De Gouvello,<sup>4</sup> Sally Wetten,<sup>1</sup> Marianne Cunningham.<sup>1</sup> <sup>1</sup>GlaxoSmithKline, Brentford, United Kingdom; <sup>2</sup>CKD REIN, Paris, France; <sup>3</sup>Hôpital Ambroise Paré, AP-HP, Paris, France; <sup>4</sup>GlaxoSmithKline, Paris, France.

**Background:** New treatments for anemia of chronic kidney disease (CKD) within the hypoxia-inducible factor prolyl hydroxylase inhibitors (HIF-PHI) class have recently been approved or are in development. Evidence of background rates of major events of interest in the eligible population will improve the understanding of the benefit/risk of these new products. We describe rates of events of interest among eligible non-dialysis dependent (NDD) patients with anemia of CKD not receiving an erythropoiesis-stimulating agent (ESA).

**Methods:** CKD-REIN is a prospective cohort study that collected demographic and clinical information from 3033 NDD patients with CKD (stage 3-5 at enrollment) in France. All participants were assessed annually between July 2013-Dec 2019, and outcomes data were limited to fatal and hospitalization events. Anemia was defined by hemoglobin level ( $< 13$  g/dl for men,  $< 12$  g/dl for women). Patients were followed from the study entry (index date) until the event of interest or censoring for end of the study period, ESA use, dialysis, kidney transplant or death.

**Results:** 1,118 patients had anemia and were ESA-naïve at entry into CKD-REIN. Mean age was 68 yrs and 67% were men. The most common comorbidities were hypertension (97%), hyperlipidemia (67%) and diabetes (50%). The highest event rates of interest were all-cause mortality, heart failure, septicemia and malignancies (Table).

**Conclusions:** Results indicate that septicemia, heart failure and malignancies were common among these anemic CKD patients. The major complications observed will help physicians to better understand and manage these patients.

Patients untreated N=1,118	Events (n, %)	Event rate per 100py [95%CI]
Death (all cause)	335 (30%)	9.5 [8.5-10.5]
Myocardial Infarction	33 (3%)	1 [0.6-1.3]
Stroke	38 (3%)	1.1 [0.8-1.5]
Heart Failure	121 (11%)	3.6 [3-4.3]
Thromboembolic Event	19 (2%)	0.5 [0.3-0.8]
Pulmonary Arterial Hypertension	1 (0.1%)	0.03 [0-0.1]
Oesophageal and Gastric Ulcers	12 (1%)	0.3 [0.1-0.5]
Duodenum ulcer and unspecified peptic ulcer	9 (1%)	0.3 [0.1-0.4]
Malignancy	98 (9%)	2.9 [2.3-3.4]
Seizures	5 (0.4%)	0.1 [0-0.3]
Septicemia, Septic Shock, Other Infection	240 (21%)	7.3 [6.4-8.3]
Fractures	58 (5%)	1.7 [1.3-2.1]

TH-PO659

**Anemia and Dementia Risk in US Veterans With New-Onset CKD**  
Alain Koyama,<sup>1</sup> Wei Yu,<sup>2</sup> Nilka Rios Burrows,<sup>1</sup> Devasmita Choudhury,<sup>2,3</sup> Robert Nee,<sup>4</sup> Alfred K. Cheung,<sup>5,6</sup> Keith C. Norris,<sup>7</sup> Monique E. Cho,<sup>5</sup> Guofen Yan.<sup>2</sup> <sup>1</sup>*Centers for Disease Control and Prevention, Atlanta, GA;* <sup>2</sup>*University of Virginia, Charlottesville, VA;* <sup>3</sup>*VA Medical Center Salem, Salem, VA;* <sup>4</sup>*Walter Reed National Military Medical Center, Bethesda, MD;* <sup>5</sup>*University of Utah Health, Salt Lake City, UT;* <sup>6</sup>*VA Salt Lake City Health Care System, Salt Lake City, UT;* <sup>7</sup>*University of California Los Angeles, Los Angeles, CA.*

**Background:** Current evidence suggests anemia is a risk factor for dementia. Older adults with chronic kidney disease CKD are at increased risk of both anemia and dementia; however, it is unclear how CKD influences the association between these two conditions. We examined the association between anemia and risk of dementia in US veterans with new-onset CKD.

**Methods:** The cohort included 444,474 veterans, aged ≥65 years, with new-onset CKD (estimated GFR<60 mL/min/1.73 m<sup>2</sup> for >3 months) in 2005-2016 in the Veterans Health Administration (VHA), followed for 2-14 years. At baseline, veterans were free of dementia and end-stage kidney disease. The severity of anemia was determined using baseline hemoglobin with pre-defined thresholds (g/dL): moderate or severe, <11.0; mild, 11.0-11.9; and none ≥12.0 for women; and <11.0, 11.0-12.9, and ≥13.0 for men, respectively. The outcome was incident dementia over follow-up identified using ICD-9/10 codes in claims from the VHA and Centers for Medicare & Medicaid Services. We estimated unadjusted and adjusted risks of dementia using cause-specific hazard ratios to account for the competing risk of death.

**Results:** The cohort had a mean±SD age of 76.3±7.2 years, and 98% were men. At baseline, 22,329 (5%), 114,314 (26%), and 307,831 (69%) veterans had moderate or severe anemia, mild anemia, and no anemia, respectively. Dementia incidence per 1,000 person-years was 52.7, 46.1, and 35.9 cases for patients with moderate or severe, mild, and no anemia, respectively. After multivariable adjustment, compared to patients without anemia, those with moderate or severe anemia had a 23% significant increased risk of dementia, while those with mild anemia had a 12% significant increased risk (Table).

**Conclusions:** Among patients with incident CKD, anemia was independently associated with an increased risk of dementia.

Dementia risk by anemia status among veterans with incident CKD

	Incidence of dementia (per 1000 patient-years)	Unadjusted hazard ratio (95% CI)	Adjusted hazard ratio (95% CI)*
No anemia	35.9	1.00 (reference)	1.00 (reference)
Mild anemia	46.1	1.35 (1.32-1.37)	1.12 (1.10-1.14)
Moderate or severe anemia	52.7	1.60 (1.55-1.65)	1.23 (1.19-1.27)

\*adjusted for demographics and baseline clinical characteristics (eGFR, erythropoietin-stimulating agent use, body mass index, systolic and diastolic blood pressure, smoking status, and a wide range of prevalent comorbidities)

TH-PO660

**Psychometric Properties of the SF-36 Vitality Scale in Patients With Anemia of CKD**  
Tom J. Keeley,<sup>1</sup> Wen-Hung Chen,<sup>2</sup> Rodrigo Refoios Camejo,<sup>1</sup> Tony Okoro,<sup>2</sup> Margaret Vernon,<sup>3</sup> Ray Hsieh,<sup>4</sup> Sonja M. Stringer,<sup>4</sup> Kirsten L. Johansen.<sup>5</sup> <sup>1</sup>*GlaxoSmithKline, Brentford, United Kingdom;* <sup>2</sup>*GlaxoSmithKline, Collegeville, PA;* <sup>3</sup>*Evidera, London, United Kingdom;* <sup>4</sup>*Evidera, Bethesda, MD;* <sup>5</sup>*Hennepin Healthcare, University of Minnesota, Minneapolis, MN.*

**Background:** The Short-Form 36 is a widely used generic health-related quality of life (HRQoL) measure. The Vitality domain of the SF-36 (SF-36VT) offers a 4-item assessment of fatigue and energy levels. We evaluate the psychometric properties and score interpretation of SF-36VT in patients with anemia of chronic kidney disease (CKD).

**Methods:** A sample of 450 patients with anemia of CKD not currently receiving dialysis and patients initiating dialysis was used in these analyses. Assessments included reliability, construct validity and responsiveness. Thresholds for within-patient meaningful change were estimated by anchor-based (*a priori* anchors: Patient Global Impression of Severity [PGI-S] and PGI-Change [PGI-C]) and distribution-based methods.

**Results:** Internal-consistency reliability was good (Cronbach's alpha 0.83), and test-retest reliability was acceptable (intraclass correlation coefficient 0.68). Convergent validity was strong based on correlations (≥0.5) with the Chronic Kidney Disease-Anemia Questionnaire (CKD-AQ) and the Work Productivity and Activity Impairment Questionnaire: Anemic Symptoms Clinical Practice Version (WPAI-ANS-CPV). Greater impairment based on SF-36VT score was associated with more severe ratings on PGI-S, supporting known-groups validity. SF-36VT scores were responsive to change, with consistent patterns of increase observed with improvements in other measures (eg PGI-S, SF-36 Physical Functioning, SF-36 General Health, Euroqol 5-dimension). Anchor-based methods yielded a within-patient meaningful change from Day 1 to Week 28 of 11.9 and 6.1 points on the SF-36VT based on 2-point and 1-point improvements in PGI-S, respectively. Within-patient meaningful change based on PGI-C ratings were 6.8 (very much improved) and 4.5 (moderately improved). Distribution-based estimates of within-patient meaningful change thresholds were 6.78 (0.3 SD), 11.31 (0.5 SD) and 9.56 (delta 0.50 SD).

**Conclusions:** SF-36VT is a reliable, construct-valid and responsive measure for assessing fatigue/energy in patients with anemia of CKD. SF-36VT within-patient meaningful change estimates help interpret the benefit of a medical intervention.

**Funding:** Commercial Support - GlaxoSmithKline

TH-PO661

**CKD and Anemia Questionnaire (CKD-AQ): A Reliable and Sound Patient-Reported Outcome Measure for Use in Patients With Anemia of CKD**  
Tom J. Keeley,<sup>1</sup> Wen-Hung Chen,<sup>2</sup> Rodrigo Refoios Camejo,<sup>1</sup> Tony Okoro,<sup>2</sup> Purav R. Bhatt,<sup>2</sup> Margaret Vernon,<sup>3</sup> Ray Hsieh,<sup>4</sup> Sonja M. Stringer,<sup>4</sup> Kirsten L. Johansen.<sup>5</sup> <sup>1</sup>*GlaxoSmithKline, Brentford, United Kingdom;* <sup>2</sup>*GlaxoSmithKline, Collegeville, PA;* <sup>3</sup>*Evidera, London, United Kingdom;* <sup>4</sup>*Evidera, Bethesda, MD;* <sup>5</sup>*Hennepin Healthcare, University of Minnesota, Minneapolis, MN.*

**Background:** CKD-AQ is the first patient-reported outcome (PRO) measure designed specifically to assess the symptom burden of anemia of CKD. It includes 21 items that give three domain scores (Tired/Low Energy/Weak, 10 items; Chest Pain/Shortness of Breath, 4 items; Cognitive, 3 items) and four individual item scores (difficulty sleeping, difficulty standing for long periods of time, severity-shortness of breath while sitting/resting, time with shortness of breath while not doing activity). We report on the measurement properties of CKD-AQ in patients with anemia of CKD.

**Methods:** Two separate samples (n=399, n=450) of combined data from patients with anemia of CKD not currently receiving dialysis and patients initiating dialysis were used. Factor structure was identified and tested using exploratory and confirmatory factor analyses (EFA/CFA). Other assessments: internal-consistency and test-retest reliability; construct validity; responsiveness; differential item functioning (DIF) analysis between patients on and not on dialysis.

**Results:** The three multi-item domain structure identified through EFA was confirmed with CFA, with factor analytic fit statistics above or just slightly below the recommended standard. Internal-consistency reliability was good (Cronbach's alpha 0.734–0.955) and test-retest reliability was adequate (intraclass correlation coefficient 0.555–0.701) for all scales. Convergent validity analysis showed hypothesized associations with Short-Form (SF)-36, Euroqol 5-dimension, and Work Productivity and Activity Impairment scores. CKD-AQ scores were significantly different among Patient Global Impression of Severity groups, supporting known-groups validity. Supporting responsiveness, improvements in CKD-AQ scale scores were consistently associated (r>0.3) with improvements in multiple external validation anchors (including SF-36 domains and component scores). There was no systematic difference in the way that dialysis and non-dialysis patients answered the CKD-AQ items.

**Conclusions:** CKD-AQ is a valid, fit-for-purpose and psychometrically sound PRO tool suitable for use in patients with anemia of CKD. The measure is licensable and ready for future use.

## TH-PO662

## Patient and Physician Preferences for Treatments of Anemia in CKD: Insights From the Qualitative Pilot of a Choice Experiment

Anna Richards,<sup>1</sup> Jaemin Seo,<sup>2</sup> Sarah Mulnick,<sup>2</sup> Ember Lu,<sup>3</sup> Tony Okoro,<sup>3</sup> Sebastian Heidenreich,<sup>4</sup> Rodrigo Refoios Camejo.<sup>1</sup> <sup>1</sup>GlaxoSmithKline, Brentford, United Kingdom; <sup>2</sup>Evidera, Bethesda, MD; <sup>3</sup>GlaxoSmithKline, Collegeville, PA; <sup>4</sup>Evidera, London, United Kingdom.

**Background:** A choice experiment (CE) was developed following literature review and qualitative interviews to understand patient/physician preferences for treatments of anemia of CKD. This pilot phase asked CE participants to make trade-offs between five treatment attributes.

**Methods:** The CE was pilot tested in virtual interviews with non-dialysis (ND; CKD stages 3–5) and peritoneal dialysis (PD) patients and nephrologists in US, Germany and Japan. Interviews explored if CE was understandable; the attributes relevant; and participants willing and able to make trade-offs. A think-aloud method from cognitive psychology was used to observe participants' understanding of the CE. Interviewers completed structured notes templates with their observations. Participants were asked if attributes of treatment profiles were more and less important to them when making choices.

**Results:** 18 patients (ND=13; PD=5) and 12 nephrologists participated. Attributes and levels were considered relevant and meaningful; relative importance within treatment profiles differed (**Table**). Patients focused more on route and frequency of administration (n=11, 61%) and reducing fatigue (n=10, 56%); physicians prioritized keeping Hb levels within target range (n=9, 75%) and 1-year risk of major cardiovascular events (n=6, 50%). Dosing restriction requirement (required time interval between taking phosphorous or iron supplements and anemia of CKD treatment) was less important for some patients and physicians (n=5, 28%; n=4, 33%), but more important to other patients (n=4, 22%).

**Conclusions:** Pilot testing met objectives for attribute comprehension, relevance, and tradability. Differences in importance of attributes presented in treatment profiles suggest divergent treatment priorities and presence of preference heterogeneity.

Table: Directly Stated More or Less Important Attributes in Pilot Interviews

Treatment Attributes within Profiles	Patients (n=18)		Physicians (n=12)	
	More Important*	Less Important*	More Important*	Less Important*
Route and frequency of administration	11 (61%)	1 (6%)	1 (8%)	0 (0%)
Keeping Hb in the target range	8 (44%)	1 (6%)	9 (75%)	0 (0%)
1-yr risk of major cardiovascular events*	3 (17%)	4 (22%)	6 (50%)	3 (25%)
Reducing fatigue	10 (56%)	2 (11%)	3 (25%)	2 (17%)
Dosing restriction requirement	4 (22%)	5 (28%)	1 (8%)	4 (33%)

\*Not mutually exclusive

## Artificial Intelligence (AI) Tool Decreases Epoetin Beta (Mircera) Drug Exposure and Maintains Hemoglobin at Desired Levels

Michael E. Brier,<sup>1,2</sup> Adam E. Gaweda,<sup>1</sup> George R. Aronoff,<sup>3</sup> <sup>1</sup>University of Louisville, Louisville, KY; <sup>2</sup>VA Robley Rex Medical Center, Louisville, KY; <sup>3</sup>Dosis Inc, San Francisco, CA.

**Background:** We innovated a clinical decision support tool for anemia management with epoetin alfa. This tool uses AI methods to classify patients into multiple dose-response categories combined with predictive control to achieve target hemoglobin over time. The tool was modified for use with long acting epoetin isoforms. We report clinical results with epoetin beta.

**Methods:** Data were abstracted from commercially available software Strategic Anemia Advisor (SAA, Dosis Inc, San Francisco, CA) between Dec 2018 and Mar 2022 and include dose and hemoglobin information on 2116 patients in 19 dialysis facilities receiving epoetin beta. Data were aggregated by month SAA use. Not every patient provided prior initiation data. Comparisons were the 12 month control period prior to SAA use, a 1 month washout period and a 12 month treatment period by linear regression and ANOVA using the factors Time (1-12) and SAA use. Epoetin beta is reported as the total monthly dose and hemoglobin as the mean monthly concentration.

**Results:** Statistical analysis demonstrated a mean monthly use of epoetin beta of 140 mcg/patient/month in the control period and an initial 40 mcg decrease with the use of SAA (p<0.001) that decreased over time (p=0.009) achieving a final dose of 84 mcg/patient/month. Achieved hemoglobin was 10.7 g/dL and not different in the Control periods and in SAA months 5-12. Mean Hb was 10.5 g/dL in SAA months 1-4 (p=0.05). These results are shown in Figure 1.

**Conclusions:** An AI-powered anemia management program developed using epoetin alfa response data was adapted for use with epoetin beta. Treatment of patients in a real-world setting confirm previous observations where efficacy is maintained over a 12 month period while decreasing epoetin beta dose 29% initially ending with a mean dose of 84 mcg/month (Months 9-12). Further, the tool achieves the stated goal for ESA therapy using the least amount of ESA to avoid transfusion.

## TH-PO664

## Discontinuation of Artificial Intelligence (AI) Tool for Anemia Management Results in Higher Drug Exposure, Lower Hemoglobin (Hb)

Michael E. Brier,<sup>1,2</sup> Adam E. Gaweda,<sup>1</sup> George R. Aronoff,<sup>3</sup> <sup>1</sup>University of Louisville, Louisville, KY; <sup>2</sup>VA Robley Rex Medical Center, Louisville, KY; <sup>3</sup>Dosis Inc, San Francisco, CA.

**Background:** We innovated a clinical decision support tool for anemia management. This tool uses AI methods to classify patients into multiple dose-response categories combined with predictive control to achieve target Hb over time. The tool was modified for use with long acting epoetin isoforms (epoetin beta, Mircera®). We tested the hypothesis that dropping anemia management guidance will decrease quality.

**Methods:** Data were abstracted from a commercially available software Strategic Anemia Advisor (SAA, Dosis Inc, San Francisco, CA) between Dec 2018 and Mar 2022 on 855 patients in 5 dialysis facilities receiving epoetin beta located in the same geographic area. SAA use was left at the discretion of the facility medical director. Two facilities used SAA over the duration of the data capture (Facility 1 and 2), one facility never used SAA (Facility 3) and two facilities discontinued SAA at month 53 and 54 (Facility 4 and 5). Data were aggregated by month and an indicator of SAA recommendations.

**Results:** Facilities that used SAA guidance had higher Hb and lower monthly dose of epoetin beta/patient than the facility that did not use SAA (p<0.001). Discontinuation of SAA caused Hb to fall by about 0.6 g/dL and dose increased 30-39 mcg/patient/month. Mean Hb and dose are shown in Table 1. SAA use is shown as a solid line and no SAA use is shown as a dashed line in Figure 1.

**Conclusions:** Discontinuing AI management results in an immediate, detrimental effect on Hb and ESA dose. Those facilities that never used SAA or discontinued use observed an increased dose of epoetin beta and a decrease in Hb obtained. This is likely due to increased manipulation of the dose in resulting in over control the Hb concentration.

Facility	1	2	3	4	5
SAA	Yes	Yes	No	Yes	No
Hb (g/dL)	11.1	10.6	10.3	10.5	9.8
Dose (mcg/patient/month)	47	70	139	65	102

TH-PO665

An Explainable Model of ESA Prescription in the Hemodialysis Population

Yi-Wen Chiu,<sup>1,3</sup> Ming-Yen Lin,<sup>1</sup> Chan-Tung Ku,<sup>2</sup> Hong-Ren Yen,<sup>2</sup> Chan Hsu,<sup>2</sup> Yihuang Kang,<sup>2</sup> <sup>1</sup>Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, Taiwan; <sup>2</sup>National Sun Yat-sen University, Kaohsiung, Taiwan; <sup>3</sup>Kaohsiung Medical University, Kaohsiung, Taiwan.

**Background:** Our RCT (NCT04185519) has demonstrated the AI-assisted ESA prescription can maintain the Hb therapeutic target in HD patients, not inferior to physicians, and ESA dose-saving. However, the mechanism is untransparent.

**Methods:** A Generalized Linear Mixed-Effects Model (GLMM) was trained by ESA doses, Iron supplement, Hb levels, and demographic and biochemical data of HD patients between 2014 and 2020. Except for mean absolute error (MAE), the traditional ESA dose prescription algorithm (TEA) was compared for the model efficiency. An index named “Confidence” was calculated as the percentage of optimal ESA dose predicted by a model. The optimal ESA dose was defined as within one syringe dose different from the ones maintaining the Hb within 10.8-11.2 gm/dL.

**Results:** 25,979 records of 316 ESKD patients were included, with 71.9% of Hb between 10-12mg/dL. The MAE were 0.4534 and 0.4964 gm/dl in training and testing data, respectively. Increasing the tree number and the depth of tree may further lower the MAE at the cost of model interpretability. The determinants of Hb changing by ESA dose included Hb, Hb changes, ESA dose, ESA dose changes, and iron supplement. There were 13 branches in our model to classify all records and demonstrate the ESA prescription algorithms. Compared with the TEA, our model showed similar efficiency in optimal ESA dose prediction. (Table)

**Conclusions:** A simple mixed-effect tree model with 13 leaf nodes can predict and explain the relationship between ESA dose and Hb changes. The “Confidence” used in our study helps evaluate the model. A further RCT (NCT05032651) is ongoing to confirm its clinical application.

**Funding:** Clinical Revenue Support

	Records size	GLMM		TEA
	N (%)	MAE, gm/dL	ESA Confidence, %	ESA Confidence, %

TH-PO666

Prevalence of Hyporesponse to Erythropoiesis-Stimulating Agents Among Medicare Patients With CKD-Related Anemia According to Absolute or Weight-Based Definitions

Todd Berner,<sup>1</sup> Christine Ferro,<sup>2</sup> Gabriela Dieguez,<sup>2</sup> Steve Metz,<sup>2</sup> Darrin W. Benjumea,<sup>3</sup> Kirsten L. Johansen.<sup>4,5</sup> <sup>1</sup>Akebia Therapeutics Inc, Cambridge, MA; <sup>2</sup>Milliman USA, New York, NY; <sup>3</sup>Genesis Research LLC, Hoboken, NJ; <sup>4</sup>Hennepin Healthcare, Minneapolis, MN; <sup>5</sup>University of Minnesota, Minneapolis, MN.

**Background:** Erythropoiesis-stimulating agents (ESAs) are widely used to treat anemia of chronic kidney disease (CKD). ESA hyporesponsiveness is associated with adverse events, leading to higher healthcare resource utilization. Hyporesponse (HR) has been defined vaguely as need for high doses of ESAs with or without achieving target hemoglobin levels. No standard definition of HR exists, and terms offered in literature vary widely. Using data representing 100% of Medicare fee-for-service beneficiaries, we examined the prevalence of hyporesponsiveness using different definitions in a dialysis-dependent (DD)-CKD patient population in the US.

**Methods:** We identified patients with DD-CKD receiving 3+ months of outpatient dialysis (in-center or at home) with concurrent ESA use in 2019. For each patient, we defined months of HR as those where the hemoglobin level for the prior month was <10 g/dL and the current month’s average ESA weekly dose surpassed weight dependent and weight agnostic thresholds: 300 epoetin alfa (epo) units (U)/kg of body weight, 375U/kg, 450U/kg, and 18,000U. We assessed the number and percent of patients at least one month of HR or with at least 60% of months of HR.

**Results:** We identified 247,992 patients with DD-CKD and 3+ months of ESA use. Table 1 presents the number of patients and prevalence of HR by average weekly ESA dose threshold.

**Conclusions:** Different definitions of ESA hyporesponse among people with CKD-related anemia produced a range of prevalence rates. In our study, between 7.0% and 31.2% of patients experienced at least one month of HR; however, only a fraction of these (0.4% to 3.0%) were hyporesponsive for at least 60% of the time, reflective of the transient nature of the condition. Further research is needed to understand the clinical trajectories of episodically hyporesponsive patients.

**Funding:** Commercial Support - Akebia Therapeutics, Inc.

Table 1: Prevalence of hyporesponse to ESA therapy (2019 Medicare FFS)

Patient Counts (% Prevalence)	ESA Threshold (epoetin alfa U per week)			
	300/kg	375/kg	450/kg	18,000
With ≥1 Months HR	48,966 (19.7%)	29,332 (11.8%)	17,376 (7.0%)	77,380 (31.2%)
With ≥60% Months HR	3,663 (1.5%)	1,882 (0.8%)	1,006 (0.4%)	7,556 (3.0%)

ESA, erythropoiesis-stimulating agent; FFS, fee-for-service; HR, hyporesponse.

TH-PO667

Variation in Hemoglobin Distribution in Patients With CKD: The International Network of CKD Cohorts (iNET-CKD)

Mark Canney,<sup>1</sup> Dilshani Induruwage,<sup>2</sup> Mila Tang,<sup>2</sup> Lee Er,<sup>2</sup> Yinshan Zhao,<sup>3</sup> Natalia Alencar de Pinho,<sup>4</sup> Benedicte Stengel,<sup>4</sup> Maarten W. Taal,<sup>5</sup> Janis M. Dionne,<sup>6</sup> Harold I. Feldman,<sup>7</sup> Thomas Hiemstra,<sup>8</sup> Anna Richards,<sup>8</sup> Ognjenka Djurdjev,<sup>2</sup> Adeera Levin,<sup>3</sup> iNET-CKD Investigators <sup>1</sup>Ottawa Hospital Research Institute Clinical Epidemiology Program, Ottawa, ON, Canada; <sup>2</sup>BC Provincial Renal Agency, Vancouver, BC, Canada; <sup>3</sup>The University of British Columbia, Vancouver, BC, Canada; <sup>4</sup>Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; <sup>5</sup>Royal Derby Hospital, Derby, United Kingdom; <sup>6</sup>BC Children’s Hospital, Vancouver, BC, Canada; <sup>7</sup>University of Pennsylvania, Philadelphia, PA; <sup>8</sup>GlaxoSmithKline Plc, Brentford, United Kingdom.

**Background:** Hemoglobin (Hb) has a narrow target range in patients with CKD but little is known about geographical differences in Hb distribution. The aims of this global collaborative study were to compare the distribution of Hb across international CKD populations and evaluate predictors of Hb.

**Methods:** Two-stage individual participant data meta-analysis of cross-sectional data from participating iNET-CKD cohorts. Included participants were >18 years with non-dialysis CKD (eGFR <60 mL/min). Using a standardized protocol with harmonized definitions, the relationships between candidate predictors and Hb were evaluated in linear regression models and estimates were subsequently pooled in a random effects model.

**Results:** A total of 54,368 participants from 19 cohorts (median eGFR 17 to 49 mL/min) were included with broad geographic representation. Hb values varied substantially among the cohorts even within strata of eGFR and sex (Figure). Across the eGFR range, women had a lower Hb compared to men; however, these differences were smaller at lower eGFR (mean difference 13.2 g/L (95% CI 10.8-15.6) at eGFR of 60 mL/min versus 5.2 g/L (95% CI 3.5-7.0) at eGFR of 15 mL/min, p<0.001 for interaction). In a multivariable model, lower eGFR, female sex, older age, lower body mass index and diabetic kidney disease were independent predictors of a lower Hb value, but this only explained a minority of variance in Hb (median R<sup>2</sup> of 21% [range 7 to 44%] across the cohorts).

**Conclusions:** There are substantial regional differences in Hb distribution among individuals with CKD. The majority of variance in Hb is unexplained by demographics, GFR or comorbidities. A better understanding of international variation in Hb, and the factors that contribute to it, could change the way Hb values are interpreted in CKD.

**Funding:** Commercial Support - GSK

Figure: Hemoglobin distribution among international CKD cohorts by eGFR category and sex.

All cohorts are represented in the violin plots. The shaded bars represent the median and interquartile range. Wider sections of the plot represent a higher probability that members of the population take on a given value.

TH-PO668

Variation of Hemoglobin and Hematocrit by Timing of Blood Sampling in Hemodialysis Patients

Pichaya Tantiyavarong, Jakkraphip Weeravittayasate. Thammasat University Faculty of Medicine, Khlong Nueng, Thailand.

**Background:** Hemoglobin (Hb) and hematocrit (Hct) have been used to monitor anemia treatment and their values depending on plasma volume. In long hemodialysis interval, patients usually incur higher weight gain, which may lower Hb and Hct levels. This study aimed to compare Hb and Hct regarding blood sampling times.

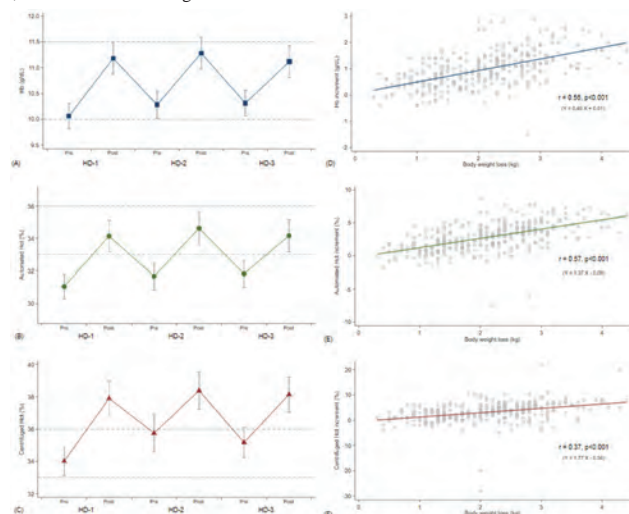

**Methods:** The prospective observational study was conducted in 103 patients receiving three hemodialysis sessions per week. Hb, automated and centrifuged Hct were collected pre- and post-dialysis in three consecutive sessions. Primary outcome

was to compare these measures between blood sampling periods (one long and two short intervals). Secondary outcomes were correlation with body weight loss, correlation between Hb and Hct, and agreement of automated and centrifuged Hct.

**Results:** There was no difference in the mean pre-dialysis Hb ( $10.1 \pm 1.2$  vs  $10.3 \pm 1.3$  vs  $10.3 \pm 1.3$  g/dL in long and two short intervals respectively;  $p = 0.320$ ), automated Hct ( $31.0 \pm 4.0$  vs  $31.7 \pm 4.4$  vs  $31.8 \pm 4.2\%$ ;  $p = 0.372$ ) and centrifuged Hct ( $34.0 \pm 4.6$  vs  $35.8 \pm 6.1$  vs  $35.2 \pm 4.8\%$ ;  $p = 0.054$ ). Weight losses were correlated with all incremental measures. Hb were strongly correlated with automated Hct ( $r = 0.98$ ,  $p < 0.001$ ) and centrifuged Hct ( $r = 0.86$ ,  $p < 0.001$ ). Centrifuged Hct was higher than automated Hct (mean difference of 3.65%).

**Conclusions:** Timing of pre-dialysis blood samplings did not impact the level of Hb, automated or centrifuged Hct. Either Hb or Hct can be used to monitor renal anemia.

**Effects of hydration status on hemoglobin, automated and centrifuged hematocrit: A – C) Comparison between pre and post-dialysis among three dialysis sessions; D – F) Incremental changes and body weight losses.**

Abbreviation: HD-1, the first hemodialysis session (long interval); HD-2, the second hemodialysis session (short interval); HD-3, the third hemodialysis session (short interval).

## TH-PO669

**Maintenance Intravenous Iron in Hemodialysis Patients to Minimize Erythropoietin Doses: A Double-Blinded, Randomized Controlled Trial**  
Pichaya Tantiyavarong,<sup>1,3</sup> Suthiya A. Anumas,<sup>2,3</sup> Aphichat Chatkraitlert.<sup>3</sup>  
<sup>1</sup>Thammasat University Faculty of Medicine, Khlong Nueng, Thailand;  
<sup>2</sup>Thammasat University, Pathum Thani, Thailand; <sup>3</sup>Thammasat University Hospital, Khlong Nueng, Thailand.

**Background:** There is no standard regimen for maintenance iron supplementation in chronic hemodialysis patients. We investigated fixed-appropriate doses of intravenous (IV) iron protocols for maintaining hemoglobin levels and minimizing erythropoietic-stimulating agents (ESA).

**Methods:** A double-blinded, randomized controlled trial was conducted in hemodialysis patients who had ferritin levels of 200-700 ng/dL and transferrin saturation (TSAT) 20-40%. Patients were randomized to receive either 100-mg or 200-mg monthly IV iron. ESA was adjusted monthly to maintain Hb of 10-12 g/dL. The primary endpoint was ESA dose at 12 months. Key secondary endpoints were all-cause mortality, cardiovascular events, absolute iron deficiency anemia (IDA), blood transfusion, adverse events, and iron withholding rate.

**Results:** Of 79 eligible patients, 40 were in the 100-mg IV iron group and 39 in the 200-mg. Mean monthly ESA dose at month 12 was  $35,706 \pm 21,637$  IU in the 100-mg IV iron group versus  $26,382 \pm 14,983$  IU in the 200-mg group ( $P = 0.03$ ). Twelve patients (30%) in 100-mg group and four patients (10.5%) in 200-mg one had IDA ( $P = 0.05$ ). Three patients in each group died ( $P = 0.9$ ). There were no significant differences in hospitalization, venous access thrombosis, and infection rate in both groups, but these were slightly higher in the 200-mg cohort. The withholding rate was 25% and 64.1% ( $P = 0.03$ ).

**Conclusions:** Monthly 200-mg IV iron doses were effective at minimizing ESA doses in hemodialysis patients but with a higher withholding rate. In high-ferritin patients, we suggest starting with 100-mg IV iron.

Mean monthly dosages of erythropoietin at month 0 (baseline), month 6, and month 12 (primary endpoint) between 100-mg and 200-mg intravenous iron groups

## TH-PO670

**Impact of Angiotensin Converting Enzyme Inhibitors and Angiotensin II Receptor Blockers on Erythropoiesis-Stimulating Agents in the CKD Population in Singapore**

Karmen Quek. Changi General Hospital, Singapore, Singapore.

**Background:** The hypothesis that angiotensin converting enzyme inhibitors (ACEi) and angiotensin II receptor blockers (ARB) affect erythropoiesis stimulating agent (ESA) dosing requirement remains controversial. To test this hypothesis in the local population, a retrospective observational cohort study was conducted in a group of chronic kidney disease patients with renal anaemia.

**Methods:** The effect of ACEi and ARBs were evaluated by tracing the ESA dosing requirement and haemoglobin concentration achieved within 6 months of newly initiating an ACEi or ARB. Results from 200 patients were compared between patients receiving ESA alone (control arm, N=100) and patients receiving both ESA and ACEi or ARB (intervention arm, N=100). Patients were further divided into 3 groups: ESA alone (N=100), ESA and ACEi (N=50), ESA and ARB (N=50) for stratified analysis. The outcomes evaluated after a 6-month follow-up include ESA dose, haemoglobin concentration and erythropoietin resistance index (ERI). Multiple linear regression analysis with adjustment was performed to eliminate the influence of confounding factors in the heterogeneous patient groups.

**Results:** The ACEi studied were enalapril (N=33), lisinopril (N=15) and perindopril (N=2). The ARBs studied were losartan (N=23), irbesartan (N=13), telmisartan (N=12) and valsartan (N=2). The addition of ACEi and ARB did not have an effect on ESA dosing requirement ( $84.1 \pm 50.6$  vs  $91.1 \pm 58.1$  U/kg/week,  $P=0.37$ ) and haemoglobin concentration ( $10.7 \pm 1.3$  vs  $10.6 \pm 1.2$  g/dL,  $P=0.67$ ) in both direct comparison and multiple linear regression analysis. For the stratified analysis, two parameters in the multiple linear regression model, baseline haemoglobin concentration and ESA dose had an effect on ESA dose ( $P=0.033$  and  $P=0.001$ , respectively) and ERI ( $P<0.001$  for both) at the end of the 6-month follow-up period.

**Conclusions:** The findings of this study suggest that ACE inhibitors and ARBs do not contribute to ESA resistance and may be used as indicated in the local CKD population. Nevertheless, given the wide divide in current opinion, it may be prudent to trial dose reduction or cessation of ACEi or ARB in patients if there is no other clearly definable cause for ESA hyporesponsiveness and if the anticipated benefits exceed the anticipated risks.

## TH-PO671

**Don't Forget About Trace Minerals: A Rare Case of Erythropoietin-Resistant Anemia**

Andrew Yanik, Josephine Abraham, Tooran Lavasani. University of Utah Health, Salt Lake City, UT.

**Introduction:** Erythropoietin (EPO) resistant anemia is a problem often encountered in patients with end stage renal disease (ESRD), and a rare cause of this is copper deficiency. We report the case of a patient with EPO resistant anemia attributable to zinc induced copper deficiency.

**Case Description:** A 69-year-old male with ESRD due to type I diabetes mellitus on intermittent hemodialysis and darbepoetin for anemia was referred to hematology for EPO resistant anemia as well as pancytopenia. Notably, he also followed with ophthalmology for a history of acute angle closure glaucoma. His hemoglobin had ranged from 9.0-12 g/dL for a period of about three years. Six months prior to referral, he was admitted for a hip fracture complicated by severe anemia with a hemoglobin to 6.2 g/dL. There was no evidence of blood loss and anemia was attributed to ESRD. His hemoglobin had remained at 6.5-8 g/dL despite an escalating dosing of erythropoietin and pancytopenia was noted, prompting referral to hematology. Labs were pertinent for hyperzincemia to 124 ug/dL (ref 60-120) with hypocupremia to 20.6 ug/dL (ref 70-140). On further investigation, he was noted to have been taking a multivitamin regimen prescribed by ophthalmology that

contained 160 mg of daily zinc. This was held and copper supplementation was initiated. Repeat studies later revealed zinc and copper to be normal at 90.9 µg/dL and 88.8 µg/dL respectively. His hemoglobin has remained 10-12.1 g/dL since.

**Discussion:** EPO resistant anemia is not uncommon for patients with ESRD on dialysis, and hypocupremia is an underreported etiology. Zinc deficiency is reported in up to 80% of patients with ESRD and is therefore often supplemented. Zinc competes with other metals at the metallothionein protein receptor in the small intestine. In the setting of hyperzincemia, this receptor upregulates as a homeostatic mechanism and copper's higher affinity for the receptor promotes its binding and ultimate loss in the stool, causing hypocupremia. As illustrated in the case presented here, zinc induced copper deficiency is a clinically relevant cause of EPO resistant anemia in ESRD.

## TH-PO672

### The Direct Effect of the Vitamin D Receptor Activation in Hemoglobin: Opening a New Treatment Approach in Renal Anaemia

Miguel Uriol Rivera,<sup>1,2</sup> Gemma Arrufat Goterris,<sup>1</sup> Aina Obrador,<sup>1</sup> Angel Garcia-Alvarez,<sup>3</sup> Sonia Jimenez,<sup>1</sup> <sup>1</sup>Hospital Universitari Son Espases, Palma de Mallorca, Spain; <sup>2</sup>Fundacio Institut d'Investigacio Sanitaria Illes Balears, Palma de Mallorca, Spain; <sup>3</sup>Hospital Comarcal d'Inca, Inca, Spain.

**Background:** Renal anemia (RA) is a major problem in chronic kidney disease (CKD). Correcting the relatively low plasma erythropoietin levels as a treatment strategy has safety concerns. The supraphysiological erythropoiesis stimulus increases the number of reticulocytes that could be associated with detrimental effects especially increasing anisocytosis which is easily determined by the changes in red blood cell distribution width (RDW) values. The benefit of the selective vitamin D receptor activation improving hemoglobin levels has been described; however, whether the effect of the paricalcitol in RA is independent of the secondary hyperparathyroidism (SHPT), renal function and its effect on RDW is unknown.

**Methods:** This is a retrospective study. Patients were treated with paricalcitol and followed up for 6 months. Patients were stratified according to the presence of SHPT (plasma parathyroid hormone < 72 pg/ml) and chronic kidney disease (CKD, plasma creatinine < 1.3 mg/dl) and renal anemia (hemoglobin < 12 g/dl for female and < 13 g/dl for male. Neither recombinant erythropoietin nor iron supplements were administered. Exclusion criteria were bleeding or recent blood transfusion history.

**Results:** 40 patients were included. Sex (M/F): 26/14. Mean age: 57 (18) years. Overall, the mean (95%CI) was 0.8 (0.4 to 1.2) g/dL, P<0.001. Hemoglobin increased in patients with and without SHPT [0.9 (0.2 to 1.6) and 0.7 (0.2 to 1.1) g/dL, P<0.014 and P=0.004, respectively], in patients with or without CKD [0.9 (0.3 to 1.6) g/dl and 0.6 (0.1 to 1.1), P<0.013, P=0.004, respectively] and in anemic versus non-anemic patients [0.9 (0.2 to 1.7) g/dl and 0.6 (0.2 to 1.0) g/dL, P=0.01 and P=0.004, respectively]. Interestingly red blood cells count (RBC) increased in all groups, but no changes in mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH) and RDW were observed.

**Conclusions:** Paricalcitol therapy increased significantly hemoglobin levels independently of SHPT and chronic kidney disease. Paricalcitol increased the RBC number maintaining the degree of anisocytosis in the physiological range. These results represent a real opportunity for exploring the use of paricalcitol as a safe and effective therapy for renal anemia.

## TH-PO673

### ESAs in Hemodialysis Patients With Malignancy: A Multicenter, Retrospective Cohort Study

Junkyu Park, Sungjin Chung, Eun Sil Koh, Wonji Jo. *Catholic University of Korea School of Medicine, Seoul, Republic of Korea.*

**Background:** Anemia is a common complication in both chronic kidney disease (CKD) and malignancy, associated with mortality and decreased quality of life. Erythropoiesis-stimulating agents (ESAs) are commonly used to treat anemia in CKD patients. However, the risk of cancer progression of ESAs use has been constantly implicated. KDIGO guideline recommends to use ESAs with great caution for anemia in CKD patients combined with malignancy due to the risk of cancer progression. Recently, Several studies showed that it might be irrelevant. In this study, the impact of ESAs use on the risk of cancer progression and mortality has been explored.

**Methods:** A retrospective, multi-centered cohort was established using electronic medical records from 5 different medical institutes. Patients who were 18 years old or older, had been newly diagnosed end-stage renal disease and begun hemodialysis were considered as eligible participants. A total of 894 patients were enrolled from March 1, 2010 to December 31, 2017. The patients were classified into three groups based on ESAs prescription patterns: never users, dynamic users, and always users. The association between ESAs use and the occurrence of newly diagnosed malignancy, recurrence of pre-existing cancer, and mortality were investigated.

**Results:** The mean age of the patients was 62 years and 58% were male. Diabetes consisted of 61.0% of the patients and 81.5% were hypertensive. The mean hemodialysis vintage was 6.9 years. Primary incidence of malignancy recurrence, newly diagnosed malignancy and mortality was 9 (1.9%), 52 (5.8%), 133 (14.9%), respectively. Multivariable cox regression analysis revealed that ESAs use is not significantly associated with mortality (Hazard ratio (HR), 0.55; Confidential index (CI), 0.19-1.52; P=0.246). The risk for newly diagnosed cancer decreased in always users compared with never users (HR, 0.12; CI, 0.02-0.67; P=0.016). The risk of newly diagnosed cancer for dynamic users were statistically insignificant compared with never users (HR, 0.23; CI, 0.05-1.08; P=0.063).

**Conclusions:** This study showed that there is no statistically significant difference in mortality risk among ESAs use patterns, and partially decreased risk for cancer progression. A careful, individualized administration of ESAs to patients with ESRD and malignancy can be considered for anemia treatment.

## TH-PO674

### The Effect of Intravenous Iron on Exercise Capacity in Iron-Deficient but Not Anaemic Patients With CKD: A Multicentre Prospective Double-Blind Randomised Controlled Trial

Sharlene A. Greenwood,<sup>1,2</sup> Benjamin A. Oliveira,<sup>2</sup> Elham Asgari,<sup>4</sup> Salma Ayis,<sup>2</sup> Luke A. Baker,<sup>3</sup> Debasish Banerjee,<sup>5</sup> Sunil Bhandari,<sup>6</sup> Joseph Chilcot,<sup>2</sup> James Burton,<sup>3</sup> Philip A. Kalra,<sup>7</sup> Courtney J. Lightfoot,<sup>3</sup> Iain C. Macdougall,<sup>1</sup> Anastasios Mangelis,<sup>2</sup> Kieran McCafferty,<sup>8</sup> Darlington Okonko,<sup>2</sup> Fiona Reid,<sup>2</sup> Alice C. Smith,<sup>3</sup> Pauline A. Swift,<sup>9</sup> Emma L. Watson,<sup>3</sup> David C. Wheeler,<sup>10</sup> Thomas J. Wilkinson,<sup>3</sup> Kate Bramham,<sup>2</sup> <sup>1</sup>King's College Hospital NHS Foundation Trust, London, United Kingdom; <sup>2</sup>King's College London, London, United Kingdom; <sup>3</sup>University of Leicester, Leicester, United Kingdom; <sup>4</sup>Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; <sup>5</sup>St George's University Hospitals NHS Foundation Trust, London, United Kingdom; <sup>6</sup>Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom; <sup>7</sup>Salford Royal Hospital, Salford, United Kingdom; <sup>8</sup>Royal London Hospital Cardiovascular Services, London, United Kingdom; <sup>9</sup>Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom; <sup>10</sup>University College London, London, United Kingdom.

**Background:** Many people living with chronic kidney disease (CKD) are iron deficient, even though they may not be anaemic. The Iron and Muscle study aimed to evaluate whether iron supplementation leads to enhanced exercise capacity and physical function.

**Methods:** Prospective, double-blind multicentre randomised controlled trial (RCT) with non-dialysis CKD patients with iron deficiency but without anaemia. Patients were randomly assigned (1:1) to either: i) intravenous (IV) iron therapy, or ii) placebo. Primary outcome was difference in six-minute walk test (6MWT) between groups at 4 weeks. Secondary outcomes included: fatigue, physical function, muscle strength, quality of life, clinical chemistry, safety and harms at baseline, 4, and 12 weeks. Difference in means for all outcomes between groups was analysed using an ANCOVA model.

**Results:** We randomly assigned 75 patients with mean (SD) age for iron therapy [(n=38) 54(16) yrs vs placebo (n=37) 61(12) yrs], mean (SD) eGFR [34(12) vs. 35(11) ml/min/1.73m<sup>2</sup>], mean (SD) transferrin saturation (TSAT) [23 (12) vs. 21 (6)%], mean (SD) serum ferritin (SF) [57 (64) vs. 62 (33) µg/L] and mean (SD) 6MWT [384 (195) vs. 469 (142) metres] at baseline, respectively. Adjusting for baseline measures, 6MWT showed no statistically significant difference between arms at 4 weeks (p=0.263), or 12 weeks (p=0.321). There were non-significant increases in 6MWT from baseline to 12 weeks in the IViron arm. There were statistically significant increases in SF and TSAT at 4 and 12 weeks (p<0.001) and haemoglobin at 12 weeks (p=0.0135). There were no adverse events attributable to IV iron.

**Conclusions:** This study did not demonstrate any significant beneficial effect of IV iron on exercise capacity despite improvements in parameters of iron status and Hb concentration, and numerical increases in functional capacity scores. A larger study is required to confirm if IV iron is beneficial in non-dialysis patients with CKD who are iron-deficient but not anaemic to improve exercise capacity.

**Funding:** Private Foundation Support

## TH-PO675

### Urinary Iron and Death in Kidney Transplant Recipients

Daan Kremer,<sup>1</sup> Tim J. Knobbe,<sup>1</sup> Joanna Sophia J. Vinke,<sup>1</sup> Kai Luersen,<sup>2</sup> David E. Leaf,<sup>3</sup> Martin H. De Borst,<sup>1</sup> Gerald Rimbach,<sup>2</sup> Stephan J. Bakker,<sup>1</sup> Michele F. Eisenga,<sup>1</sup> <sup>1</sup>University Medical Center Groningen, Groningen, Netherlands; <sup>2</sup>Christian-Albrechts-Universität zu Kiel Agrar- und Ernährungswissenschaftliche Fakultät, Kiel, Germany; <sup>3</sup>Brigham and Women's Hospital, Boston, MA.

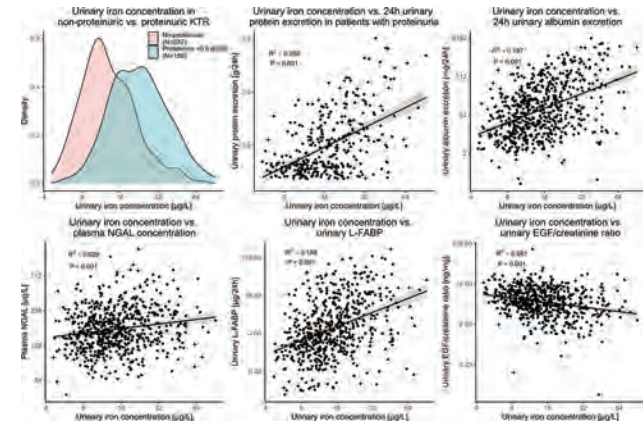

**Background:** Circulating markers of iron status are associated with adverse outcomes among kidney transplant recipients (KTRs), but limited data are available on urinary iron. Increased urinary iron can result from (i) increased iron delivery to the kidneys, (ii) increased glomerular passage, or (iii) decreased tubular reuptake. We studied associations of urinary iron with these pathways and with clinical outcomes in KTRs.

**Methods:** We used data from the prospective TxL FN cohort study, which included prevalent KTRs ≥1y after transplantation. Urinary iron concentrations were measured using mass-spectrometry.

**Results:** We included 693 KTRs (age 53±13y, 43% female, eGFR 45±19 ml/min/1.73m<sup>2</sup>). Urinary iron concentrations were assessed at a median of 5.4 years post-transplant [IQR, 2.0 to 12.0]. In linear regression, higher urinary iron was associated with lower eGFR (St. β -0.20; P<0.001), and more tubular injury as assessed using urinary and circulating markers (**Figure**). In contrast, urinary iron was not associated with transferrin saturation, ferritin, and iron after adjustment for age, sex, and eGFR (P>0.05 for all). Prospectively, higher urinary iron was associated with graft failure, but the association was eliminated after adjustment for proteinuria (**Table**). Higher urinary iron was independently associated with increased mortality (**Table**).

**Conclusions:** Higher urinary iron was associated with worse kidney function, more proteinuria, and increased markers of tubular injury, but not with systemic iron status. In addition, higher urinary iron was independently associated with higher mortality risk in KTRs, which warrants further investigation into the potential of urinary iron as a biomarker in KTRs and other populations.

**Table 1** Univariable and adjusted Cox proportional hazards analyses for the association of urinary iron concentration with graft failure and mortality

Model	Graft Failure (N=83, 12%)			Mortality (N=150, 22%)		
	HR per doubling (95% CI)	P-value		HR per doubling (95% CI)	P-value	
Crude	1.65 (1.38 to 1.97)	<0.001		1.30 (1.11 to 1.51)	<0.001	
Model 1	1.63 (1.11 to 1.63)	<0.001		1.45 (1.24 to 1.70)	<0.001	
Model 2	1.34 (1.11 to 1.63)	0.003		1.38 (1.18 to 1.62)	<0.001	
Model 3	1.08 (0.86 to 1.37)	0.5		1.28 (1.07 to 1.52)	0.006	
Model 4	1.14 (0.89 to 1.47)	0.3		1.26 (1.05 to 1.50)	0.014	
Model 5	1.11 (0.85 to 1.44)	0.4		1.28 (1.07 to 1.54)	0.007	

**Model 1**, adjustment for age, sex, time after transplantation. **Model 2**, adjusted for variables in model 1 + eGFR. **Model 3**, adjusted for variables in model 2 + log<sub>2</sub> 24h urinary protein excretion. **Model 4**, adjusted for variables in model 3 + urinary epidermal growth factor to creatinine ratio, plasma NGAL, liver-type fatty acid-binding protein. **Model 5**, adjusted for variables in model 4 + circulating iron and ferritin, transferrin saturation, and use of iron supplementation.

TH-PO676

Iron Status and Cause-Specific Mortality in Kidney Transplant Recipients

Joanna Sophia J. Vinke, Daan Kremer, Tim J. Knobbe, Stefan P. Berger, Stephan J. Bakker, Martin H. De Borst, Michele F. Eisenga. *Department of Nephrology, University Medical Center Groningen, Groningen, Netherlands.*

**Background:** Iron deficiency (ID) is highly prevalent after kidney transplantation. Previously, we showed that ID, independent of anemia, is associated with an increased risk of all-cause mortality in kidney transplant recipients (KTRs). Iron is involved in myriad processes, ranging from cardiomyocyte metabolism to being fuel for bacteria. We further explored the associations of iron status parameters with different cause-specific mortality reasons in KTRs.

**Methods:** We used data from the prospective Transplantlines Food and Nutrition Study, for which baseline measurements were performed in KTRs that were ≥1 year post-transplantation. Cox regression analyses of recently updated follow-up data were used to assess associations of ferritin, reflecting iron storage, and transferrin saturation (TSAT), reflecting functional iron status, with cause-specific mortality. Analyses were adjusted for age, sex, eGFR, 24-hour urinary protein excretion, time since transplantation, hs-CRP, systolic blood pressure, smoking status and presence of anemia. Anemia was defined as Hb <13 g/dL (M) or <12 g/dL (F).

**Results:** We included 695 KTRs (age 53±13 years, 57% males, eGFR 52±20 mL/min/1.73 m<sup>2</sup>, ferritin 118 µg/L [IQR 54–222], and TSAT 25±11%). 292 (41%) KTRs had anemia. During 5.9 [IQR 5.3–6.6] years of follow-up, 148 (21%) died: 59 (9%) from cardiovascular causes, 41 (6%) from infections and 25 (4%) from cancer. Tertiles of ferritin were not associated with all-cause mortality or with any of the cause-specific mortality endpoints. A lower TSAT was associated with a higher risk of all-cause mortality [HR 1.26 (95% CI: 1.06–1.50) per 10% decrease, P=0.01] after adjustment for potential confounders. Upon cause-specific analysis, a lower TSAT was not independently associated with a higher risk of death from infection [HR 0.96 (95% CI 0.71–1.29), P=0.77] or cancer [HR 1.10 (95% CI 0.73–1.66), P=0.64], but was associated with a higher risk of cardiovascular mortality [HR 1.39 (95% CI 1.04–1.85), P=0.03].

**Conclusions:** Lower TSAT was associated with an increased risk of cardiovascular mortality in KTRs, independent of anemia and potential confounders, but not with a higher risk of mortality from other causes. These findings set the stage for prospective studies addressing cardiovascular effects of iron supplementation after kidney transplantation.

TH-PO677

Iron Deficiency Is More Common in Incident Peritoneal Dialysis Patients Without Anemia

Brianna Hartley,<sup>1</sup> Vladimir Rigodon,<sup>1,2</sup> John W. Larkin,<sup>2</sup> Yue Jiao,<sup>2</sup> Len A. Usvyat,<sup>2</sup> Franklin W. Maddux,<sup>3</sup> Peter Kotanko,<sup>4</sup> Roberto Pecoito-Filho,<sup>1</sup> Thyago P. Moraes,<sup>1</sup> Murilo H. Guedes.<sup>1</sup> <sup>1</sup>Pontificia Universidade Catolica do Parana, Curitiba, Brazil; <sup>2</sup>Fresenius Medical Care, Global Medical Office, Waltham, MA; <sup>3</sup>Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany; <sup>4</sup>Renal Research Institute, New York, NY.

**Background:** Iron deficiency (ID) and anemia often coexist. Recent findings showed ID associates with mortality in chronic kidney disease (CKD), irrespective of anemia (Guedes, et al JASN 2021). Functional ID appears to confer higher risks for negative outcomes versus absolute ID in CKD. ID states and associated outcomes are uncertain in dialysis, particularly in peritoneal dialysis (PD). We aimed to characterize ID states and all-cause mortality rates in incident PD.

**Methods:** We used data from BRAZPD, an adult PD cohort across 122 clinics in Brazil (2004-2011) and included incident PD patients who had ≥1 transferrin saturation (TSAT), ferritin, and hemoglobin (hgb) lab during baseline (≤6 months after PD start). We defined prevalence of ID (i.e. TSAT <20%), patient characteristics, and crude mortality rates per 1000 patient years (p1000py) by ID states: 1. functional ID: (hgb ≥10 g/dL, TSAT <20%, ferritin ≥200 ng/mL), 2. functional ID with anemia: (hgb <10 g/dL, TSAT <20%, ferritin ≥200 ng/mL), 3. absolute ID (hgb ≥10 g/dL, TSAT <20%, ferritin <200 ng/mL), and 4. absolute ID with anemia (hgb <10 g/dL, TSAT <20%, ferritin <200 ng/mL).

**Results:** Among a cohort of 1,365 incident PD patients (mean age 59.7 years, 46.4% male, 49.1% diabetes), the prevalence of ID was 14.9% (n=203). Prevalence of ID states was 5.2% for functional ID, 1.5% for functional ID with anemia, 6.3% for absolute ID, and 1.8% for absolute ID with anemia (Figure 1). The mortality rate was observed to be the highest for functional ID at 195.6 deaths p1000py, as compared to other ID states.

**Conclusions:** In incident PD, we found a 14.9% prevalence of ID; most patients had ID without anemia. This finding may be of importance given screening for ID is recommended with low hgb. Anemic patients were infrequently iron deficient, which may suggest more active iron replacement triggered by low hgb. Incident PD patients with functional ID without anemia appeared to exhibit a higher all-cause mortality rate than other ID states. Further studies are needed to confirm these findings.

TH-PO678

Iron Deficiency and Incident Heart Failure in Community Dwelling Individuals

Shilpa Sharma,<sup>1,2</sup> Ronit Katz,<sup>3</sup> Paulo H. Chaves,<sup>4</sup> Andrew N. Hoofnagle,<sup>3</sup> Jorge R. Kizer,<sup>5</sup> Michael Shlipak,<sup>5</sup> Nisha Bansal,<sup>3</sup> Tomas Ganz,<sup>1</sup> Joachim H. Ix.<sup>6,7</sup> <sup>1</sup>University of California Los Angeles, Los Angeles, CA; <sup>2</sup>VA Greater Los Angeles Healthcare System, Los Angeles, CA; <sup>3</sup>University of Washington, Seattle, WA; <sup>4</sup>Florida International University, Miami, FL; <sup>5</sup>University of California San Francisco, San Francisco, CA; <sup>6</sup>University of California San Diego, La Jolla, CA; <sup>7</sup>Veterans Medical Research Foundation, San Diego, CA.

**Background:** Iron deficiency has been linked to heart failure (HF) admissions in persons with prevalent HF and clinical trials demonstrate IV iron improves outcomes in prevalent HF. We examined the relationship of iron status with incident HF in community dwelling older adults and evaluated separately in those with and without CKD.

**Methods:** In 980 Cardiovascular Health Study participants aged > 65 years without HF (41% with CKD), we used a case-cohort design and weighted Cox models to evaluate associations of iron status with incident HF. Participants were categorized based on quartiles of transferrin saturation and ferritin as “Iron Replete” (13.9 % of participants; referent group), “Functional Iron Deficiency” (7.7%), “Iron Deficiency” (11.6%), “Mixed Iron Deficiency” (iron indices between the Iron Deficiency and Functional Iron Deficiency groups; 5.6%), “High Iron” (9.7%) and “Non-classified” (51.3%), consistent with prior studies. As c-terminal (but not intact) fibroblast growth factor-23 (FGF23) marks iron deficiency, we explored whether adjustment attenuated associations. We tested for interaction by CKD status (eGFR ≥60 vs. less).

**Results:** Compared to those deemed iron replete, iron deficiency independently associated with incident HF (HR 1.47; 1.03-2.11) whereas other iron categories did not, in models adjusted for traditional risk factors and kidney function (Table). Further adjustment for C-terminal FGF23 attenuated the association (HR 1.21; 0.83-1.76) whereas intact FGF23 did not (HR 1.48; 1.04-2.11). The relationship of iron deficiency with incident HF was similar irrespective of CKD status (P interaction = 0.4).

**Conclusions:** Among older community-living persons, iron deficiency is independently associated with incident HF, an association that was similar irrespective of CKD status. Our findings support conduct of clinical trials of iron replacement for prevention of HF in older adults with iron deficiency.

Role of Reticulocyte-Hemoglobin in Predicting Hemoglobin Changes in Patients With Anemia Undergoing Maintenance Hemodialysis

Beong Woo Kim, Taehee Kim, Yeong Hoon Kim, Yunmi Kim, Hyuk Huh. *Inje University College of Medicine, Busan, Republic of Korea.*

**Background:** It has been suggested that reticulocyte-hemoglobin (Ret-Hb) may be useful as a tool for managing iron deficiency anemia in hemodialysis (HD) patients on erythropoiesis-stimulating agents (ESA). The purpose of this study was to determine the correlation between Ret-Hb and traditional predictors of iron deficiency anemia, and to compare their function as predictors of anemia.

**Methods:** From July 2021 to October 2022, hemoglobin changes for 3 months ( $\Delta$ Hb), Ret-Hb, Transferrin saturation (TSAT), and ferritin were measured every quarter in patients receiving regular HD for more than 90 days. The correlation between Ret-Hb, TSAT, and ferritin was confirmed through linear regression analysis. Subsequently, Ret-Hb, TSAT and ferritin were analyzed for correlation with  $\Delta$ Hb to compare their potential as predictors of anemia. Patients with ESA hyporesponsiveness, bleeding, infection, hematologic disease and malignancy were excluded from the study.

**Results:** A total of 72 patients were included in the study, the mean age was  $63.40 \pm 7.79$  years, 33 men (54.15%), and 61 patients (84.7%) receiving iron therapy. Ret-Hb showed a clear positive correlation with TSAT ( $r = 0.397, p < 0.001$ ), but not with ferritin ( $r = 0.039, p = 0.746$ ). Regarding the association with  $\Delta$ Hb, only Ret-Hb had a statistically significant negative correlation ( $r = -0.274, p = 0.021$ ), and TSAT ( $r = 0.015, p = 0.904$ ) and ferritin ( $r = -0.184, p = 0.125$ ) did not show significant correlation.

**Conclusions:** Ret-Hb showed a significant correlation with TSAT, it was shown that it can be used as an auxiliary indicator to evaluate iron deficiency. In addition, since it showed a significant correlation with hemoglobin changes, Ret-Hb may have an additional role in evaluating the response to anemia treatment in patients undergoing hemodialysis in the future.

Iron Deficiency Impairs Skeletal Muscle Mitochondrial Function and Exercise Performance in CKD

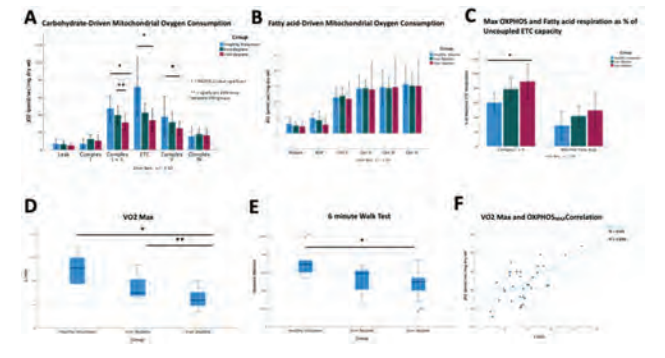

Benjamin A. Oliveira,<sup>1</sup> Emmanuel Mangahis,<sup>3</sup> Fiona Reid,<sup>1</sup> James Burton,<sup>2</sup> Kieran McCafferty,<sup>4</sup> Thomas J. Wilkinson,<sup>2</sup> Elham Asgari,<sup>6</sup> Nick Beckley-Hoelscher,<sup>1</sup> Debasish Banerjee,<sup>5</sup> Emma L. Watson,<sup>2</sup> Pauline A. Swift,<sup>7</sup> Courtney J. Lightfoot,<sup>2</sup> Luke A. Baker,<sup>2</sup> Chante Reid,<sup>3</sup> David C. Wheeler,<sup>10</sup> Alice C. Smith,<sup>2</sup> Sharlene A. Greenwood,<sup>3</sup> Kate Bramham,<sup>1</sup> Salma Ayis,<sup>1</sup> Philip A. Kalra,<sup>8</sup> Sunil Bhandari,<sup>9</sup> Iain C. Macdougall,<sup>3</sup> Darlington Okonko.<sup>1</sup> <sup>1</sup>King's College London, London, United Kingdom; <sup>2</sup>University of Leicester, Leicester, United Kingdom; <sup>3</sup>King's College Hospital NHS Foundation Trust, London, United Kingdom; <sup>4</sup>The Royal London Hospital, London, United Kingdom; <sup>5</sup>St George's University Hospitals NHS Foundation Trust, London, United Kingdom; <sup>6</sup>Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; <sup>7</sup>Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom; <sup>8</sup>Salford Royal NHS Foundation Trust, Salford, United Kingdom; <sup>9</sup>Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom; <sup>10</sup>University College London, London, United Kingdom.

**Background:** Skeletal muscle (SM) mitochondrial oxidative phosphorylation (OXPHOS) is impaired in patients with CKD and could be worsened by iron deficiency (ID).

**Methods:** We quantified SM OXPHOS and exercise capacity in CKD pts with a Hb  $> 110$  g/dL (n=38, **Table 1**), and in healthy volunteers (n=6). SM OXPHOS was measured using high resolution respirometry (HRR) of quadriceps biopsies and using 31-phosphorus magnetic resonance spectroscopy (31P-MRS).

**Results:** On HRR, carbohydrate (**Fig A**) but not fatty-acid (**Fig B**) driven maximal coupled OXPHOS capacity was lowest in pts with ID, but was a higher % of maximal uncoupled ETC capacity in these pts (**Fig C**) implying that mitochondria were operating at their maxima. Pts with ID also had longer phosphocreatinine recovery halftime on 31P-MRS (33 vs. 25 vs. 17 s,  $P < 0.01$ ) and lower exercise capacity (**Fig D, E**). Adjustment for Hb did not alter results.

**Conclusions:** ID intrinsically correlates with worse SM OXPHOS in CKD. **Funding:** Private Foundation Support

TH-PO681

Association of Iron Therapy With Incidence of CKD

Prabin Shrestha,<sup>1</sup> Shejuti Paul,<sup>1</sup> Keiichi Sumida,<sup>1</sup> Fridtjof Thomas,<sup>1</sup> Satya Surbhi,<sup>1</sup> Abu Mohd Naser,<sup>2</sup> Elani Streja,<sup>3</sup> Connie Rhee,<sup>3</sup> Kamyar Kalantar-Zadeh,<sup>3</sup> Csaba P. Kovesdy.<sup>1,4</sup> <sup>1</sup>The University of Tennessee Health Science Center, Memphis, TN; <sup>2</sup>The University of Memphis, Memphis, TN; <sup>3</sup>University of California Irvine, Irvine, CA; <sup>4</sup>VA Memphis Medical Center, Memphis, TN.

**Background:** Iron replacement therapy (IRT) is effective in treating iron deficiency, but there are concerns about its effects on kidney function due to the impact of oral iron on the gut microbiome and to the oxidative stress caused by intravenous iron. We aimed to investigate the association of IRT with the incidence of new onset chronic kidney disease.

**Methods:** We identified 210,209 patients with normal eGFR and no albuminuria (N=51,448 on IRT and N=158,761 not on IRT) from 2004-2018 in a large national cohort of US Veterans. Of the patients receiving IRT, 48,946 (95%) received oral iron only, 63 (0.1%) received intravenous iron only, and 2,439 (4.7%) received both modalities. We used clinical trial emulation methods including propensity score (PS) matching to examine the association of IRT with the incidence of eGFR  $< 60$  ml/min/1.73m<sup>2</sup> and with incident urine albumin creatinine ratio (UACR)  $> 30$  mg/gm (both defined as two values at least 90 days apart) using competing risk regression.

**Results:** In the PS matched cohort of 64,446 patients (32,223 on IRT and 32,223 not on IRT) characteristics were well matched. The overall mean (SD) age was  $66 \pm 13$  years, 92% were male, 74% were white, and the baseline eGFR, hemoglobin and ferritin levels were  $86 \pm 16$  ml/min/1.73m<sup>2</sup>,  $12 \pm 1.6$  g/dL and 76 (25<sup>th</sup>-75<sup>th</sup> pctl 26-188)  $\mu$ g/L, respectively. There were 10,078 cases of incident eGFR  $< 60$  (event rate 37/1000PY; 95% CI 37-38) and 7,632 cases of incident albuminuria (28/1000PY; 95% CI 27-28) over a median follow up of 3.0 years. IRT was associated with a higher risk of incident eGFR  $< 60$  (subhazard ratio, 1.23; 95% CI 1.19-1.28) and a higher risk of albuminuria (1.12; 1.07-1.18). (Table)

**Conclusions:** In this large national cohort of patients with normal kidney function, IRT was associated with modestly higher risks of incident CKD and albuminuria.

**Funding:** Veterans Affairs Support

Association of Iron Replacement Therapy with Incidence of CKD

	Incident eGFR $< 60$ ml/min/1.73m <sup>2</sup>			Incident UACR $> 30$ mg/gm

No Iron therapy (N=32,223)	34 (33,35)	Reference	$< 0.001$	26 (25, 27)	Reference	$< 0.001$
Iron therapy (N=32,223)	41 (40,42)	1.23 (1.19, 1.28)		29 (28, 30)	1.12 (1.07, 1.18)	

TH-PO682

Association of Parenteral vs. Oral Iron Therapy With Incident CKD

Prabin Shrestha,<sup>1</sup> Shejuti Paul,<sup>1</sup> Keiichi Sumida,<sup>1</sup> Fridtjof Thomas,<sup>1</sup> Satya Surbhi,<sup>1</sup> Abu Mohd Naser,<sup>2</sup> Elani Streja,<sup>3</sup> Connie Rhee,<sup>3</sup> Kamyar Kalantar-Zadeh,<sup>3</sup> Csaba P. Kovesdy.<sup>4</sup> <sup>1</sup>The University of Tennessee Health Science Center, Memphis, TN; <sup>2</sup>The University of Memphis, Memphis, TN; <sup>3</sup>University of California Irvine, Irvine, CA; <sup>4</sup>VA Memphis Medical Center, Memphis, TN.

**Background:** Parenteral (IV) iron is effective in treating iron deficiency, but there are concerns about its potential nephrotoxicity. However, little is known about the long-term comparative renal safety of oral vs IV iron in patients with normal kidney function. We aimed to investigate the association of oral vs IV iron with the incidence of new onset chronic kidney disease (CKD).

**Methods:** We identified 94,931 incident new users of iron replacement therapy (N=91,945 on oral and 2,986 on IV iron) from 2004-2018 in a large national cohort of US Veterans. We used clinical trial emulation methods including propensity score (PS) matching to account for differences in key baseline characteristics and limited the cohort to patients with eGFR  $> 60$  ml/min/1.73m<sup>2</sup> and urine albumin creatinine ratio (UACR)  $< 30$  mg/g. We examined the association of oral vs IV iron with the incidence of eGFR  $< 60$  ml/min/1.73m<sup>2</sup> and UACR  $> 30$  mg/g (both defined as two values at least 90 days apart) using competing risk regression.

**Results:** In the PS matched cohort there were 1,029 patients on oral and 1,043 on IV iron with eGFR  $\geq 60$  ml/min/1.73m<sup>2</sup> and UACR  $< 30$  mg/g at baseline. Their characteristics were well balanced, with an overall mean (SD) age of 66 $\pm$ 12 years, 92% male, 75% white, and baseline eGFR, hemoglobin and ferritin levels of 90 $\pm$ 18 ml/min/1.73m<sup>2</sup>, 9.7 $\pm$ 1.8 g/dL and 34 (25<sup>th</sup>-75<sup>th</sup> pctl: 11-190)  $\mu$ g/L, respectively. There were 370 cases of incident GFR  $< 60$  (event rate 58/1000py; 95% CI 53-65) and 251 cases of incident albuminuria (39/1000py; 95% CI 34-44) over a median follow-up of 1.8 years. IV (vs oral) iron therapy was associated with similar risk of incident eGFR  $< 60$  (subhazard ratio (95%CI): 1.12 (0.91-1.37), p=0.27) and incident albuminuria (1.01 (0.79-1.29), p=0.9) (Table).

**Conclusions:** In this large national cohort of patients with baseline normal kidney function and no proteinuria, IV iron therapy was not associated with higher risk of incident CKD when compared to oral iron.

**Funding:** Veterans Affairs Support

**TH-PO683**

## Association of Iron Replacement Therapy With Kidney Failure and Mortality in Patients With CKD

**Shejuti Paul,<sup>1</sup>** Prabin Shrestha,<sup>1</sup> Keiichi Sumida,<sup>1</sup> Fridtjof Thomas,<sup>1</sup> Satya Surbhi,<sup>1</sup> Abu Mohd Naser,<sup>2</sup> Elani Streja,<sup>3</sup> Connie Rhee,<sup>3</sup> Kamyar Kalantar-Zadeh,<sup>3</sup> Csaba P. Kovacs,<sup>1,4</sup> *<sup>1</sup>The University of Tennessee Health Science Center, Memphis, TN; <sup>2</sup>The University of Memphis, Memphis, TN; <sup>3</sup>University of California Irvine, Irvine, CA; <sup>4</sup>VA Memphis Medical Center, Memphis, TN.*

**Background:** The long term safety of iron replacement therapy (IRT) in patients with chronic kidney disease (CKD) remains unclear. We investigated the association of IRT with the incidence of end stage kidney disease (ESKD) and all-cause mortality in patients with pre-existing CKD.

**Methods:** In a national cohort of US Veterans we identified 26,315 incident new users of IRT with eGFR <60 ml/min/1.73m<sup>2</sup> and a comparable group of 43,783 patients who did not receive IRT. We used clinical trial emulation methods including propensity score (PS) matching to examine the association of IRT vs no IRT with ESKD and mortality in competing risk regressions and in Cox models, respectively.

**Results:** In the PS matched cohort 14,429 patients received IRT (95% exclusively oral iron) and 14,429 received no IRT. Baseline characteristics were well matched between the two groups; the overall mean (SD) age was 74±10 years, 97% were male, 77% were white, and the baseline eGFR, hemoglobin, and ferritin levels were 45±12 ml/min/1.73m<sup>2</sup>, 11.5±1.6 g/dL, and 97 (25<sup>th</sup>-75<sup>th</sup> pctl: 39-223) µg/L. There were 1,163 cases of incident ESKD (event rate 15/1000PY; 95%CI 14-16) and 18,191 deaths (188/1000PY; 95% CI 185-191) over a median follow-up of 1.7 and 2.4 years, respectively. IRT was not associated with higher risk of ESKD (subhazard ratio and 95% CI: 1.00, 0.89-1.12, p=0.97) or incident death (hazard ratio and 95% CI 0.98, 0.95-1.01, p=0.22) (Table).

**Conclusions:** In this large national cohort of patients with CKD, IRT (consisting mainly of oral iron replacement) was not associated with higher risk of ESKD or mortality. Notwithstanding these findings, the long term safety of IRT should be tested in clinical trials.

**Funding:** Veterans Affairs Support

# Effects of Hypoxia-Inducible Factor-Prolyl Hydroxylase Inhibitors vs. Erythropoiesis-Stimulating Agents on Iron Metabolism in Non-Dialysis-Dependent Anemic Patients With CKD: A Network Meta-Analysis

**Junlan Yang**, Institute of Nephrology / Southeast University School of Medicine / Zhong Da Hospital *Institute of Nephrology / Southeast University School of Medicine / Zhong Da Hospital, Nanjing, China.*

**Background:** Hypoxia-inducible factor- prolyl hydroxylase inhibitors (HIF-PHIs) are an emerging drug for the treatment of renal anemia, which has not yet been used in clinical practice. Although many clinical studies have proved that the ability of HIF-PHIs to treat anemia is equivalent to erythropoiesis-stimulating agents (ESAs), the mechanisms of hemoglobin production of the two drugs are different. We performed this network meta-analysis to compare the effects of HIF-PHIs, ESA, and placebo on iron regulation in patients with renal anemia who do not receive dialysis.

**Methods:** The Cochrane Library, PubMed, Web of Science, CNKI, WANGFANG DATA were used for search in documents and journals ranging from January 1946 to December 2021. The literatures with respect to the randomized controlled clinical trial comparing HIF-PHIs, ESAs, and placebo in non-dialysis-dependent anemic patients with chronic kidney disease were selected. The main outcomes were the change in hepcidin and hemoglobin (Hb) levels.

**Results:** Of 1589 original titles screened, data was extracted from 15 studies included a total of 3238 patients (Fig. 1). The league table shows pairwise comparisons of the effectiveness of hepcidin-lowering and hemoglobin-raising among the eight interventions (Fig. 2). Compared with placebo, Enarodustat (SMD = -1.52, 95% CI: -3.01 to -0.03), and Roxadustat (SMD = -1.29, 95% CI: -2.23 to -0.35) could significantly reduce the level of hepcidin. All HIF-PHIs and ESAs showed greater ability to increase Hb levels than placebo, and there was no significant difference between HIF-PHIs and ESAs.

**Conclusions:** HIF-PHIs and ESAs have different effects on iron regulation in non-dialysis-dependent anemic patients with CKD, indicating that HIF-PHIs may increase Hb levels by promoting iron mobilization.

**Funding:** Clinical Revenue Support

Hutchison,<sup>5</sup> Laurent Juillard,<sup>6,7</sup> Bart D. Maess,<sup>8</sup> Stephen Mallett,<sup>9</sup> Antonello Pani,<sup>10</sup> Mai Ots-Rosenberg,<sup>11</sup> Bonnie Shaddinger,<sup>3</sup> Frank M. Strutz,<sup>12</sup> Marc G. Vervloet,<sup>13</sup> Christoph Wanner,<sup>14</sup> Andrzej Wiecek,<sup>15</sup> John McMurray.<sup>16</sup> <sup>1</sup>Brigham and Women's Hospital and Harvard Medical School, Boston, MA; <sup>2</sup>Department of Nephrology, Odense University Hospital, Odense, Denmark; <sup>3</sup>GSK, Collegeville, PA; <sup>4</sup>Research Institute of Nephrology, Pavlov University, Saint-Petersburg, Russian Federation; <sup>5</sup>Department of Medicine, Hawke's Bay District Health Board, Hastings, New Zealand; <sup>6</sup>Université de Lyon, CarMeN, INSERM U1060, INSA de Lyon, Université Claude Bernard Lyon 1, Villeurbanne, France; <sup>7</sup>Hospices Civils de Lyon, Service de Néphrologie, Hôpital E. Herriot, Lyon, France; <sup>8</sup>Department of Nephrology, AZ Delta Hospital, Roeselare, Belgium; <sup>9</sup>GSK, Brentford, United Kingdom; <sup>10</sup>Divisione di Nefrologia e Dialisi, Azienda Ospedaliera G. Brotzu, Cagliari, Italy; <sup>11</sup>Tartu University Hospital, Tartu, Estonia; <sup>12</sup>DKD Helios Klinik Wiesbaden, KfH und Nierenzentrum-Rheumatologie Wiesbaden, Wiesbaden, Germany; <sup>13</sup>Department of Nephrology, Amsterdam University Medical Center, Amsterdam, Netherlands; <sup>14</sup>University of Würzburg, Würzburg, Germany; <sup>15</sup>Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia in Katowice, Katowice, Poland; <sup>16</sup>Glasgow University, Glasgow, United Kingdom.

**Background:** Cardiovascular (CV) etiologies, including diabetes mellitus (DM), are the most common cause of death among chronic kidney disease (CKD) patients. This post-hoc analysis of adjudicated causes of death in patients with anemia of CKD with/without DM in the ASCEND-ND trial investigated the safety of daprodustat (Dapro), a hypoxia-inducible factor prolyl hydroxylase inhibitor, for treatment of anemia of CKD in non-dialysis patients.

**Methods:** ASCEND-ND (NCT02876835) was a global, randomized, open-label, phase 3 CV outcome trial. Patients received daily oral Dapro or subcutaneous darbepoetin alfa (Darbe). Outcomes were centrally adjudicated. Survival data for the intent-to-treat population was analyzed using Kaplan-Meier methods (DM vs non-DM).

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Results:** Of 3872 randomized patients (DM N=2194, non-DM N=1678), baseline characteristics were broadly balanced across treatment arms, although DM patients were older, had greater body mass index and systolic blood pressure, and more CV disease/CV medication use than non-DM patients. All-cause mortality was significantly higher in DM vs non-DM patients (hazard ratio [HR]=1.87, 95% confidence interval [CI]: 1.57–2.23; Figure 1A); this association did not differ by treatment (HR=1.87 [Daprod] vs 1.86 [Darbe]; p=0.96). Infection and CV mortality each accounted for approximately 30% of deaths independent of DM status (Figure 1B).

**Conclusions:** In patients with anemia of CKD not on dialysis, the overall death rate was higher in DM patients, but cause of death was similar regardless of DM status; infection in patients with or without DM was the most frequent cause of death.

**Funding:** Commercial Support - This study was funded by GSK.

**Figure 1.** All-cause mortality\* (A) and causes of death (B) in patients with anemia of CKD not on dialysis with/without DM (ITT population)

### Erythropoiesis-Stimulating Agent Hyporesponsiveness and Anemia Management in the ASCEND-D Trial

**Sushrut S. Waikar,<sup>1</sup> Daniel W. Coyne,<sup>2</sup> Finnian R. McCausland,<sup>3</sup> Kirsten L. Johansen,<sup>4</sup> Vivekanand Jha,<sup>5</sup> Gregorio T. Obrador,<sup>6</sup> Purav R. Bhatt,<sup>7</sup> Stephen Mallett,<sup>8</sup> Amy M. Meadowcroft,<sup>7</sup> Ajay K. Singh.<sup>1</sup>** <sup>1</sup>Boston University School of Medicine and Boston Medical Center, Boston, MA; <sup>2</sup>Washington University School of Medicine, St. Louis, MO; <sup>3</sup>Brigham and Women's Hospital and Harvard Medical School, Boston, MA; <sup>4</sup>Hennepin Healthcare, University of Minnesota, Minneapolis, MN; <sup>5</sup>George Institute for Global Health, New Delhi, India; <sup>6</sup>Universidad Panamericana School of Medicine, Mexico City, Mexico; <sup>7</sup>GSK, Collegeville, PA; <sup>8</sup>GSK, Brentford, United Kingdom.

**Background:** Erythropoiesis-stimulating agent (ESA) hyporesponsiveness is characterized by high dose ESA and greater use of intravenous (IV) iron. Hypoxia-inducible factor prolyl hydroxylase inhibitors (HIF-PHIs) may be beneficial for iron homeostasis/utilization. Data comparing HIF-PHIs vs ESA in hyporesponders are limited.

**Methods:** ASCEND-D (NCT02879305) was a phase 3 randomized trial of daprodustat (Daprod) vs ESA in dialysis patients (pts; N=2964). ESA hyporesponsiveness was defined as baseline ESA-resistance index  $\geq 2.0$  or epoetin dose  $\geq 4500$  U/kg/week. Both treatment groups used protocolized dosing of study drug and iron to achieve/maintain hemoglobin (Hb) 10.0–11.0 g/dL. A rescue algorithm for anemia management allowed use of IV iron and/or red blood cell (RBC) transfusion, with discontinuation of study drug for persistent Hb  $<9$  g/dL or  $>2$  units RBC transfusion. Statistical analyses included analysis of covariance with treatment x subgroup interactions.

**Results:** At baseline, 12% of pts were ESA-hyporesponsive (ESA-HR) (Table). During the trial, higher Daprod and ESA doses were required in the ESA-HR vs non-ESA-HR group. Mean change in Hb from baseline to weeks 28–52 for Daprod vs ESA: ESA-HR group, 0.01 g/dL; non-ESA-HR group, 0.21 g/dL (p-interaction=0.04). Mean IV iron use was lower with Daprod vs ESA in the ESA-HR group (-31.7 mg) but similar in those not ESA-HR (-6.9 mg; p-interaction=0.09). A greater number of RBC transfusions and discontinuations due to rescue therapy was seen in Daprod vs ESA in ESA-HR pts; the opposite was observed in non-ESA-HR pts.

**Conclusions:** Baseline responsiveness to ESA led to different patterns of anemia management for Daprod vs ESA, with evidence of lower IV iron utilization with Daprod in those who were ESA hyporesponsive at baseline.

**Funding:** Commercial Support - This study was funded by GSK.

	Hyporesponsive at baseline	Not hyporesponsive at baseline

### Erythropoiesis-Stimulating Agent (ESA) Hyporesponsiveness and Major Adverse Cardiovascular Events: Results From ASCEND-D

**Finnian R. McCausland,<sup>1</sup> Sushrut S. Waikar,<sup>2</sup> Brian Claggett,<sup>1</sup> Gearoid M. McMahon,<sup>1</sup> Osvaldo M. Vieira Neto,<sup>8</sup> Anjay Rastogi,<sup>3</sup> Kearkiat Praditpornsilpa,<sup>4</sup> Ricardo Correa-Rotter,<sup>5</sup> Vijay K. Kher,<sup>6</sup> Lucia Del Vecchio,<sup>7</sup> Ajay K. Singh.<sup>1</sup>** <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Boston University School of Medicine, Boston, MA; <sup>3</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; <sup>4</sup>Chulalongkorn University, Bangkok, Thailand; <sup>5</sup>Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico; <sup>6</sup>Medanta The Medicity Medanta Institute of Kidney and Urology, Gurugram, India; <sup>7</sup>Sant'Anna Hospital, Como, Italy; <sup>8</sup>Serviço de Nefrologia de Ribeirão Preto, São Paulo, Brazil.

**Background:** Hyporesponsiveness to ESAs is associated with adverse cardiovascular (CV) outcomes. Although several definitions exist, data examining associations with CV outcomes in clinical trials are limited.

**Methods:** ASCEND-D (NCT02879305) randomized 2,964 patients on chronic dialysis to daprodustat or conventional ESAs. All received an ESA for at least 6 weeks prior to randomization and were managed with dosing algorithms for iron and randomized treatment. Three definitions of hyporesponsiveness were prespecified: 1) erythropoietin resistance index (ERI)  $\geq 2$  U/kg/wk/g/L or prior ESA dose/estimated dry weight  $\geq 4500$  U/kg/wk; 2) ERI  $\geq 1.5$  U/kg/wk/g/L; 3) baseline ESA dose (U/week) in top 20th %ile. Cox models examined associations of each definition with the CV composite (death, myocardial infarction, stroke), adjusted for dialysis modality, region, age, sex, race, dialysis vintage, CV disease, diabetes, serum albumin, SBP, hemoglobin, and C-reactive protein. Interaction terms were included to assess for effect modification by randomized treatment.

**Results:** Baseline ESA hyporesponsiveness was present in 12%, 20%, and 20% of patients for definitions HypoR1, HypoR2, and HypoR3, respectively. Compared to no hyporesponsiveness, all definitions had quantitatively similar associations with the CV outcome: hazard ratio [HR] 1.54 (95%CI 1.24–1.91) for HypoR1 (Figure); HR 1.46; 95%CI 1.22–1.76) for HypoR2; HR 1.45 (95%CI 1.21–1.74) for HypoR3. There was no evidence for effect modification by treatment (P-interaction  $>0.40$  for all).

**Conclusions:** Baseline ESA hyporesponsiveness is a potent predictor of CV outcomes in ASCEND-D. All pre-specified definitions provided similar predictive abilities.

**Funding:** Commercial Support - GSK

# Efficacy and Cardiovascular Safety of Daprodustat for the Management of Renal Anemia in Peritoneal Dialysis Patients: A Prespecified Analysis of the ASCEND-D Trial

Indranil Dasgupta,<sup>1,2</sup> Stephen Mallett,<sup>3</sup> Purav R. Bhatt,<sup>4</sup> Anjali Acharya,<sup>5</sup> Michael Aarup,<sup>6</sup> Ricardo Correa-Rotter,<sup>7</sup> Shruti Gupta,<sup>8</sup> Vijay K. Kher,<sup>9</sup> Osvaldo M. Vieira Neto,<sup>10</sup> Anjay Rastogi,<sup>11</sup> Mai Ots-Rosenberg,<sup>12</sup> Brian Rayner,<sup>13</sup> Muh Geot Wong,<sup>14</sup> Ajay K. Singh.<sup>15</sup> <sup>1</sup>University Hospitals of Birmingham NHS Foundation Trust, Birmingham, United Kingdom; <sup>2</sup>Warwick Medical School, University of Warwick, West Midlands, United Kingdom; <sup>3</sup>GSK, Brentford, United Kingdom; <sup>4</sup>GSK, Collegeville, PA; <sup>5</sup>Albert Einstein College of Medicine, Bronx, NY; <sup>6</sup>Odense University Hospital, Odense, Denmark; <sup>7</sup>Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; <sup>8</sup>Brigham and Women's Hospital, Boston, MA; <sup>9</sup>Medanta Kidney and Urology Institute, Medanta Hospital, South Delhi, India; <sup>10</sup>Sociedade Brasileira de Nefrologia, São Paulo, Brazil; <sup>11</sup>David Geffen School of Medicine UCLA, Los Angeles, CA; <sup>12</sup>Tartu University Hospital, Tartu, Estonia; <sup>13</sup>Groote Schuur Hospital and University of Cape Town, Cape Town, South Africa; <sup>14</sup>University of Sydney, Sydney, NSW, Australia; <sup>15</sup>Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

**Background:** Daprodustat (Dapro), an oral investigational hypoxia-inducible factor prolyl hydroxylase inhibitor, has been shown to be noninferior to conventional erythropoietin stimulating agents in renal anemia treatment of dialysis and non-dialysis patients (pts). This pre-specified subgroup analysis of the ASCEND-D trial examined the efficacy and cardiovascular (CV) safety of Dapro vs darbepoetin-alfa (Darbe) in end-stage kidney disease (ESKD) pts receiving peritoneal dialysis (PD).

**Methods:** ASCEND-D (NCT02879305) was an open-label, phase 3 trial in ESKD pts on dialysis with screening hemoglobin (Hb) 8.0–11.5g/dL, randomized to Dapro or Darbe. Primary outcomes were mean Hb change from baseline to wks 28 through 52 (noninferiority [NI] margin -0.75g/dL) and first occurrence of a major adverse CV event (MACE: a composite of death from any cause, nonfatal myocardial infarction [MI], or nonfatal stroke [NI margin 1.25]). Mean Hb change was analyzed via an analysis of covariance model adjusting for baseline Hb, treatment, dialysis modality, and geographic region. MACE was analyzed via a Cox proportional-hazards model adjusting for treatment, dialysis modality, and geographic region.

**Results:** Overall, 340 PD pts (Dapro n=171; Darbe n=169) were randomized (baseline [Dapro/Darbe]: mean age, years [54/53]; % male [56/54]; % dialysis vintage >5 years [18/22]; Hb, g/dL [10.25/10.23]; % stroke [5/5]; and % MI [8/7]). For Dapro and Darbe respectively, the mean change in Hb was 0.38 and 0.23g/dL (adjusted mean difference 0.15 95% confidence interval [CI] -0.04–0.34); a first occurrence of adjudicated MACE occurred in 40 (23.4%) and 46 (27.2%) pts (hazard ratio 0.84 95% CI 0.55–1.28) and the mean average monthly iron dose was 59.6g and 62.9g (adjusted mean difference -3.3 95% CI -30.7–24.0). There was no heterogeneity between PD and hemodialysis pts for these endpoints. Peritonitis rates were 26% (Dapro) and 22% (Darbe).

**Conclusions:** This pre-specified sub-group analysis of the ASCEND-D trial demonstrates comparable efficacy and CV safety of Dapro vs Darbe in PD pts, supporting use of this novel oral agent in anemic PD pts.

**Funding:** Commercial Support - This study was funded by GSK.

## TH-PO689

# Efficacy and Safety of Daprodustat for Treatment of Anemia in CKD: A Meta-Analysis

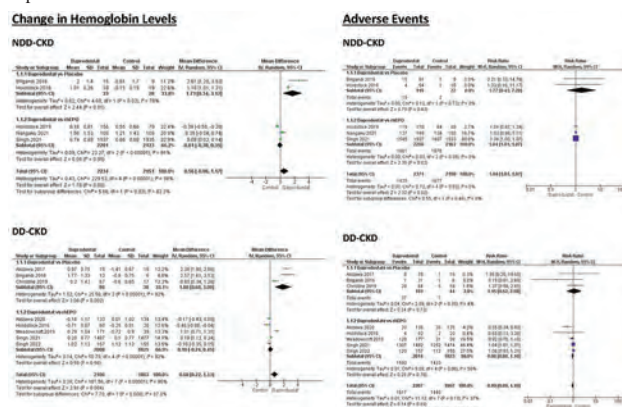

Si Yuan Khor,<sup>1</sup> Sara Alattal,<sup>1</sup> Amira S. Kamboj,<sup>1</sup> Abdullah Al-Abcha,<sup>1</sup> Issa R. Haddad,<sup>1</sup> Michael Turk,<sup>4</sup> Nora H. Hernandez Garcilazo,<sup>1</sup> Yeshwanter Radhakrishnan,<sup>3</sup> Mohamed Hassanein.<sup>2</sup> <sup>1</sup>Michigan State University College of Human Medicine, East Lansing, MI; <sup>2</sup>University of Mississippi Medical Center, Jackson, MS; <sup>3</sup>Mayo Clinic, Rochester, MN; <sup>4</sup>Allegheny General Hospital, Pittsburgh, PA.

**Background:** Anemia is a well-known complication in chronic kidney disease (CKD). Current treatments for anemia in CKD include recombinant human erythropoietin (rhEPO) or its analogs. Daprodustat, a hypoxia-inducible factor prolyl hydroxylase inhibitor is a novel drug for treatment of anemia in CKD. We sought to review the efficacy and safety of daprodustat for treatment of anemia in non-dialysis dependent (NDD) and dialysis-dependent (DD) CKD patients.

**Methods:** We performed a systematic search using PubMed, Embase and Scopus until May 2022. Inclusion criteria included randomized controlled trials that reported the efficacy and safety of daprodustat compared to placebo or rhEPO in treating anemia patients with NDD or DD-CKD. Primary and secondary outcomes include change in hemoglobin (Hb) levels and associated adverse events (AEs), respectively. A random-effect model was utilized to calculate the mean difference and risk ratio with a 95% confidence interval.

**Results:** Eleven studies were included with a total of 8354 patients. The change in Hb levels were significantly higher in the daprodustat group compared to placebo for both DD (p=0.01) and NDD (p=0.002) patients with no significant difference in the incidence of AEs between the 2 groups (16.5% vs 7.4%, p=0.43; 19.1% vs 15.9%, p=0.73). There was no significant difference in change in Hb levels between daprodustat and rhEPO. The incidence of AEs was slightly higher in daprodustat group compared to rhEPO for NDD patients (p=0.02) with no significant difference in DD patients (p=0.78).

**Conclusions:** Our meta-analysis demonstrates that daprodustat was superior to placebo and non-inferior to rhEPO in treating anemia in CKD. The risk of AEs with daprodustat was slightly higher compared to rhEPO but was not observed when compared to placebo. Further clinical trials are required to validate the long-term efficacy and safety of daprodustat.

## TH-PO690

# Maximal Change in Erythropoietin in Hemodialysis Patients Receiving Daprodustat or Epoetin Alfa in the ASCEND-TD Trial

Daniel W. Coyne,<sup>1</sup> Christoph Wanner,<sup>2</sup> Renato D. Lopes,<sup>3</sup> Christine K. Bailey,<sup>4</sup> Kelly M. Mahar,<sup>4</sup> Jennifer Shannon,<sup>4</sup> Ajay K. Singh.<sup>5</sup> <sup>1</sup>Washington University School of Medicine, St. Louis, MO; <sup>2</sup>University of Würzburg, Würzburg, Germany; <sup>3</sup>Duke University Medical Center, Durham, NC; <sup>4</sup>GSK, Collegeville, PA; <sup>5</sup>Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

**Background:** Higher erythropoiesis-stimulating agent (ESA) doses correlate with morbidity in patients treated for anemia of chronic kidney disease. Daprodustat, a hypoxia-inducible factor prolyl hydroxylase inhibitor, corrects anemia by inducing endogenous erythropoietin (EPO). Changes in EPO and vascular endothelial growth factor (VEGF) were examined in a double-blind trial of daprodustat vs epoetin alfa (epoetin) in hemodialysis patients.

**Methods:** 407 patients on ESA (baseline hemoglobin [Hb] 8–11.5 g/dL) were randomized 2:1 to daprodustat 3-times-weekly (TIW) or epoetin once-weekly or TIW for 52 weeks (ASCEND-TD, NCT03400033). The primary endpoint (change in Hb) was met and safety profiles were similar. Plasma EPO and VEGF were measured pre-dose on day 1 and once during weeks 28–52, pre-dose and 2, 4, 6, or 8h post-dose. Major adverse cardiovascular events (MACE) were adjudicated.

**Results:** Mean  $\pm$  standard deviation (SD) baseline EPO levels (IU/L) were low ( $22 \pm 45$  daprodustat vs  $18 \pm 22$  epoetin). Maximal (max) mean EPO increases across all doses were lower with daprodustat ( $161 \pm 362$ ) vs epoetin ( $12313 \pm 814$ ). Higher daprodustat and epoetin doses mostly correlated with max EPO (Figure); max post-baseline and change from baseline EPO with higher daprodustat doses (20–48mg) were similar to or lower than for the lowest epoetin dose (1500U). VEGF levels declined from baseline for daprodustat and epoetin, unrelated to dose. Daprodustat dose was not related to occurrence of first MACE; mean  $\pm$  SD dose at first MACE ( $14.6 \pm 9.5$ mg) was similar to final dose without MACE ( $17.2 \pm 13.7$ mg).

**Conclusions:** Daprodustat-induced changes in EPO were dose-dependent. Despite high daprodustat doses, the EPO levels produced were similar to levels seen at the lowest epoetin doses.

**Funding:** Commercial Support - This study was funded by GSK.

TH-PO691

**Effects of Daprodustat on Hemoglobin and Quality of Life in Non-Dialysis CKD Patients: Expanded Results of the ASCEND-NHQ Trial**  
Kirsten L. Johansen,<sup>1</sup> Fredric O. Finkelstein,<sup>2</sup> Csaba P. Kovesdy,<sup>3</sup> Purav R. Bhatt,<sup>4</sup> Ruben K. Israni,<sup>4</sup> Rodrigo Refoios Camejo,<sup>5</sup> Tom J. Keeley,<sup>5</sup> Stephen Mallett,<sup>6</sup> Ajay K. Singh.<sup>6</sup> <sup>1</sup>Hennepin Healthcare, University of Minnesota, Minneapolis, MN; <sup>2</sup>Yale University, New Haven, CT; <sup>3</sup>University of Tennessee Health Science Center, Memphis, TN; <sup>4</sup>GSK, Collegeville, PA; <sup>5</sup>GSK, Brentford, United Kingdom; <sup>6</sup>Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

**Background:** ASCEND-NHQ (a randomized, double-blind, placebo-controlled trial; NCT03409107) investigated the effects of daprodustat on hemoglobin (Hb) and quality of life in non-dialysis patients with chronic kidney disease (CKD). Daprodustat met primary and secondary endpoints, increasing Hb and improving Short Form-36 Vitality score vs placebo. We report data for the CKD Anemia Questionnaire (CKD-AQ), a new patient-reported outcome measure developed from qualitative patient interviews to specifically capture symptoms related to anemia of CKD.

**Methods:** The CKD-AQ is a 21-item questionnaire with 3 domains: tired/low energy/weak (10 items), chest pain/shortness of breath (4 items), and cognitive (3 items); and 4 individual items. Items are scored on a scale of 0–100 (worst–best). Patients in ASCEND-NHQ were randomized 1:1 (daprodustat:placebo), to achieve and maintain target Hb (11–12g/dL) over 28 weeks. Changes in scores from baseline to Week 28 were compared between treatments via a linear mixed effect repeated measures model (missing data were not imputed) (Table).

**Results:** Of 614 patients, 405 (212 daprodustat, 193 placebo) had baseline and on-treatment Week 28 CKD-AQ data. Daprodustat increased Hb vs placebo (1.58 vs 0.19g/dL; mean difference 1.40, 95% confidence interval 1.23–1.56). Patients on daprodustat had significantly greater improvement in all CKD-AQ domains and 1 of 4 individual items vs placebo (Table). Incidence of fatigue and anemia adverse events was higher for placebo vs daprodustat.

**Conclusions:** Anemia of CKD treatment with daprodustat improved tiredness, chest pain/shortness of breath, and cognition difficulties, often associated with potential productivity loss in patients with anemia of CKD.

**Funding:** Commercial Support - This study was funded by GSK

**Hemoglobin Stability in the ASCEND-D and -ND Trials**  
Vivekanand Jha,<sup>1</sup> Kirsten L. Johansen,<sup>2</sup> Pablo E. Pergola,<sup>3</sup> Daniel W. Coyne,<sup>4</sup> Katie St. Ledger,<sup>5</sup> Stephen Mallett,<sup>6</sup> Purav R. Bhatt,<sup>5</sup> Maria E. Duarte,<sup>5</sup> Ajay K. Singh.<sup>7</sup> <sup>1</sup>George Institute for Global Health, New Delhi, India; <sup>2</sup>Hennepin Healthcare, Minneapolis, MN; <sup>3</sup>Renal Associates, San Antonio, TX; <sup>4</sup>Washington University School of Medicine, St. Louis, MO; <sup>5</sup>GSK, Collegeville, PA; <sup>6</sup>GSK, Brentford, United Kingdom; <sup>7</sup>Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

**Background:** Maintaining hemoglobin (Hb) levels in target ranges per clinical care guidelines for patients (pts) with chronic kidney disease (CKD) is complex. We examined Hb stability in pts with CKD on dialysis (ASCEND-D, NCT02879305) or not on dialysis (ASCEND-ND, NCT02876835) treated with daprodustat (Dapro) or erythropoiesis-stimulating agents (ESAs).

**Methods:** ASCEND-D and -ND were global, open-label, event-driven cardiovascular outcome trials. Our analyses examined the percentage of pts who achieved a mean Hb within the analysis target range (10.0–11.5g/dL); the percentage of time within range in the evaluation period (EP: weeks 28–52) and maintenance period (MP: week 28–end of treatment); Hb excursions ( $\geq 12$ g/dL or  $< 7.5$ g/dL); Hb increases and decreases  $> 2$ g/dL during EP. Separate analyses were performed for Dapro and ESA per study.

**Results:** Of enrolled pts, 2485/2964 (83.8%; ASCEND-D) and 3011/3872 (77.8%; ASCEND-ND) had evaluable Hb during the EP. Hb was within the target range in 903/1238 (73%) Dapro pts and 866/1247 (69%) ESA pts (p=0.0367; ASCEND-D), and 1167/1491 (78%) Dapro pts and 1063/1520 (70%) ESA pts (p<0.0001; ASCEND-ND). In both studies, for Dapro vs ESA, respectively, Hb stayed within the target range for a greater proportion of time (61% vs 59%, p=0.0805 [ASCEND-D]; 71% vs 63%, p<0.0001 [ASCEND-ND]) and a greater proportion of pts exhibited an Hb increase  $> 2$ g/dL (15% vs 10%, [ASCEND-D]; 10% vs 7% [ASCEND-ND]) (Table). The proportions of Dapro pts achieving target Hb and time in the target Hb range were higher in ASCEND-ND than -D.

**Conclusions:** In ASCEND-D and -ND, more pts treated with Dapro achieved target Hb and spent more time in the target Hb range than pts treated with ESAs. This suggests that Dapro may provide increased Hb stability vs conventional ESA.

**Funding:** Commercial Support - This study was funded by GSK

**Suppression of Thyroid Profile During Roxadustat Treatment in CKD Patients**  
Yuan Cheng, Qiong Xiang, Tao Cao, Fei Tang, Qijun Wan. <sup>1</sup>Department of Nephrology, Shenzhen Second People's Hospital, the First Affiliated Hospital of Shenzhen University, Shenzhen, Guangdong, P.R. China, Shenzhen, China.

**Background:** Roxadustat has been used for renal anemia. To date, roxadustat induced suppression of thyrotropin secretion have been only described in two cases reports, but more data from a larger cohort are needed.

**Methods:** A total of 151 patients with renal anemia were collected in this retrospective cohort study. Changes in thyroid hormone and TSH were evaluated before and during the use of roxadustat or erythropoietin.

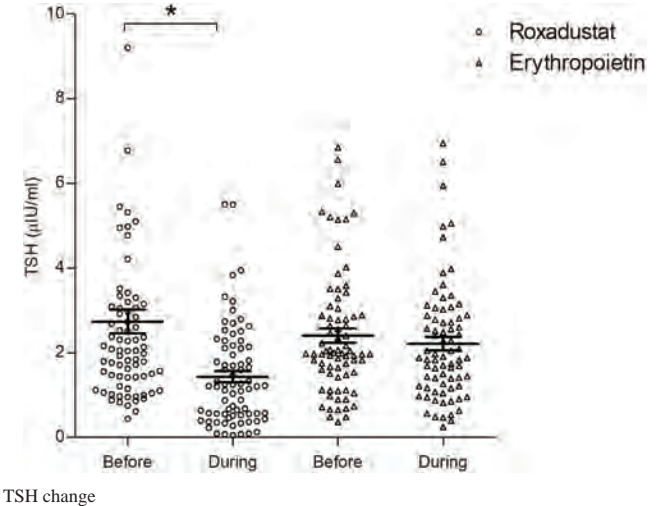

**Results:** FT3, FT4, T3, T4 and TSH level were lower during the use of roxadustat compared to baseline compared to erythropoietin group. 48.68% of patients had TSH levels dropped by more than 50%. By multivariate analysis, treatment of roxadustat was independently associated with the lower of TSH level by 41.30% (P<0.001).

**Conclusions:** This cohort study first finds that the suppression of thyroid profile is commonly related in CKD patients used roxadustat.

**Funding:** Government Support - Non-U.S.

## Real-World Use of Roxadustat, an HIF-PH Inhibitor, in the China Dialysis and Practice Patterns Study (DOPPS, 2019-2021)

Xinju Zhao,<sup>1</sup> Brian Bieber,<sup>2</sup> Liangying Gan,<sup>1</sup> Fan Fan Hou,<sup>3</sup> Xinling Liang,<sup>5</sup> Xiaonong Chen,<sup>6</sup> Zhaohui Ni,<sup>4</sup> Yuqing Chen,<sup>7</sup> Roberto Pecoits-Filho,<sup>2</sup> Bruce M. Robinson,<sup>2</sup> Li Zuo.<sup>1</sup> <sup>1</sup>Peking University People's Hospital, Beijing, China; <sup>2</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>3</sup>Southern Medical University Nanfang Hospital, Guangzhou, China; <sup>4</sup>Shanghai Jiao Tong University, Shanghai, China; <sup>5</sup>Guangdong Provincial People's Hospital, Guangzhou, China; <sup>6</sup>Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital, Shanghai, China; <sup>7</sup>Peking University First Hospital, Beijing, China.

**Background:** Erythropoiesis stimulating agents (ESA) have been the mainstay to treat anemia in hemodialysis (HD) patients for decades but have been associated with adverse outcomes. The Hypoxia-inducible factor prolyl hydroxylase (HIF-PH) inhibitor roxadustat (roxa), is an oral anemia correction agent commercially available in China since 2018. However, little is known about its use in real-world settings. The aim of this study was to explore roxa uptake in Chinese in-center HD patients.

**Methods:** China DOPPS participants initiating roxa were identified and compared to the overall China DOPPS in-center HD population (2019-21).

**Results:** Among 1763 participants roxa prescription increased from 0 (Jan 2019) to 9.1% (Nov 2021, Figure). Compared to overall, patients starting roxa during follow-up (n=116) were older (65 v 61 years); on dialysis longer (5.0 v 3.1 years); more likely diabetic (50 v 36%) or female (51 v 40%); and had lower Hgb (9.3 v 10.8 g/dL), higher CRP (0.57 v 0.35 mg/dL), and higher ferritin (300 v 212 ng/mL) levels. Compared to values at roxa initiation, Hgb increased (10.2 g/dL), ferritin decreased (204 ng/mL), CRP and s. potassium were stable, and ESA use decreased from 93 to 70% two months after roxa initiation (v 91% overall ESA use). IV iron (~30%) and oral iron (~20%) use were similar from before to after roxa initiation, and to the overall cohort.

**Conclusions:** Per DOPPS China data, approximately 10% of HD patients in major Chinese cities are now prescribed a HIF-PH inhibitor. Impressions based on preliminary data include: roxa is prescribed to both prevalent and incident HD patients, appears to correct renal anemia, may improve iron metabolism, has no effect on potassium, and is often prescribed concurrently with an ESA. Longitudinal evaluation to assess dosing patterns, effectiveness, safety, and subgroup effects of HIF-PH inhibitors in the real-world is warranted in future studies.

**Funding:** Commercial Support - Global support for the ongoing DOPPS Programs is provided without restriction on publications by a variety of funders. For details see <https://www.dopps.org/AboutUs/Support.aspx>

## TH-PO695

## Roxadustat vs. Erythropoiesis-Stimulating Agents and the Effect on Lipid Profile in Dialysis-Dependent Patients With Anemia of Renal Disease: A Meta-Analysis of Phase 3 Randomized Controlled Trials

Poemlarp Mekraksakit,<sup>1</sup> Natnicha Leelaviwat,<sup>2</sup> Siroj Dejhansathit,<sup>2</sup> Gaspar Del Rio-Pertuz,<sup>2</sup> Wisit Cheungpasitporn,<sup>1</sup> Juthipong Benjanuwattra,<sup>2</sup> Samapon Duangkham,<sup>2</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Texas Tech University Health Sciences Center School of Medicine, Lubbock, TX.

**Background:** Multiple recent studies have shown that roxadustat was non-inferior to erythropoiesis-stimulating agents (ESAs) in treatment of anemia of renal disease. However, the effects of roxadustat on lipid levels have not been well explored.

**Methods:** We searched the databases of MEDLINE and Embase from inception to April 2022. We included phase 3 randomized controlled trials (RCTs) that evaluated the efficacy of roxadustat versus ESAs in dialysis-dependent (DD) patients. Data were combined using the random-effects model and the inverse-variance method.

**Results:** Seven RCTs involving 5,391 DD patients from July 2019 to April 2022 were included. When compared to ESAs, roxadustat significantly decreased total cholesterol (mean difference [MD] -23.22 mg/dL; 95% -27.88, -18.56;  $P=72\%$ ), LDL (MD -15.04 mg/dL; 95% CI -17.16, -12.91;  $P=55\%$ ), and triglyceride levels (MD -9.61 mg/dL; 95% CI -15.29, -3.92;  $P=0\%$ ). Although HDL cholesterol levels decreased significantly (MD -3.48 mg/dL; 95% CI -4.37, -2.59;  $P=31\%$ ), an improvement in the LDL:HDL ratio was observed (MD -0.21; 95% CI -0.27, -0.15;  $P=0\%$ ). Roxadustat was non-inferior to ESAs in hemoglobin response (MD 0.21 g/dL; 95% CI 0.10, 0.33;  $P=87\%$ ) and decrease of hepcidin level (MD -17.56 ng/mL; 95% CI -31.97, -3.15;  $P=81\%$ ). There is no difference of patients having a first blood transfusion between the two groups (pooled HR 0.86; 95% CI 0.63, 1.16;  $P=55\%$ ).

**Conclusions:** Our meta-analysis indicated that roxadustat significantly decreased total cholesterol, LDL, LDL:HDL ratio, HDL, and triglyceride levels compared to ESAs. Further studies are needed to clarify this association.

## A.) Total cholesterol (mg/dL)

## B.) Triglycerides (mg/dL)

## C.) LDL (mg/dL)

# Potential Long-Term Economic Benefits of Switching From Epoetin Alfa to Hypoxia-Inducible Factor Prolyl Hydroxylase (HIF-PH) Inhibitors for the Management of Anemia in Hemodialysis (HD) Patients

Satoshi Funakoshi,<sup>1</sup> Kosei Yamaguchi,<sup>1</sup> Mineaki Kitamura,<sup>1</sup> Tomoya Nishino.<sup>2</sup>  
<sup>1</sup>Nagasaki Kidney Center, Nagasaki, Japan; <sup>2</sup>Nagasaki Daigaku Igakubu Daigakuin Ishiyakugaku Sogo Kenkyuka, Nagasaki, Japan.

**Background:** HIF-PH inhibitors, which have recently become clinically available for treating renal anemia, are attracting attention for their novel mechanisms of action. However, the cost of the starting dose of HIF-PH inhibitors is considerably higher than EPO, and it may limit the use of them. Since HIF-PH inhibitors potentially lead to the activation of numerous HIF-regulated genes, we expected savings in drug use due to improvements in physical condition (i.e. cardiovascular protection) other than direct hematopoietic effects when used over the long term.

**Methods:** Sixty-four HD patients treated with 9000 U/week of EPO were converted to roxadustat (Rox) three times a week at a dose of 100 mg, then dose of Rox was titrated to achieve Hb level between 10 to 12 g/dL. In a similar way sixty-one HD patients treated with 9000 U/week of EPO were converted to daprodustat (Dap) at daily dose of 6 mg, then dose of Dap was titrated to achieve Hb level between 10 to 12 g/dL.

**Results:** The starting amounts of Rox and Dap were approx. 4,100 and 3,000 JPY / week, respectively, while EPO was approx. 2,600 JPY / week. As shown in Figure, while spending on EPO naturally remained unchanged, but the respective drug use of Rox and Dap slowly decreased and the costs became almost equivalent to the cost of EPO in one year.

**Conclusions:** We have shown that administering Rox and Dap, HIF-PH inhibitors, had led to a reduction in cost in long-term use. Given the cost sparing advantages HIF-PH inhibitors as has been reported, they appear to be an effective alternative to ESA in the long-term management of anemia in HD patients.

## Changes in weekly costs for HIF-PH inhibitors and EPO over time

## TH-PO697

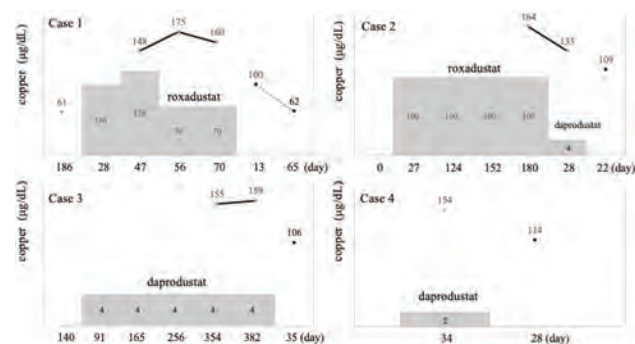

# Four Cases of Serum Copper Excess in Patients With Renal Anemia Receiving a Hypoxia-Inducible Factor-Prolyl Hydroxylase Inhibitor: A Possible Safety Concern

Hironori Nakamura, Anayama Mariko, Michiko Ueda, Masaki Nagasawa, Yasushi Makino. Department of Nephrology, Shinonoi General Hospital, Nagano, Japan.

**Introduction:** Copper is an indispensable trace metal element and is mainly absorbed in the stomach and small intestine and excreted into the bile. Hypoxia-inducible factor-prolyl hydroxylase inhibitors (HIF-PHIs) have emerged as a novel approach for renal anemia management. Many intestinal genes, including *divalent metal transporter 1* (DMT1), *duodenal cytochrome B* (DCYTB), and copper transporter ATP7A (ATP7A), related to iron or copper metabolism are transactivated by HIF- $\alpha$ , during iron deficiency.

**Case Description:** We first report four cases of patients with renal anemia who showed excess in serum copper level during roxadustat or daprodustat treatment, which were decreased to the normal level after discontinuing HIF-PHIs and changing the drug to darbepoetin alfa, suggesting that HIF-PHI is associated with serum copper excess shown in Fig 1.

**Discussion:** In a rat model, roxadustat significantly increased expression of *DMT1* and *DCYTB* mRNA and stabilized HIF-1 $\alpha$  and HIF-2 $\alpha$  in vitro. HIF- $\alpha$  protein levels rapidly declined after washout of roxadustat from cell cultures. Just as HIF-PHI modulates iron metabolism, such as absorption, sequestration and mobilization, HIF-PHI may also influence serum copper levels by mechanisms through copper absorption and/or redistribution via DMT1, ATP7A and copper transporter 1 in tissues. Therefore, it is urgent to examine the correlation between HIF-PHI use and serum copper levels because copper excess might be involved in several acute or chronic adverse events.

Changes of serum copper and days before, during, and after the HIF-PHI treatment. Half-tone dot meshing shows the term of HIF-PHI treatment and its dose.

## TH-PO698

# Iron Deficiency, Anemia, and Health-Related Quality of Life in Kidney Transplant Recipients

Tim J. Knobbe,<sup>1</sup> Daan Kremer,<sup>1</sup> Joanna Sophia J. Vinke,<sup>1</sup> Coby Annema,<sup>2</sup> Martin H. De Borst,<sup>1</sup> Stefan P. Berger,<sup>1</sup> Stephan J. Bakker,<sup>1</sup> Michele F. Eisenga.<sup>1</sup>  
<sup>1</sup>TransplantLines Investigators <sup>1</sup>University Medical Center Groningen, department of Internal Medicine, Division of Nephrology, Groningen, Netherlands; <sup>2</sup>University Medical Center Groningen, Department of Health Sciences, Section of Nursing Research, Groningen, Netherlands.

**Background:** Current guidelines focus on treatment of anemia to improve health-related quality of life (HRQoL) among kidney transplant recipients (KTRs), with limited effects. Iron fulfills a myriad of functions besides stimulating erythropoiesis, and there is increasing consensus that iron deficiency, rather than anemia alone, may be a promising target to improve HRQoL. However, epidemiological support for this notion is sparse. We therefore investigated the association of iron deficiency with HRQoL in KTRs, adjusting for co-existing anemia.

**Methods:** Data of KTRs ( $\geq 1$  year after transplantation) from the TransplantLines Biobank and Cohort Study were used. Iron deficiency was defined as serum transferrin saturation  $< 20\%$  and ferritin  $< 100$   $\mu\text{g/L}$ . Anemia was defined as Hb  $< 13$  g/dL (M) or  $< 12$  g/dL (F). HRQoL was assessed using the validated Short Form-36 questionnaire.

**Results:** A total of 814 KTRs (62% male, mean age  $56 \pm 13$  years) were included at a median of 3 [1-10] years after transplantation. In total, 229 (28%) KTRs suffered from iron deficiency and 237 (29%) were anemic. In linear regression analyses, both iron deficiency and anemia were associated with physical (B -4.82, 95% CI -8.06 to -1.59,  $p=0.004$  and B -3.45, 95% CI -6.77 to -0.13,  $p=0.042$ , respectively) and mental (B -3.63, 95% CI -6.42 to -0.84,  $p=0.011$  and B -1.22, 95% CI -4.09 to 1.64,  $p=0.4$ , respectively) HRQoL, independent of age, sex, eGFR, time since transplantation, diabetes mellitus, pre-emptive transplantation, living donor, calcineurin inhibitor use, angiotensin receptor blocker use and ACE inhibitor use. In addition, the associations between iron deficiency and HRQoL remained materially unchanged after additional adjustment for anemia (physical: -4.43, 95% CI -7.69 to -1.16,  $p=0.008$ ; mental: B -3.53, 95% CI -6.35 to -0.71,  $p=0.014$ ).

**Conclusions:** Iron deficiency, independent of anemia, is associated with lower physical and mental HRQoL among KTRs. These data highlight the need for interventional studies investigating whether correction of iron deficiency improves HRQoL among KTRs, even in the absence of anemia.

**Funding:** Commercial Support - The TransplantLines Biobank and Cohort study was supported by a grant from Astellas BV and Chiesi Pharmaceuticals BV, and co-financed by the Dutch Ministry of Economic Affairs and Climate Policy by means of the PPP-allowance made available by the Top Sector Life Sciences & Health to stimulate public-private partnerships.

## TH-PO699

# Burden of Anemia in Patients With CKD Stages 3-5 Managed in Primary Care

Marie Evans,<sup>1</sup> Yang Xu,<sup>1,3</sup> Faizan Mazhar,<sup>1</sup> Johan Arnlov,<sup>1</sup> Elinor Cockburn,<sup>4</sup> Peter F. Barany,<sup>2,1</sup> Juan J. Carrero.<sup>1</sup> <sup>1</sup>Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Karolinska Universitetssjukhuset, Stockholm, Sweden; <sup>3</sup>Peking University, Beijing, China; <sup>4</sup>Astellas Pharma A/S, Kastrup, Denmark.

**Background:** General practitioners (GPs) are the first point of contact for patients with chronic kidney disease (CKD), who often remain in the care of their GP until advanced stages of disease. Anemia is a common complication of CKD, but there are limited studies quantifying the burden of CKD-associated anemia in primary care. In this study, we explored anemia incidence, treatment selection, and adverse clinical outcomes in primary care patients with CKD.

**Methods:** We evaluated patients  $\geq 18$  years with CKD stages 3-5 managed in primary care in Stockholm, Sweden, from 2012 to 2018, who did not have anemia and had no history of nephrology referral. Incident anemia was defined as persistently low hemoglobin (Hb) values ( $< 12.0$  g/dL in women and  $< 13.0$  g/dL in men,  $> 3$  months apart), anemia international classification of disease diagnosis, or a single low Hb measurement

with treatment initiation within 90 days. We evaluated baseline factors associated with anemia incidence and treatment selection, and the association between incident anemia and major adverse cardiovascular events (MACE) or death.

**Results:** The study included 45,637 adults with CKD stages 3-5 (mean age 78 years, 64% female, 79% CKD stage 3a) managed in primary care; 11,987 (26%) developed anemia during follow-up (median 2.4 years, interquartile range 1.0-4.7). Anemia incidence increased with CKD severity: 78 cases/1000 person-years in CKD stage 3a, to 185 cases/1000 person-years in stages 4-5. The main factors associated with anemia occurrence were older age, male sex, diabetes, and lower estimated glomerular filtration rate. In the six months following incident anemia, treatment was initiated in 2272 (19%) patients, including oral iron (9.9%), blood transfusion (6.6%), and erythropoiesis-stimulating agent (0.2%). Treatment initiation increased with anemia severity. Developing anemia was associated with a higher risk of death (adjusted hazard ratio [HR] 1.33 [95% CI: 1.25–1.42]) and MACE (HR 1.91 [95% CI: 1.77–2.06]).

**Conclusions:** One in four patients with CKD stages 3–5 developed anemia while managed in primary care. Developing anemia was associated with low treatment rates and poor outcomes, highlighting an opportunity to improve management of CKD-associated complications in primary care.

**Funding:** Commercial Support - Commercial Support (Astellas Pharma A/S Denmark)

## TH-PO700

### Examining the Magnitude of Erythropoiesis-Stimulating Agent Hyporesponsiveness in Hemodialysis Patients

Eric D. Weinhandl,<sup>1,2</sup> Yunji Hwang,<sup>3</sup> David T. Gilbertson,<sup>1,2</sup> Jeffrey Petersen.<sup>3</sup>  
<sup>1</sup>Chronic Disease Research Group, Minneapolis, MN; <sup>2</sup>University of Minnesota Twin Cities, Minneapolis, MN; <sup>3</sup>Amgen Inc, Thousand Oaks, CA.

**Background:** Anemia is common in patients undergoing maintenance hemodialysis (HD) and is treated with erythropoiesis-stimulating agents (ESAs) and intravenous iron. ESA hyporesponsiveness is an oft-cited unmet medical need, but the scope of the problem is obscured by complex statistical quantities, including the erythropoietin resistance index (ERI). We analyzed a contemporary, nationally representative cohort to describe anemia-related parameters of HD patients with high ERI and/or chronically low hemoglobin (Hb).

**Methods:** We analyzed CROWNWeb records of HD patients in 2016-2019. The study cohort included 6-month patient-intervals characterized by treatment with either epoetin alfa (EPO) or darbepoetin alfa (DPO), monthly measurements of Hb, and at least one measurement of transferrin saturation (TSAT). We stratified patient-intervals by the cross-classification of normal vs high ERI (definition:  $\geq 20$  EPO-equivalent IU/wk/kg/g/dL, where 1 mcg DPO = 250 IU EPO) and transiently vs chronically low Hb (definition: Hb <10 g/dL in every month of the interval). In each stratum, we estimated median values of weekly ESA dose, Hb, ERI, and TSAT.

**Results:** We identified 7,824,640 patient-intervals. Prevalence of high ERI was 17.2% in single patient-months and 15.6% during 6-month patient-intervals. In both cases, ERI was strongly correlated with weekly ESA dose ( $R^2 = 0.87$ ). In contrast, prevalence of Hb <10 g/dL was 23.0% in single patient-months, whereas prevalence of chronically low Hb was 2.5% during 6-month patient-intervals (table). Among 15.6% of patients with high ERI, 13.8% experienced only transiently low Hb, with median Hb of 10.1 g/dL and median TSAT of 25.0%. Among 2.5% of patients with chronically low Hb, 1.8% experienced high ERI, with median TSAT of 23.0%.

**Conclusions:** Prevalence of high ERI in HD patients exceeds 15%, mostly due to the scale of ESA dosing, but this overstates the prevalence of chronic anemia hyporesponsive to treatment. Lower TSAT is common in patients with high ERI and/or chronically low Hb, suggesting potential iron deficiency.

**Funding:** Commercial Support - Amgen Inc.

	Normal ERI		High ERI	
	Transiently low Hb	Chronically low Hb	Transiently low Hb	Chronically low Hb
Patient-intervals (row %)	85.7%	0.7%	13.8%	1.8%
ESA dose (EPO-equivalent IU/wk)	5136	8624	19,809	25,106
Hb (g/dL)	10.7	8.9	10.1	8.5
ERI (IU/wk/kg/g/dL)	3.9	3.5	25.0	33.3
TSAT (%)	30.0	26.0	25.0	23.0

## TH-PO701

### Adverse Additive Effect of Iron Deficiency on Cardiac Death in Incident Hemodialysis Patients With Left Ventricular Systolic Dysfunction

Mai Hitaka,<sup>1</sup> Kenji Nakata,<sup>1</sup> Toshihide Hayashi,<sup>1</sup> Minako Harada,<sup>1</sup> Ayaka Yamamura,<sup>1</sup> Yasushi Ohashi,<sup>2</sup> Yuri Tanaka,<sup>1</sup> Nobuhiko Joki.<sup>1</sup>  
<sup>1</sup>Department of Nephrology, Toho University Ohashi Medical Center, Tokyo, Japan; <sup>2</sup>Department of Nephrology, Toho University Sakura Medical Center, Chiba, Japan.

**Background:** Iron deficiency (ID), especially low transferrin saturation (TSAT), has a great impact on cardiac events in patients with heart failure (HF) reduced ejection fraction. Our previous study has shown low TSAT is closely associated with an enlarged heart, independent of hemoglobin level in incident hemodialysis (HD) patients. The purpose of this study is to examine the adverse effect of ID depending on the cardiac functional status.

**Methods:** 705 patients with iron data were included in this study, out of 809 consecutive end-stage kidney disease(ESKD) patients who started maintenance HD therapy during January 1993 and December 2021. The primary endpoint was defined

as cardiac death including death of myocardial infarction, HF and sudden death. ID was defined as TSAT<20% regardless of the ferritin level. 5-year cumulative survival rate was calculated by Kaplan Meier curve in 4 ESKD patient groups with/without ID and with/without ejection fraction (EF) <50%. Hazard ratios (HR) and 95% confidence intervals (CI) were estimated by Cox proportional hazard model.

**Results:** Mean age was 68 years, 30% female. During the mean follow-up period of  $3.0 \pm 1.9$  years, 188 deaths occurred, 46 of which were cardiac deaths. About 16% and 40% of patients suffered from ID and EF<50% respectively at the initiation of HD. 5-year survival rate was 93.9% in non-ID group, which is significantly higher than that of ID group of 83.4%. Lower survival rate of 74.3% was found in ID with EF<50% group compared to 86.5% of non-ID with EF<50% group. As shown in the table, Cox regression analysis revealed that in patients with low-EF, HR is showing abrupt increment from 2.3 to 7.4 when combined with ID.

**Conclusions:** The additive adverse effect of ID on cardiac death was indicated in incident HD patients with left ventricular systolic dysfunction. Further study is needed to confirm the effect of iron supplementation for better prognosis in maintenance HD patients with cardiac dysfunction.

	HR	95% CI	p
Non-ID/EF≥50%	1		
Non-ID/EF<50%	2.3	0.72-7.39	0.1585
ID/EF≥50%	3.1	1.44-6.74	0.0037
ID/EF<50%	7.4	2.97-18.44	<0.0001

Adjusted by age, gender, diabetes mellitus, and hemoglobin.

### Pegmomesatide for the Treatment of Anemia in NDD-CKD Patients: A Multicenter Randomized Active-Controlled Phase 3 Trial

Ting Lin,<sup>1</sup> Aicheng Yang,<sup>2</sup> Hongyu Qiu,<sup>3</sup> Xiaomei Peng,<sup>4</sup> Wanhong Lu,<sup>5</sup> Shuifu Tang,<sup>9</sup> Qinkai Chen,<sup>6</sup> Xiangyang Huang,<sup>7</sup> Aimin Zhong,<sup>8</sup> Xueqing Yu.<sup>1</sup>  
<sup>1</sup>Guangdong General Hospital, Guangzhou, China; <sup>2</sup>Jiangmen Wuyi Traditional Chinese Medicine Hospital, Jiangmen, China; <sup>3</sup>Sichuan University West China Hospital, Chengdu, China; <sup>4</sup>The people hospital of Guangxi Zhuang Autonomous Region, Nanning, China; <sup>5</sup>The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; <sup>6</sup>The First Affiliated Hospital of Nanchang University, Nanchang, China; <sup>7</sup>Liu Zhou worker's hospital, Liuzhou, China; <sup>8</sup>Jiangxi Provincial People's Hospital, Nanchang, China; <sup>9</sup>The First Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China.

**Background:** Pegmomesatide, a synthetic peptide-based erythropoiesis-stimulating agent (ESA), is a potential long-acting drug for the treatment of anemia in chronic kidney disease (CKD) patients. Efficacy and safety of Pegmomesatide would be evaluated in non-dialysis-dependent(NDD)-CKD populations.

**Methods:** A multicenter, randomized, open-label, active-controlled, non-inferiority phase 3 trial was conducted at 38 centers in China. Eligible NDD-CKD patients who were not receiving ESAs were randomly assigned (2:1) to receive Pegmomesatide once in every four weeks (at a starting dose of 0.04 mg/kg) or Epoetin alfa weekly or biweekly (at a starting dose of 6000 IU per week). During the 52-week study, dosages were adjusted as needed to achieve and maintain hemoglobin(Hb) level between 10.0 and 12.0 g/dL. The primary endpoint was the change in Hb level from baseline to the evaluation period (week 17 through 24). Non-inferiority would be established if the lower boundary of 95% confidence interval for the Hb change difference (Pegmomesatide-Epoetin alfa) was greater than -1.0 g/dL. Safety profile was assessed. Cardiovascular safety was evaluated on the basis of composite safety endpoints (death, stroke and myocardial infarction).

**Results:** A total of 175 patients were randomized, and 135 patients (86 in the Pegmomesatide group and 49 in the Epoetin alfa group) completed a 24-week treatment. The median duration of exposure was 36.63 and 37.95 weeks respectively in the Pegmomesatide and Epoetin alfa group. The demographics and baseline characteristics were balanced between two groups. The non-inferiority was reached in Full-Analysis Set and Per-Protocol Set. Of the 173 patients who received at least one dose, the incidences of adverse events (AEs) and serious AEs (SAEs) were similar in both groups, and hypertension was the most common AE related to the study drug (5.2% in the Pegmomesatide group and 13.8% in the Epoetin alfa group). The composite safety endpoints were occurred in 1 patient (0.9%) who received Pegmomesatide and in 2 patients (3.4%) who received Epoetin alfa.

**Conclusions:** Long-acting Pegmomesatide was similar to Epoetin alfa in efficacy and safety, which could be used for treatment of anemia in NDD-CKD patients.

## TH-PO703

### Long-Term P-Selectin Deficiency Does Not Prevent Progressive Renal Disease in Humanized Sickle Cell Mice

Malgorzata Kasztan,<sup>1</sup> Erica Sparkenbaugh,<sup>2</sup> Elizabeth Binning,<sup>3</sup> Fatima Trebak,<sup>2</sup> Rafal Pawlinski.<sup>2</sup> <sup>1</sup>The University of Alabama at Birmingham Department of Pediatrics, Birmingham, AL; <sup>2</sup>The University of North Carolina at Chapel Hill Department of Medicine, Chapel Hill, NC; <sup>3</sup>The University of Alabama at Birmingham Department of Medicine, Birmingham, AL.

**Background:** Sickle cell disease (SCD) is a hemoglobinopathy characterized by chronic hemolysis, endothelial activation, and vaso-occlusion, ultimately leading to multiple organ damage. P-selectin is an adhesion molecule that mediates vascular stasis in SCD, and monoclonal antibody against P-selectin reduces the frequency of acute

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

vaso-occlusive crisis in SCD patients. Sick cell nephropathy is largely determined by renal vasculopathy, thus, we aimed to assess the effect of chronic P-selectin deficiency on kidney disease in murine model of SCD.

**Methods:** We evaluated kidney structure and function in 11-12 months old, male and female, humanized sickle cell (HbSS, n=14-17) and non-sickle control (HbAA, n=16-27) mice with or without P-selectin expression.

**Results:** The absence of P-selectin did not prevent progressive renal disease in HbSS mice as evidenced by hyposthenuria, proteinuria and loss of kidney function, determined by reduced GFR. We also determined if chronic P-selectin deficiency contributes to the development of glomerulopathy by measuring structural and functional markers of glomerular injury. Even though we observed a significant reduction in glomerular congestion score (0.16±0.05 vs. 0.37±0.06, p<0.05), P-selectin deficiency did not prevent albuminuria, glomerular sclerosis, hypertrophy, and podocyte loss in HbSS mice. Interestingly, significant hypercellularity, extensive mesangial expansion (2.3±0.1 vs. 1.3±0.1, p<0.05) and mesangiolysis were observed in P-selectin<sup>-/-</sup> HbSS when compared to P-selectin<sup>+/+</sup> HbSS mice. We also examined the effect of P-selectin deficiency on tubular injury. Regardless of P-selectin genotype, HbSS mice had greater urinary KIM-1 excretion and tubular simplification with brush border loss than non-sickle control mice. Also, despite a reduction in inflammatory cell recruitment in the kidney, P-selectin<sup>-/-</sup> HbSS mice presented with the same degree of renal fibrosis as P-selectin<sup>+/+</sup> HbSS mice. Secondary to reduced macrophage renal recruitment P-selectin deficient HbSS mice had significantly elevated renal iron accumulation when compared to HbSS mice with normal P-selectin expression (12.2±1.1 vs. 8.8±0.6, p<0.05).

**Conclusions:** These results suggest that despite reducing vaso-occlusion chronic P-selectin deficiency does not prevent progressive kidney disease in murine model of SCD.

**3-Carboxy-4-Methyl-5-Propyl-2-Furanpropionate (CMPF), a Protein-Bound Uremic Solute, Augments RBC Osmotic Fragility**  
Beatriz Akemi K. Van Spitzenbergen,<sup>1</sup> Gabriela Ferreira Dias,<sup>2</sup> Nadja Grobe,<sup>2</sup> Peter Kotanko,<sup>2,3</sup> Andrea N. Moreno-Amaral.<sup>1</sup> <sup>1</sup>Pontificia Universidade Catolica do Parana, Curitiba, Brazil; <sup>2</sup>Renal Research Institute, New York, NY; <sup>3</sup>Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** While contributing to renal anemia, shortened red blood cell (RBC) life span in end-stage kidney disease (ESKD) is poorly understood. Recently, the interaction between the protein-bound uremic solute 3-Carboxy-4-methyl-5-propyl-2-furanpropionate (CMPF) and the RBC Piezo1 mechanoreceptor has been hypothesized to shorten the RBC life span (Kotanko *et al.*, FASEB J BioAdvances, 2022). In the present study, we evaluated the effect of CMPF on RBC osmotic resistance.

**Methods:** RBC were isolated from healthy subjects (n=6). CMPF (8 µM, 17 µM, 87 µM, 170 µM) dissolved in DMSO was added to cell suspensions. Buffer plus DMSO served as a negative control. From these suspensions, 10µL were added to increasing NaCl solutions, from 3 to 9 g/L. After centrifugation (1500 rpm; 10 min), Hg (540 nM) was measured in the supernatant. Data were fitted to a 4-parameter logistic regression curve. The osmotic fragility index (IC50) was defined as a NaCl concentration that exerted 50% hemolysis.

**Results:** CMPF increased osmotic fragility in a dose-dependent manner. IC50 at 17 µM, 87 µM, and 170 µM, respectively, exceeded controls (4.47±0.15 vs. 4.19±0.07, 4.66±0.10 vs. 4.12±0.11, 4.82±1.34 vs. 4.65±1.88), indicating increased hemolysis in the presence of CMPF (Table 1).

**Conclusions:** Our results indicate that CMPF increases RBC osmotic fragility in a dose-dependent manner. If and to what extent an interaction between CMPF and Piezo1 is the causal pathway warrants further studies.

Table 1 - Dose-dependent increase of RBC osmotic fragility induced by CMPF

	IC50 DMSO Neg Ctrl (A)	IC50 CMPF (B)	Mean of differences (B - A)	p value
8 µM	4.18±0.09	4.23±0.36	0.05	0.843
17 µM	4.19±0.07	4.47±0.15	0.28*	0.022
87 µM	4.12±0.11	4.66±0.10	0.54**	0.003
170 µM	4.65±1.88	4.82±1.34	0.17*	0.015

TH-PO705

**Iron Therapy Mitigates Kidney Fibrosis by Regulating Intracellular Iron Status of Kidney Macrophages**  
Edwin Patino,<sup>1</sup> Divya Bhatia,<sup>1</sup> Shahd Jaouni,<sup>1</sup> Rie Uni,<sup>1</sup> Carlo G. Castillo,<sup>1,4</sup> Francesca Vinchi,<sup>2,1</sup> Mary E. Choi,<sup>1,3</sup> Oleh M. Akchurin.<sup>1,3</sup> <sup>1</sup>Weill Cornell Medicine, New York, NY; <sup>2</sup>New York Blood Center, New York, NY; <sup>3</sup>NewYork-Presbyterian Hospital/Weill Cornell Medical Center, New York, NY; <sup>4</sup>Cornell University, Ithaca, NY.

**Background:** Systemic iron metabolism is disrupted in CKD. However, little is known about local kidney iron homeostasis and its role in kidney fibrosis. Kidney-specific effects of iron therapy in CKD also remain elusive. Here, we assess the role of macrophage iron status in kidney fibrosis and report preclinical data suggesting that it can be used as a therapeutic target.

**Methods:** We used two mouse models of kidney fibrosis: adenine diet and unilateral urethral obstruction (UUO), applied to wild type mice and to ferritin heavy chain (*Fth1*) myloid-specific (LysM-cre) knockout mice. A subset of mice received weekly intraperitoneal injections of iron dextran (0.5 g/kg body weight) or adoptive transfer of iron-loaded macrophages. Mice were euthanized after 8 weeks of adenine diet or 7 days after UUO. Kidney macrophages were analyzed by flow cytometry using single cell suspensions of homogenized and digested kidney tissues. Effects of iron on macrophage phenotype were also assessed *in vitro* with and without concurrent TGF-β stimulation.

**Results:** In both models of kidney fibrosis, kidney macrophages exhibited depletion of labile iron pool (LIP) and induction of transferrin receptor 1, indicating intracellular iron deficiency. Low LIP in kidney macrophages was associated with their defective antioxidant response and pro-inflammatory polarization. Repletion of LIP in kidney macrophages through knockout of *Fth1* reduced oxidative stress and mitigated fibrosis. Iron significantly decreased TGF-β expression and suppressed TGF-β-driven fibrotic response of macrophages. Similar to *Fth1* knockout, iron dextran therapy, through replenishing macrophage LIP, reduced oxidative stress, decreased production of pro-inflammatory cytokines, and alleviated kidney fibrosis. Iron dextran therapy and Fth1 suppression had additive protective effect against fibrosis. Adoptive transfer of iron-loaded macrophages also alleviated kidney fibrosis, confirming the protective effect of iron-replete macrophages in CKD.

**Conclusions:** Depletion of LIP in kidney macrophages paradoxically drives their pro-oxidative, pro-inflammatory, and pro-fibrotic qualities in CKD. Repletion of intracellular LIP in macrophages attenuates kidney fibrosis. Thus, intracellular iron status of kidney macrophages appears to be a promising therapeutic target in CKD.

**Documentation of Social, Environmental, and Behavioral Determinants of Health in Administrative Claims Data in US Medicare and Commercially Insured Populations**  
Yun Han,<sup>1</sup> Diane Steffick,<sup>1</sup> Yiting Li,<sup>1</sup> Jennifer L. Bragg-Gresham,<sup>1</sup> Tiffany C. Veinot,<sup>1</sup> Brenda W. Gillespie,<sup>1</sup> Vahakn Shahinian,<sup>1</sup> Kai M. Bullard,<sup>2</sup> Meda E. Pavkov,<sup>2</sup> Rajiv Saran.<sup>1</sup> <sup>1</sup>University of Michigan, Ann Arbor, MI; <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA.

**Background:** Attention to social, environmental, and behavioral determinants of health (SEBDOH) is important for addressing health disparities, especially for conditions like chronic kidney disease (CKD). SEBDOH documentation practices may vary by patient factors. We investigate SEBDOH documentation in US claims data in outpatient settings and patient factors associated with such documentation.

**Methods:** We examined ICD-10 SEBDOH-Z codes in the Medicare 5% sample (Medicare Fee-for-Services plans, FFS, 2015-2019) and the Optum data (Medicare Advantage plans and commercial plans, 2015- 2020). Patient demographics, CKD, and other conditions predicting SEBDOH were assessed using logistic regression.

**Results:** SEBDOH documentation in claims was consistently low among people with different insurance: Medicare FFS (3%), Medicare Advantage (4%), and commercial plans (2%). Across insurance groups, tobacco use was the most commonly recorded behavior(33%-59% of the SEBDOH claims); younger age, non-Hispanic Black race, male sex, CKD, hypertension, cardiovascular diseases, and anemia were less likely to have SEBDOH documentation, after adjusting for patient factors (Table). Diabetes is related with more documentation in Medicare FFS (adjusted OR: 1.10, 95% CI 1.08-1.13, p<0.0001) and Medicare Advantage (adjusted OR: 1.13, 1.13-1.14, p<0.0001) but related with less documentation in commercial plans (adjusted OR: 0.97, 0.96-0.98, p<0.0001).

**Conclusions:** We observed a uniformly low-level uptake of SEBDOH-Z codes in both Medicare and Optum data. The negative association of CKD and other conditions with SEBOH documentation suggests missed opportunities in health care delivery. Increased SEBOH documentation can identify vulnerable CKD patients who may benefit from supplemental services.

**Funding:** Other U.S. Government Support

## TH-PO707

**Comparison of Actual vs. ZIP Code-Predicted Highest Educational Attainment in ESKD and Non-ESKD Participants**

Yang Dai, Huei Hsun Wen, Girish N. Nadkarni, Lili Chan. *Icahn School of Medicine at Mount Sinai, New York, NY.*

**Background:** Research on the association of social determinants of health (SDOH) and clinical outcomes in participants with kidney disease often use SDOH measures identified using participants' zip code and census data. However, in urban neighborhoods, zip code and census derived SDOH measures may be inaccurate.

**Methods:** We utilized data from participants  $\geq 25$  years old enrolled in the BioMe Biobank and from the Mount Sinai Kidney Center hemodialysis (HD) unit. All participants completed a questionnaire regarding the highest education obtained, age, gender, and race/ethnicity. The participants' zip code was obtained from the EHR and those with a New York City zip code were kept. We then used data from the American Community Survey data from the year the participant completed the survey to predict the highest level of education given participants' zip code, gender, and race/ethnicity. ESKD participants were identified by ICD9/10 codes or by enrollment in a HD unit. Non-ESKD participants were age, gender, and race/ethnicity matched to the ESKD participants.

**Results:** 732 participants with ESKD and 732 matched non-ESKD participants were identified. Patient demographics are presented in Figure 1A. Average age was  $58 \pm 13$  years in both ESKD and non-ESKD cohorts, and the number of unique zip codes was 130 and 137 respectively. Correct prediction of education was significantly different between participants with and without ESKD, correctly identified in 32% of participants with ESKD and 27% of non-ESKD participants (Figure 1B & C),  $P=0.02$ . Lower prediction means that the predicted education level is lower than the participant's actual education level. Higher prediction means predicted education was higher than the real degree. Results were similar across genders. Blacks and Hispanics had the highest concordance in ESKD participants and non-ESKD participants. Concordance between survey results and zip code predicted results was poor for both ESKD and non-ESKD participants, K0.05 and K 0.02 respectively.

**Conclusions:** In an urban city, zip code predicted educational attainment using census data is inaccurate in two thirds of participants with and without ESKD. Smaller geographic areas may result in improved concordance.

**Funding:** NIDDK Support

## TH-PO708

**Association Between Renal Disease Management and Hospital Care Utilization**

Rahul Dhawan, Ashley Crossman, Gregory Wysocky, Karen Moran, Grace Keers, Kevin Plosser, Jiang Tao, Elizabeth Benusa. Optum KRS nurses and product team and the OHS Medical Office Team *Optum Inc, Eden Prairie, MN.*

**Background:** Evidence about impacts of disease management programs among patients with advanced stages of chronic kidney disease (CKD) is still limited. The study objectives were to evaluate the association between a renal disease management program which focuses on permanent access placement, home based dialysis initiation and patient education and hospital care utilization among patients with advanced CKD.

**Methods:** A case-control study was performed. The treatment group contained CKD 4-5 and ESRD health plan members in Utah with access to the renal care management program ( $N = 25,332$  member months). The control group contain CKD 4-5 and ESRD health plan members in Nevada without access to the renal care management program ( $N = 36,225$  member months). Data sources included medical claims and lab result data. Inverse propensity score weighting (IPSW), based on confounding factors such as age, gender, prevalent comorbidities and CKD stages, was employed to reduce selection bias. Changes in hospital admissions and length of hospital stay (LOS) were compared to evaluate the impacts of the program.

**Results:** Generalized linear models with IPSW showed hospital admissions among the treatment group with ESRD declined by 32 per 1,000 patients per month from 2017-2018 while hospital admissions in the control group with ESRD increased by 36 per 1,000 patients per month during the same period ( $P < 0.01$ ). Changes in LOS between the treatment and control groups with ESRD showed the same pattern but were not statistically significant ( $P=0.09$ ). Among members with CKD 4/5, hospital admissions among the treatment group increased by 4 admissions per 1,000 patients per month while hospital admissions in the control group increased by 6 admissions per 1,000 patients per month during the same period, but this difference was not significant ( $P=0.71$ ). Changes in LOS between the treatment and control groups with CKD showed the same pattern but were also not statistically significant ( $P=0.93$ ).

**Conclusions:** A disease specific renal care management program significantly reduces hospital admissions within 1 year after the program implementation among patients with ESRD. Impacts of renal care management in a longer period need to be further studied.

## TH-PO709

**Race and the Risk of Heart Failure in CKD**

Sydney E. Hartsell,<sup>1,2</sup> Xiangyang Ye,<sup>1,2</sup> Robert E. Boucher,<sup>1,2</sup> Amara Sarwal,<sup>1,2</sup> Guo Wei,<sup>1,2</sup> Srinivasan Beddhu,<sup>1,2</sup> <sup>1</sup>The University of Utah School of Medicine, Salt Lake City, UT; <sup>2</sup>VA Salt Lake City Health Care System, Salt Lake City, UT.

**Background:** Minority populations are disproportionately affected by poor outcomes in CKD. It is unknown whether there are racial disparities in HF incidence in CKD.

**Methods:** We created a national VA cohort ( $N = 801,572$ ) extracted using the VA Informatics and Computing Infrastructure (VINCI) platform. We included patients with CKD stage 3A, 3B or 4 by outpatient CKD-EPI 2021 eGFR values collected 2010-2015, and excluded those with baseline HF by ICD9/10 codes. Incident HF through August 2018 were defined by ICD codes. We related race to incident HF with multivariable cox regression models, adjusting for demographics, comorbidities, and baseline BP.

**Results:** 74.8% were white, 18.4% black and 6.8% other races. Median age was 74.2 yrs, 96.4% male, and skewed to early-stage CKD (70.7%, 23.9%, 5.4% with stages 3A, 3B, 4). HTN was slightly more common in black patients (93.1% vs 92.3% in other races vs 91.3% in whites). There were 125,965 HF events over 3.5 million patient-years of follow up. In the entire cohort, compared to whites, blacks (HR 1.02, 95% CI 1.01-1.04) and other races (HR 1.01, 95% CI 0.99-1.04) did not have appreciably higher risk of HF. However, within CKD stages, compared to whites, black veterans with CKD stage 3B and 4 had a higher hazard of HF (Figure).

**Conclusions:** Black patients with more advanced CKD have a higher risk of incident HF than white patients. Interventions to reduce HF risk in black patients with advanced CKD are needed.

HF by race and CKD stage

## TH-PO710

**Incidence of Heart Failure in CKD Patients Is Not Affected by Rurality**

Stephen R. Sammons, Xiangyang Ye, Guo Wei, Sydney E. Hartsell, Robert E. Boucher, Srinivasan Beddhu. *University of Utah Health, Salt Lake City, UT.*

**Background:** While there is a well-known interplay between Chronic Kidney Disease (CKD) and Heart Failure (HF), little is known about how social determinants of health such as rurality affect this relationship.

**Methods:** We analyzed a national cohort ( $n = 740,233$ ) of veterans with CKD and without HF at baseline. Veterans with eGFR  $< 60$  on two consecutive outpatient serum creatinine measurements that were at least 60 days apart from 1/1/2010 to 12/31/2015 were included. The index date was defined as the date of the second eGFR  $< 60$ . Metropolitan, micropolitan, or small town/rural residences were defined by Rural-Urban Commuting Area (RUCA) codes. HF incidence was defined as the number of new HF diagnoses from index date until 6/30/2018. Cox regression models adjusted for age, gender, and comorbidities were used to relate rurality and CKD categories to the risk of HF.

**Results:** The distribution of metropolitan, micropolitan, or small town/rural residences were 74.8%, 13.2% and 12.0%, respectively; for CKD 3A, 3B and 4 70.9%, 23.8% and 5.3%, respectively. There were 116,298 HF events over 3.3 million person-years of follow-up. Compared to metropolitan residence, small/town rural residence was associated with statistically significant but clinically negligible higher risk of HF in the entire cohort (Table 1). There was no evidence that these associations were modified by the stage of CKD (Table 1).

**Conclusions:** Rurality does not appear to have a clear impact on incidence of heart failure in veterans with CKD. Further studies are needed to examine whether death as a competing risk might explain this finding as rural veterans with advanced CKD and HF might be at higher risk of death.

**Funding:** NIDDK Support, Other NIH Support - NIA R01 AG074592, Veterans Affairs Support

Table 1

RUCA Category	CKD3a	CKD3b	CKD4	Entire cohort
Metropolitan	1.00	1.00	1.00	1.00
Metropolitan	0.99 (0.97-1.02)	0.99 (0.96-1.02)	0.97 (0.91-1.04)	0.99 (0.97-1.01)
Small Town/Rural	1.02 (1.00-1.04)	1.04 (1.00-1.07)*	0.97 (0.91-1.04)	1.02 (1.00-1.04)

Hazard ratios with confidence intervals for incidence of HF in CKD patients stratified by RUCA category, with metropolitan category as a reference. Asterisk indicates hazard ratio is significant at  $p < 0.05$ .

## TH-PO711

### Racial Disparity in Anemia of CKD in the Adult US Population: Results From NHANES 1999-2018

Ajay K. Singh,<sup>1</sup> Youssef M. Farag,<sup>2</sup> <sup>1</sup>Harvard Medical School, Boston, MA; <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.

**Background:** Racial disparities have been reported in the U.S for many aspects of clinical care, including in CKD. Evaluation of anemia in CKD patients in a representative population in the United States has not been examined.

**Methods:** We analyzed data from NHANES 1999 to 2018 which included 101,316 participants. eGFR was calculated using the race-free CKD-EPI 2021 equation. CKD was defined and staged based on KDIGO guidelines. Anemia was defined using WHO criteria. Appropriate sample weights were used to account for the complex survey design. To test the association between race and anemia, we used multiple logistic regression adjusting for demographics and clinical variables.

**Results:** The weighted period prevalence of CKD in adult US population was 14.1%, of whom 14.6% were anemic, 1.35% and 0.55% had hemoglobin  $<10\text{g/dL}$  and  $9\text{g/dL}$ , respectively, and increased over the 20-year period. Non-Hispanic Blacks had consistently higher prevalence of anemia of CKD compared to other races, and such prevalence increased over time. Fig 1 shows prevalence of anemia by race and CKD stage. Marked disparity was observed among non-Hispanic Blacks, with significantly higher prevalence of anemia compared to non-Hispanic Whites at each stage of CKD ( $p < 0.001$ ). Non-Hispanic Blacks had 3.6-fold higher odds of being anemic compared to non-Hispanic Whites (adjusted OR 3.6, 95% CI, 3.0, 4.3,  $p < 0.001$ ).

**Conclusions:** A racial disparity exists with CKD anemia in non-Hispanic Blacks in the US population. While NHANES data may have some limitations, these findings raise public health concerns that suggest gaps in CKD care disadvantaging Black's with CKD in the US.

## TH-PO712

### Analysis of Racial and Socioeconomic Disparities in African American Patients Older Than 40 Years With CKD in the United States

Raghav K. Ranga, Georgetown University Medical Center, Washington, DC.

**Background:** Chronic kidney disease and end-stage renal disease are rapidly growing conditions across the world. Due to the ever-increasing burden of the predominant causes of these conditions, hypertension and type 2 diabetes mellitus, it is critical that everyone who develops chronic kidney disease has equal access to care. African Americans in the United States often face an uphill battle due to age-old unwritten policies of systemic discrimination, racism, and barriers that prevent their access to healthcare.

**Methods:** Articles that were written after 2000 were analyzed looking for quantifiable differences in outcomes of African Americans vs. non-Hispanic white people in chronic kidney disease, as well as confounders within the data that could explain the strong correlation between being African American and having a higher probability of death from chronic kidney disease. Articles were obtained from databases such as PubMed, Google Scholar, SciHub, ClinicalKey, eJournals, and MEDLINE. Once this was done, two potential interventions were suggested that could help to address these disparities. The PRISMA Database was used to evaluate study quality.

**Results:** The articles showed that there was a hazard ratio between 1.30 and 3.00 for African Americans getting all manifestations of kidney disease compared to non-Hispanic White Americans and it showed that one of the main confounding variables

affecting racial disparities in kidney care was socioeconomic status. The mean African American household in the United States made more than \$30,000 less than non-Hispanic Americans in the year 2019, and this could lead to other barriers.

**Conclusions:** Race and socioeconomic status both affect kidney disease by a factor of approximately 1.50 times for African Americans as compared to non-Hispanic people. The interventions that were chosen that could impact outcomes increased screenings for variations of polymorphisms of apolipoprotein L1 and sensitivity training for primary care physicians making them aware of the barriers that their African American patients may face in order to provide the most culturally competent care.

## TH-PO713

### The Association Between Household Income, Food Security, and Prevalence of CKD in Older Patients

Jinsuk Bae,<sup>1,2</sup> Hyuk Huh,<sup>3,5</sup> Jehun Song,<sup>1,2</sup> Jong Soo Lee,<sup>1,2</sup> Ho seok Koo,<sup>4,5</sup> Kyung Don Yoo,<sup>1,2</sup> <sup>1</sup>University of Ulsan College of Medicine, Songpa-gu, Seoul, Republic of Korea; <sup>2</sup>Ulsan University Hospital, Ulsan, Dong-gu, Republic of Korea; <sup>3</sup>Inje University Busan Paik Hospital, Busan, Republic of Korea; <sup>4</sup>Inje University Seoul Paik Hospital, Jung-gu, Seoul, Republic of Korea; <sup>5</sup>Inje University College of Medicine, Busan, Republic of Korea.

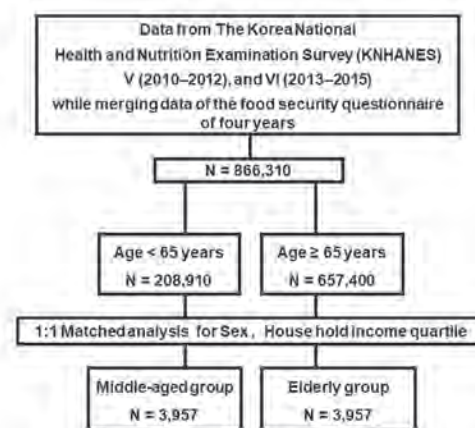

**Background:** This study aimed to clarify the association between food security and the prevalence of chronic kidney disease in Korean older patients.

**Methods:** We analyzed the variables of The Korea National Health and Nutrition Examination Survey V (2010–2012), and VI (2013–2015) while merging data from the food security questionnaire for four years. We included 15,945 participants, performed propensity score-matched analysis by quartile of household income (i.e., low, low-mid, high-mid, high) and sex, and presented the results by age group (Figure 1).

**Results:** Systolic blood pressure and proportion of current smokers were significantly higher in the elderly group, compared with the middle-aged group. The prevalence of hypertension, diabetes mellitus (DM), metabolic syndrome, and chronic kidney disease (CKD) did not differ significantly by income level in the elderly group. The food security questionnaire revealed that food security insurance was significantly lower in the low-income level (1<sup>st</sup> quartile), compared with that in the high-income level (4<sup>th</sup> quartile). The logistic regression analysis for the association between the prevalence of chronic disease and food insecurity confirmed no significant association between hypertension and DM.

**Conclusions:** There might be a correlation between self-reported food insecurity and the incidence of chronic kidney disease (CKD), particularly in the elderly populations older than 65 years.

Figure 1.

## TH-PO714

### Social Determinants and Health Care Utilization Among a CKD Population in North Philadelphia: An Exploratory, Mixed Methods Approach

Nicole M. Sifontis,<sup>1</sup> Jean Lee,<sup>2</sup> Avrum Gillespie,<sup>2</sup> Colleen Rabbitt,<sup>2</sup> Serban Constantinescu,<sup>2</sup> <sup>1</sup>Temple University School of Pharmacy, Philadelphia, PA; <sup>2</sup>Lewis Katz School of Medicine at Temple University, Philadelphia, PA.

**Background:** Patients with CKD exhibit multiple comorbidities, resulting in increased health care utilization and costs. Health disparities are common across the kidney disease spectrum resulting in poorer management of chronic illnesses. The starkest contrast in these disparities are seen based on social determinants like race and socioeconomic status. This project aims to better understand health disparities that drive health care utilization in patients with CKD who receive care at our institution.

**Methods:** This sequential mixed methods study identified the social determinants of health (SDoH) needs of patients with CKD at our institution. It explored available resources to address these determinants and barriers that limit access to services. Quantitative data were collected utilizing the Center for Medicare & Medicaid Services (CMS) Health-Related Social Needs (HRSN) screening tool to interview patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

Qualitative data were collected via a focus group session with community health workers (CHWs) employed by the institution, to identify facilitators and barriers to the social needs established by the quantitative analysis.

**Results:** 34 patients with CKD were interviewed. Food insecurity (29.4%), reliable transportation (26.5%) and utility needs (23.5%) were the most common social determinants noted. Bivariate analyses revealed a statistically significant relationship between living situation and food insecurity;  $p=0.0031$ , living situation and utility needs;  $p=0.0094$ , and transportation and food insecurity,  $p=0.0227$ . CHWs expressed the importance of building trust with their patients, engaging community-based partners to assist with social needs, and robust patient engagement as important facilitators of SDoH. Reported barriers to connecting patients to supportive services included: inability to contact patients readily, provider burn out, time constraints, and the challenges of addressing overlapping social needs simultaneously.

**Conclusions:** These data highlight the need for better screening tools and more efficient care models that would allow the time and resources necessary to complete these tasks. These pilot data will help inform a systems-based approach to improving health equity among the CKD population who receive care at our center.

## TH-PO715

### Individual and Community-Level Risk Factors for Food Insecurity Among Patients on Hemodialysis

**Kathryn Taylor,<sup>1</sup> Sydney Santos,<sup>3</sup> Nancy A. Perrin,<sup>1</sup> Deidra C. Crews.<sup>2</sup>** <sup>1</sup>Johns Hopkins School of Nursing, Baltimore, MD; <sup>2</sup>Johns Hopkins Medicine, Baltimore, MD; <sup>3</sup>Johns Hopkins University, Baltimore, MD.

**Background:** Patients experiencing food insecurity are at increased risk to progress from chronic kidney disease to end-stage kidney disease (ESKD). However, sociodemographic risk factors and rates of food insecurity among patients on hemodialysis are largely unknown.

**Methods:** We analyzed food security data from an ongoing prospective cohort study of patients on hemodialysis at Maryland facilities of a large dialysis organization. We enrolled participants from February through November 2021. At baseline they completed a demographic survey and the US Adult Food Security Survey Module. We cross referenced participant zip codes with area-level indicators of socioeconomic status from the 2020 American Community Survey and Rand State Statistics. We conducted logistic regression to test associations between individual-level demographic variables and low or very low food security. For area-level predictors we used a mixed effects model to account for clustering by zip code.

**Results:** Food security was assessed for 293 participants. 12.6% of the sample had low food security and 9.9% had very low food security (e.g. went hungry because there was not enough money for food). A one-year decrease in age increased odds of low or very low food security by 3%. Table 1 displays rates of low or very low food security among participants by other individual- and community-level demographics. Rates of low or very low food security were over 2 times higher in the sample compared to the broader Maryland population according to 2020 census data.

**Conclusions:** Younger age and community-level poverty were associated with low or very low food security among patients on hemodialysis. Additional research is needed to estimate food security and its implications for patient outcomes among patients on hemodialysis.

**Funding:** Other NIH Support - National Institute of Nursing Research; National Heart, Lung, and Blood Institute

Table 1. Individual- and Community-level Demographic Risk Factors for Low or Very Low Food Security

	High or Marginal	Low or Very Low	OR, 95% CI
<b>Gender</b>

## TH-PO716

### Comparing Methods of Food Insecurity Screening in a Pediatric ESKD Population

**Victoria H. Besser,<sup>1</sup> Donna J. Claes.<sup>1,2</sup>** <sup>1</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH; <sup>2</sup>University of Cincinnati, Cincinnati, OH.

**Background:** Food insecurity (FI) has been reported to affect 65% of pediatric dialysis patients. Our center noted FI prevalence of 6% during initial screening in our kidney transplant (KTx) population. We aimed to identify characteristics of FI & compare different screening methods (verbal vs paper questionnaire) within our single-center, pediatric ESKD (HD, PD & KTx) population.

**Methods:** We assessed ESKD pts for FI using the Hunger Vital Sign® by a verbal screen and later by paper questionnaire. Patients were considered FI if they answered positive on either screen. Relevant patient data [i.e. gender assigned at birth, age, race, etiology of kidney disease, BMI, weight status, eGFR, KRT modality & presence of hypertension] were obtained at the time of initial screening.

**Results:** 139 pts (19 HD, 11 PD, 109 KTx; 52.5% male; mean age 11.6 yr) completed 225 screens (113 verbal screen, 112 paper questionnaire) with a mean of 5.4 months between screens. 16 pts (11.5%; 5 HD, 1 PD, 10 KTx) were found to be FI. There was a trend of a higher rate of FI in pts of black race (44% vs 20%;  $p=0.076$ ) & HD pts (31% vs 11.4%;  $p=0.094$ ) when compared to food secure (FS) pts. There was no difference in other relevant variables between FI & FS pts (table 1). 86 pts completed both the verbal screen & paper questionnaire. Concordance of verbal & written screening was 92% ( $n=79$ ). 5 pts (6%) were found to be FI on written screen but FS on verbal screen; 2 pts (2%) were FI on verbal screen but FS on written screen.

**Conclusions:** We report FI prevalence of 11.5% in our pediatric ESKD population. We were able to demonstrate concordance of FI screening by comparing verbal & written screening methods. Further multicenter studies are needed to understand the prevalence, associated relevant outcomes, & potential risk factors of FI in the pediatric ESKD population.

Table 1 - Baseline Characteristics			
	Food Insecure (n = 16)	Food Secure (n = 123)

Abstract Withdrawn

TH-PO718

**Social Determinants of Health Predict Annual CKD Screening and Disease Development Among Newly Diagnosed Hypertensive and Type 2 Diabetic Patients in a Large Midwestern Health System**  
Marybeth Ingle,<sup>1</sup> Sarang Baman,<sup>1</sup> Yuxian Du,<sup>2</sup> Vesta Valuckaite,<sup>2</sup> Rakesh Singh,<sup>2</sup> Sheldon X. Kong,<sup>2</sup> Todd E. Williamson,<sup>2</sup> Rasha Khatib.<sup>1</sup>  
<sup>1</sup>Advocate Health Care Inc, Downers Grove, IL; <sup>2</sup>Bayer AG, Leverkusen, Germany.

**Background:** Clinical guidelines suggest regular chronic kidney disease (CKD) screening after diagnosis of hypertension (HTN) or type 2 diabetes (T2DM), as both are risk factors. Monitoring of kidney function allows for early detection of CKD & can improve quality of life. However, social determinants of health (SDOH) can impact access to routine care, including CKD screening. We explore how SDOH factors from electronic health records (EHR) predict CKD screening & CKD development among newly diagnosed HTN and/or T2DM patients.

**Methods:** EHR of patients (n=235,208) with a new HTN and/or T2DM diagnosis between 2015-2018 were abstracted. Patients were followed for 3 years to assess annual CKD screening (1 estimated glomerular filtration rate & 1 urinary albumin-to-creatinine ratio) and CKD development (CKD or end stage renal disease). Multivariable logistic regression models evaluated SDOH factors with CKD screening & CKD development.

**Results:** Most patients were White (57%) females (55%) with HTN (65%). Few had only T2DM (9%) & 26% had both. Screening was highest for patients who developed HTN & T2DM during the study (44%) compared to T2DM (38%) or HTN (4%). CKD developed for 9% of patients. Public health insurance patients were 66% more likely to not be screened for CKD compared to patients with private insurance (Odds Ratio (OR)=1.66, 95% Confidence interval (CI):1.60,1.73). Retired patients were less likely to not be screened (OR=0.77, 95%CI:0.72,0.82). Black (OR=0.54, 95%CI:0.52,0.56), Hispanic (OR=0.55, 95%CI:0.53,0.58), & Asians (OR=0.64, 95%CI:0.60,0.68) were less likely to not be screened compared to Whites. Figure 1 depicts SDOH factors & CKD development. Blacks were over twice as likely to develop CKD (OR=2.11, 95%CI:1.95,2.29).

**Conclusions:** The increase in CKD incidence among Black and retired patients could be due to frequent screenings. However, employment and single status were not a predictor of screening, yet a predictor of CKD. It's possible lifestyle factors unique to this population contribute to CKD development.

**Association Between Social Support and Hospitalization Risk Among Adults With CKD**  
Flor Alvarado,<sup>1</sup> Siyi Geng,<sup>2</sup> Jing Chen,<sup>1,2</sup> Hua He,<sup>2</sup> Eleanor Rivera,<sup>3</sup> Milda R. Saunders,<sup>4</sup> Vallabh O. Shah,<sup>5</sup> Robert G. Nelson,<sup>6</sup> Bernard G. Jaar,<sup>7</sup> Mark L. Unruh,<sup>5</sup> Ana C. Ricardo,<sup>3</sup> Deidra C. Crews,<sup>7</sup> Amanda H. Anderson,<sup>2</sup> Jiang He.<sup>1,2</sup>  
<sup>1</sup>Tulane University School of Medicine, New Orleans, LA; <sup>2</sup>Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; <sup>3</sup>University of Illinois Chicago UI Health, Chicago, IL; <sup>4</sup>The University of Chicago Medicine, Chicago, IL; <sup>5</sup>University of New Mexico School of Medicine, Albuquerque, NM; <sup>6</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ; <sup>7</sup>Johns Hopkins Medicine, Baltimore, MD.

**Background:** Adults with chronic kidney disease (CKD) have a higher risk of hospitalization than the general population. We evaluated the association of social support, a potentially modifiable factor, with hospitalization risk among adults with CKD.

**Methods:** This was a prospective cohort study of adults with mild to moderate CKD enrolled in the Chronic Renal Insufficiency Cohort (CRIC) Study. Social support was assessed using the six-item Lubben Social Network Scale (LSNS-6). The summary score ranged from 0-30. A score  $\leq 12$  was considered "at-risk" for social isolation, reflecting low social support. The LSNS-6 was administered between 2013 to 2018, which was considered the baseline for the present study; and follow-up occurred until death, study withdrawal, or May 2020. Hospitalizations were ascertained based on participant self-report and review of medical records and were recorded as the number of hospitalizations. Number of hospitalizations per 1000 person-years was calculated. Counts of hospitalization by isolation risk status were assessed using a Poisson regression model controlled for the duration of follow-up.

**Results:** Among a subset of 1155 CRIC participants with baseline LSNS-6 assessments available, mean age was 69, 39% were female, 16% were Hispanic, 41% non-Hispanic Black, 41% non-Hispanic White, mean eGFR was 55 mL/min/1.73m<sup>2</sup>, and 30% were considered at-risk for social isolation. There were 4015 hospitalizations, and the maximum follow-up period was 6.7 years. In unadjusted analyses, an increased risk of all-cause hospitalization was found among those at-risk for social isolation in the whole cohort and in all racial/ethnic subsets (Table). After multivariable adjustment for other sociodemographic variables, the risk remained for Hispanic participants (Incidence Rate Ratio 2.09; 95% CI 1.62-2.68).

**Conclusions:** Low social support was associated with increased all-cause hospitalization risk among Hispanic individuals with CKD.

**Funding:** NIDDK Support

TH-PO720

**Electronic Health Literacy: A Key Determinant in Televisit Acceptance in Inner-City Patients With CKD**  
Nicholas Baglieri,<sup>1</sup> Rohan Goyal,<sup>1</sup> Mariana S. Markell.<sup>2</sup>  
<sup>1</sup>Montefiore Medical Center, Bronx, NY; <sup>2</sup>SUNY Downstate Health Sciences University, Brooklyn, NY.

**Background:** Televisits have become a more widely used since the COVID pandemic in 2020. However, pts in underserved populations may not be as knowledgeable about electronic health resources and may not be able to access this type of health care visit, worsening health care disparities. We examined the relationship between electronic health literacy and acceptance of televisits in an underserved inner-city population of pts with CKD.

**Methods:** 38 randomly selected CKD pts were surveyed in a face to face fashion including a demographics section, the eHEALS electronic health literacy assessment (scored from 8 to 40), and additional sections on televisit history. eHEALS is a validated 8 question survey that characterizes the subjective ability to find and use electronic health resources.

**Results:** Mean age of the pts. was 67±15 yrs. 66% were female, 74% did not attend any college, 60% make less than \$25,000 per year. 21% did not have any Internet access, 5.3% did not own a cell phone, and 5.3% of cell phone owners did not own a smart phone. 61% need help using the internet. The mean eHEALS of those who need help using the internet is 21.1±6.0 vs 27.5±8.6 (p<0.05) for those who do not need help. 76% of pts. had a televisit before the survey, of which 76% were telephone only and 24% had visits by both telephone and video. No participant had only used video.

Those who had televisits did not differ based on age, education, gender and income from those who did not. Of the 24% of participants who did not have televisits, 100% need help using the internet vs 48% who had televisits ( $p=0.006$ ). Mean eHEALS score of those who had a televisit was  $25.1 \pm 7.9$  vs  $18.9 \pm 4.9$  for those who did not ( $p=0.01$ ).

**Conclusions:** In our population of older inner-city CKD patients, 1. Almost one quarter had no home internet access, and over half needed help using it 2. Pts who needed help had lower eHealth literacy and were less likely to have televisits. 3. Televisit use related to eHealth literacy rather than age, education or income. 4. Administering eHEALS may identify people who would benefit most from in person visits, directed educational materials to help with televisits or for whom support should be provided 5. The rise in use of telehealth may further health resource inequities if eHealth literacy is not recognized as a potential negative social determinant in vulnerable populations.

## TH-PO721

### Frequency of Text Messaging as a Screening Tool for Assessing Electronic Health (eHealth) Literacy in Patients With CKD/ESKD and Low Health App Usage

Rohan Goyal,<sup>1</sup> Nicholas Baglieri,<sup>1</sup> Mariana S. Markell,<sup>2</sup> <sup>1</sup>Monte iore Medical Center, Bronx, NY; <sup>2</sup>SUNY Downstate Health Sciences University, Brooklyn, NY.

**Background:** There are many mobile health apps available for pts with kidney disease but pts may be unable to use them due to low eHealth literacy. We assessed eHealth literacy and potential barriers to app use in an underserved inner-City population of CKD and HD pts.

**Methods:** 38 CKD pts and 31 HD pts were questioned face to face using the eHEALS electronic health literacy assessment (scored from 8 to 40), and questions regarding text messaging/app usage. eHEALS is an 8 question survey that characterizes subjective ability to find and use electronic health resources. Independent t-tests, Pearson correlation coefficient calculations, and generalized linear models were performed when appropriate.

**Results:** CKD pts were older ( $67.5 \pm 15.1$  vs.  $60.6 \pm 13.0$  for HD,  $p=0.045$ ). 61% of HD pts are male vs 34% of CKD pts ( $p=0.025$ ). 51% of HD pts have attended some college or more vs 74% of CKD pts ( $p=0.034$ ). Income was similar with 51% making < \$25,000 per year. Mean eHEALS score for CKD pts was 23.6 (SD = 7.7) vs 27.6 (SD = 8.2) for HD with no difference controlling for age and education. 97% of pts owned a cell phone, 91% owned a smartphone. 26% of pts reported never sending text messages, 22% reported sending a few times per week, 12% reported sending once or twice daily, and 41% reported sending more than twice daily. 45% of pts reported needing help downloading apps; 64% of pts did not report using any mobile health apps with no difference by clinic setting. Per a generalized linear model, frequency of text messaging was associated with eHEALS score with a  $p = 0.001$  after controlling for age, education, and clinic setting.

**Conclusions:** In our population of inner city pts with kidney disease, 1. The vast majority of pts own a smart phone but do not use any mobile health apps. 2. Almost half of all pts need help downloading apps. 3. Almost half of patients surveyed do not send text messages or send them less than 1-2x per week. 4. Frequency of text messaging is significantly associated with eHealth literacy suggesting that this parameter can be used to quickly assess this potential social determinant in kidney pts. 5. Inability to utilize health apps may further accentuate health disparities and this simple question may help identify pts who need education or support in order to fully utilize available healthcare resources.

## TH-PO722

### A Demographic and Community Characteristic Comparison of Advanced CKD Patients Seeing vs. Not Seeing a Nephrologist

Susan M. Devaraj,<sup>1</sup> Jonathan Yabes,<sup>1</sup> Manqi Cai,<sup>1</sup> Linda-Marie U. Lavenburg,<sup>3</sup> Khaled Abdel-Kader,<sup>2</sup> Manisha Jhamb.<sup>1</sup> <sup>1</sup>University of Pittsburgh Department of Medicine, Pittsburgh, PA; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>3</sup>University of Pennsylvania Department of Medicine, Philadelphia, PA.

**Background:** Despite the health benefits of receiving specialized care from a nephrologist, the majority of chronic kidney disease (CKD) patients are managed by primary care providers (PCPs). We explored potential individual and neighborhood level demographic differences among patients with high-risk CKD seeing versus not seeing a nephrologist.

**Methods:** Adult patients (age >18 years) in Western PA with advanced CKD (eGFR <30) who were managed by a PCP and not seeing a nephrologist were identified from an ongoing population health management study called Kidney CHAMP (enrolled years 2018-22). Their baseline characteristics were compared to a cohort of patients seeing a nephrologist at the kidney clinic at an academic center in Western PA between 2010-2012. Differences in individual patient (age, race, gender) and zip-code level characteristics [Social Deprivation Index (SDI) and Rural Urban Commuting Area] between those seeing vs not seeing a nephrologist were compared using chi-square

and t-tests. Multivariable logistic regression models including patient demographics and serum creatinine were used to determine the odds of having seen a nephrologist. Additional analyses are planned to explore other drivers of care.

**Results:** A total of 1,594 patients were not seeing a nephrologist, and 577 were seeing a nephrologist. Compared to patients seeing a nephrologist, patients not seeing a nephrologist were older (age 74 vs. 67 years,  $p<0.01$ ), more likely to be women (58% vs. 49%,  $p<0.01$ ), white (91% vs. 75%,  $p<0.01$ ), were living in rural areas (11% vs. 2%,  $p<0.01$ ), and had lower SDI scores meaning less social deprivation (score 40 vs. 43,  $p=0.01$ ). Multivariable models showed a significantly lower odds of seeing a nephrologist with each year of age (OR: 0.97,  $p<0.01$ ), white vs. black race (OR: 0.56,  $p<0.01$ ), micropolitan vs metropolitan (OR: 0.37,  $p<0.01$ ), and rural vs. metropolitan home address (OR: 0.13,  $p<0.01$ ), and higher odds with each unit increase in creatinine (OR: 3.18,  $p<0.01$ ).

**Conclusions:** Older age, white race, and living in a non-metropolitan area were independently associated with less engagement in nephrology care. Understanding factors associated with receiving specialty care may help to inform interventions to improve access for those most in need.

**Funding:** NIDDK Support

### Addressing Disparities in Kidney Health Outcomes for First Nations Peoples of the United States, Canada, Australia, and New Zealand: A Systematic Review

Michael D. Riceman,<sup>1,2</sup> Samantha Bateman,<sup>1,2</sup> David J. Tunnicliffe,<sup>3,4</sup> Rhane Lester,<sup>1</sup> Nari Sinclair,<sup>1</sup> Kelli Owen,<sup>1</sup> Martin Howell,<sup>3,4</sup> Odette R. Pearson,<sup>1,5</sup> Stephen P. McDonald,<sup>1,2</sup> Shilpa Jesudason.<sup>1,2</sup> <sup>1</sup>The University of Adelaide, Adelaide, SA, Australia; <sup>2</sup>Central Adelaide Local Health Network, Adelaide, SA, Australia; <sup>3</sup>University of Sydney, Sydney, NSW, Australia; <sup>4</sup>Centre for Kidney Research, The Children's Hospital at Westmead, Sydney, NSW, Australia; <sup>5</sup>South Australian Health and Medical Research Institute Limited, Adelaide, SA, Australia.

**Background:** First Nations Peoples of colonised counties are disproportionately burdened with kidney failure. Current systems of kidney care are failing to meet their needs, despite strong advocacy from community. We aimed to identify how disparities in health outcomes for First Nations Peoples of colonial countries living with kidney failure are addressed through different models of care.

**Methods:** We conducted a systematic review according to the PRISMA Checklist, governed by a First Nations reference group. Included studies involved First Nations Peoples of the USA, Canada, New Zealand and Australia and interventions to address the management or complications of kidney failure. The certainty of the evidence was assessed using GRADE.

**Results:** We identified 31 studies across 5 domains: dialysis care, dialysis access (vascular/peritoneal), transplantation, kidney failure complications, nutrition, and cultural safety. Few First Nations-specific randomised trials were identified. The largest body of evidence came from Australia and related to community-based dialysis care. From the Americas there is a moderate level of evidence for co-created, community-based living kidney donor transplant education and awareness campaigns.

**Conclusions:** Within the limited literature, there is evidence that purposeful, First Nations-led interventions can have positive impacts. However, considering the inequities faced by First Nations Peoples of colonial countries there is an unacceptable paucity of intervention studies evaluating First Nations specific models of kidney care.

**Funding:** Government Support - Non-U.S.

## Investigating Disparities in Telehealth Among CKD Patients in a US Integrated Healthcare System

Hui Zhou,<sup>1,2</sup> Matt M. Zhou,<sup>1</sup> Donald P. McCarthy,<sup>1</sup> Margo A. Sidell,<sup>1</sup> Benjamin Broder,<sup>1,3</sup> Emma L. Dolan,<sup>3</sup> Anthony Morena,<sup>3</sup> John J. Sim.<sup>2,3</sup> <sup>1</sup>KPSC Research and Evaluation, Pasadena, CA; <sup>2</sup>Kaiser Permanente Bernard J Tyson School of Medicine, Pasadena, CA; <sup>3</sup>Southern California Permanente Medical Group, Pasadena, CA.

**Background:** Telehealth utilization, including the use of telephone appointments (TAV) and video appointment visits (VAV), are a valuable alternative to in-person visits and were a crucial form of health delivery during the COVID-19 national emergency. Among chronic kidney disease (CKD) patients within an integrated healthcare system, we evaluated the rate of successfully completed telehealth visits and assess differences in adoption using an equity lens.

**Methods:** A retrospective cohort study was conducted among individuals (age ≥ 18 yrs) with CKD stage 3 and 4 receiving care at Kaiser Permanente Southern California (KPSC). We limited our sample to patients with at least one in-person visit within 12 months prior to Mar 1, 2020 and followed them for 1 year. A successfully completed telehealth visit was defined as a ≥ 20 min completed appointment via TAV/VAV. Poisson regression with robust variance error was conducted to estimate the rate ratio for a successful telehealth visit.

**Results:** Of 161,088 patients, 74% (N=118,456) had ≥ 1 successfully completed telehealth visit, 34% of which were VAVs. Younger age, female gender, white race, and English as spoken language were associated with the successful completion of a telehealth visit. Senior persons (85+) were less likely to have a successfully TAV/VAV compared to young adults (18-34 yrs) (RR:0.82; 95% CI:0.79-0.86) (Figure). Those having a KPSC online account were more likely to have successful TAV/VAV (RR:1.11; 95% CI:1.10-1.12). Medicaid patients had more successful telehealth visits while patients living in neighborhoods with less internet access were marginally less likely to have successful TAV/VAV (p=0.05).

**Conclusions:** We observed disparities in adoption of telehealth care among CKD patients within an integrated health system. Our findings suggest that further studies and management strategies are needed to facilitate and improve equitable patient-centered care.

**Funding:** Private Foundation Support

Figure. Rate Ratio of successful completion of telehealth among CKD patients

## TH-PO725

## Black, Non-Hispanic Individuals Are More Likely to Have Slower eGFR Decline Before Dialysis

Michael A. Kraus,<sup>1</sup> Yuedong Wang,<sup>2</sup> Catherine Y. Wang,<sup>5</sup> Len A. Usvyat,<sup>1</sup> Carly Hahn Contino,<sup>1</sup> Peter Kotanko,<sup>3,4</sup> Robert J. Kossman,<sup>1</sup> Harvey W. Kaufman.<sup>6</sup> <sup>1</sup>Fresenius Medical Care North America, Waltham, MA; <sup>2</sup>University of California System, Oakland, CA; <sup>3</sup>Renal Research Institute, New York, NY; <sup>4</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>5</sup>Carnegie Mellon University, Pittsburgh, PA; <sup>6</sup>Quest Diagnostics Inc, Secaucus, NJ.

**Background:** Race/ethnic inequities exist in ESRD care with regard to preemptive transplantation, ESRD primary access, and home therapies. Further, Blacks are >3x as likely and Hispanics and 1.3x more likely to have kidney failure versus Whites. Understanding pre-dialysis GFR decline may provide insights into the race disparity and aid in developing population-based tools. We report pre-dialysis eGFR decline using CKD-EPI 2021 equation without a race coefficient.

**Methods:** Patients initiated on dialysis at Fresenius Medical Care with matched clinical testing from Quest Diagnostics, 1/1/2015 - 9/30/2020 were included and deidentified. Inclusion criteria: a) 2 yrs of lab data prior to dialysis; b) ≥ 10 serum creatinine (Scr) measurements; c) ≥ 1 Scr within 45 days of initiation; d) ≥ 2 Scr distributed over 2 quarters. Exclusion criteria were sudden eGFR increase > 20 mL/min/1.73 m<sup>2</sup> or mean eGFR > 30 mL/min/1.73 m<sup>2</sup> within 45 days of dialysis. The revised CKD-EPI 2021 eGFR calculation was applied. A cubic spline was fitted to eGFRs from each patient followed by functional data clustering methods to categorize eGFR trajectories. Both K-mean and functional principal component analysis were used. One-way ANOVA and  $\chi^2$  tests were used to compare the trajectory groups for continuous and categorical variables.

**Results:** 2341 patients: 42% female, age 64.9 ± 12.3 years, 62.7% White non-Hispanic, 15.7% Black non-Hispanic, and 15.0% Hispanic. Patients grouped into 4 clusters of eGFR progression velocity: 1076 stable low cluster (slc); 920 slow decay cluster (sdc); 285 fast decay cluster (fdc); and 60 in the very fast decay cluster (vfdc). eGFR decreases were steepest for the vfdc, followed sequentially by fdc, sdc, slc. Mean time from eGFR of 20 to dialysis was 669.5 days (94.8) for slc, 271.2 days (155.5) for sdc, 121.4 days (93.1) for fdc, and 75.2 days (61.8) for vfdc. Faster decay groups were younger\*, male\*, and Hispanic\*. Black non-Hispanics were more likely to be in sdc than other clusters\*. Whites, non-Hispanics were equally distributed through all 4 clusters. (\* P<.001) (# P<.05)

**Conclusions:** AAs as a group, Black, non-Hispanics were 1.3x more likely to display a slower pre-dialysis eGFR decline. This suggests that there is more time to allow for improved CKD care and education and potentially better outcomes in this group.

**Funding:** Commercial Support - Fresenius Medical Care

## TH-PO726

## Economic and Humanistic Burden Among Individuals With CKD in the United States: A Systematic Literature Review

Katherine M. Oslenko,<sup>1</sup> Satadhi Chatterjee,<sup>2</sup> Saurabh Ray,<sup>2</sup> Tina Li,<sup>1</sup> Bonnie M. Donato.<sup>2</sup> <sup>1</sup>Broadstreet HEOR, Vancouver, BC, Canada; <sup>2</sup>Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT.

**Background:** Chronic kidney disease (CKD) is associated with substantial economic, humanistic, and clinical burden. While the clinical burden and direct medical costs are well characterized, less is known about the humanistic and economic burden, including lost productivity. The objective of this review was to synthesize contemporary estimates of economic and humanistic impact among individuals with CKD in the United States (US).

**Methods:** A systematic review was conducted using MEDLINE and Embase to identify studies reporting estimates of CKD economic or humanistic patient burden in the US, published between 2016-2021. Study selection and data extraction were performed in duplicate, in accordance with PRISMA guidelines. A grey literature search was conducted for the past 5 years. Characteristics of patients with CKD, and estimates of economic and humanistic burden, were summarized.

**Results:** From 4,880 abstracts, 38 eligible studies were included. Mean patient age ranged from 46.3-63.7 years; proportion of males ranged from 41.70-63.0%. Reported comorbidities included diabetes (23.0-55.8%), cardiovascular disease (20.5-63.0%), and hypertension (45.5-97.0%). Two studies reported out-of-pocket (OOP) expenditures for patients with CKD, estimated at \$1,599 (mean) and \$1,807 (median) annually (2022 USD), with more than 16% of patients reported to face high OOP burden. One study reported that 46.9% of non-elderly patients with CKD experienced financial hardship within the past year due to medical bills, with lack of health insurance being the strongest determinant; impacts included non-adherence and delayed/foregone medical care. Health-related quality of life (HRQoL) was assessed in 32 studies using a variety of instruments; high burden to patients with CKD was consistently demonstrated, with higher CKD stage associated with greater burden. Limited data were available on lost productivity.

**Conclusions:** The findings of this review demonstrate the high economic and humanistic burden to individuals with CKD, although HRQoL data were heterogeneous and economic data were limited. Further research is needed to better characterize the burden to individuals with CKD, in particular the economic impact and lost productivity, as well as drivers of burden.

## TH-PO727

**Predictors of Evidence-Based Medication Use Among Black Patients With Hypertension and CKD**

Mona Abraham,<sup>1</sup> Kathryn A. Carson,<sup>2</sup> Mary Ann C. Stephens,<sup>1</sup> Edgar R. Miller,<sup>1</sup> Deidra C. Crews,<sup>1</sup> Five Plus Nuts and Beans for Kidneys Study Investigators  
<sup>1</sup>*Johns Hopkins University School of Medicine, Baltimore, MD;* <sup>2</sup>*Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

**Background:** Black individuals may experience therapeutic inertia on the part of their clinicians which can result in poor control of CKD risk factors, including hypertension, and can contribute to racial disparities in CKD. Among a sample of Black adults with hypertension and CKD (with albuminuria), we examined predictors of evidence-based medication use. We hypothesized that lower socioeconomic status would be associated with less use of evidence-based medications.

**Methods:** We examined baseline self-reported medication use of 142 participants of a clinical trial for Black Americans with hypertension and CKD (urinary albumin-to-creatinine ratio (ACR)  $\geq 30$  mg/g and eGFR  $\geq 30$  ml/min/1.73m<sup>2</sup>). Participant enrollment was from 2018-2021, and all were actively under the care of a primary care clinician and/or a nephrologist. Primary medication classes of interest were (1) angiotensin-converting enzyme inhibitors (ACEi) or angiotensin receptor blockers (ARBs); and (2) sodium-glucose cotransporter 2 inhibitors (SGLT2i). Examined predictors of evidence-based medication use included: age, sex, income category, insurance type, employment status, systolic blood pressure, diabetes, hemoglobin A1C, obesity, eGFR, urine ACR. Statistical analyses included descriptive statistics and multivariable logistic regression.

**Results:** Participants' mean age was 61.1 years; 36.6% were male; 44.4% had diabetes; mean eGFR was 75 ml/min/1.73m<sup>2</sup>; mean ACR was 173 mg/g and 18.3% had urine ACR  $\geq 300$  mg/g. A total of 91 (64%) participants were taking an ACEi or ARB. Socioeconomic status (assessed by income category, insurance type and employment status) was not statistically significantly associated with ACEi or ARB use in univariate analyses. In logistic regression models inclusive of age, sex, diabetes and obesity status, each 5 years of older age was associated with a 15% lower odds of taking an ACEi or ARB [Odds Ratio (OR) 0.85, 95% Confidence Interval (CI) 0.73-0.99]. Diabetes was associated with greater odds of taking an ACEi or ARB (OR 3.52, 95% CI 1.59-7.79). Only 4 (2.8%) participants were taking an SGLT2i, and all had diabetes.

**Conclusions:** Among a population of Black adults with hypertension and albuminuria, older age was associated with lesser ACEi or ARB use, and few were taking an SGLT2i. These findings may have implications for pharmacotherapy in kidney care.

**Funding:** Other NIH Support - National Institute on Minority Health and Health Disparities, Commercial Support - Baxter

## TH-PO728

**CKD Care: Perspectives From Providers and Administrators About African American and Latinx Patients**

Sadia Anjum Ashrafi, Laura Quintero Silva, Alice A. Oloo, Andiana Schwingel.  
*University of Illinois Urbana-Champaign, Urbana, IL.*

**Background:** African Americans (AA) and Latinx are the most vulnerable populations concerning chronic kidney disease (CKD) progression and adverse health outcomes. The formal healthcare system often lacks equal access and quality of care for all patients, driving disparities in CKD. This qualitative study explored the challenges associated with caring for AA and Latinx patients from the perspectives of healthcare providers and administrators in the nephrology field.

**Methods:** We interviewed 27 healthcare providers and administrators from 10 states and 22 different organizations. Interviews were conducted virtually from January 31, 2022, to May 16, 2022, and transcribed verbatim. Trained researchers coded the transcriptions and identified emerging themes.

**Results:** Three emerging themes described perceptions of healthcare providers and administrators about AA and Latinx CKD patients, as follow: (1) **Unattainable treatment regimens**—reflecting challenges patients have in following dietary guidelines and fluid adherence due to limited access to healthy foods and low health literacy, medication managements due to having little support, limited access to care and missing dialysis due to maintaining employment, lack of awareness about treatment options and home support for home dialysis. These issues are worsened when patients are un/under-insured and lack transportation. (2) **Difficulties in meeting patients' needs** - reflecting communication barriers such as language, implicit bias regarding disease progression, and overall mistrust patients have towards the healthcare system. Patients' emotional needs are tremendous, and providers experience difficulties when trying to be a listening ear or someone that brings them hope. (3) **Need for cultural humility in the multidisciplinary care model**—a multidisciplinary health team is needed to provide more effective treatment that understands these patients as a whole. The team needs people able to provide personalized care within their experiences with oppression and discrimination and socio-economic, language, and cultural struggle. However, the current healthcare system mostly lacks such an environment.

**Conclusions:** The study findings underscore essential areas of improvement in AA and Latinx CKD patients' care, including increasing culturally sensitive support and programs for them.

## TH-PO729

**2021 CKD-EPI: Unintended Consequences in Living Kidney Donation**

Vineeta Kumar, Babak J. Orandi, Rhiannon D. Reed, Paul A. MacLennan, Brittany A. Shelton, Marshall C. McLeod, Jayme E. Locke. University of Alabama at Birmingham, Comprehensive Transplant Institute *University of Alabama at Birmingham Bone Marrow Transplant Program, Birmingham, AL.*

**Background:** Chronic Kidney Disease (CKD) Epidemiology Collaboration eGFR formula (2021 CKD-EPI) removed Black race from the 2009 equation, with the goal of not disproportionately affecting one racial group. Unintended consequences may lead to reclassifying potential Black living kidney donors (LKD) as having more advanced CKD, potentially exacerbating living donation disparities.

**Methods:** Using national data, we identified LKD with pre-donation eGFR  $\geq 60$  ml/min/1.73m<sup>2</sup> consistent with living donor screening guidelines to quantify the CKD stage reclassification based on eGFR for Black LKD.

**Results:** Among 63,246 LKD, 11.2% (n=6,365) were Black with a mean creatinine of 0.88 mg/dl. Black LKD eGFR was 109.7 ml/min/1.73m<sup>2</sup> using the 2009 formula and 97.7 ml/min/1.73m<sup>2</sup> using the 2021 formula. **Overall, 17.7% of Black LKD were reclassified as having a higher CKD stage pre-donation with the 2021 formula.** (Fig. 1) Among 44,525 LKD with  $\geq 2$  creatinine measurements post-donation, 9.3% (n=4,149) were Black with a mean creatinine of 1.24 mg/dl. Black LKD mean eGFR was 73.2 ml/min using the 2009 formula and 65.6 ml/min/1.73m<sup>2</sup> using the 2021 formula. **Overall, 25.5% of Black LKD were reclassified as having a higher CKD stage post-donation with the 2021 formula.** (Fig. 1)

**Conclusions:** While eGFR formulas were not developed for use in LKD, many centers use eGFR in screening and most use eGFR in post donation follow up. Exclusion of race in the formula may inappropriately label potential LKD with CKD thus exacerbate existing racial disparities. Post donation label of CKD may cause undue distress to LKD and health care consequences. These data highlight the need for a validated eGFR formula for LKD, use of measured and not eGFR & education of non-transplant care teams regarding interpretation of CKD staging in LKD.

**Funding:** NIDDK Support

Table 1. Demographics and CKD stage for Black and non-Black kidney donors pre- and post-donation.

	Pre-donation				Post-donation			
	Black donors (n=6,365)	Non-Black donors (n=56,881)	P-value		Black donors (n=4,149)	Non-Black donors (n=40,376)	P-value	
Mean age (SD)	38.6 (11.3)	43.3 (12.1)	<0.001		40.5 (11.4)	45.2 (12.1)	<0.001	
Female (%)	3,859 (60.6%)	36,022 (63.3%)	<0.001		2,610 (62.9%)	26,053 (64.5%)	0.04	
Mean systolic blood pressure (SD)	—	—	—		12.8 (7.1)	12.7 (7.1)	0.8	
Mean serum creatinine (mg/dl)	0.88 (0.19)	0.81 (0.16)	<0.001		1.24 (0.37)	1.15 (0.23)	<0.001	
eGFR formula	2009	2021	2009	2021	2009	2021	2009	2021
Mean eGFR (ml/min/1.73 m <sup>2</sup> ) (SD)	109.69 (20.39)	97.69 (17.12)	97.90 (16.32)	101.17 (15.52)	73.22 (16.78)	65.64 (14.32)	66.60 (15.04)	69.40 (15.02)
CKD Stage (%)								
1	5,217 (82.0%)	4,147 (65.2%)	36,378 (67.5%)	42,443 (74.6%)	590 (14.2%)	335 (5.7%)	2,856 (7.3%)	3,772 (9.3%)
2	1,148 (18.0%)	2,161 (34.0%)	18,503 (32.5%)	14,438 (25.4%)	2,563 (64.2%)	2,313 (55.7%)	22,609 (56.0%)	25,078 (63.1%)
3	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	1,600 (38.8%)	14,808 (36.7%)	11,524 (28.5%)
4	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)
5	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)
Cohen's kappa coefficient (95% CI)	0.56 (0.54-0.58)	0.83 (0.82-0.83)			0.54 (0.51-0.56)	0.82 (0.81-0.82)		

SD = standard deviation, CI = confidence interval.

\* The Cohen's kappa coefficient is used to assess inter-rater (or in this case, inter-formula) agreement. Generally, coefficient values 0.40-0.59 suggest weak agreement and values 0.60-0.80 suggest strong agreement (McHugh ML. Interrater reliability: the kappa statistic. *Biochem Med (Zagreb)*. 2012;22(3):276-82).

## TH-PO730

**Patients' Perspectives on Race and the Use of Race-Based Algorithms in Clinical Decision-Making: A Qualitative Study**

Insa M. Schmidt,<sup>1</sup> Merav Shohet,<sup>2</sup> Mariana Serrano,<sup>4</sup> Pranav Yadati,<sup>1</sup> Hanni Menn-Josephy,<sup>1</sup> Nwamaka D. Eneanya,<sup>3</sup> Emily C. C. Cleveland Manchanda,<sup>1</sup> Sushrut S. Waikar.<sup>1</sup> *<sup>1</sup>Boston University School of Medicine, Boston, MA; <sup>2</sup>Boston University College of Arts and Sciences, Boston, MA; <sup>3</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>4</sup>Massachusetts Department of Public Health, Boston, MA.*

**Background:** Clinical algorithms that incorporate race as a modifying factor to guide clinical decision-making have recently been criticized for propagating racial bias in medicine. The calculation of kidney function is an example of a clinical equation that has different diagnostic parameters depending on an individual's race (Black vs. non-Black). While this clinical measure has multiple implications for clinical care, patients' awareness of and their perspectives on the application of such algorithms is not known.

**Methods:** This qualitative study included 23 adult participants who were recruited from Nephrology Clinics at a safety-net hospital in Boston, Massachusetts. We conducted individual semi-structured interviews to examine patients' perspectives on race and the

use of race-based algorithms in clinical decision-making. Interviews were audiotaped, transcribed, and analyzed using thematic content analysis and modified grounded theory.

**Results:** Among the 23 study participants, 11 (48%) were women and 15 (65%) self-identified as Black or African American. Three categories of themes emerged: The first theme described definitions and the individual meanings participants ascribed to the term race. The second theme described perspectives on the role and consideration of race in clinical decision-making. Most study participants were unaware that race has been used as a modifying factor in clinical equations and rejected the incorporation of race in these equations. The third theme related to exposure to and experience of racism in healthcare settings. Experiences described by non-white participants ranged from microaggressions to overt acts of racism, including perceived racist encounters with healthcare providers. In addition, participants alluded to a deep mistrust in the healthcare system as a major barrier to equitable care.

**Conclusions:** Findings from this study suggest that most patients are unaware of how race has been used to make risk assessments and guide clinical care. Further research on patients' perspectives is needed to inform the development of anti-racist policies and regulatory agendas as we move forward to combat systemic racism in medicine.

## TH-PO731

### Race Independent eGFR Equations in Assessing Renal Function in Patients With Liver Disease

Jeff W. Meeusen,<sup>1</sup> Surendra Dasari,<sup>1</sup> John C. Lieske,<sup>1,2</sup> Sandrine Lemoine,<sup>3</sup> Laurence Dubourg,<sup>3</sup> Frank Stämmler,<sup>4</sup> Eric Schiffer.<sup>4</sup> <sup>1</sup>Mayo Clinic Department of Laboratory Medicine and Pathology, Rochester, MN; <sup>2</sup>Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; <sup>3</sup>Department Néphrologie, Dialyse, Hypertension et Exploration Fonctionnelle Rénale, Groupement Hospitalier Edouard Herriot, Hospices Civils de Lyon, Université Claude Bernard, Lyon, France; <sup>4</sup>Numares AG, Regensburg, Germany.

**Background:** Renal impairment is commonly associated with liver disease, and the degree of renal dysfunction impacts decisions regarding drug dosing, therapeutic interventions, and suitability for liver transplantation. Altered hemodynamics in liver disease often result in overestimation of glomerular filtration rate (GFR) by creatinine based GFR estimating equations. Recently, we have analytically and clinically validated a novel GFR estimation equation based on serum myoinositol, valine, and creatinine quantified by nuclear magnetic resonance spectroscopy in combination with cystatin-C, age and sex (AXINON® GFR(NMR)). We hypothesized that AXINON® GFR(NMR) (GFR<sub>NMR</sub>) could improve CKD classification in the setting of liver disease.

**Methods:** We compared GFR estimation equations in a multicenter retrospective study of patients (n=203) with liver disease and renal tracer clearance measured GFR (mGFR). Stored serum was analyzed and used to estimate GFR based on GFR<sub>NMR</sub>, CKD-EPI 2021 eGFRcr-cys, and CKD-EPI 2021 eGFRcr.

**Results:** eGFRcr overestimated mGFR with a mean bias of 7.5 [4.9 - 9.8] mL/min/1.73m<sup>2</sup> compared to a smaller bias of -2.9 [-4.8 - -1.3] for eGFRcr-cys and -1.64 [-3.43 - 0.16] for GFR<sub>NMR</sub> (both p<0.001). P<sub>30</sub> was similar in GFR<sub>NMR</sub> and eGFRcr-cys (83% [79 - 89] and 86% [81 - 90]) but lower for eGFRcr (74% [68 - 80]). P<sub>15</sub> was highest for GFR<sub>NMR</sub> at 59% [53 - 65] compared to 47% [40 - 53] for eGFRcr and 54% [47 - 61] for eGFRcr-cys. Concordant classification by mGFR CKD stage was 104 (51%), 109 (54%), and 120 (59%), for eGFRcr, eGFRcr-cys, and GFR<sub>NMR</sub> respectively (GFR<sub>NMR</sub> vs. eGFRcr: p = 0.074; GFR<sub>NMR</sub> vs. eGFRcr-cys: p = 0.138; eGFRcr vs. eGFRcr-cys: p = 0.588).

**Conclusions:** Our findings confirm that the new 2021 eGFRcr equation overestimates GFR among patients with liver disease, presumably due to reduced muscle mass. Addition of myoinositol and valine improved correlation of GFR<sub>NMR</sub> with mGFR and accurately stratified liver disease patients into CKD stages.

## TH-PO732

### Performance of a Novel Race-Independent GFR Estimating Equation in Kidney Transplant Recipients Based on NMR-Measured Metabolites

Jeff W. Meeusen,<sup>1</sup> Surendra Dasari,<sup>1,2</sup> John C. Lieske,<sup>1,2</sup> Marcello Grassi,<sup>3</sup> Frank Stämmler,<sup>3</sup> Eric Schiffer.<sup>3</sup> <sup>1</sup>Mayo Clinic Department of Laboratory Medicine and Pathology, Rochester, MN; <sup>2</sup>Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; <sup>3</sup>numares AG, Regensburg, Germany.

**Background:** Close monitoring of GFR is essential for the management of patient's post kidney transplantation. The gold-standard tracer determined measured GFR (mGFR) is not readily accessible in most centers. Furthermore, the performance of new estimated GFR (eGFR) equations based upon creatinine and cystatin C have not been validated in kidney transplant patients. We have recently developed a novel eGFR equation that uses creatinine, cystatin C, myoinositol and valine.

**Methods:** Here we evaluate this new equation (eGFR<sub>NMR</sub>) along with the 2021 CKD EPI equations using creatinine alone (eGFRcr), and in combination with cystatin C (eGFRcr-cys) in a cohort of kidney transplant patients with protocol iohalamate renal clearance mGFR (n=220).

**Results:** Compared to mGFR, there was no significant bias for eGFRcr or eGFR<sub>NMR</sub>, while eGFRcr-cys underestimated mGFR. P30 values were similar for all eGFR, while P15 was higher for eGFR<sub>NMR</sub> compared to eGFRcr. (Table 1) Agreement with mGFR CKD stages of <15, 30, 45, 60 and 90 mL/min/1.73m<sup>2</sup> was identical for eGFRcr and eGFRcr-cys while eGFR<sub>NMR</sub> was significantly higher. eGFRcr concordantly classified 86% of patients below and 78% above 60mL/min/1.73m<sup>2</sup>. Applying the eGFRcr-cys method would reclassify 8.2% of patients as <60mL/min/1.73m<sup>2</sup> and incorrectly reclassify

5.1% as >60 mL/min/1.73m<sup>2</sup> for a net reclassification improvement (NRI) of 3.1%. The eGFR<sub>NMR</sub> method correctly reclassified 3.3% lower and 4.1% higher for a net NRI of 7.1% (Table 1).

**Conclusions:** The 2021 CKD-EPI eGFRcr and eGFRcr-cys have similar bias, P15, and agreement while eGFR<sub>NMR</sub> more closely matched mGFR among kidney transplant recipients.

Table 1

	eGFRcr	eGFRcr-cys	p-value*	eGFRNMR	p-value*
Median Difference, mL/min/1.73m <sup>2</sup> (95CI)	-0.05 (-1.67 to 1.36)	-3.84 (-4.83 to -2.51)	<0.01	0.412 (-1.30 to 1.68)	0.82
P15: % (95CI)	57.3 (50.7 to 63.8)	60.9 (54.5 to 67.4)	0.43	67.3 (61.1 to 73.5)	0.03
P30: % (95CI)	85.0 (80.3 to 89.7)	90.0 (86.1 to 94.0)	0.11	90.9 (87.1 to 94.7)	0.06
Agreement: % (95CI)	61.8 (55.4 to 68.2)	61.8 (55.4 to 68.2)	1.00	66.4 (60.1 to 72.6)	0.04

### The Effect of CKD-EPI Race Adjustment on CKD Lab Monitoring Guidelines

Harrison C. Gottlich, Rachel Giblon, Maria Astudillo Potes, LaTonya J. Hickson, Robert C. Albright, Suzanne M. Norby, Bjoerg Thorsteinsdottir. Mayo Clinic Minnesota, Rochester, MN.

**Background:** Chronic kidney disease (CKD) affects 1 in 7 Americans with 90% of adults unaware of their disease. Routine lab monitoring is crucial for optimal CKD disease management and to avoid "crashing into dialysis". Historically, eGFR estimation has used a race adjustment for Black patients, contributing to inequity in CKD care. In this study, we investigated the impact of the race adjustment and other predictors on guideline concordance in a cohort of primary care patients.

**Methods:** We compiled a dataset of 1,167,056 lab results of 125,415 adults receiving care at 75 mid-west primary care practices in an integrated health system, with at least one creatinine level measured between 2014-2016. Relevant covariates were extracted from the medical chart. We characterized using descriptive statistics and recalculated GFR for self-identified Black patients without race adjustment to observe any changes in CKD stage and lab monitoring. Guideline concordant care was modeled as a binary outcome, and considered positive if patients had the recommended number of labs. Predictors of guideline concordance were examined using generalized additive models with random effects for repeat labs over time.

**Results:** Without race adjustment, 458 (33%) of Black patients would be reclassified to a higher CKD stage based on GFR alone. We found a significant gap in baseline albuminuria, with only 10% of Black and 29.1% of non-Black patients having albuminuria measures (p<.0001). This prevented proper risk stratification of many Black patients in CKD stage 3-5 (22% without race correction vs. 13% with race correction), representing a gap care for proper management. For predictors of guideline concordance assuming patients without baseline albuminuria had a status of A1, patients identifying as Black (OR: 1.35, 95% CI: 1.21-1.43) or who were diagnosed with Hypertension (OR: 3.29, 95% CI: 3.22-3.54), Diabetes (OR: 1.55, 95% CI: 1.50-1.60), or AKI (OR: 1.96, 95% CI: 1.91-2.00) were more likely to be concordant.

**Conclusions:** In addition to considering the appropriateness of the race adjustment in the CKD-EPI eGFR calculation, we found disparities exist in routine albuminuria labs, particularly for Black patients. This finding underscores the importance of screening as patients are more likely to reach lab compliance when risk factors are identified.

## TH-PO734

### Prognostic Risk Score for Kidney Disease Progression in African Americans Without Type 2 Diabetes

Girish N. Nadkarni,<sup>1</sup> Dipti Takale,<sup>2</sup> Sharon Stapleton,<sup>3</sup> Fergus Fleming,<sup>3</sup> Steven G. Coca.<sup>1</sup> <sup>1</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>2</sup>Persistent Systems Ltd, Pune, India; <sup>3</sup>Renalytix, New York, NY.

**Background:** African Americans (AAs), even without type 2 diabetes have a higher incidence of adverse kidney outcomes, compared to other populations. This is driven in part by genetic (APOL1 risk genotype) and multiple non-genetic factors. We sought to develop a composite prognostic risk score combining clinical data elements and biomarkers using machine learning for identification of AAs with non-diabetic CKD at highest risk of progression.

**Methods:** We conducted an observational study in a biobank that linked banked plasma samples and genetic information to longitudinal electronic health record (EHR) data in AAs with impaired kidney function. We measured plasma levels of soluble tumor necrosis factor receptor (sTNFR)1, sTNFR2, and kidney injury molecule-1 (KIM1) using previously validated assays. We then trained a random forest model using a 75:25 split for predicting a composite outcome of eGFR decline of ≥5 mL/min per year, ≥40% sustained decline in eGFR, or kidney failure within 5 years.

**Results:** In 472 AAs with non-diabetic CKD, the median age was 62 years, 62% were female, the baseline eGFR was 66 mL/min/1.73 m<sup>2</sup>, and 14% had the APOL1 risk genotype. Over 5 years, 7% experienced the composite endpoint. The composite risk score had an AUC of 0.78 (95% CI 0.72, 0.86). On applying a risk cutoff that considered 10% of the population as high-risk, the positive predictive value (PPV) for the outcome was 51%, and the NPV was 91% in the bottom 90% of the population. In a sub-analysis

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

of AAs with the *APOL1* risk genotype, the PPV and NPVs were also 50% and 91%, respectively. The hazard ratio (HR) was 31 (95% CI 15 to 68) for the top decile of risk score vs. the rest of the population.

**Conclusions:** A composite risk score accurately risk-stratified AAs with and without *APOL1* risk genotype for kidney outcomes. With further validation, this is a valuable tool for population health management, clinical trial enrichment, and ensuring health equity.

TH-PO735

National Fundholding and Support Policies for Kidney Disease Management  
Jiwon M. Lee. Korea Disease Control and Prevention Agency, Cheongju, Chungcheongbuk-do, Republic of Korea.

**Background:** Chronic kidney disease (CKD) imposes a large socioeconomic burden for a country due to its lifelong medical expenses. In addition, rare genetic kidney diseases often progress to CKD and the burden is inherited in the family, which impacts national health through generations.

**Methods:** We reviewed the records of national fundholding system to support patients with chronic kidney disease and rare kidney diseases in the Republic of Korea, over the past 20 years.

**Results:** Since the year 2001, South Korea has been running a special fundholding program which exempts medical expenses for low-income individuals with rare and/or intractable diseases, including chronic kidney disease and rare genetic kidney disease. The disease list is designated by the government and, to date, there are 1,123 rare and 24 intractable diseases supported by this fundholding system. Over the past 20 years, chronic kidney disease had the largest number of applicants. In the year 2021, there were 8,518 patients with CKD who received full-governmental coverage for their medical expenses, which approximated 200,000,000 US dollars. In addition, South Korea also supports the expenses for dialysate fluids for patients receiving peritoneal dialysis. Through this national fundholding system, the recipients are maintaining their household finance maintenance rate (which is calculated by the income and property standards) of 97% after their diagnosis of rare and/or intractable diseases including CKD.

**Conclusions:** The Republic of Korea exerts diverse national efforts and runs policies to achieve kidney health equity for individuals in the real-world social system. We hope to continue with this effort through more improved and effective strategies in the future.

TH-PO736

Examining the Role of KidneyIntelX in Addressing Health Inequity in CKD  
Barry I. Freedman, Rebekah A. Paige, Mitzie H. Spainhour, Benjamin M. Bagwell, Jennifer Houlihan, Richard W. Lord. Wake Forest Baptist Medical Center, Winston-Salem, NC.

**Background:** Compared to European Americans (EAs), African Americans (AAs) have a significantly higher burden of chronic kidney disease (CKD) and end-stage kidney disease (ESKD). This finding results from biologic differences and environmental factors. Failure to identify patients with early stage CKD and the limited availability of prognostic tools predicting disease progression contribute to these health disparities.

**Methods:** KidneyIntelX is a novel bioprognostic™ test that combines results from blood biomarkers with electronic health record (EHR) data using a machine learning algorithm to assess near-term risk of progressive kidney function decline in patients with type 2 diabetes (T2D) and CKD. To assess the impact and effectiveness of KidneyIntelX on outcomes, 2000 patients with T2D and estimated glomerular filtration rate (eGFR) 30-59 ml/min/1.73 m<sup>2</sup> [G3a, G3b]\* or eGFR ≥ 60 with urine albumin:creatinine ratio (UACR) ≥ 30 mg/g [A2, A3] are being enrolled into a prospective study at Atrium Health Wake Forest Baptist/Atrium Health primary care provider (PCP) clinics in North Carolina. We examined ancestry-based differences in KidneyIntelX test results and assessed their impact on medication prescription, blood pressure control, and engagement with consult services in an attempt to optimize care and address inequities in CKD among AAs.

**Results:** Of the initial 185 patients recruited from 46 unique PCPs, 43% (79) self-identified as AA and 57% (106) as non-AA (predominantly EA). As observed, despite similar degrees of kidney function (median eGFR 58 vs. 53 ml/min/1.73 m<sup>2</sup> and median UACR 78 vs. 51 mg/g in AAs vs. non-AAs, respectively), the proportion of AAs scored as “high risk” by KidneyIntelX was 3.5-fold higher (18% in AA vs. 5% in non-AA). Of the 14 AA high-risk patients, 6 (43%) had adjustments in clinical care.

**Conclusions:** The KidneyIntelX risk score is being assessed for its ability to predict progressive decline in kidney function in patients with T2D and early-stage CKD. It is hoped results will allow PCPs and healthcare systems to optimize allocation of treatments and clinical resources to those at highest risk, beyond traditional clinical metrics. Early data suggests that AA patients exhibit higher risk levels that may trigger more timely and effective interventions at earlier stages.

TH-PO737

Impact of Advancing American Kidney Health on Access to Kidney Transplant  
Luis Ng Sueng,<sup>1</sup> Nawal Peracha,<sup>2</sup> Andrew Wu,<sup>1</sup> Nadeen J. Khoury,<sup>1</sup> Milagros D. Samaniego-Picota,<sup>1</sup> Michelle Jesse,<sup>1</sup> Pritika Shrivastava,<sup>1</sup> <sup>1</sup>Henry Ford Health System, Detroit, MI; <sup>2</sup>Wayne State University School of Medicine, Detroit, MI.

**Background:** In July 2019, the US Federal Government launched the executive order (EO) Advancing American Kidney Health (AAKH). The focus of this EO was to reduce kidney failure rates and increase rates of kidney transplant. Herein, we explore the impact of the EO on referral (REF), evaluation (EVAL), waitlist (WL), and kidney transplants (T) across racial groups before and after the signing of AAKH.

**Methods:** Retrospective chart review of all patients referred for kidney transplant evaluation at a large, urban healthcare system in Detroit, MI. To ensure equal pre-post timeframes, data collected from all patients referred within 30 months pre- (1/1/2017-6/30/2019) and post-EO (10/1/2019-3/31/2022). Patients referred in the three months immediate post-EO (7/1/2019-9/30/2019) were excluded to account for system-level adjustment to the EO. Data extracted via existing internal systems included patient race/ethnicity, gender, frequency and dates of events (i.e., REF, EVAL, WL, and T). An event was coded each time a patient was referred for possible evaluation and categorized as the furthest step achieved (i.e., REF, EVAL, WL, T).

**Results:** A total of 4949 unique patients were identified, though 673 patients had more than one event. Patients were predominantly male (60.4%) and Black (50.8%), followed by White (37.4%) and Other (11.7%). There were significantly greater increases in referrals and evaluations for Black patients compared to White and Other racial categories. Since local average wait time for kidney transplant is >30 months, EO impact on transplant may be too early to assess. WL and T was equitable across groups. Table 1 reports on frequency of events across racial groups pre- to post-EO.

**Conclusions:** Since the passage of EO, minority populations may have better access to kidney transplant, as noted by increase in referrals and evaluation.

Table 1. Frequency of Events by Race Pre- and Post-EO

	Pre-EO	Post-EO	p-value
Referrals			
Black	705 (50.1%)	1138 (55.6%)	0.002
White	497 (35.3%)	688 (33.6%)	0.286
Other/Unknown	204 (14.5%)	222 (10.8%)	0.001
Evaluations			
Black	404 (49.4%)	570 (55.1%)	0.015
White	324 (39.7%)	378 (36.6%)	0.172
Other/Unknown	89 (10.9%)	86 (8.3%)	0.060
Waitlist			
Black	50 (48.1%)	104 (45.4%)	0.652
White	42 (40.4%)	102 (45.4%)	0.391
Other/Unknown	12 (11.5%)	21 (9.2%)	0.503
Transplanted			
Black	17 (36.2%)	10 (25.0%)	0.262
White	22 (46.8%)	22 (55.0%)	0.446

TH-PO738

Impact of Insurance Type on Kidney Transplant Wait-List Status and Post-Transplant Outcomes in the United States  
Anna M. Morenz,<sup>1</sup> James D. Perkins,<sup>2,3</sup> Andre Dick,<sup>5</sup> Yue-Harn Ng,<sup>4,2</sup> <sup>1</sup>University of Washington Department of Medicine, Seattle, WA; <sup>2</sup>Clinical and Bio-Analytics Transplant Laboratory, University of Washington, Seattle, WA; <sup>3</sup>University of Washington Department of Surgery, Seattle, WA; <sup>4</sup>University of Washington Division of Nephrology, Seattle, WA; <sup>5</sup>Seattle Children's Hospital, Seattle, WA.

**Background:** Insurance type has been associated with lower access to kidney transplant (KT) and worse KT outcomes. In this study, we assessed if insurance type remains a risk marker for worse KT outcomes post Affordable Care Act and Kidney Allocation System.

**Methods:** We conducted a retrospective analysis of the Organ Procurement and Transplantation Network data from 12/14 to 6/21. We used competing risk analyses to study the association of private versus public (Medicare, Medicaid,

or government-sponsored) insurance on wait-list status and post-transplant outcomes, controlling for candidate, donor and transplant variables.

**Results:** Table 1 depicts baseline characteristics and wait-list status by insurance type. KT candidates with public insurance were significantly more likely to die/become too sick for KT or receive a DDKT, but less likely to receive a living donor KT (LDKT). As shown in Figure 1, after KT, recipients with public insurance had higher mortality but comparable allograft survival.

**Conclusions:** Publicly insured KT candidates are at higher risk wait-list removal, have lower probability of LDKT, and higher probability of dying post-KT. Factors contributing to these disparities need to be addressed in future studies to achieve equity in KT.

#### Funding: Clinical Revenue Support

#### TH-PO739

#### Racial and Ethnic Minorities Are Poorly Represented in High-Impact Nephrology Trials

Qandeel H. Soomro,<sup>1,2</sup> Angela L. McCarthy,<sup>2</sup> Dalila Varela,<sup>2</sup> Colin J. Keane,<sup>2</sup> Javaughn M. Ways,<sup>2</sup> Amalya M. Charytan,<sup>2</sup> Giana Kristy C. Ramos,<sup>1</sup> Joey Nicholson,<sup>2</sup> David M. Charytan.<sup>1</sup> <sup>1</sup>NYU Langone Health, New York, NY; <sup>2</sup>NYU School of Medicine, New York, NY.

**Background:** Kidney disease disproportionately impacts underrepresented racial and ethnic minorities (URM), but only limited data are available on their representation in kidney disease randomized clinical trials

**Methods:** We analyzed how frequently race and ethnicity of trial participants were reported as well as trends in enrollment of URM in nephrology RCTs. We systematically identified RCTs between 2000 and 2021 published in 10 high impact journals and extracted data from manuscripts, supplementary material and clinical trials.gov. Race and ethnicity were classified using standard NIH PHS inclusion enrollment form categories. Enrollment of URM and reporting on race and ethnicity were analyzed according to trial type, enrollment site, and publication date

**Results:** We screened 4494 and identified 370 RCTs meeting inclusion criteria with a total enrollment of 339,047. Participant race was reported in 55% whereas ethnicity was reported in only 12% of RCTs. Among trials reporting race, White participants accounted for 87% of subjects in AKI, 75% of CKD, 62% of dialysis, 42% of glomerulonephritis and 81% of kidney transplant trials whereas Black individuals accounted for <10% of trial subjects with the exception of dialysis trials (26%). Asians accounted for 39% of GN trials-mainly IgA trials. Similarly, in trials reporting race, the majority of participants were White regardless of site but the proportion was lower in US only trials: International 79%, US only 59%, Outside US 76%, Europe only 89.5%. The enrollment trend from 2000-2021 for White participants remained between 75-83%

**Conclusions:** Despite kidney diseases disproportionately affecting URM, reporting on participant race is infrequent and URM are underrepresented in nephrology clinical trials. This impacts clinical practice and generalizability of findings from trials.

Trial Category (Total N = 345,269)					
Racial Category	Acute Kidney Injury	Chronic Kidney Disease	Glomerulonephritis	Hemodialysis or Peritoneal Dialysis	Kidney Transplant

#### TH-PO740

#### Racism, Discrimination, and Kidney Transplant Success in the Southern United States

Prince M. Anand,<sup>1</sup> Teri Browne,<sup>2</sup> <sup>1</sup>Medical University of South Carolina, Charleston, SC; <sup>2</sup>University of South Carolina System, Columbia, SC.

**Background:** Kidney transplant racial disparities are prevalent in the United States. African Americans are almost half as likely as White patients to receive a kidney transplant. No previous research in the Southern U.S. (with the greatest transplant disparities) has focused on African American patients' lived experiences with racism, racial prejudice, and discrimination and their impact on kidney transplant parity. This study examines these phenomena and can inform future research and interventions to increase kidney transplant parity.

**Methods:** This community-engaged and interdisciplinary project uses qualitative content analyses of in-depth interviews with 100 African Americans who are on dialysis or have chronic kidney disease in a southern US state. We used a combination of deductive and inductive approaches for analyses, establishing a preliminary codebook of provisional codes guided by our interview prompts. We then added emergent codes to the provisional codebook, iteratively refining the codebook. Data are analyzed qualitatively using MAXQDA software.

**Results:** The most prominent themes that emerged from the analyses included the impact of racism and discrimination on 1. access to kidney transplants, 2. gaps in education, understanding, and awareness of kidney transplant, and 3. the quality of life of people living with kidney disease. Most respondents desire a kidney transplant (80%), few express concerns about transplantation (18%), but < 1/3 (29%) were referred for transplant evaluation. Few patients report receiving information from their kidney health providers on how to obtain a kidney. Most patients demonstrated limited knowledge and awareness regarding the kidney transplantation process. Many respondents also report that White patients are treated better than them, often attributing these patterns of

differential treatment to differences in class (e.g., income, poverty), race, or residential context (e.g., rural, suburb, urban).

**Conclusions:** Racial disparities have long existed in kidney transplantation, yet the impact of racism and discrimination on these health inequities is under-studied. This study can offer insight into new interventions and research to help improve kidney transplant parity, and findings can also help inform interdisciplinary practice in dialysis and transplant centers.

TH-PO741

**The Disparities Map: It's Gone South!**  
Fatima Ayub, Andrea K. Easom, Manisha Singh. *University of Arkansas for Medical Sciences, Little Rock, AR.*

**Background:** Over 300,000 Arkansans have chronic kidney disease (CKD) but are unaware they have it. Many live in rural, underserved areas. The Arkansas State CKD Advisory Council (ARCKDAC), was established in 2019 to promote CKD awareness and raise regional stakeholder engagement by identifying systemic barriers to equity. This initiative launched a model for early recognition and treatment of CKD, targeting the slowing of CKD progression and preparation for end-stage renal disease (ESRD), if needed. ARCKDAC identified gaps in CKD awareness and patient care through regional comparative data analysis and devised remedies that could be used by local stakeholders. This statewide collaborative approach to addressing CKD may be the nation's first.

**Methods:** ARCKDAC obtained regional data from ESRD Network 13 and compared incident data for 2016 and 2017 to better understand the differences. The analyses were distributed to stakeholders statewide to compare and contrast their outcomes and develop action plans for areas of concern in their region. ARCKDAC devised measures to support these plans and increase CKD awareness by developing a "Ten Point Checklist for Managing CKD" toolkit for primary care providers and a "Know Your Kidney Number (eGFR)" poster campaign to generate public awareness and identifying other available resources.

**Results:** Approximately 1,200 Arkansans start ESRD therapies yearly. More minorities were in the two southern regions (54 to 65%) compared to 36% statewide. Medical coverage was not an issue, with 98% having insurance. Yet clinical outcomes were lowest in the south. Fewer patients (<3%) started on home dialysis in 2017 compared to 12% statewide and 19% in the central region where early CKD patient education is more accessible. Access to renal dietitians was low statewide (7%) but lower in the southern regions (1% and 3%). Pre-ESRD nephrology care was lowest in the southeast (45%) with 98% of patients starting hemodialysis and 93% using a catheter for access.

**Conclusions:** The ARCKDAC data reveals significant gaps, leading to poorer outcomes especially in rural areas. Having regional data analyzed and used by local stakeholders is the key to engagement and changes to address inequities. Public, provider and patient awareness and education campaigns may help mitigate this discordance. This approach could be a model that can be used to improve CKD outcomes nationally.

TH-PO742

**Multi-Ancestry Proteo-Genomic Association Study of eGFR**  
Matthew B. Lanktree,<sup>1,2</sup> Nicolas Perrot,<sup>2</sup> Andrew Smyth,<sup>2,3</sup> Sukrit Narula,<sup>2</sup> Marie Pigeyre,<sup>2</sup> Joan C. Krepinsky,<sup>1</sup> Salim Yusuf,<sup>2,1</sup> Guillaume Pare,<sup>2,1</sup> <sup>1</sup>McMaster University Faculty of Health Sciences, Hamilton, ON, Canada; <sup>2</sup>Population Health Research Institute, Hamilton, ON, Canada; <sup>3</sup>HRB Clinical Research Facility, Galway, Ireland.

**Background:** Reduced eGFR impacts the concentration of proteins circulating in the plasma. Biomarkers may be released during injury without being harmful themselves. Thus, biomarker studies of CKD are prone to confounding by reverse causation. The concentration of plasma protein biomarkers is also influenced by genetic variation. As genotypes are static from birth, life-long differences in genetically predicted protein concentration can be used to identify potentially causal pathogenic or protective proteins while minimizing confounding and reverse causality. Jointly considering the impact of multiple variants on life-long protein concentration can discover novel associations in addition to variants identified in genome-wide association studies (GWAS). In a proteo-genomic association study, we sought to test the impact of genetically predicted variation in 1,161 plasma proteins on eGFR.

**Methods:** We searched for *cis* protein quantitative trait loci (pQTL) genetic variants associated with the concentration of 1,161 plasma proteins in a multi-ancestry sample of 10,753 participants from the Prospective Urban and Rural Epidemiological (PURE) study. Using two-sample Mendelian randomization, we tested if pQTL variants were also associated with eGFR and kidney traits in >1 million participants of published GWAS. We also examined colocalization of pQTL signals and eGFR GWAS results and the phenome-wide impact of genetically altered concentration of the identified proteins.

**Results:** 419 pQTL instruments were constructed in PURE including 4665 genetic variants. In GWAS data, genetically altered concentration of 27 protein biomarkers was associated with eGFR ( $P < 9.5 \times 10^{-5}$ ). *UMOD* was the strongest signal, a positive control of the analysis. Six of the significant biomarkers were previously identified in GWAS; 12 were in identified loci but the causal gene under the GWAS peak was unknown; and 9 loci were unidentified in GWAS. Novel biomarker associations with eGFR include interesting biological candidates such as inhibin beta chain C, a subunit of activins, and proteinase-3, the antigen in PR3-ANCA vasculitis.

**Conclusions:** Using a proteo-genomic association study, 27 biomarkers whose genetically predicted concentration were causally associated with changes in kidney function and risk of kidney disease including interesting biological candidates.

TH-PO743

**The Impact of the New Creatinine-Based GFR Estimating Equation Without Race in Korean and US Asian Populations**  
Jimin Hwang, Josef Coresh, Morgan Grams, Lesley A. Inker, Jung-Im Shin. *Johns Hopkins University Center for Teaching and Learning, Baltimore, MD.*

**Background:** Guidelines recommend the replacement of the 2009 CKD-EPI creatinine equation using age, sex, and race with the 2021 CKD-EPI creatinine equation without race to calculate estimated glomerular filtration rate (eGFR). This study aimed to examine the impact of the new 2021 CKD-EPI creatinine equation on chronic kidney disease (CKD) prevalence estimates in two distinct Asian populations in Korea and the US.

**Methods:** We conducted a cross-sectional analysis of 5,735 participants from the 2019 cycle of the Korea National Health and Nutrition Survey (KNHANES), and 928 participants who self-reported as Asian from the 2017-2020 pre-pandemic cycle of the United States National Health and Nutrition Survey (NHANES). We compared the prevalence of CKD (eGFR <60 ml/min/1.73 m<sup>2</sup> or urine albumin-to-creatinine ratio ≥30 mg/g) and CKD GFR Stages 3 and higher (eGFR <30, 45, 60 ml/min/1.73 m<sup>2</sup>) using the 2009 CKD-EPI creatinine equation and the 2021 equation.

**Results:** In our study, the prevalence of CKD and eGFR <60 ml/min/1.73 m<sup>2</sup> were higher in US Asians (mean age 46 years, 55% female, 47.3% hypertension, and 17.5% diabetes) than Koreans (mean age 48 years, 49% female, 49.2% hypertension, and 12.2% diabetes). The CKD prevalence estimates by the 2021 CKD-EPI creatinine equation were slightly lower compared with the estimates by the 2009 equation (-0.63 ± 0.10% for Koreans and -0.56 ± 0.23% for US Asians; **Table 1**).

**Conclusions:** The 2021 CKD-EPI creatinine GFR estimating equation without race led to a small decrease in CKD prevalence of similar magnitude in both Korean and US Asian populations.

Prevalence of CKD and eGFR in Korean and US Asian populations, using three eGFR equations

**Contraception Use Among a Cohort of Reproductive Aged Women With CKD**  
Audrey V. Carr,<sup>1</sup> Ian A. Strohbehn,<sup>2</sup> Danielle L. Saly,<sup>2</sup> Jessica S. Tangren,<sup>2</sup> <sup>1</sup>Massachusetts General Hospital Department of Medicine, Boston, MA; <sup>2</sup>Massachusetts General Hospital Division of Nephrology, Boston, MA.

**Background:** Pregnancy in women with chronic kidney disease (CKD) carries an elevated risk of preeclampsia, premature birth, low birth weight, and cesarean section. However, studies also suggest that family planning occurs infrequently in nephrology practices. Little is known about contraception practices in patients with CKD. Here we present data on contraception use in a cohort of reproductive-aged women receiving nephrology care in an academic medical network.

**Methods:** We conducted a retrospective analysis of women ages 18-40 years receiving ambulatory nephrology care in an academic hospital network between 2016-2020. Patients with documented tubal ligation, hysterectomy, or without two eGFR measurements >3 months apart were excluded. We analyzed contraception use patterns by age, CKD stage and teratogenic medication usage.

**Results:** 593 patients met the inclusion criteria. Mean age in the cohort was 29 years. 77% (n=459) of patients had stage 1 or 2 CKD, 12% (n=70) had stage 3 CKD, 4% (n=24) had stage 4 CKD, and 7% (n=40) had stage 5 CKD. 54% of all patients had no documented method of contraception. Contraception use decreased with increasing CKD stage (p for trend <0.01, Figure 1). 52% patients treated with an ACEi or ARB had no documented form of contraception. Of those with a documented method of contraception, 22% used long-active reversible contraception (intrauterine device or implant), 22% used combined oral contraceptives or other estrogen containing method, and 18% used progesterone-only methods.

**Conclusions:** In this analysis of reproductive aged women with kidney disease, more than half had no documented method of contraception despite high rates of teratogenic medication use. Rates of contraceptive use were lowest in women with advanced CKD. More efforts are needed to increase use of contraception in women with kidney disease, especially in groups at high risk for adverse outcomes with unplanned pregnancies.

**Funding:** NIDDK Support

Use of contraception method by CKD stage. Contraception use decreased with increasing CKD stage (p for trend <0.01).

### Menstruation and Contraception in Females With CKD: A Global Mixed-Methods Study

Danica H. Chang,<sup>1,2</sup> Sandi M. Dumanski,<sup>1,2</sup> Erin A. Brennand,<sup>1</sup> Shannon M. Ruzyski,<sup>1</sup> Kaylee Ramage,<sup>1</sup> Taryn Gantar,<sup>3</sup> Sofia B. Ahmed.<sup>1,2</sup>  
<sup>1</sup>University of Calgary, Calgary, AB, Canada; <sup>2</sup>Libin Cardiovascular Institute of Alberta, Calgary, AB, Canada; <sup>3</sup>University of Alberta, Edmonton, AB, Canada.

**Background:** Chronic kidney disease (CKD) in reproductive-aged females is accompanied by menstrual disorders and low contraceptive use. However, most data are limited to the dialysis and transplant populations and in-depth experiences describing this within the scope of CKD have not been studied. Therefore, this mixed-methods study aimed to describe self-assessed menstruation and contraceptive use among females across all stages of CKD.

**Methods:** People aged 18-50 years, with a uterus, and diagnosed with CKD were invited to participate in an online survey followed by an optional telephone interview. The survey was disseminated globally through 112 kidney organizations, patient groups, and social media.

**Results:** Of 152 respondents, 98 satisfied the inclusion criteria [n=20 dialysis (age 35±1 years), n=59 non-dialysis (age 32±1 years), n=19 transplant (age 35±2 years)], representing 3 continents and predominantly self-identifying as white cisgender women. The most common causes of CKD were congenital anomalies of the kidney and urinary tract (30%), acute kidney injury and glomerulonephritis (15% each), and IgA nephropathy (21%) among the dialysis, non-dialysis, and transplant groups, respectively. One participant each in the dialysis and non-dialysis groups experienced primary amenorrhea, though more reported secondary amenorrhea (25% dialysis, 15% non-dialysis, 26% transplant). Of participants with current menses, 86%, 94%, and 100% of the dialysis, non-dialysis, and transplant groups reported heavy menstrual bleeding; however, only 50%, 69%, and 43% were always able to afford period products. Regarding, contraception, 50%, 63%, and 37% of dialysis, non-dialysis, and transplant participants reported no use, though among users, male condoms were notably popular in the dialysis (33%) and non-dialysis (48%) groups. Further, the interviews revealed a need for greater multidisciplinary care in the management of reproductive health in the context of CKD.

**Conclusions:** Abnormal menstruation and period poverty are common, and contraception use is low among females with CKD, highlighting an important gap in the sex-specific care of this population.

**Funding:** Government Support - Non-U.S.

## TH-PO746

### Effect of Hormonal Contraception on Kidney Outcomes in Females: A Systematic Review and Meta-Analysis

Danica H. Chang,<sup>1,2</sup> Victoria J. Riehl-Tonn,<sup>1,2</sup> Paul E. Ronksley,<sup>1</sup> Sofia B. Ahmed,<sup>1,2</sup> Heather Ganshorn,<sup>1</sup> Erin A. Brennand,<sup>1</sup> Sandi M. Dumanski,<sup>1,2</sup> <sup>1</sup>University of Calgary, Calgary, AB, Canada; <sup>2</sup>Libin Cardiovascular Institute of Alberta, Calgary, AB, Canada.

**Background:** Over 70% of reproductive-aged females in Canada use contraception. Previous literature demonstrates that hormonal contraception has important implications for cardiovascular health, but its effect on kidney health outcomes is poorly understood. Therefore, this systematic review and meta-analysis aimed to determine the effect of hormonal contraception on kidney outcomes in females.

**Methods:** A literature search of MEDLINE, Embase, and CENTRAL (from database inception-November 2021) was developed and reviewed by a health librarian, to identify original studies that reported kidney health outcomes (e.g., kidney function, proteinuria, progression or development of chronic kidney disease or kidney failure) in female hormonal contraception users. Two independent reviewers evaluated articles, extracted data, and assessed study quality in duplicate using the National Institutes of Health Study Quality Assessment Tools. Outcome measures were reported as weighted mean differences and meta-analyzed using a random effects model. Heterogeneity was assessed with the I<sup>2</sup> statistic. A stratified meta-analysis by type of hormonal contraception (oral vs other) was conducted for the outcome of change in serum creatinine.

**Results:** Of the 10,350 references identified within the search strategy, 18 observational studies were included, and 14 were eligible for meta-analysis. Most studies reported on oral contraceptives (N=14). Meta-analyses revealed no difference in mean serum creatinine [0.00 mg/dL (95% CI: -0.05, 0.05); I<sup>2</sup>=68.5%], creatinine clearance [10.01 mL/min (95% CI: -1.48, 21.50); I<sup>2</sup>=90.6%], and estimated glomerular filtration rate [0.37 mL/min/1.73m<sup>2</sup> (95% CI: -8.77, 9.51); I<sup>2</sup>=37.1%] between hormonal contraception users and non-users. When stratified by type of hormonal contraception, the overall pooled estimate also showed no difference in serum creatinine between groups. Overall study quality was fair.

**Conclusions:** This systematic review and meta-analysis found no association between hormonal contraception and various kidney outcomes. While the included studies had significant limitations and heterogeneity, this highlights the need for rigorous prospective studies examining the effect of hormonal contraception on kidney outcomes in females.

**Funding:** Government Support - Non-U.S.

## TH-PO747

### Abnormal Menstruation and Female Reproductive Hormones in Kidney Failure

Danica H. Chang,<sup>1,2</sup> Sofia B. Ahmed,<sup>1,2</sup> Erin A. Brennand,<sup>1</sup> Shannon M. Ruzyski,<sup>1</sup> Sandi M. Dumanski.<sup>1,2</sup> <sup>1</sup>University of Calgary, Calgary, AB, Canada; <sup>2</sup>Libin Cardiovascular Institute of Alberta, Calgary, AB, Canada.

**Background:** Kidney failure disrupts the hypothalamic-pituitary-ovarian axis, resulting in reproductive hormone abnormalities. It is not fully understood if these disturbances impact menstruation in females living with kidney failure treated with dialysis. Therefore, this study aimed to (1) describe menstruation and changes in menstrual patterns with chronic kidney disease (CKD) progression, and (2) assess associations between reproductive hormones and menstrual patterns among females with kidney failure.

**Methods:** Females aged 18-50 years were recruited from dialysis clinics around Calgary, Alberta, Canada. Using a self-administered survey, demographic, kidney health, and menstrual health histories were recorded. Blood samples were collected to measure follicle-stimulating hormone, luteinizing hormone, estradiol, progesterone, testosterone, prolactin, sex hormone binding globulin, and anti-Müllerian hormone levels. Descriptive and bivariate analyses were performed as appropriate.

**Results:** Twenty-seven females [n=23 hemodialysis (age 36 (IQR: 31,44) years), n=4 peritoneal dialysis (age 38 (IQR: 30,45) years)], largely identifying as white cisgender women were included. In the hemodialysis group, 52% reported absent menstrual bleeding during dialysis, though only 17% reported this during CKD and 9% before CKD diagnosis (P=0.01); however, there was no difference in proportions across timepoints in the peritoneal dialysis group (25% each) (P=0.92). In the hemodialysis group, 48% described heavy menstrual bleeding during dialysis; this proportion did not differ during CKD (65%) and before CKD diagnosis (70%) (P=0.20). Among participants on peritoneal dialysis, 25% described heavy menstrual bleeding during dialysis, which did not significantly differ during CKD (25%) and before CKD diagnosis (50%) (P=0.91). All the hormone levels did not differ between those with absent and present menstrual bleeding during dialysis, nor did it differ between those with heavy and normal menstrual bleeding.

**Conclusions:** Among females with dialysis-dependent kidney failure, proportions of absent and heavy menstrual bleeding were high. No associations between reproductive hormone levels and menstrual status were observed, underscoring the uncertainty around how kidney disease affects female reproductive health.

**Funding:** Government Support - Non-U.S.

## TH-PO748

### A Qualitative Study to Understand Contraceptive Use in Women With Kidney Disease

Silvi Shah,<sup>1</sup> Priyanka Gudsoorkar,<sup>1</sup> Prema D. Vyas,<sup>2</sup> Meredith J. Pensak.<sup>1</sup>  
<sup>1</sup>University of Cincinnati, Cincinnati, OH; <sup>2</sup>Texas Christian University, Fort Worth, TX.

**Background:** Pregnancy in women with kidney disease is not uncommon and is associated with adverse maternal and fetal outcomes. The use of contraception in women with kidney disease remains low. Little is known about patients' experiences regarding contraceptive use with kidney disease.

**Methods:** The qualitative approach included five focus group discussions (n=13) among women of reproductive age between 18-44 years from a large academic center with a history of kidney disease. Participants shared their experiences and perceptions of contraceptive use, including barriers and facilitators. Interviews were audio-recorded, transcribed, analyzed by two independent reviewers, and coded using a thematic analysis approach.

**Results:** Five major themes emerged in the analyses emerged. 'Knowledge gap' reflected variability ranging from low to considerable understanding regarding reproductive health including knowledge about impaired fertility with kidney disease, use of teratogenic medications that may lead to birth defects, and risk of adverse pregnancy outcomes. 'Lack of counseling' was attributed to time constraints and inadequate counseling by physicians regarding contraceptive use. Women stressed the importance of needing to advocate for one's own reproductive health, and family and spousal support. 'Lack of interdisciplinary approach' involved a lack of coordination of care between nephrologists and gynecologists regarding contraceptive use. Interestingly, a few transplant recipients were better informed about contraceptive use due to follow-up by multidisciplinary transplant teams. 'Insufficient educational resources' referred to the unavailability of educational materials to guide contraception discussion, resulting in a lack of trust in the medical system, and an increase in the utilization of the internet

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

for health information. The final theme, 'need for research' highlighted that not enough importance is placed on family planning. Women expressed the fear of unintended pregnancy and frequent decisional conflicts between their own and their baby's health.

**Conclusions:** Participants with kidney disease reported emotional challenges with reproductive health care and a lack of counseling for contraceptive use. A critical need exists to bridge the knowledge gap for women with kidney disease and the interdisciplinary care approach.

**Funding:** Other NIH Support - NHLBI K23 career development award, under Award Number 1K23HL151816-01A1

## TH-PO749

### Preeclampsia or Lupus Nephritis in Pregnancy: The Role of Renal Biopsy

Angelie Santos, Tripti Singh. *University of Wisconsin-Madison, Madison, WI.*

**Introduction:** Lupus nephritis (LN) in pregnancy is a significant risk factor for adverse obstetric outcomes, including preeclampsia and fetal demise. Preeclampsia and LN have similar manifestations, but treatment is different. Renal biopsy is indicated but there is limited knowledge on its role in pregnancy as it has its own risk. We present a challenging case of a pregnant woman with clinical features suggesting new-onset LN and manifested as preeclampsia at 25 weeks age of gestation (AOG).

**Case Description:** A 34-year-old female with history of benign ethnic neutropenia and thrombocytopenia, was found to have transaminitis, worsening thrombocytopenia and proteinuria of 5 grams at 19th week AOG. Labs also revealed positive antinuclear antibodies, positive anti-Ro, and negative double-stranded DNA. She was treated with steroids for 4 days which led to normalization of her platelet counts. She presented with acute kidney injury (AKI) with serum creatinine (SCr) increasing from 0.4 to 0.7 mg/dL and hypertension (HTN) at 24 weeks AOG. Work up revealed severe intrauterine fetal growth restriction (IUGR). She underwent kidney biopsy at 25 weeks AOG and was empirically started on LN treatment with steroids and hydroxychloroquine. Her course rapidly worsened with AKI (SCr 1.05 mg/dL), increasing proteinuria and hypoalbuminemia, HTN and symptoms of volume overload including ascites, pleural and pericardial effusions. Kidney biopsy revealed immune complex deposition consistent with lupus nephritis and endothelial cell injury consistent with preeclampsia. Emergent induction was planned, as expectant management becomes a contraindication. After induction and delivery to a demised fetus, AKI and HTN improved to baseline and proteinuria decreased to 4.5 grams/24 hours in 48 hours post-partum.

**Discussion:** The patient presented with AKI, HTN and nephrotic syndrome that can be seen in LN as well as preeclampsia. LN can be treated empirically with steroids, but establishing the diagnosis was essential, especially at 25 weeks AOG, as inducing delivery for preeclampsia would be fatal for the fetus due to IUGR. In conclusion, distinguishing LN and preeclampsia is challenging, but rapid diagnosis is essential as complications can be fatal for both the mother and the fetus. Kidney biopsy is high risk in advanced pregnancies but is essential in management if there is diagnostic dilemma.

## TH-PO750

### Preeclampsia and Long-Term Kidney Outcomes

Nityasree Srialluri,<sup>1</sup> Aditya L. Surapaneni,<sup>1</sup> Alex R. Chang,<sup>2</sup> Morgan Grams,<sup>1,3</sup>  
<sup>1</sup>*Johns Hopkins University, Baltimore, MD;* <sup>2</sup>*Geisinger Health, Danville, PA;*  
<sup>3</sup>*New York University Grossman School of Medicine, New York, NY.*

**Background:** Preeclampsia is a complication of pregnancy characterized by acute hypertension and end-organ dysfunction. We aimed to evaluate the long-term association between preeclampsia and the risk of developing chronic hypertension and kidney disease.

**Methods:** We identified adult women without pre-existing hypertension or kidney disease who underwent deliveries in the Geisinger Health System between 1996- 2019 over a median follow up of 21 years. We used propensity-score matching to compare women who developed preeclampsia during pregnancy with women who did not. Cox proportional hazards models were used to evaluate the association between preeclampsia and incident hypertension, reduced estimated glomerular filtration rate (eGFR; <60 ml/min/1.73 m<sup>2</sup>), and albuminuria > 300mg/g.

**Results:** Of the 27800 women with pregnancies during the study period (mean [SD] age, 28[5.6] years; 3% black race), 2340 (8.4%) had at least one pregnancy complicated by preeclampsia. Women with preeclampsia had higher risk of developing chronic hypertension (HR, 1.72; 95% CI 1.41 - 2.11), eGFR < 60ml/min/1.73 m<sup>2</sup> (HR 2.27; 1.26 - 4.09), and albuminuria (HR, 3.85; 95% CI 2.52 - 5.88), compared to matched controls without preeclampsia (Fig. 1). Additionally, the risk of a subsequent episode of preeclampsia was higher in women with preeclampsia compared to the matched controls (HR, 12.03; 95% CI 7.31 - 19.81).

**Conclusions:** Women with a pregnancy complicated by preeclampsia have a higher risk of hypertension, reduced eGFR, and albuminuria later in life compared to women without preeclampsia. Preeclampsia should be considered an important risk factor for hypertension and kidney disease. Further focus should be placed on implementing appropriate preventive strategies and vigilant post-partum follow-up in this population.

**Funding:** NIDDK Support

Kaplan Meier estimates of cumulative incidence of Hypertension, eGFR <60, and albuminuria among women with and without preeclampsia

## TH-PO751

### Preeclampsia Is Associated With Complement Activation in Maternal and Fetal Circulation and Placental Tissue

Hannah Blakey,<sup>1,2</sup> Nadia Sarween,<sup>1</sup> Edwin K. Wong,<sup>4</sup> Neil S. Sheerin,<sup>4</sup> Kate Bramham,<sup>5</sup> Claire L. Harris,<sup>4</sup> Ellen Knox,<sup>3</sup> Mark T. Drayson,<sup>2</sup> Graham Lipkin.<sup>1</sup> <sup>1</sup>*Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom;* <sup>2</sup>*University of Birmingham, Birmingham, United Kingdom;* <sup>3</sup>*Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom;* <sup>4</sup>*Newcastle University, Newcastle upon Tyne, United Kingdom;* <sup>5</sup>*King's College London, London, United Kingdom.*

**Background:** Pre-eclampsia (PE) is a leading cause of obstetric morbidity. There remains no definitive therapy other than delivery. Long-term sequelae include an increased lifetime risk of chronic kidney disease. Complement dysregulation has been implicated in the pathogenesis of PE, although the current evidence base is limited. Our aim was to compare patterns of placental and maternal and fetal circulatory complement activity in healthy pregnant women and those with PE, to gain insight into complement activation and guide potential complement-modifying therapies.

**Methods:** Women with PE and healthy pregnant controls were recruited from a tertiary obstetric centre. Samples of maternal and umbilical cord blood were tested for iC3b, C3, C4, properdin, Ba and C5b-9, and placental tissue stained for C3d, C4d, C9 and C1q, from women with PE (n=34) and healthy pregnant controls (n=33). Properdin and Ba concentrations were validated in maternal plasma samples (PE n=35; controls n=35) from a separate tertiary centre cohort.

**Results:** Women with PE had significantly lower blood concentrations of properdin (mean 4828 vs 6877 ng/ml, p<0.001) and C4 (mean 0.20 vs 0.31 g/l, p<0.001), and higher Ba (median 150 vs 113 ng/ml, p=0.012), compared to controls. Properdin findings were replicated in the validation cohort (mean 5282 in PE vs 7021 ng/ml in controls, p<0.001). Combined cohort average properdin concentrations were 1945 ng/ml lower in PE vs controls (p<0.001), AUROC 0.87. Umbilical cord Ba was higher in PE vs controls (mean 380.7 vs 210.5 ng/ml, p=0.015). There was increased placental C4d deposition at the syncytiotrophoblast membrane in PE vs controls (median immunoreactivity score 3 vs 0, p<0.001). Maternal plasma properdin and C4 were strongly negatively correlated with placental C4d deposition.

**Conclusions:** Our data confirm excessive complement activation products in maternal and fetal circulation, strongly associated with placental complement deposition in women with PE. Classical or lectin pathway activity drives placental C4d deposition, which is amplified by the alternative pathway amplification loop, leading to significant changes in plasma complement biomarkers. Inhibition of complement activation is a potential therapeutic target in the treatment of PE.

## TH-PO752

### Fetal APOL1 Risk Variants Association With Adverse Maternal Outcomes of Early Onset Preeclampsia

Desiree Fiorentino,<sup>1</sup> Rebecca C. Hjorten,<sup>5</sup> Jeffrey B. Kopp,<sup>3</sup> Joseph T. Myrie,<sup>4</sup> Sandra E. Reznik,<sup>1</sup> Tao Wang,<sup>1</sup> Cheryl A. Winkler,<sup>2</sup> Kimberly J. Reidy.<sup>1</sup> <sup>1</sup>*Montefiore Medical Center, Bronx, NY;* <sup>2</sup>*National Cancer Institute, Bethesda, MD;* <sup>3</sup>*National Institutes of Health, Bethesda, MD;* <sup>4</sup>*Stanford University, Stanford, CA;* <sup>5</sup>*University of Washington, Seattle, WA.*

**Background:** Preeclampsia, a hypertensive disorder unique to pregnancy, has a higher incidence in women of African descent. Fetal APOL1 gene variants have been associated with increased risk of preeclampsia, but their association with maternal outcomes of preeclampsia has not been examined. We hypothesized fetal APOL1 high risk gene variants are associated with increased risk of maternal complications of preeclampsia.

**Methods:** Fetal APOL1 genotypes were performed in 56 mother-infant dyads affected by early onset preeclampsia diagnosed at less than 34 weeks of gestation. Births were eligible for inclusion if preeclampsia was mentioned in the placental pathology report and if the EMR identified the mother as "black or African American". Diagnosis of preeclampsia was confirmed using ACOG criteria. Clinical data on complications was obtained from the medical record. Fisher's exact test was performed comparing the incidence of complications in mothers with fetal APOL1 high risk variants (APOL1 G1,G1; G1,G2; or G2,G2) vs. those with fetal APOL1 low risk variants (G1,G0 or G2,G0 or G0,G0).

**Results:** There were no statistically significant differences in the occurrence of maternal mortality, transaminitis, coagulopathy, hepatic hematoma, Glasgow coma score <13, stroke, visual disturbances, dialysis, postpartum hemorrhage, placental abruption, thrombocytopenia, blood transfusion, myocardial ischemia, eclampsia, pulmonary edema, intubation or oxygen supplementation for more than one hour amongst the two

groups. There was a significant increase in the rate of acute kidney injury in mothers with preeclampsia with fetal *APOL1* HR variants ( $p=0.035$ ). While there was no difference in the risk of having at least one complication, the composite score obtained as the sum of all complications experienced showed a trend towards greater complications for the fetal *APOL1* HR group with a mean number of complications of 2.7 vs 1.4. This difference did not reach statistical significance ( $p$ -value 0.16). (OR 1.45, 95% CI -0.6-3.2).

**Conclusions:** Rate of AKI in patients diagnosed with early onset preeclampsia was higher in women with fetal *APOL1* high risk alleles. The overall number of complications trended higher in this group, although it did not reach statistical significance.

### The Influence of Normal and Preeclamptic Syncytiotrophoblast Extracellular Vesicles on Human Podocytes

Shuhan Jiang,<sup>1</sup> Toluwalase Awoyemi,<sup>1</sup> Maryam Rahbar,<sup>1</sup> Prassana V. Logenthiran,<sup>1</sup> Wei Zhang,<sup>1</sup> Jack P. Tuffin,<sup>2</sup> Moin Saleem,<sup>2</sup> Manu Vatish.<sup>1</sup>  
<sup>1</sup>University of Oxford, Oxford, United Kingdom; <sup>2</sup>University of Bristol, Bristol, United Kingdom.

**Background:** Circulating levels of syncytiotrophoblast extracellular vesicles (sTBEVs) increase throughout gestation in normal pregnant (NP) women, and their levels are higher in preeclampsia (PE). In NP, glomerular filtration rates (GFR) increase by 50%, while in PE GFR can reduce by up to 32% which implicates the impaired glomerular filtration barrier (GFB) function. Podocytes are specialised renal cells which are involved in GFB maintenance. We aimed to evaluate whether small sTBEVs (sTBEVs) from NP and PE can be internalized by podocytes and influence function.

**Methods:** NP ( $n=3$ ) and PE ( $n=3$ ) sTBEVs were isolated by dual-lobe placental perfusion and differential centrifugation. sTBEVs were phenotyped by immunoblotting, nanoparticle tracking analysis and transmission electron microscopy. sTBEVs internalization by podocytes was assessed by flow cytometry and confocal microscopy. qPCR was used to analyze if sTBEVs could transfer placental specific C19 miRNA into podocytes. Podocyte nephrin expression, migration ability, actin cytoskeleton and adhesion ability were assessed after treatment with sTBEVs.

**Results:** The internalization of sTBEVs by podocytes could be observed from 30mins and was time and dose dependent. There was no significant difference in number of sTBEVs from NP and PE internalised by podocytes. We were able to detect placental specific C19 miRNA in podocytes treated with these sTBEVs. Podocyte nephrin expression was increased by 1.9-fold ( $p<0.05$ ) and podocyte migration ability was upregulated by 1.2-fold ( $p<0.05$ ). F-actin staining was enhanced across the podocytes after NP sTBEVs treatment ( $p<0.05$ ). In contrast, PE sTBEVs treatment showed no change in nephrin expression or podocyte migration ability. Additionally, podocyte adhesion ability was impaired and F-actin appeared stressed (cortical ring formation).

**Conclusions:** NP and PE sTBEVs can be taken up by podocytes. NP sTBEVs enhanced podocyte function via elevated nephrin expression and migration ability. In contrast, PE sTBEVs impaired podocyte via reduced adhesion ability and nephrin expression was unchanged. We speculate the enhanced functions of podocytes after NP sTBEVs treatment may contribute GFB maintenance while sTBEVs from PE may contribute to GFB damage.

## TH-PO754

### Preeclamptic Phenotype in Transgenic Mice With Fetuses Carrying APOL1 Risk Variants

Teruhiko Yoshida,<sup>1</sup> Khun Zaw Latt,<sup>1</sup> Huiyan Lu,<sup>1</sup> Kimberly J. Reidy,<sup>2</sup> Jennifer R. Charlton,<sup>3</sup> Yongmei Zhao,<sup>4</sup> Shashi Shrivastav,<sup>1</sup> Sandra E. Reznik,<sup>2</sup> Avi Z. Rosenberg,<sup>3</sup> Cheryl A. Winkler,<sup>4</sup> Jeffrey B. Kopp.<sup>1</sup> <sup>1</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>2</sup>Children's Hospital at Montefiore, Bronx, NY; <sup>3</sup>University of Virginia, Charlottesville, VA; <sup>4</sup>Frederick National Laboratory for Cancer Research, Frederick, MD; <sup>5</sup>Johns Hopkins University, Baltimore, MD.

**Background:** African Americans experience more pregnancy complications, including preeclampsia, compared to others. African-origin genetic variants in apolipoprotein L1 (*APOL1*), promote various renal disorders. Recent clinical studies showed that fetuses with two *APOL1* risk variants predispose the mother to preeclampsia. The mechanisms of *APOL1*-associated preeclampsia remain poorly understood. Here we made use of a transgenic mouse model to investigate these mechanisms.

**Methods:** We in-vitro-fertilized CD-1 female mice using sperm from human *APOL1* gene locus transgenic mice carrying a bacterial artificial chromosome bearing either the *APOL1*-G0 allele (common variant) or the *APOL1*-G1 allele (risk variant). We measured systolic blood pressure with a tail cuff. We euthanized mice at E18.5 and collected fetuses, placenta and maternal plasma. We evaluated the phenotype of the dam by plasma chemistry and assessed weight of fetuses and placenta. We characterized placental transcriptomic profiles by single-nuclear RNA-seq.

**Results:** Compared with a dam with *APOL1*-G0 fetuses, a dam with *APOL1*-G1 fetuses had higher systolic blood pressure, 158 [141-163] vs 116 [115-131] mmHg; median [IQR],  $P=0.01$ ) and had lower plasma placental growth factor-2 levels (32 [20-82] vs 126 [98-260] pg/mL;  $P=0.047$ ). *APOL1*-G1 fetuses had lower relative weights, (0.95 [0.90-0.98] vs 1.0 [0.96-1.04];  $P=0.03$ ) when compared with WT fetuses. By contrast, *APOL1*-G0 fetuses had relative weights similar to wild-type (WT) fetuses (0.99 [0.95-1.08];  $P=1.0$ ). Single-nucleus RNA-seq demonstrated increased expression of

inflammation-related genes (*e.g. Spp1*, encoding osteopontin; *Lyz2*, encoding lysozyme2) in *APOL1*-expressing endothelial cells and trophoblasts in placentas of *APOL1*-G1 fetuses compared with placentas of *APOL1*-G0 and WT fetuses.

**Conclusions:** This *APOL1* mouse preeclampsia model suggests that the *APOL1*-G1 allele promotes endothelial and trophoblastic inflammation and thus contributes to placental dysfunction and preeclamptic phenotypes, similar to human disease.

### The Role of miR-143-3p in Podocyte Damage in Preeclampsia

Sonja Suvakov, Tamara Gojkovic, Vesna D. Garovic. Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN.

**Background:** Preeclampsia (PE) is a pregnancy-specific disease characterized by hypertension accompanied by either proteinuria and/or end-organ damage. Previous research has shown that PE is associated with podocytyria and an increased number of podocyte-derived urinary extracellular vesicles (EV), but underlying the mechanism is not well understood. We aimed to elucidate the potential role of miR-143-3p in podocyte injury in PE.

**Methods:** XRNA Exosome RNA-Seq Library Kit and qPCR were used to identify miRNA candidate(s) to study. Micro RNA 143-3p was identified and its expression was studied in an immortalized human podocyte cell line treated with either PE sera or TNF- $\alpha$ . We also investigated miR143-3p roles in inflammation, VEGF secretion, podocyte migration, both in the absence and presence of its inhibitor.

**Results:** Upon assessing differential miRNA expressions in urinary EV and validating candidates relevant for kidney injury, we identified miR143-3p as significantly increased in PE. Treatment of an immortalized podocyte cell line with either pooled PE sera or TNF- $\alpha$ . Treatment with pooled sera showed increase in miR143-3p expression in dose-dependent manner. In conditioned media, TGF- $\beta$  was increased while VEGF was decreased, both reversed by treatment with mir-143-3p inhibitor. Podocytes incubated with TNF- $\alpha$  showed higher gene expressions of miR143-3p and pro-inflammatory cytokines, IL-6, IL-8 and MCP-1, which were attenuated by a miRNA-143-3p inhibitor. No significant changes in p16 and p21 gene expressions were observed with either treatment. Beta-gal staining for senescence indicated increased senescent phenotype in podocytes treated with PE sera. Wound healing assay showed that both treatments decreased migration of podocytes, whereas the miRNA inhibitor improved migration. Finally, the total number of both podocin and nephrin positive EVs was increased in cultured media upon podocyte treatment with PE sera.

**Conclusions:** Micro RNA 143-3p is abundant in urinary EVs of preeclamptic women. It mediates expressions of pro-inflammatory cytokines in podocytes and affects their migration. These results indicate that miR-143-3p may contribute to the pathophysiology of podocyte injury in preeclampsia.

## TH-PO756

### Podocyte Loss and Progression of CKD in Pregnancy

Dilara Eren,<sup>1</sup> Carolyn Gill,<sup>1,3</sup> Jennifer R. Joslin,<sup>1,2</sup> Kate Bramham,<sup>1,2</sup> Priscilla Smith.<sup>1,2</sup> <sup>1</sup>King's College London, London, United Kingdom; <sup>2</sup>King's College Hospital NHS Foundation Trust, London, United Kingdom; <sup>3</sup>Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom.

**Background:** Chronic kidney disease (CKD) in pregnancy is associated with deterioration in kidney function, but there are no biomarkers to predict or detect progression. Urinary podocyte loss is recognised in progressive glomerular diseases outside of pregnancy and preeclampsia but has not been explored in CKD pregnancy.

**Methods:** Urine pellets collected in two prospective studies of pregnant women with CKD were analysed for podocyte proteins (Nephrin, Podocalyxin and Podocin) using validated sandwich enzyme-linked immunosorbent assays. Participants included 20 with pregnancy associated progression of CKD (PrCKD), 10 with stable CKD (StCKD), and 10 without CKD (Controls).

**Results:** Serum creatinine increased in women with PrCKD throughout pregnancy and post-partum. Placental growth factor concentrations were normal in all women, but podocin concentrations in controls were significantly higher in women with PrCKD and StCKD than Controls (see figure 1); there were no differences between women with PrCKD and StCKD. There were no significant differences between groups for Nephrin and Podocalyxin. Demographic data are shown in Figure 2.

**Conclusions:** Nephrin, Podocin and Podocalyxin can be identified in the urine pellet in pregnancy, with increased podocin concentrations in CKD pregnancy suggesting increased podocyte cell loss, which requires confirmation in a larger prospective cohort.

TH-PO757

**An Intriguing Case of Hypertension and Hypokalemia in a Third Trimester Pregnancy: Early-Onset Autosomal Dominant With Severe Exacerbation in Pregnancy**  
Boonyanuth N. Maturostrakul, Abhishek Nimkar, Mala Sachdeva, Kenar D. Jhaveri. Northwell Health, New Hyde Park, NY.

**Introduction:** Geller et al described a familial syndrome of hypertension (HTN) and hypokalemia, exacerbated by pregnancy, caused by an activating mutation of the mineralocorticoid receptor (MR). Here we describe a case of hypokalemia and hypertension with pregnancy that is consistent with the diagnosis of Geller syndrome.  
**Case Description:** A 35 yo woman(G1P0) was admitted at 37 weeks gestation for HTN and hypokalemia. She had no prior history of HTN prior to this and had normal K values during most of her pregnancy. She had a family history of both mother and father with HTN since their 30s. She was noted to have a low serum K of 2.9mmol/L and BP in 145/90mmHG range, highest blood pressure recorded of 156/88 mmHG, and was persistent for 2 weeks prior to admission. She denied nausea, vomiting, or diarrhea. Physical examination showed 1+ bilateral lower extremity edema. There was no

proteinuria. Urine K was 19 mmol/L, urine Cr 55 mg/dl, plasma Aldosterone <3.0 ng/dL, and plasma renin activity 1.10 g/ml/hr. The urine K/crt ratio was 36.3 meq/g. Her serum cortisol was not low or too high. She was started on potassium supplements with prompt delivery. She delivered a healthy baby girl and 3 weeks post-delivery; her BP is in 90-100mmHg SBP and 50-60mmHg DBP range. She is off her K supplements as repeat K after 3 weeks post delivery was 5.1mmol/L. Her repeat aldosterone level 4 weeks post delivery was 32.3ng/dL. Genetic testing for Liddle's syndrome and Geller's syndrome was performed and pending results.  
**Discussion:** Normally the MR is activated by aldosterone but inhibited by progesterone. The novel MR S810L, described by Geller et al, is activated by both aldosterone and progesterone. In the initial description, two MR L810 carriers had a pregnancy-induced exacerbation of HTN and hypokalemia in 5 pregnancies, with low aldosterone levels. High progesterone in pregnancy was implicated. Our patient experienced new HTN and new hypokalemia in pregnancy, with renal potassium wasting and low renin and aldosterone levels, consistent with autosomal dominant early onset HTN with hypokalemia exacerbated during pregnancy. This resolved few weeks post delivery as noted with labs above. Classically in pregnancy, aldosterone and renin levels are higher than baseline. Genetic testing will confirm the diagnosis.

TH-PO758

**Involvement of Tubulo-Interstitial Impairment in the Renal Disorders Associated With Hypertensive Disorder in Pregnancy (HDP)**  
Mariko Sato, Kaori Takayanagi, Koki Ogawa, Erika Sawada, Atsuko Yasui, Takatsugu Iwashita, Tomonari Ogawa, Akito Maeshima, Hajime Hasegawa. Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.

**Background:** Renal involvement is frequently complicated in the Hypertensive Disorder in Pregnancy (HDP). Since enlargement of glomerular endothelial cells (endotheliosis) is observed in HDP, glomerular disorder has been considered as the principal locus of renal involvement in HDP. In the meantime, the vasospasm in the HDP is believed to be observed not only in the placenta but also systemically, and the involvement of the vasoconstriction-related tubulo-interstitial disorder (TID) is also speculated in the kidney, but the report is limited. In this study, we aim to investigate time-differential changes in multiple parameters with TID to examine its participation in HDP.  
**Methods:** Twenty patients diagnosed with HDP at obstetrics department were prospectively studied. Three blood and urine samples around 30 weeks of gestation (P1), around 38 weeks of gestation (P2) and 1 month postpartum (P3) were used for the analysis. Mean home-measured morning blood pressure (BP) during the 3 days before sample collection was used as BP value.  
**Results:** The mean age was 35.5 years, and half were taking methyldopa orally (mean 825 mg/day). Mean systolic BP was P1: 121.1, P2: 128.8, and P3: 122.3 mmHg. The median urine Alb was P1: 12.9, P2: 24.2, P3 30.2 mg/gCr, and there were few cases with overt albuminuria or proteinuria in this population. Among TID-related parameters, urine MCP-1, in urine NAG, urine activin and urine alpha1-MG, differences were observed in P1, P2 and P3. When stratified into high BP group (BPH) and low BP group (BPL) at systolic BP level of P1, there was a difference in the median value between BPH and BPL in urine MCP-1 (BPH P1: 1076.3, P2: 1098.1, P3: 358.0; BPL P1: 644.4, P2: 582.5, P3: 333.9) and urine NAG.  
**Conclusions:** The changes of multiple TID parameters during the course of gestation, and the relevance of TID parameters with the degree of blood pressure at P1 phase might suggest an association between the severity of HDP and TID. In conclusion, it was suggested that the renal TID might be involved in HDP regardless of the existence of proteinuria.

TH-PO759

**Investigating the Psychological and Clinical Correlates of Pregnancy Risk and Pregnancy Intention in Women With CKD**  
Elizabeth R. Ralston,<sup>1</sup> Joseph Chilcot,<sup>3</sup> Katherine R. Clark,<sup>1,2</sup> Priscilla Smith,<sup>1,2</sup> Kate Bramham,<sup>1,2</sup> <sup>1</sup>King's College London Faculty of Life Sciences and Medicine, London, United Kingdom; <sup>2</sup>King's College Hospital, London, United Kingdom; <sup>3</sup>King's College London Institute of Psychiatry Psychology and Neuroscience, London, United Kingdom.

**Background:** Women with Chronic Kidney Disease (CKD) are at increased risk of adverse pregnancy and renal outcomes. Risk perception is recognised to impact behaviour. This study aimed to understand how women with CKD perceive their pregnancy risk and understand what clinical and psychological factors are associated with perceived pregnancy risk and pregnancy intention.  
**Methods:** Women aged between 18 and 50 years with CKD Stages 1-5 were recruited from nine renal units in the United Kingdom and asked to complete an online survey (October 2020 to December 2021). Demographic, pregnancy preference information, and psychological attributes (with validated tools) were measured. Clinical data were extracted from local databases. Multivariable linear regressions were performed.  
**Results:** 315 women participated, mean age 35 (7.1) with mean estimated glomerular filtration rate (eGFR) 62.2 ml/min/1.73m<sup>2</sup> (SD 34.7). 108 (34.4%) women had previously attended pre-pregnancy counselling and 234 (74%) reported pregnancy being important to very important. Women with CKD appear to have greater perceived pregnancy risk (46.0, SD 23) than previously reported in lower risk groups (24.0, SD 14.5). After adjustment no associations were reported between clinical characteristics including eGFR and women's perceived pregnancy risk, but attendance to pre-pregnancy counselling (*b* = 6.5, 95% CI 1.5 to 11.4, *p* = 0.011) and women's perceived kidney disease severity (*b* = 0.15, 95% CI 0.04 to 0.26, *p* = 0.010) were associated with perceived pregnancy risk. No correlation

was reported between perceived pregnancy risk and pregnancy intention ( $r = -0.002$ , 95% CI -0.12 to 0.11,  $p = 0.97$ ), there was also no association with clinical risk factors and pregnancy intention. Importance of pregnancy was the strongest associated factor with pregnancy intention ( $b = 0.4$ , 95% CI 0.2 to 0.5,  $p < 0.001$ ).

**Conclusions:** Women with CKD appear to perceive their pregnancy risk to be greater compared to pregnancies uncomplicated by CKD. The importance of pregnancy for women with CKD is high, but clinical status is not associated with their future pregnancy intention or perceived pregnancy risk.

## TH-PO760

### Pregnancy History and Disease Progression Among Women Enrolled in Cure Glomerulopathy (CureGN)

Monica L. Reynolds,<sup>1</sup> Andrea L. Oliverio,<sup>2</sup> Jarcy Zee,<sup>3</sup> Isabelle Ayoub,<sup>4</sup> Saleem Almaani,<sup>4</sup> Dana Rizk,<sup>5</sup> Michelle M. O'Shaughnessy,<sup>6</sup> Elizabeth M. Hendren,<sup>7</sup> Tetyana L. Vasylyeva,<sup>8</sup> Shikha Wadhvani,<sup>9</sup> Julia M. Steinke,<sup>10</sup> Meryl A. Waldman,<sup>11</sup> Margaret Helmuth,<sup>12</sup> Carla M. Nester,<sup>13</sup> Nada Alachkar,<sup>15</sup> Carmen Avila-Casado,<sup>16</sup> Michelle A. Hladunewich,<sup>14</sup> Laura H. Mariani.<sup>2</sup> <sup>1</sup>University of North Carolina System, Chapel Hill, NC; <sup>2</sup>University of Michigan, Ann Arbor, MI; <sup>3</sup>University of Pennsylvania, Philadelphia, PA; <sup>4</sup>The Ohio State University, Columbus, OH; <sup>5</sup>The University of Alabama at Birmingham College of Arts and Sciences, Birmingham, AL; <sup>6</sup>University College Cork, Cork, Ireland; <sup>7</sup>Columbia University, New York, NY; <sup>8</sup>Texas Tech University System, Amarillo, TX; <sup>9</sup>Northwestern University, Evanston, IL; <sup>10</sup>Spectrum Health Helen DeVos Children's Hospital, Grand Rapids, MI; <sup>11</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>12</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>13</sup>University of Iowa, Iowa City, IA; <sup>14</sup>Sunnybrook Health Sciences Centre, Toronto, ON, Canada; <sup>15</sup>Johns Hopkins University, Baltimore, MD; <sup>16</sup>University of Toronto, Toronto, ON, Canada.

**Background:** Preeclampsia increases risk for future CKD, possibly through sustained endothelial and podocyte dysfunction. Utilizing CureGN, a longitudinal glomerular disease cohort study, we assessed if complicated pregnancy history was associated with disease progression.

**Methods:** Adult women were classified based on self-reported history of complicated pregnancy (worsening blood pressure, worsening kidney function, increased proteinuria, preeclampsia, eclampsia, or HELLP), pregnancy without these complications, or no pregnancy prior to CureGN enrollment. Linear mixed models assessed associations between complicated pregnancy history and eGFR trajectory as well as UPCR from enrollment.

**Results:** Of 780 women with median follow-up of 32 months, the adjusted eGFR decline [95% CI] was faster in women with a history of complicated pregnancy compared to those without complications or no pregnancy (-2.1 [-2.9, -1.4] vs -0.9 [-1.4, -0.5] and -0.7 [-1.3, -0.1] mL/min/1.73m<sup>2</sup> per year,  $p = 0.01$ ) (Figure). Proteinuria trend did not differ significantly by pregnancy history. Among women with complicated pregnancy ( $n=124$ ), eGFR slope did not differ significantly by timing of first complicated pregnancy relative to GN diagnosis.

**Conclusions:** A history of complicated pregnancy, occurring at any length of time from GN diagnosis, was associated with faster eGFR decline following CureGN enrollment. A detailed obstetric history may inform counseling regarding disease progression in women with GN. Continued research is warranted to identify biological pathways between complicated pregnancy and progressive glomerular disease.

Predicted values of eGFR (95% CI) by pregnancy history from adjusted linear mixed model

## TH-PO761

### International Pregnancy Outcomes in Alport Syndrome (COL4A3-5 Related Disease) vs. CKD in General

Margriet Gosselink,<sup>1</sup> Rozemarijn Snoek,<sup>1</sup> Sofia P. van Bakel,<sup>1</sup> Agne Cerkauskaitė,<sup>6</sup> Rimante Cerkauskienė,<sup>6</sup> Marius Miglinas,<sup>6</sup> Kalman Tory,<sup>9</sup> Kathleen Claes,<sup>5</sup> Kristel Van Calsteren,<sup>5</sup> Aude Servais,<sup>3</sup> Margriet de Jong,<sup>8</sup> Valentine Gillion,<sup>7</sup> Liffert Vogt,<sup>2</sup> Monica Furlano,<sup>4</sup> Roser Torra,<sup>4</sup> Antonio Mastrangelo,<sup>10</sup> Titia Lely,<sup>1</sup> Albertien M. van Eerde.<sup>1</sup> ALPART working group <sup>1</sup>Universitair Medisch Centrum Utrecht - Locatie Wilhelmina Kinderziekenhuis, Utrecht, Netherlands; <sup>2</sup>Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; <sup>3</sup>Hopital universitaire Necker-Enfants malades, Paris, France; <sup>4</sup>Fundacio Puigvert, Barcelona, Spain; <sup>5</sup>Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven Campus Gasthuisberg, Leuven, Belgium; <sup>6</sup>Vilniaus universiteto ligoninė Santaros klinikos, Vilnius, Lithuania; <sup>7</sup>Universite catholique de Louvain, Louvain-la-Neuve, Belgium; <sup>8</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>9</sup>Semmelweis Egyetem Klinikai Központ, Budapest, Hungary; <sup>10</sup>Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.

**Background:** Women with chronic kidney disease (CKD) have high risks of adverse pregnancy outcomes such as preeclampsia, preterm birth, small for gestational age (SGA). Pregnancy outcomes in CKD patients are often presented per CKD-stage without considering etiology of kidney disease. On pregnancy in COL4A3-5 related disease (Alport Syndrome, AS), a prevalent monogenic kidney disease, merely case reports are published. This study investigates pregnancy outcomes in women with AS on a large scale and compare these with pregnancies in general CKD.

**Methods:** The ALPART-network (mAtenaL and fetal PregnAncy outcomes of women with AlpoRT syndrome) was established by 15 centers in Europe and aims to include ~200 pregnancies. Women with AS and  $\geq 1$  pregnancy >20 weeks are included. Data is collected retrospectively from medical records. For these intermediary analyses, a combined adverse pregnancy outcome (cAPO) was established consisting of preterm birth <34 weeks, SGA and NICU admission. Pregnancy outcomes were compared with similar CKD stage 1-2 pregnancies of diverse etiology from the UMC Utrecht outpatient clinic.

**Results:** Data on 149 AS-pregnancies in 88 women were compared to 104 pregnancies in CKD of various causes. Prepregnancy hypertension was lower (22 vs 53%) and proteinuria levels ( $>1$ g/day) were higher (50 vs 33%). AS pregnancy outcomes were significantly better: mean birth weight 3215 gram (SD 678) vs 2735 (913), mean gestational age 38.6 weeks (SD 2.3) vs 37.0 weeks (4.3) and cAPO occurred less frequently (24% vs 40%,  $p < 0.004$ ). Though new-onset/doubling of proteinuria did not differ significantly, missing values hinder interpretation. Mean eGFR was lower after pregnancy vs before (96.1 vs 105.5,  $p = 0.001$ ), but eGFR-slope did not differ significantly after pregnancy (eGFR decline -0.69 mL/min/1.73m<sup>2</sup> per year, mean follow up 5.6 years postpartum,  $p = 0.746$ ).

**Conclusions:** This is the largest cohort of pregnancies in women with AS. Preliminary analyses show favourable outcomes compared to CKD in general. This emphasizes the need for more data on pregnancy outcomes stratified per etiology of CKD, to improve preconception counselling and care.

## TH-PO762

### Association of Marijuana, Tobacco, and Alcohol Use With Estimated Glomerular Filtration Rate in Women Living With HIV and Women Without HIV

Molly Fisher,<sup>1</sup> Donald Hoover,<sup>2</sup> Qiuhu Shi,<sup>3</sup> Anjali Sharma,<sup>1</sup> Michelle M. Estrella,<sup>4</sup> Maria L. Alcaide,<sup>5</sup> Lauren F. Collins,<sup>6</sup> Jodie Dionne,<sup>7</sup> Audrey French,<sup>8</sup> Samy I. McFarlane,<sup>9</sup> Heather S. Mckay,<sup>11</sup> Frank J. Palella,<sup>10</sup> Sudipa Sarkar,<sup>11</sup> Amanda B. Spence,<sup>12</sup> Mallory D. Witt,<sup>13</sup> Michael J. Ross.<sup>1</sup> <sup>1</sup>Albert Einstein College of Medicine, Bronx, NY; <sup>2</sup>Rutgers The State University of New Jersey, New Brunswick, NJ; <sup>3</sup>New York Medical College, Valhalla, NY; <sup>4</sup>University of California San Francisco, San Francisco, CA; <sup>5</sup>University of Miami School of Medicine, Miami, FL; <sup>6</sup>Emory University School of Medicine, Atlanta, GA; <sup>7</sup>University of Alabama at Birmingham, Birmingham, AL; <sup>8</sup>John H Stroger Jr Hospital of Cook County, Chicago, IL; <sup>9</sup>SUNY Downstate Health Sciences University, New York City, NY; <sup>10</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>11</sup>Johns Hopkins University, Baltimore, MD; <sup>12</sup>Georgetown University, Washington, DC; <sup>13</sup>The Lundquist Institute, Torrance, CA.

**Background:** Marijuana, tobacco and alcohol use are behavioral risk factors for impaired kidney function, which have not been thoroughly evaluated in persons living with HIV (PLWH). We evaluated associations between use of these substances with estimated glomerular filtration rate (eGFR) among women living with HIV (WLWH) and women without HIV.

**Methods:** We undertook a repeated measures cross-sectional study of WLWH and women without HIV nested within the Women's Interagency HIV Study, a multicenter, prospective women's cohort in the United States. Substance use was ascertained using semi-annual questionnaires. Multivariable linear regression adjusting for sociodemographic, chronic kidney disease risk factors and HIV-related factors were used to assess associations of current and cumulative marijuana, tobacco and alcohol exposures with eGFR between 2009 and 2019.

**Results:** Among 1512 participants, 1043 were WLWH with 14,481 study visits and 469 were women without HIV with 6,660 study visits. At baseline, WLWH had a lower median eGFR (99.8 mL/min/1.73m<sup>2</sup> (IQR 80.9-114) vs 102.7 mL/min/1.73m<sup>2</sup> (IQR 88.4-116.2),  $p=0.003$ ), lower prevalence of current marijuana use (14% vs 22%,  $p<0.0001$ ), lower current alcohol use (39% vs 50%,  $p<0.0001$ ) and trend toward lower current tobacco use (40% vs 46%,  $p=0.06$ ) compared to women without HIV. Alcohol use of >7 drinks/week compared with no use was associated with a 3.95 mL/min/1.73m<sup>2</sup> (95% confidence interval 1.03, 6.86;  $p=0.008$ ) higher eGFR. Neither current marijuana use versus no use nor 10-year cumulative use of >1.6 versus 0-0.02 marijuana-years were associated with eGFR. Current tobacco use compared to never use and lifetime tobacco use of >10 compared to 0 pack-years were also not associated with eGFR.

**Conclusions:** In a large cohort of WLWH and women without HIV, heavy alcohol use was associated with a higher eGFR and there was no association of marijuana or tobacco use with eGFR. Despite lack of evidence of harmful effects on kidney function from marijuana and tobacco use, clinical care of PLWH should include substance use screening and counseling on other known health risks associated with substance use.

## TH-PO763

### Early Pregnancy-Associated Atypical Hemolytic Uremic Syndrome (aHUS)

Michael Che,<sup>1</sup> Sarah M. Moran,<sup>2</sup> Richard J. Smith,<sup>3</sup> Miriam Galbusera,<sup>4</sup> Sara Gastoldi,<sup>4</sup> Jocelyn S. Garland.<sup>1</sup> <sup>1</sup>*Queen's University, Kingston, ON, Canada;* <sup>2</sup>*Department of Nephrology, Cork University, Cork, Ireland;* <sup>3</sup>*Molecular Otolaryngology and Renal Research Laboratories, Carver College of Medicine, University of Iowa, Iowa City, IA;* <sup>4</sup>*Istituto di Ricerche Farmacologiche Mario Negri-IRCCS; Clinical Research Center for Rare Diseases Aldo e Cele Daccò Ranica, Bergamo, Italy.*

**Introduction:** aHUS in pregnancy is typically reported to occur in the third trimester. Here we report a case of aHUS presenting in the first trimester of pregnancy.

**Case Description:** A 30 year old G2P0A1 diabetic biracial woman presented at 9 weeks gestation with new hypertension. By 18 weeks, she developed acute kidney injury and macular edema. Investigations revealed hemoglobin 68 g/L, platelets  $120 \times 10^3/L$ , LDH 588 U/L, undetectable haptoglobin and schistocytes. Creatinine increased from 50 to 88  $\mu\text{mol/L}$ , and microscopic hematuria and proteinuria >1 g/day were detected. ASA 162 mg, low molecular weight heparin, and anti-hypertensives were prescribed. Pre-eclampsia (PET) was ruled out as her symptoms began within the first trimester, and normal uterine artery doppler results were obtained. Placental growth factor levels at 24 and 28 weeks were >100 pg/mL. HELLP syndrome was excluded given the timing in pregnancy (<20 weeks) and normal liver transaminases. TTP was excluded by normal ADAMTS13. Complement Factor H autoantibody was negative. Complement studies revealed elevated plasma C5b-9 level of 1.05 (normal <0.3 mg/L). aHUS was diagnosed and eculizumab (ECU) was prescribed. Ex-vivo serum C5b-9 deposition on human microvascular endothelial cells (Noris, Blood, 2014) was abnormal pre-treatment with ECU (activated 223%, normal <150%), and normalized with ECU therapy (activated 123%, normal <150%). Genetic testing revealed a Complement Factor I mutation, NM\_000204.3:c.550G/A, p. Vall84Met reported as pathogenic, confirming primary aHUS. Due to worsening renal function, she delivered a healthy baby at 30 weeks gestation by Caesarean section. A renal biopsy performed 3 weeks postpartum demonstrated features of TMA, mainly chronic (i.e. treated) and advanced diabetic nephropathy. Six months postpartum, she required dialysis. aHUS is in clinical remission on ECU, and she awaits kidney transplantation.

**Discussion:** aHUS is classically described to occur late in pregnancy or postpartum. Here, this patient presented uniquely during the first trimester with complement function testing aiding the diagnosis. Thus, TMA in pregnancy is not always PET or HELLP and aHUS should be considered as the diagnosis particularly for presentations occurring prior to 20 weeks gestation. Episodes of severe PET/HELLP should trigger TMA workup for underlying complement disorder.

## TH-PO764

### Severe Postpartum HELLP Syndrome: Is This Atypical Hemolytic Uremic Syndrome?

Michael Che,<sup>1</sup> Sarah M. Moran,<sup>2</sup> Richard J. Smith,<sup>3</sup> Sara Gastoldi,<sup>4</sup> Jocelyn S. Garland.<sup>1</sup> <sup>1</sup>*Division on Nephrology, Department of Medicine, Queen's University, Kingston, ON, Canada;* <sup>2</sup>*Department of Nephrology, Cork University, Cork, Ireland;* <sup>3</sup>*University of Iowa Molecular Otolaryngology and Renal Research Laboratories, Iowa City, IA;* <sup>4</sup>*Istituto di Ricerche Farmacologiche Mario Negri-IRCCS; Clinical Research Center for Rare Diseases Aldo e Cele Daccò Ranica, Bergamo, Italy.*

**Introduction:** Complement dysregulation is implicated in the pathogenesis of atypical hemolytic uremic syndrome (aHUS) and there is growing evidence to support its role in HELLP (hemolysis, elevated liver enzymes, low platelets) syndrome. Here we present a case of post-partum thrombotic microangiopathy (TMA) in the setting of HELLP syndrome.

**Case Description:** A 22 year old G1P0 Caucasian woman presents at 37 weeks gestation with abdominal pain and severe hypertension. Labs demonstrated hemoglobin 95, platelets 30, LDH 2597, schistocytes, severe transaminitis (AST 1845, ALT 830), and proteinuric acute kidney injury. She was diagnosed with HELLP syndrome and treated with anti-hypertensives and emergency Caesarean section. Unfortunately, the infant did not survive; there was no placental abruption. Platelets recovered by day 5 postpartum, LDH by day 7. However, renal function worsened and by day 6 postpartum, she required

hemodialysis when creatinine peaked at 812. A renal biopsy revealed acute and chronic TMA. She did not have cortical necrosis. Further workup revealed normal C3, C4 and ADAMTS13 levels. Dialysis was stopped after two weeks. By 6 months, her renal function and proteinuria returned to normal. Complement function testing revealed negative complement factor H autoantibody, but elevated plasma C5b-9 level (0.42 mg/L, normal <0.3). Ex-vivo serum C5b-9 deposition on human microvascular endothelial cells was assessed both on resting (182%, normal <150%) and on ADP-activated endothelial cells (273%, normal <150%). This test was repeated 6 months postpartum when renal function had normalized, and results were persistently abnormal both on resting (215%, normal <150%) and on ADP-activated endothelial cells (282%, normal <150%). aHUS genetic testing was negative.

**Discussion:** The severity of HELLP syndrome associated organ dysfunction prompted the assessment for aHUS. Identifiable aHUS genetic mutations only occur in 50% of aHUS patients; however, the persistence of increased C5b-9 deposition mimics the findings of patients who have aHUS (Noris, Blood, 2014). Complement function testing is not routinely assessed for postpartum HELLP, and these unique results suggest the patient may be at risk for recurrent TMA/aHUS, particularly if another pregnancy is being considered. Future research should explore which pregnancy associated TMA patients may benefit from anti-complement therapy.

**Background:** Diabetic Kidney Disease (DKD) is recognized as the leading cause of Chronic Kidney Disease (CKD). Male sex is a risk factor for CKD, and is generally associated with a more severe DKD. However, female sex renoprotection is often lost in the setting of diabetes. The molecular reasons behind the sex-specific progression of DKD, and their link to sex chromosomes and sex hormones, are unknown. Here, we identify a sex dimorphism in glucose and glutamine metabolism that is conserved in healthy and diabetic mice and humans.

**Methods:** We employed primary human proximal tubular epithelial cells (PTECs) from male and female donors (n=3/sex), and exposed them to sex hormones, under normal or under high glucose conditions (n=6/group). We studied male and female mice with and without gonads, as well as male and female type 1 diabetic mice (n=5-8/group). We also interrogated the serum metabolome of male and female adolescents with type 2 diabetes and their controls (n=180).

**Results:** Female PTECs displayed decreased glycolysis, mitochondrial respiration, oxidative stress, apoptosis, and high glucose-induced injury, compared to male PTECs. The more oxidative phenotype of male PTECs was enhanced by dihydrotestosterone (DHT) and linked to increased mitochondrial utilization of glucose and glutamine. Studies *in vivo* pointed towards decreased glutamine anaplerosis in diabetic female kidneys. Female PTECs displayed increased levels of pyruvate, glutamyl-cysteine, cysteinylglycine, and a higher GSH/GSSG ratio than male PTECs, indicative of enhanced redox homeostasis. Conversely, male sex was linked to increased levels of glutamate, TCA cycle, and glutathione cycle metabolites, in PTECs and in the blood metabolome of healthy youth and youth with type 2 diabetes. Finally, we identified transcriptional mechanisms that control kidney metabolism in a sex-specific fashion. While X-linked demethylase KDM6A facilitated metabolic homeostasis in female PTECs, transcription factor HNF4A mediated the deleterious effects of DHT in male PTECs.

**Conclusions:** This work uncovers the role of sex in renal glucose and glutamine metabolism, that may explain the roots of sex dimorphism in kidney health and DKD, and inspires new paradigms based on patient sex.

## TH-PO766

**Sexual Dimorphism in AKI Outcomes: Does Menopause Tie the Match?**

Maria Isabel Acosta-Ochoa, Armando Coca, Arturo Lorenzo. *Hospital Clinico Universitario de Valladolid, Valladolid, Spain.*

**Background:** Many studies focus on gender differences when suffering AKI, some reporting that female sex could be protective against AKI adverse outcomes, this “protection” could be lost in menopause due to the absence of estrogen among other female hormones. We studied a cohort of individuals suffering from AKI and compared hard outcomes between female and masculine patients older than 55 years.

**Methods:** Retrospective cohorts’ study, of nephrology ward and consultation, AKI severity was categorized by KDIGO-2012 criteria; we included all patients  $\geq 55$  y, analyzed clinical variables and compared the rates of occurrence of the hard outcomes length of hospital stay (LOS), need for dialysis (HD), dialysis dependence at discharge (DDD), and in-hospital mortality (IHM) between groups.

**Results:** We included 1135 individuals. 70% were male, these patients were older and had a higher Charlson’s Index because they suffered more frequently of COPD, cancer, and peripheral arterial disease among other; women were hospitalized more frequently in medical wards. Table 1A summarizes our findings. We found no statistically significant differences in LOS, HD, DDD and IHM. In Table 1B we summarize the results between groups.

**Conclusions:** In our study we found that males were older and had a worst Charlson’s Index, and we found no statistically significant differences in the studied hard outcomes between males and females. In conclusion, women in the range of age of menopause ( $\geq 55$  y) that suffer an episode of AKI do not differ significantly from males in the occurrence of hard clinical and renal outcomes, but males have worst clinical characteristics.

**Sex and Gender Considerations in Randomized Controlled Trials in Adults Receiving Chronic Dialysis: A Meta-Epidemiologic Study**

David T. Collister,<sup>1</sup> Lonnie Pyne,<sup>5</sup> Artti A. Bhasin,<sup>5</sup> Sofia B. Ahmed,<sup>2</sup> Brendan Smyth,<sup>4</sup> William G. Herrington,<sup>3</sup> Meg Jardine,<sup>4</sup> Michael Walsh.<sup>5</sup>  
<sup>1</sup>University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; <sup>2</sup>University of Calgary Cumming School of Medicine, Calgary, AB, Canada; <sup>3</sup>University of Oxford, Oxford, United Kingdom; <sup>4</sup>The University of Sydney Faculty of Medicine and Health, Sydney, NSW, Australia; <sup>5</sup>McMaster University, Hamilton, ON, Canada.

**Background:** How sex and gender concepts are incorporated in randomized controlled trials (RCTs) in adults with kidney failure receiving chronic dialysis is unknown.

**Methods:** Meta-epidemiologic study of RCTs in chronic dialysis from the highest impact journals from 2000 to 2020. Meta-regression was performed to identify trial characteristics independently associated with the proportion of female/women participants.

**Results:** Of 561 included RCTs, 69.7% were parallel and 28.0% were crossover in design. 80.6% were in the hemodialysis population. 1/4 were placebo controlled, 1/4 were compared to usual care and 1/2 were compared to an active therapy. 37.6% of RCTs were blinded. The median (IQR) size was 60 participants (26, 151) and the median (IQR) follow-up was 154 days (42, 365). The mean (SD) proportion of female/women participants was 0.40 (0.13). 39.0% of trials reported sex and 26.6% reported gender of participants. 56.2% referred to participants as females, 25.3% referred to participants as women and 15.5% referred to both females and women. No trial characteristic other than region (Asia, B 0.062 95% CI 0.007-0.117) was associated with the proportion of female/women participants. Considering trial design and conduct, 2.7% used male/female sex and/or man/woman gender as an inclusion criteria, 26.6% as exclusion criteria (e.g. related to pregnancy, contraception, lactation), 4.5% for randomization, 4.8% for subgroup analyses and 15.7% for covariate adjustment.

**Conclusions:** RCTs in dialysis are representative of the general dialysis population with regards to sex/gender but rarely report both sex and gender separately and often do not include either in their reporting or analysis.

## TH-PO768

**Purple Urine Bag Syndrome in an Elderly Female With Constipation and Urinary Tract Infection**

Allison A. Bauman,<sup>1</sup> Lakshmi Kannan,<sup>2</sup> Brandon Nelson.<sup>2</sup> <sup>1</sup>University of Pikeville Kentucky College of Osteopathic Medicine, Pikeville, KY; <sup>2</sup>Pikeville Medical Center, Pikeville, KY.

**Introduction:** Purple Urine Bag Syndrome (PUBS) is an uncommon event that causes the urine of those affected to turn various shades of purple. Risk factors for PUBS include female gender, chronic catheterization, advanced age, constipation, chronic kidney disease (CKD), and urinary tract infections (UTI’s).<sup>(1)</sup> The purple urine is caused by elevated levels of the pigments indigo and indirubin.<sup>(1)</sup> In this article, we present a case in which an elderly female with a history of long-dwelling catheterization and CKD develops purple urine in the setting of a UTI and constipation.

**Case Description:** A 76-year-old female with a history of stage III CKD who was chronically catheterized presented to the hospital with shortness of breath from CHF exacerbation. After experiencing constipation for four days, her urine was noted to be purple (**Figure 1**). Urinalysis showed alkaline urine (pH of 8.5) with a large amount of blood, nitrites, leukocyte esterase, and proteins, and urine culture revealed more than 100,000 CFU/mL of *Proteus mirabilis*. In the setting of her discolored urine, these findings are consistent with PUBS. She was started on empiric ceftriaxone for UTI and miralax/senna twice daily for constipation. Her constipation resolved, and a 5-day course of antibiotics was completed.

**Discussion:** PUBS tends to occur primarily in constipated women with sulphatase/phosphatase-producing bacteria in their urinary tracts.<sup>(2)</sup> These bacteria convert indoxyl sulfate into indoxyl which, when metabolized in an alkaline environment, gives rise to indirubin and indigo.<sup>(1)</sup> PUBS is generally considered benign; however, if the infection underlying PUBS becomes too severe, serious disease (i.e. Fournier’s gangrene) can result.<sup>(3)</sup>

**Figure 1.** Dark purple urine in a Foley catheter bag. Patient’s urine turned dark purple after four days of constipation.

## TH-PO769

## Albuminuria in Older Adults: Data on Prevalence and Trends Over 8 Years in the Berlin Initiative Study (BIS)

Tim Bothe,<sup>1,3</sup> Elke Schaeffner,<sup>1</sup> Nina Mielke,<sup>1</sup> Alice Schneider,<sup>1</sup> Muhammad Barghouth,<sup>1</sup> Markus van der Giet,<sup>1</sup> Martin K. Kuhlmann,<sup>2</sup> Natalie Ebert,<sup>1</sup> <sup>1</sup>Charite Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>Vivantes Klinikum im Friedrichshain, Berlin, Germany; <sup>3</sup>InGef - Institut für angewandte Gesundheitsforschung Berlin GmbH, Berlin, Germany.

**Background:** Data on the course of albumin-creatinine ratio (ACR) in the elderly are scarce. Identifying patterns of ACR progression is important for a better understanding of albuminuria in old age.

**Methods:** We used data of the BIS, a community-dwelling cohort of 2,069 persons aged 70 or older. Baseline visit was conducted between 2010 and 2011, followed by four biennial follow-up visits. Prevalence of albuminuria (no: ACR<30 mg/g; micro: ACR 30–299 mg/g; macro: ACR≥300 mg/g) was assessed from spot urine at all study visits. In a sub-analysis, we included only non-deceased participants with complete attendance and valid ACR measures at all study visits.

**Results:** At baseline, mean age was 80.4 years (range: 70–100) and 52.6% were females. Median ACR increased from 10.7 at baseline to 13.3 mg/g after 8 years. Prevalence of micro- and macroalbuminuria remained nearly stable over time (21.6–25.3% and 3.3–4.1%, respectively). In the subgroup with complete attendance, median ACR raised from 7.3 to 13.2 mg/g, whereas prevalence of micro- and macroalbuminuria increased from 14.9 to 25.6% and 1.7 to 3.3% after 8 years, respectively.

**Conclusions:** We found that over the observation period of 8 years, ACR increased longitudinally in the subgroup with complete attendance only slightly by about 6 mg/g and prevalence of microalbuminuria by 11%. Cross-sectionally, ACR increased in the total population by only 3 mg/g and prevalence of micro- and macroalbuminuria remained nearly stable over 8 years at approximately 25% and 4%, respectively. The coefficient of variation for ACR measurement is known to be relatively high, therefore values should be considered as rough estimates only.

Figure: Boxplots and flat violin plots of ACR distribution.

Table: Sociodemographic variables and albuminuria prevalence for both study populations.

Population	Outcome	Baseline	Follow-Up 4
Total	N <sup>1</sup>	2,055	845
	Age, mean (SD)	80.4 (6.7)	85.6 (5.2)
	Females, N (%)	1,081 (52.6)	470 (55.6)
	Deceased <sup>2,3</sup> , N (%)	125 (6.1)	94 (11.1)
	ACR, median (q25; q75)	10.7 (4.5; 30.6)	13.3 (5.4; 35.9)
	Albuminuria, N (%)		
	no (ACR < 30)	1,523 (74.1)	599 (70.9)
	micro (ACR 30–299)	458 (22.3)	218 (25.8)
	macro (ACR ≥ 300)	74 (3.6)	28 (3.3)
Complete attendance <sup>1</sup>	N	784	784
	Age, mean (SD)	77.3 (5.2)	85.5 (5.2)
	Females, N (%)	422 (53.8)	422 (53.8)
	ACR, median (q25; q75)	7.3 (3.7; 18.1)	13.2 (5.5; 37.0)
	Albuminuria, N (%)		
	no (ACR < 30)	654 (83.4)	557 (71.0)
	micro (ACR 30–299)	117 (14.9)	201 (25.6)
	macro (ACR ≥ 300)	13 (1.7)	26 (3.3)

<sup>1</sup> Complete attendance population refers to non-deceased individuals who participated in all study visits and had valid ACR values for all measurements. <sup>2</sup> N refers to persons with valid ACR measurements at each study visit. N = 1,667, 1,411, and 1,086 for Follow-Up 1 – 3. Excluded due to missing lab values were: N = 14, 32, 29, 80, and 99 (Baseline – Follow-Up 4). <sup>3</sup> Deceased<sup>2,3</sup> was calculated as number of persons who died within 2 years after their respective study visit date. Abbreviations: SD: standard deviation; q25: 25<sup>th</sup> percentile; q75: 75<sup>th</sup> percentile.

## TH-PO770

## Mortality Risk According to eGFR and Proteinuria in Persons Older Than 65 Years: Results From a Nationwide Study in Iceland

Arnar J. Jonsson,<sup>1,2</sup> Sigrún H. Lund,<sup>3</sup> Bjorn O. Eriksen,<sup>4</sup> Runolfur Palsson,<sup>1,2</sup> Olafur S. Indridason.<sup>1</sup> <sup>1</sup>Landspítali–The National University Hospital of Iceland, Reykjavik, Iceland; <sup>2</sup>Haskoli Islands, Reykjavik, Iceland; <sup>3</sup>deCODE Genetics Inc, Reykjavik, Iceland; <sup>4</sup>University Hospital of North Norway, Tromsø, Norway.

**Background:** Kidney function is known to decline with age, nevertheless, a uniform definition of glomerular filtration rate (GFR) has been applied to define chronic kidney disease irrespective of age. This has mostly been based on cross-sectional studies using single assessment of estimated glomerular filtration rate (eGFR), that have indicated worse outcome at eGFR <60 mL/min/1.73 m<sup>2</sup>. The aim of this study was to examine the risk of all-cause mortality according to eGFR and proteinuria in persons aged >65 years in the general population.

**Methods:** We obtained all serum creatinine (Scr) and urine protein measurements from all clinical laboratories in Iceland in the years 2008–2016. Clinical data were obtained from nationwide electronic medical records. eGFR was calculated using the CKD-EPI equation and classified into categories; 0–29, 30–44, 45–59, 60–74, 75–89, 90–104 and >104 mL/min/1.73 m<sup>2</sup> eGFR category and proteinuria had to be persistent for >3 months. A multiple imputation method was used to account for missing urine protein measurement data. A joint model using repeated measurements was used to assess mortality and simultaneously account for decline in eGFR over time, adjusting for age as a continuous variable, sex and multiple comorbid conditions.

**Results:** We obtained 782,995 Scr values for 37,937 individuals aged over 65 years, of whom 23,344 (62%) had information on proteinuria. The median age was 75 (range, 66–106) years and 46% were men. Adjusted hazard ratios for all-cause mortality are demonstrated in the table.

**Conclusions:** Among elderly individuals, eGFR >104 mL/min/1.73 m<sup>2</sup> carries a high mortality risk, whereas eGFR of 45–74 without proteinuria is associated with the lowest mortality.

**Funding:** Government Support - Non-U.S.

Adjusted hazard ratio (95% CI) for death according to eGFR and proteinuria

eGFR (mL/min/1.73 m <sup>2</sup> )	No proteinuria	Proteinuria
> 104	4.28 (2.89–6.36)	4.47 (2.15–9.31)
90–104	1.55 (1.40–1.73)	2.23 (1.92–2.60)
75–89	1.08 (1.02–1.15)	1.62 (1.50–1.75)
60–74	Reference	1.42 (1.32–1.54)
45–59	1.05 (0.99–1.12)	1.46 (1.35–1.57)
30–44	1.33 (1.23–1.44)	1.41 (1.28–1.55)
0–29	1.97 (1.75–2.21)	2.09 (1.84–2.37)

## TH-PO771

## Predialysis Care Pathways and Early Morbidity and Mortality After Transition to Dialysis in French Elderly

Aghile Hamroun,<sup>1,2</sup> Estelle Aymes,<sup>1</sup> Cécile Couchoud,<sup>3</sup> Luc Dauchet,<sup>1</sup> Victoria Gauthier,<sup>1</sup> Philippe Amouyel,<sup>1</sup> François Glowacki,<sup>1</sup> Benedicte Stengel.<sup>2</sup> <sup>1</sup>Centre Hospitalier Universitaire de Lille, Lille, France; <sup>2</sup>Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; <sup>3</sup>Agence de la biomedecine, La Plaine Saint-Denis, France.

**Background:** The ageing of the population with advanced chronic kidney disease (CKD) increases the complexity of care pathways. Our aim was to identify subgroups of elderly patients according to predialysis care pathways and describe their association with early death and hospitalization after transition to dialysis.

**Methods:** We included 22,128 incident patients aged 75 or over (median age 82 years, 63% men) from the national ESKD REIN registry, 2010–2016, linked with the National Health Claim Data System. Predialysis care pathways were identified by multiple correspondence analyzes and ascending hierarchical classification, based on healthcare use. Their associations with death or hospitalization ≥ 50% of the time off dialysis within the first year of dialysis were studied by multivariate logistic regressions.

**Results:** Five care pathway profiles were identified characterized by nephrology ambulatory follow-up (37% of the patients), limited healthcare use (28%), non-nephrology ambulatory care (17%), and a high level of non-nephrology (9%) or nephrology hospitalizations (9%). Profile subgroups did not significantly differ according to demographic and clinical characteristics, and early mortality after dialysis initiation. Compared to the nephrology ambulatory follow-up profile, all other care pathway profiles were at higher risk of prolonged hospitalization after dialysis initiation (Figure 1, n = 1,195 patients).

**Conclusions:** Elderly patients with advanced CKD experienced very heterogeneous predialysis care pathways, which do not seem to be explained by their clinical profile. Improving nephrology outpatient follow-up may help reduce the burden of hospitalizations after the transition of dialysis in this population.

Predialysis care profile and risk of prolonged hospitalization

TH-PO772

**Informed Kidney Therapy Decision Making for Patients With ESKD Receiving Maintenance Dialysis: What Do Patients Say?**  
Spencer Dahl, Fahad Saeed. *University of Rochester Medical Center, Rochester, NY.*

**Background:** Informed decision making has legal and ethical implications for the kidney therapy (KT) decision-making process. However, previous small scale studies suggest significant lapses in informed decision making for people receiving dialysis. To advance the field, we undertook the current study examining patient’s recall of various aspects of informed decision making during KT decisions.

**Methods:** We surveyed 223 hospitalized patients (223/578, 59% response rate) receiving maintenance dialysis at an academic tertiary care hospital in upstate New York. We assessed informed KT decision making using a previously published informed KT decision making questionnaire<sup>1</sup>. We present descriptive analyses of our findings.

**Results:** The mean age of the respondents was 68 years (SD ±15.4), 50% had attained a high school level education or lower, 39% were Black, 24% White non-Hispanic, and 21% of Hispanic or Latino origin. Patients had been receiving dialysis treatment for an average of 3.1 years (SD ±2.4). Patient’s responses are grouped into three categories: (1) dialysis knowledge and (2) decision making, and (3) prognosis. In response to questions about disease knowledge, 41% of patients responded “No” to whether they had been informed about the condition that led to kidney failure, 40% were not informed of dialysis options such as peritoneal and hemodialysis, and 57% were not aware of the potential benefits and burdens of each option. Regarding decision making, nearly 71% reported that conservative kidney management was never presented as an option, and 78% did not recall being informed of the option to withdraw from dialysis. In response to questions about prognostic awareness, 53% did not report being informed about life expectancy with and without dialysis, and 38% did not recall an explanation for how their daily life might change after initiating dialysis.

**Conclusions:** An assessment of informed decision making among hospitalized patients receiving maintenance dialysis revealed significant lapses in the informed decision making process. Interventions to improve informed decision making in people with CKD are urgently needed. Citations: 1: Song MK, Lin FC, Gilet CA, Arnold RM, Bridgman JC, Ward SE. Patient perspectives on informed decision-making surrounding dialysis initiation. *Nephrology Dialysis Transplantation*. 2013;28(11):2815-2823.

TH-PO773

**Dialysis Regret Among Patients Receiving Dialysis: A Qualitative Study**  
Spencer Dahl,<sup>1</sup> Cameron E. Comrie,<sup>3</sup> Areeba Jawed,<sup>2</sup> Basil S. Kazi,<sup>1</sup> Fahad Saeed.<sup>1</sup> <sup>1</sup>*University of Rochester Medical Center, Rochester, NY;* <sup>2</sup>*University of Michigan Michigan Medicine, Ann Arbor, MI;* <sup>3</sup>*Harvard Medical School, Boston, MA.*

**Background:** Dialysis regret is common among people receiving maintenance dialysis; however, there is a lack in depth patient perspectives explaining the underlying reasons.

**Methods:** We conducted semi-structured interviews with 32 patients receiving maintenance dialysis, 22 hospitalized and 10 outpatients. To initiate discussion on regret, we asked “do you have any regrets about starting dialysis.” Transcripts were analyzed with MaxQDA software using thematic analysis and assessed for concordance among the research team until thematic saturation was achieved. Among transcripts classified as ‘high regret,’ we studied other potential explanations for dissatisfaction with dialysis within the same transcript.

**Results:** In this sample, the mean age of patients was 61.5 (SD ±15), years, 40% had attained less than a high school level education, and 60% earned annual income <\$20,000 a year. Three prominent themes related to decisional regret emerged: 1) *Poor Dialysis Education:* We found that patients expressing dialysis regret reported lack of understanding of their disease and dialysis treatment. Patients described feeling frustrated, embarrassed and apathetic due to their lack of understanding of their condition. 2) *Medical paternalism:* Medical paternalism appears to also be a key factor in decisional regret – patients frequently expressed that they felt that dialysis initiation was a choice made for them rather than by them with no sense of agency during this process. 3) *Expression of Feelings of Regret:* The majority of patients had not communicated their feeling of regret to their physician and did not feel they could.

**Conclusions:** The majority of patients experiencing dialysis regret reported a lack of education on dialysis care and a presence of medical paternalism. Few patients were willing to discuss their regret with their physician. Future shared decision making interventions are needed to examine their effect on regret.

TH-PO774

**Cognitive Impairment and Trajectories in CKD: The REGARDS Study**  
Katharine L. Cheung,<sup>1</sup> Miguel Arce Renteria,<sup>5</sup> Peter W. Callas,<sup>1</sup> Manjula Tamura,<sup>2,3</sup> Orlando M. Gutierrez,<sup>4</sup> Mary Cushman.<sup>1</sup> <sup>1</sup>*University of Vermont College of Medicine, Burlington, VT;* <sup>2</sup>*Stanford University School of Medicine, Stanford, CA;* <sup>3</sup>*VA Palo Alto Health Care System, Palo Alto, CA;* <sup>4</sup>*The University of Alabama at Birmingham School of Medicine, Birmingham, AL;* <sup>5</sup>*Columbia University, New York, NY.*

**Background:** CKD is associated with incident cognitive impairment (ICI) but it is unknown if longitudinal cognitive function has a different trajectory in CKD, or if age or race differences exist.

**Methods:** We studied 22,435 participants from the REGARDS study without baseline cognitive impairment. Participants completed the six-item screener (SIS) of global cognition every 6 months and 3 cognitive domain tests every 2 years for 10 years. ICI was defined as a SIS score ≤4. Multivariable logistic regression was used to calculate odds ratios of ICI as a function of eGFR. Latent growth curve models were used to determine the relationship of eGFR<60 ml/min/1.73m<sup>2</sup> to intercept and slope of each cognitive domain test (episodic memory, semantic and letter F fluencies) over time. Up to five cognitive examinations were analyzed.

**Results:** 13% (n=2,959) developed ICI over 10 years. As compared to eGFR ≥90 ml/min/1.73m<sup>2</sup> (reference), eGFR 60-<90, 45-<60, and <45 had unadjusted ORs (95%CI) of 1.8 (1.6, 1.9), 2.7 (2.3, 3.1) and 2.7 (2.2, 3.3). Accounting for other risk factors, there was a significant interaction of eGFR and age (p<0.001); compared to eGFR>90, the OR for ICI at eGFR <45 was 1.9 (1.2, 3.0) for age <65, whereas OR for eGFR<45 v eGFR>90 was 0.9 (0.7, 1.1) for age≥65 (Table 1). Compared to those with eGFR≥60, eGFR<60 was associated with lower baseline scores across all 3 cognitive domains, but the slope did not differ (Table 2). Baseline scores were lower in mid-life compared to late-life, whereas no differences by race were observed.

**Conclusions:** CKD is associated with increased risk of ICI and lower cognitive domain testing in mid-life compared to late-life. Strategies to reduce cognitive impairment should focus on mid-life.

**Funding:** Other NIH Support - NIGMS P20GM135007

**Table 1: Odds Ratios (95% CI) of Incident Cognitive Impairment across clinical categories of eGFR in the REGARDS Study**

	eGFR	≥90	<90≥60	<60≥45	<45	Linear Trend P values

## TH-PO775

**A Population-Based Assessment of Kidney Function and the Risk of Heart Failure Among Older Adults**

Antonios Douros,<sup>1</sup> Alice Schneider,<sup>2</sup> Nina Mielke,<sup>2</sup> Martin K. Kuhlmann,<sup>3</sup> Markus van der Giet,<sup>2</sup> Natalie Ebert,<sup>2</sup> Elke Schaeffner.<sup>2</sup> *<sup>1</sup>McGill University, Montreal, QC, Canada; <sup>2</sup>Charite Universitätsmedizin Berlin, Berlin, Germany; <sup>3</sup>Vivantes Netzwerk für Gesundheit GmbH, Berlin, Germany.*

**Background:** Decreased kidney function (KF) increases the risk of heart failure (HF) and other adverse cardiovascular (CV) outcomes and death. However, the role of KF in this regard among old and very old adults is poorly understood. This is an important knowledge gap since the decline of KF in advanced age can affect both healthy and multimorbid individuals. Thus, our population-based study assessed whether decreased KF is associated with an increased risk of HF, CV and all-cause mortality in a prospective cohort of community-dwelling older adults.

**Methods:** Participants of the Berlin Initiative Study (BIS), all aged  $\geq 70$  years, with baseline estimated glomerular filtration rate (eGFR<sub>BIS2</sub>) and no prior HF were followed from baseline (2009-2011) until the occurrence of a study outcome (hospitalization for HF [HHF], CV death, all-cause mortality) or 12/2020. HHF was defined via inpatient diagnostic codes, and mortality outcomes were defined via claims data, death certificates, and hospital discharge notes. Potential confounders included demographics, body mass index, alcohol consumption, smoking, physical exercise, education, income, comedication and comorbidities, measured at baseline using face-to-face interviews and claims data. Time-dependent Cox models estimated hazard ratios (HRs) with 95% confidence intervals (CIs) of the outcomes associated with decreased KF (eGFR<sub>BIS2</sub>  $< 60$  mL/min/1.73m<sup>2</sup>) compared with retained KF (eGFR<sub>BIS2</sub>  $\geq 60$  mL/min/1.73m<sup>2</sup>). eGFR values were updated biennially.

**Results:** Our cohort included 1466 HF free older adults (mean age 79 years; 55% female). Compared with retained KF, decreased KF was not associated with an increased risk of HHF (HR, 1.17; CI, 0.92-1.49), but was associated with increased risks of CV death (HR, 1.59; CI, 1.01-2.50), and all-cause mortality (HR, 1.33; CI, 1.02-1.72) (Figure).

**Conclusions:** Our population-based study showed that decreased KF is associated with an increased risk of CV and all-cause death among older adults. The role of HF in this association seems to be limited.

**Funding:** Private Foundation Support

	N Events	N PY	IR per 100 PY	Crude HR (95% CI)	Adjusted HR (95% CI)
<b>HHF</b>					
Decreased KF	393	5805	6.8	2.13 (1.76-2.59)	1.17 (0.92-1.49)
Retained KF	140	4412	3.2	Ref	Ref
<b>CV death</b>					
Decreased KF	198	7037	2.8	4.05 (2.73-5.99)	1.59 (1.01-2.50)
Retained KF	29	4742	0.6	Ref	Ref
<b>All-cause mortality</b>					
Decreased KF	475	7233	6.6	2.51 (2.04-3.09)	1.33 (1.02-1.72)

Risk of outcomes with decreased KF among older adults

## TH-PO776

**Perspectives of Pakistani Dialysis Patients on the Financial and Psychological Impact of Dialysis, Dialysis Decision Making, Prognostic Understanding, Use of Alternative Medicine, and End-of-Life Care**  
Sheza Malik,<sup>1</sup> Ayesha Anwar,<sup>4</sup> Rebecca J. Allen,<sup>3</sup> Abdullah Zaki,<sup>5</sup> Fahad Saeed.<sup>2</sup> *<sup>1</sup>Rochester General Health System, Rochester, NY; <sup>2</sup>University of Rochester, Rochester, NY; <sup>3</sup>Mount St. Joseph University, Cincinnati, OH; <sup>4</sup>Allam Iqbal Medical College, Lahore, Pakistan; <sup>5</sup>Shifa International Hospitals Ltd, Islamabad, Pakistan.*

**Background:** With the increasing prevalence and mortality of end-stage kidney disease (ESKD) in developing countries, it is imperative to examine these patients' experiences with dialysis care and their attitudes toward end-of-life decisions.

**Methods:** Using convenience sampling methodology, we surveyed 221 patients (221/245, 90% response rate) receiving dialysis at five different dialysis facilities in Pakistan. The survey comprised 52 questions in Urdu to seek patients' perspectives on the impact of financial difficulties on the receipt of regular dialysis, the psychological impact of chronic dialysis, dialysis decision making, prognostic understanding, use of alternative medicine, and preparation for end-of-life care. Survey questions were administered orally to all participants.

**Results:** The mean age of the participants was 46.3 $\pm$ 9.1 years, and 97.7% were Muslims. About 72% were married. Fifty-eight percent reported difficulty managing their finances due to the cost of dialysis. In addition, nearly 57% suggested establishing free dialysis facilities. A majority (77%) expressed a lack of understanding and knowledge about chronic kidney disease (CKD) and the available treatment options for end-stage kidney disease. Some (12%) used alternative medicine to treat their CKD. Nearly two-thirds (75%) cited faith as their greatest motivation for continuing with dialysis despite the adverse psychological effects of dialysis (29%) and feelings of social isolation (29%). The majority (81%) felt their prognosis was  $>10$  years. Patients reported feeling almost evenly split on choosing between a comfort-based only (39%) and a life-prolonging

approach (41%), while the remaining 20% have not thought about it. Most patients did not talk to anyone about their end-of-life care (91%) and did not have a living will (96.4%).

**Conclusions:** Our study highlights major lapses in the care of Pakistani patients receiving maintenance dialysis and calls for greater awareness of kidney disease among the general population and more financial and psychosocial support for dialysis patients. Amidst major financial challenges that these patients face, honest yet compassionate prognostic conversations are still needed to facilitate end-of-life planning.

## TH-PO777

**The Effectiveness of SPIRIT in Preparing Patients on Dialysis and Their Surrogates for End-of-Life Decision Making: A Pragmatic Trial**

Mi-Kyung Song,<sup>1</sup> Maureen J. Metzger,<sup>2</sup> Amita Manatunga,<sup>1</sup> Emily Wu,<sup>1</sup> Jacob R. Englert,<sup>1</sup> Abhijit V. Kshirsagar,<sup>3</sup> Janice P. Lea,<sup>1</sup> Laura Plantinga,<sup>1</sup> Emaad M. Abdel-Rahman,<sup>2</sup> Sandra E. Ward,<sup>4</sup> Manisha Jhamb,<sup>5</sup> Mary C. Laszlo,<sup>1</sup> Souad Benloukil,<sup>2</sup> Linda Turberville-Trujillo.<sup>1</sup> SPIRIT Trial Investigators <sup>1</sup>Emory University, Atlanta, GA; <sup>2</sup>University of Virginia, Charlottesville, VA; <sup>3</sup>University of North Carolina System, Chapel Hill, NC; <sup>4</sup>University of Wisconsin-Madison, Madison, WI; <sup>5</sup>University of Pittsburgh, Pittsburgh, PA.

**Background:** SPIRIT (Sharing Patient's Illness Representations to Increase Trust), a patient and family-centered advance care planning intervention with established efficacy in preparing patients on dialysis and their surrogates (dyads) for difficult end-of-life decision making, was tested for its real-world effectiveness when implemented as part of routine dialysis care.

**Methods:** In this cluster randomized trial, 39 outpatient dialysis clinics across 5 states (GA, NC, VA, PA, NM) were randomized by state and clinic size (22 intervention and 17 usual care). Each clinic selected at least one SPIRIT Champion (SWs, RNs, or APRNs) to identify potential patients and, in the intervention clinics, to conduct SPIRIT sessions with the dyads. SPIRIT included a 45- to 60-min. counseling session to help the patient articulate his/her values and to help the dyad understand likely end-of-life decision-making situations. A brief follow-up session was provided as needed. The preparedness outcomes (dyad congruence, patient decisional conflict, surrogate decision-making confidence, and a composite of congruence and surrogate confidence) were assessed at baseline and 2 weeks postintervention by phone.

**Results:** 426 patients and their chosen surrogates (231 dyads from intervention and 195 from usual care clinics) completed the baseline measures and were included in ITT analyses using GEEs. The sample included 72% dyads from minority groups, 51.2% women; patients were 61.9 years old ( $SD=12.7$ ) and on dialysis for 4.6 years ( $SD=5.2$ ) and 16% had an advance directive. Changes in dyad congruence ( $OR=1.6$ ,  $p=.01$ ), patient decisional conflict ( $b=-.1$ ,  $p<.001$ ), and the composite outcome ( $OR=1.6$ ,  $p=.03$ ) were better in SPIRIT than usual care, and these treatment effects were greater in non-white dyads

**Conclusions:** SPIRIT was associated with improvements in dyad preparation for end-of-life decision making in a real-world dialysis care setting, with treatment effects comparable to those seen in previous efficacy trials of SPIRIT.

**Funding:** Other NIH Support - NINR

## TH-PO778

**Informal Caregiving Networks of Older Adults With Dementia Superimposed on ESRD: A Social Network Study**

Mi-Kyung Song,<sup>1</sup> Sudeshna Paul,<sup>1</sup> Mary Beth Happ,<sup>2</sup> Janice P. Lea,<sup>1</sup> Linda Turberville-Trujillo,<sup>1</sup> James L. Pirkle.<sup>3</sup> *<sup>1</sup>Emory University, Atlanta, GA; <sup>2</sup>The Ohio State University, Columbus, OH; <sup>3</sup>Wake Forest University School of Medicine, Winston-Salem, NC.*

**Background:** It is common for older adults with ESRD to have multiple caregivers to provide instrumental help and care-related decision making. Yet, most caregiving research has been focused on the primary caregivers. This study was to characterize informal/unpaid caregiving networks of older adults with moderate to severe cognitive impairment superimposed on ESRD and their associations with caregiver and older adult health outcomes.

**Methods:** We conducted an egocentric social network study to obtain caregiving information of 46 older adults on hemodialysis with cognitive impairment. Starting with the primary family caregiver (FCG), up to 2 additional FCGs were recruited for each patient, totaling 76 FCGs (46 primary, 30 non-primary). FCGs completed a social network survey and measures of caregiving burden and reward, financial hardship, and depressive symptoms. We abstracted information about patient's ED visits and hospital admissions during the past 12 months from the medical records.

**Results:** Most patients were Black ( $n=35$ , 77.8%), 22 (47.8%) were male. The mean age was 73.9 years. Most FCGs were a child of the patient ( $n=39$ , 51.3%) and female ( $n=57$ , 75%), and had a mean age of 54.2 years. Of the 46 networks, 16 (35%) included only one FCG (singletons). Multimember networks ( $n=30$ , 65%) provided longer caregiving than singletons (7.7 vs 3.8 years,  $p=0.008$ ). The average network size was 3.8. The density (overall member connection) was 0.9, and mean degree and maximum degree (number of ties per member to other network members) were 2.5 and 2.8, respectively. Among the caregiver outcomes, the primary FCG's financial hardship decreased as the network density increased but at the expense of increased non-primary FCGs' financial hardship ( $p<0.001$ ). For every one unit increase in mean and maximum degrees, the odds of no hospital admission increased by 3.7 ( $p=0.03$ ) and 3.6 folds ( $p=0.04$ ), respectively.

**Conclusions:** Our study using a social network approach revealed the scope and potential impact of informal caregiving networks of older adults with ESRD and dementia. Our findings may have significant implications for future intervention development and implementation strategies targeting ESRD population and caregivers but need to be confirmed in a larger, longitudinal study.

## TH-PO779

### Prevalence, Overlap, and Prognostic Impact of Multiple Frailty Domains in Older Patients on Hemodialysis

Keigo Imamura,<sup>1,2</sup> Shohei Yamamoto,<sup>3</sup> Yuta Suzuki,<sup>4</sup> Shun Yoshikoshi,<sup>1</sup> Juri Uchida,<sup>1</sup> Takuya Nakajima,<sup>1</sup> Narumi Fukuzaki,<sup>1</sup> Manae Harada,<sup>5</sup> Atsuhiko Matsunaga.<sup>1</sup> <sup>1</sup>Kitasato University Graduate School of Medical Sciences, Sagami-hara, Japan; <sup>2</sup>Tokyo Metropolitan Institute of Gerontology, Itabashi, Japan; <sup>3</sup>Center for Clinical Sciences, National Center for Global Health and Medicine, Shinjuku, Japan; <sup>4</sup>National Institute of Public Health, Wako, Japan; <sup>5</sup>Sagami Circulatory Organ Clinic, Sagami-hara, Japan.

**Background:** Frailty is a state of increased vulnerability due to adverse health outcomes and is recognized as a multidimensional construct comprising physical, psychological, and social domains. There is limited evidence, however, on the association between multiple domains of frailty and risks of adverse events in patients undergoing hemodialysis (HD). Here we report the prevalence, degree of overlap, and prognostic impact of multiple frailty domains in older patients with HD.

**Methods:** Outpatients (aged  $\geq 60$  years) who underwent HD between 2017 and 2020 were retrospectively enrolled. Outcomes were all-cause mortality and hospitalization. We used the Cox proportional hazard model for examine the associations.

**Results:** Among 344 older patients (mean age, 72 years; 61% were male), the prevalence of physical, psychological, and social domains of frailty was 56.7%, 26.7%, and 57.3%, respectively. In addition, 15.4% of patients had overlap in all three domains. In the Cox model, the greater number of frailty domains was associated with higher risks of all-cause mortality (P for trend=0.001, Figure 1) and hospitalization (P for trend<0.001, Figure 2).

**Conclusions:** Older patients with HD had overlapping frailty domains, which were associated with poor prognosis. These results suggest that multidimensional assessment of frailty is important for disease management in patients requiring HD.

**Funding:** Government Support - Non-U.S.

Figure 1. Associations between number of frailty domains and all-cause mortality.

CI: confidence interval; HR: hazard ratio. Incidence rate\* = Incidence rate per 100 person-years.

Adjusted for age, sex, body mass index, hemodialysis vintage, comorbidity score, serum albumin, C-reactive protein. 0 to 3 indicates the number of frailty domains. Higher number indicates more severe frailty.

Figure 2. Associations between number of frailty domains and all-cause hospitalization.

CI: confidence interval; HR: hazard ratio. Incidence rate\* = Incidence rate per 100 person-years.

Adjusted for age, sex, body mass index, hemodialysis vintage, comorbidity score, serum albumin, C-reactive protein. 0 to 3 indicates the number of frailty domains. Higher number indicates more severe frailty.

## TH-PO780

### Validation of the Novel "Race Free" CKD-EPI Equation in Persons Aged 70 and Older: The Berlin Initiative Study

Natalie Ebert,<sup>1</sup> Hans Pottel,<sup>2</sup> Pierre Delanaye,<sup>3</sup> Markus van der Giet,<sup>1</sup> Martin K. Kuhlmann,<sup>4</sup> Elke Schaeffner.<sup>1</sup> <sup>1</sup>Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>KU Leuven University, Kortrijk, Belgium; <sup>3</sup>Sart Tilman University, Liège, Belgium; <sup>4</sup>Vivantes Klinikum im Friedrichshain, Berlin, Germany.

**Background:** The creatinine-based CKD-EPI (AS) equation from 2009 (AS: age, sex, and race) has been replaced by the CKD-EPI (AS) equation using the same mathematical form without the race variable because the former has been considered a source of discrimination. NKF recently recommended using the "race free" CKD-EPI (AS) equation for patients in the US. It is unclear whether this is favorable for older patients. Our study compares the performance of CKD-EPI (AS), CKD-EPI (ASR), and the European Kidney Function Consortium (EKFC) equation.

**Methods:** We analyzed data from 570 participants of the "Berlin Initiative Study" (BIS), a community-dwelling cohort of white older adults. We measured GFR (mGFR) with iothexol plasma clearance as gold standard. We calculated bias as estimated GFR (eGFR) minus mGFR, precision (interquartile range, IQR), and accuracy (P30: percentage of eGFR values within  $\pm 30\%$  mGFR). CKD-EPI (ASR), CKD-EPI (AS) and EKFC equations were validated using mGFR.

**Results:** Mean age was 78.5 yrs, 57% were male, and mean mGFR was 60.3 ml/min/1.73m<sup>2</sup>. Mean Bias for CKD-EPI (AS) was highest with 13.0 compared to 8.4 and 1.6 ml/min/1.73m<sup>2</sup> for CKD-EPI (ASR) and EKFC (Tbl. 1). P30 value was lowest for CKD-EPI (AS) (67%) compared to CKD-EPI (ASR, 81%) and EKFC (92%). Stratified by age ( $\geq 80$  yrs) and mGFR (mGFR  $< 60$ ), we found even worse P30 results for CKD-EPI (AS) with 58% and 52% (Fig. 1).

**Conclusions:** In the US, the novel "race-free" CKD-EPI (AS) equation is recommended for diagnosing CKD. Our results suggest that CKD-EPI (AS) leads to a considerable systematic overestimation and worse prediction of eGFR in older patients. In pts. with GFR  $< 60$ , P30 was even worse with only 52%, enhancing the risk of drug overdosing and delayed CKD diagnosis.

**Funding:** Private Foundation Support

Table 1. Bias, precision and accuracy

All n = 570	Bias [95%CI]	IQR [Pct25; Pct75]	P30 [%]
CKD-EPI (ASR)	8.40 [7.0; 9.0]	12.8 [1.7; 14.4]	81.4 [78.2; 84.6]
CKD-EPI (AS)	13.0 [12.1; 14.0]	13.8 [6.0; 19.8]	66.5 [62.6; 70.4]

TH-PO781

**Potassium Diet Restriction in Elderly Patients With CKD: Is It Needed?**  
Mariana L. Inneccchi,<sup>1</sup> Carla M. Avesani,<sup>2</sup> Venceslau A. Coelho,<sup>1</sup> Julia Lauar,<sup>1</sup> Tiago E. Costa,<sup>1</sup> Rosa M. Moyses,<sup>1</sup> Rosilene M. Elias.<sup>1</sup> <sup>1</sup>Universidade de Sao Paulo Instituto de Ciencias Biomedicas, Sao Paulo, Brazil; <sup>2</sup>Karolinska Institutet, Stockholm, Sweden.

**Background:** Most guidelines in chronic kidney disease (CKD) advise that potassium (K+) intake is to be restricted if hyperkalemia is present. For older patients with CKD, this dietary recommendation which decreases the intake of vegetables, legumes, fruits, and whole cereals may lead to poor diet and predispose the development of malnutrition and sarcopenia. Since observational studies have challenged the association between K intake and hyperkalemia, we aimed to investigate in a group of older patients with CKD the association between K+ intake and serum K+.

**Methods:** This is a cross-sectional analysis of patients > 70 yrs. with stage 4/5 CKD on conservative management. We assessed dietary K+ intake by 24-hour dietary recall. Hyperkalemia was defined as K > 5.0mmol/L.

**Results:** We included 54 patients (81 ± 7 yr, 59.3% men, body mass index 25.5 ± 4.4 kg/m<sup>2</sup>, 61.1% diabetic, eGFR 20.1 ± 6.9 ml/min, 20.4% below recommended weight). Hyperkalemia was found in 19 patients (35.2%), being more frequent among diabetics (80% vs 20% of non-diabetics, p=0.014). Serum K+ did not correlate with eGFR, albumin, sex, age, or urea. K+ dietary intake and serum K+ were 1,375 mg/day (870-1,812) and 4.8 ± 0.6 mEq/L, respectively, without a significant correlation between them (r=0.210, p=0.160). Also, K+ intake was similar between patients with and without hyperkalemia [1,581 (863-2,000) and 1,375 (878-1,543), p=0.363].

**Conclusions:** Older patients with moderate/advanced CKD did not have a high K+ intake and it was not associated with serum K+. Considering that these patients may be at risk for malnutrition, a K+ dietary restriction must be individually evaluated considering the patients clinical and nutritional condition.

TH-PO782

**Restriction of Protein: Leveraging the Risk of Sarcopenia and the Progression of CKD in Older Patients**  
Mariana L. Inneccchi,<sup>1</sup> Carla M. Avesani,<sup>2</sup> Venceslau A. Coelho,<sup>1</sup> Julia Lauar,<sup>1</sup> Tiago E. Costa,<sup>1</sup> Rosa M. Moyses,<sup>1</sup> Rosilene M. Elias.<sup>1</sup> <sup>1</sup>Universidade de Sao Paulo Instituto de Ciencias Biomedicas, Sao Paulo, Brazil; <sup>2</sup>Karolinska Institutet, Stockholm, Sweden.

**Background:** Most guidelines recommend a restriction in protein intake to slow the progression of CKD. However, older patients are at high risk for sarcopenia which can be worsened with low energy and protein intake. Since older patients are often excluded from clinical trials, there is a scarcity of data to support this recommendation in this population. We aimed to evaluate nutritional status and sarcopenia in older patients with CKD.

**Methods:** This is a cross-sectional analysis of older patients (>70 yr) with stage 4 and 5 CKD on conservative management. We assessed biochemical data, 24-hour dietary recall, skinfold thicknesses, and other anthropometric measurements. Sarcopenia was assessed by the SARC-F and SARCF-Calf circumference (SARCF-CC) questionnaires (higher scores indicate higher risk for sarcopenia).

**Results:** We included 54 patients (81 ± 7 yr, 59.3% men, body mass index 25.5 ± 4.4 kg/m<sup>2</sup>, 61.1% diabetes, eGFR 20.1 ± 6.9 ml/min, 20.4% below recommended weight). Patients were divided in 3 groups: 70-80, 81-90 and > 90 yr. (Table 1). Body mass index, CC and percentage of body fat were lower in those >90yr, for similar renal function. SARCF was similar among groups (p=0.348) and SARCF-CC was higher among patients >90 yr (p=0.031). Adherence to ingesting protein intake 0.6-0.8g/Kg was followed by 26.9%, 21.1% and 11.1 % of patients in groups 70-80, 80-90 and > 90yr, respectively (p=0.065).

**Conclusions:** This analysis suggests that the older patients, particularly those > 90yr, are more susceptible to malnutrition and sarcopenia. Therefore, protein-restricted diets must be considered with caution according to the patients clinical and nutritional condition to avoid further worsening in the nutritional status.

**Older Patients' and Caregivers' Perspectives on Kidney Therapy Decision-Making**  
Ramya Sampath,<sup>1</sup> Sandhya Seshadri,<sup>1</sup> Tramanh Phan,<sup>1</sup> Paul Duberstein,<sup>2</sup> Ronald M. Epstein,<sup>1</sup> Fahad Saeed.<sup>1</sup> <sup>1</sup>University of Rochester Medical Center, Rochester, NY; <sup>2</sup>Rutgers School of Public Health, Piscataway, NJ.

**Background:** Growing evidence suggests that dialysis may not significantly improve survival or quality of life (QOL) for some older, frail patients with significant comorbidities. Studies also suggest that decisions to initiate dialysis are not always concordant with patients' expressed treatment preferences. Thus, it is critical to gain knowledge of patients' and their caregivers' perspectives on kidney therapy (KT) decision-making. Our study describes the perceptions and preferences of older adults and their caregivers during KT decision-making.

**Methods:** We designed a survey and administered it orally to ascertain patients' and caregivers' perceptions and preferences regarding KT decisions. Our sample included 26 patients and 15 caregivers enrolled in the intervention arm of the CKD-EDU Study, a palliative care intervention to help older adults and their caregivers with KT decision-making. Using qualitative content analysis, four study team members individually coded the data and met regularly to review the coded data. Consistent with qualitative research methods, differences were resolved through discussion and consensus to enhance rigor.

**Results:** The average ages of patients and caregivers were 82.7± 5.7 years and 66.4 ± 13.7 years respectively. Thirteen patients and eleven caregivers were women; twenty patients and twelve caregivers were White. Four overarching themes of patient and caregiver perceptions and preferences regarding KT decision-making emerged: 1) It is important for patients to both prolong life and have good a quality of life; 2) Some patients' desires for longevity conflicted with their preferred treatment choices; 3) Thoughts of CKD progression and consequences of treatment options on QOL were worrisome; 4) "Deciding not to decide" was a common way to cope with stressors of decision-making and to maintain a sense of control.

**Conclusions:** Patients' and caregivers' preferences for KT options are multifaceted and affect-laden. Improved communication and shared decision-making to improve KT decision-making are necessary to ensure goal-concordant care for older adults.

**Funding:** Other NIH Support - KL2 Grant funded by the NIH Renal Research Institute (NCT03465449)

TH-PO784

**Outcomes of Palliative Care Consultation in Patients With CKD Hospitalized With Acute Stroke**  
Areeba Jawed,<sup>1</sup> Fahad Saeed,<sup>2</sup> James Slaven,<sup>3</sup> Amber Comer.<sup>3</sup> <sup>1</sup>University of Michigan Michigan Medicine, Ann Arbor, MI; <sup>2</sup>University of Rochester School of Medicine and Dentistry, Rochester, NY; <sup>3</sup>Indiana University School of Medicine, Indianapolis, IN.

**Background:** There is a heightened mortality risk for patients with Chronic Kidney Disease (CKD) hospitalized with acute stroke. Both American Heart Association and American Stroke Association endorse involvement of palliative care in these patients.

**Methods:** We report a secondary analysis of a retrospective observational study performed in adult patients with CKD discharged with a diagnosis of acute ischemic stroke from four large, urban hospitals in the mid-west between January 2016 to December 2018. We obtained data on demographics, co-morbid conditions, code status on admission and discharge, involvement of ethics and spiritual care and palliative care services. We compared outcomes between acute stroke patients with CKD who received a palliative care consultation versus those who did not. Outcome measures included:in-hospital mortality, mechanical ventilation, tracheostomy, artificial Nutrition/gastrostomy tube, thrombolytic therapy (tPA), thrombectomy, ICU Admission, dialysis, cardiopulmonary resuscitation, and end-of-life quality measures including completion of advanced care directives and documentation of goals of care conversations.

**Results:** Among the 1480 patients (mean age = 73.1±14.4, 57.3% female, and 75.2% white) admitted with acute stroke, 206 had CKD stages 3-5D, and 26.2% (n=54) were seen by palliative care. Those who received palliative care consultation were older (mean age 81.1 vs. 70.2, p<0.0001), had do-not-resuscitate code status at discharge (77.8% vs. 24.3%, OR=10.88 (5.19, 22.82) p<.0001), and were more likely to receive spiritual care (81.5% vs. 57.9%, OR=3.20 (1.50, 6.83), p<0.0001). A higher proportion of patients seen by palliative care died during the same hospitalization (32.1% vs. 10.6%, OR=3.98 (1.84, 8.65), p=.0003), enrolled in hospice (24.5% vs. 4.0%, OR=7.91 (2.83, 22.11), p<.0001), transitioned to comfort care (51.9% vs. 11.9%, OR=7.96 (3.85, 16.45), p<.0001), discontinued artificial nutrition (25.9% vs. 4.6%, OR=7.20 (2.72, 19.04, p <0.0001, and had vent withdrawn: 16.7% vs. 6.6%, OR=2.82 (1.08, 7.37); p=.0289 at discharge.

**Conclusions:** Palliative Care consultation is associated with improved end of life quality outcomes and an increase in hospice enrollment in patients with acute stroke and CKD.

## TH-PO785

**Older Patients Are Less Prone to Fast Decline of Renal Function: A Propensity-Matched Study**

Paula M. Pina, Luis C. Arcon, Roberto Zatz, Rosa M. Moyses, Rosilene M. Elias. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

**Background:** Although Chronic Kidney Disease (CKD) is common among aging patients, and although factors associated with its progression have been studied over decades, little is known about the rate of renal functional decay in this population.

**Methods:** Between January 2012 and December 2017, we included 1071 adult CKD patients on conservative treatment in a 1:1 propensity-score matched study of older (O, >65yr) and younger (Y, ≤65yr) individuals. Factors associated with the slope of the decline of eGFR (S), such as proteinuria, initial eGFR, diabetes, sex, and use of angiotensin-converting enzyme inhibitors/angiotensin receptor blockers (ACEI/ARB) were analyzed. Inclusion criteria were at least two consultations in the service, and an initial eGFR lower than 45 mL/min/m<sup>2</sup>. Patients were classified as fast progressors when S exceeded 5 mL/min/1.73 m<sup>2</sup>/yr.

**Results:** Crude analysis of eGFR decline showed slower progression of O when compared to Y, both in terms of absolute change [-2.0 (-4.5, -1.0) vs. -3.0 (-7.0, -1.0) mL/min/1.73m<sup>2</sup>, p<0.001] and of S [-2.2 (-4.4, -1.0) vs. -3.1 (-6.7, -1.2) mL/min/1.73m<sup>2</sup>, p<0.001]. Patients considered fast progressors were less likely to be older (35.2% younger vs. 22.0% older, p<0.001). Accordingly, adjusted logistic multivariate regression revealed that the odds ratio of fast eGFR decline was lower in O than in Y (p=0.0001), independently of proteinuria (p=0.063), diabetes (p=0.017), ACEI/ARB use (p=0.0001), sex (p=0.0001), or baseline values for eGFR (p=0.001), phosphate (p=0.0001) and 25(OH) vitamin D (p=0.0001). The reasons for these differences between O and Y are unclear.

**Conclusions:** In patients over 65 years of age, CKD progression was slower than in younger patients even after multiple adjustments. This finding should be taken into consideration during both conservative management and preparation for dialysis.

**Funding:** Government Support - Non-U.S.

Odds ratio of fast progressor of renal function decline, defined as a reduction above 5 mL/min/1.73m<sup>2</sup>/year

## TH-PO786

**Risks Associated With Low eGFRcr, eGFRcys, and eGFRcr-cys at Older Age**

Edouard Fu,<sup>1,2</sup> Juan J. Carrero,<sup>3</sup> Yingying Sang,<sup>4</sup> Marie Evans,<sup>3</sup> Shoshana Ballew,<sup>4</sup> Lesley A. Inker,<sup>5</sup> Morgan Grams,<sup>4</sup> Andrew S. Levey,<sup>5</sup> Josef Coresh,<sup>4</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>Karolinska Institutet, Stockholm, Sweden; <sup>4</sup>Johns Hopkins University, Baltimore, MD; <sup>5</sup>Tufts Medical Center, Boston, MA.

**Background:** Understanding the risk consequences of CKD at older age has often been limited to kidney failure replacement therapy (KFRT) and all-cause mortality (ACM), and to GFR estimated using serum creatinine (eGFRcr). However, eGFRcr may be falsely elevated in the elderly due to low muscle mass. We sought to compare the risks of several clinically relevant outcomes associated with both eGFR<sub>cr</sub> and cystatin C-based eGFR (unrelated to muscle mass), in elderly patients in routine health care.

**Methods:** We included all 79,995 patients (mean age 77 years, 50% female) in Stockholm region, Sweden (SCREAM) age 65+ years who undertook routine outpatient tests of IDMS calibrated creatinine and cystatin C on the same day during 2011-2018. We modeled CKD-EPI eGFR using creatinine (eGFRcr), cystatin C (eGFRcys) or both (eGFRcr-cys) as a spline in adjusted negative binomial and Cox regressions of subsequent risk for 7 clinical outcomes: acute kidney injury, KFRT, any hospitalization, heart failure hospitalization, major adverse cardiovascular events, cardiovascular and all-cause mortality.

**Results:** 22% of older adults with creatinine testing also had routine cystatin C measurements. **Figure 1** shows the HRs for each outcome at eGFR 30 or 60 vs. 80 mL/min/1.73m<sup>2</sup> by age group. Overall, eGFRcr was not as consistently associated across the range of outcomes as eGFRcys or eGFRcr-cys, especially at greater age. A

U-shaped relationship was observed for all-cause mortality, cardiovascular mortality and hospitalization for eGFRcr, but not for eGFRcys or eGFRcr-cys (**Figure 2**).

**Conclusions:** eGFRcys and eGFRcr-cys reveal risk associations which are missed by eGFRcr. The U-shaped relationship with eGFRcr, not seen for eGFRcys, suggests the increased risk at high eGFRcr is associated with low creatinine generation, not true high GFR. Looking at outcomes beyond KFRT and mortality and using cystatin C allows for a better understanding of risks in CKD.

## TH-PO787

**Rates and Predictors of Mortality in Different Age Groups of Elderly With Maintenance Hemodialysis: A Large Observational Cohort Study in 17,354 Patients**

Kajohnsak Noppakun,<sup>1,2</sup> Chidchanok Ruengorn,<sup>2,3</sup> Apichat Tantraworasin,<sup>2,4</sup> Jiraporn Khorana,<sup>4</sup> <sup>1</sup>Division of Nephrology, Department of Internal Medicine, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand; <sup>2</sup>Pharmacoeconomics and Statistics Research Center (PESRC), Faculty of Pharmacy, Chiang Mai University, Chiang Mai, Thailand; <sup>3</sup>Department of Pharmaceutical Care, Faculty of Pharmacy, Chiang Mai University, Chiang Mai, Thailand; <sup>4</sup>Clinical Epidemiology and Clinical Statistic Center, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand.

**Background:** Maintenance hemodialysis (MHD) is a life-saving procedure for end-stage kidney disease (ESKD) patients. Although there is no age limit for an initiation of MHD, survival benefits of HD in very elderly patients are questionable. We aimed to identify the groups of elderly patients who have high mortality rates after an initiation of MHD.

**Methods:** Elderly (≥70 years) patients initiated MHD between Jan 2005 and Dec 2020 were recruited. All data were retrieved from Thailand Renal Replacement Therapy Registry data. Patients were divided into 3 groups according to the age at dialysis initiation: 70 to <85 (n=15955), 85 to <90 (n=1151), and ≥90 years (n=248).

**Results:** 17,354 patients were recruited, 46.46% were male with mean age of 76.9±5.1 years. The total mortality rate was 36.35% with the median (IQR) follow-up time of 40.45 (0.03-192.1) months and the total time-at-risk of 76,624 years. Comparing with the group aged 70 to <85 years, the group aged 85 to <90 and ≥90 years had increased risk of death with hazard ratio (HR) 1.93 (95%CI 1.76-2.13; p<0.001) and 3.06 (95%CI 2.51-3.74; p<0.001), respectively. About 82.2% (95%CI 81.6-82.8) of the patients aged between 70 and <85 years died during 7-8 years after dialysis initiation, while 81.4% (95%CI 79.3-83.4) of patients ≥85 years of age died during 4-5 years after dialysis initiation. From multivariable analyses, predictors for mortality in the group ≥85 years of age were Karnofsky Performance Status Scale (KPSS) ≤50 (vs ≥60) with HR 4.56 (95%CI 1.57-13.29; p=0.005), eGFR at dialysis initiation ≥7 mL/min/1.73m<sup>2</sup> (vs <7) with HR 2.26 (95%CI 1.11-4.60; p=0.024), and serum albumin <3.5 g/dL (vs ≥3.5) with HR 2.22 (95%CI 1.19-4.15; p=0.012). The HR for death in patients ≥85 years of age with combination of the three potential predictors; KPSS ≤50 and eGFR ≥7 mL/min/1.73m<sup>2</sup> and serum albumin at dialysis initiation <3.5 g/dL, was 5.02 (95%CI 2.12-11.88; p<0.001) compared to patients in the same age group without those characteristics.

**Conclusions:** In elderly with ESKD, MHD is justified in patients aged between 70 and 85 years as most of them had reasonable survival rates. However, in patients who were older than 85 years, mortality rate was high in those with KPSS ≤50, eGFR ≥7 mL/min/1.73m<sup>2</sup> and serum albumin at dialysis initiation <3.5 g/dL.

## TH-PO788

**Protein Biomarkers Associated With Cardiovascular Events in Older People With Advanced CKD: Results From the EQUAL Study**

Samantha J. Hayward,<sup>1,2</sup> Nicholas C. Chesnaye,<sup>3</sup> Barnaby D. Hole,<sup>4,2</sup> Ryan E. Aylward,<sup>4</sup> Yvette Meuleman,<sup>5</sup> Claudia Torino,<sup>6</sup> Gaetana Porto,<sup>7</sup> Maciej Szymczak,<sup>8</sup> Christiane Drechsler,<sup>9</sup> Friedo W. Dekker,<sup>5</sup> Marie Evans,<sup>10</sup> Kitty J. Jager,<sup>3</sup> Christoph Wanner,<sup>9</sup> Fergus Caskey,<sup>4,2</sup> <sup>1</sup>University of Bristol Translational Health Sciences, Bristol, United Kingdom; <sup>2</sup>Southmead Hospital, Bristol, United Kingdom; <sup>3</sup>ERA-EDTA Registry, Amsterdam, Netherlands; <sup>4</sup>Population health sciences, Bristol Medical School, Bristol, United Kingdom; <sup>5</sup>Leids Universitair Medisch Centrum Afdeling Klinische Epidemiologie, Leiden, Netherlands; <sup>6</sup>Istituto di Fisiologia Clinica Consiglio Nazionale delle Ricerche Sezione di Reggio Calabria, Reggio Calabria, Italy; <sup>7</sup>GOM Bianchi Melacrino Morelli, Reggio Calabria, Reggio Calabria, Italy; <sup>8</sup>Uniwersytet Medyczny im Piastów Śląskich we Wrocławiu Katedra i Klinika Nefrologii i Medycyny Transplantacyjnej, Wrocław, Poland; <sup>9</sup>Division of Nephrology, University Hospital of Würzburg, Würzburg, Germany; <sup>10</sup>Karolinska Institutet, Stockholm, Sweden.

**Background:** Cardiovascular disease is the leading cause of morbidity and mortality in people with chronic kidney disease (CKD). We investigated a panel of proteins associated with inflammatory and cardiovascular disease to determine their potential as biomarkers for major cardiovascular events (MACE) amongst individuals with CKD.

**Methods:** The EQUAL study enrolled people aged ≥65 years with eGFR ≤20. EQUAL recruits were split into Discovery (n=611) and Replication cohorts (n=292). Baseline blood samples were tested for 184 proteins using OLINK proximity extension assay technology. Cox proportional hazard models adjusted for age, sex, eGFR and country were used to determine the risk of MACE. Proteins with false discovery rate

(FDR) values <0.05 in the Discovery cohort were considered significant and were tested in the Replication cohort. Sensitivity analyses, adjusting for traditional (hypertension, diabetes, previous myocardial infarction, cholesterol, smoking and body mass index) and CKD-specific (calcium, phosphate and PTH) risk factors for MACE, were performed.

**Results:** During a median follow-up of 2.9 years 325 people (36%) had MACE. 63 proteins were associated with MACE in the Discovery cohort (FDR p values <0.05); 12 of these proteins had similar effect sizes in the Replication cohort (Figure 1). Tenascin, Vascular cell adhesion protein 1 (VCAM1), V-set and Immunoglobulin Domain containing protein 2 (VSIG2) and Fibroblast growth factor 23 (FGF23) maintained their association with MACE after adjustment for traditional and CKD-specific risk factors.

**Conclusions:** Increased levels of Tenascin, VCAM1, VSIG2 and FGF23 were associated with an increased risk of MACE in older people with advanced CKD. Our findings highlight VSIG2 as a new potential cardiovascular biomarker and corroborate those of previous studies linking Tenascin, VCAM1 and FGF23 with MACE in people with CKD.

TH-PO789

**Indoxyl Sulfate Mediated Lower Handgrip Strength, in Comparison With Sarcopenia, Was Predictive of Higher Hospitalization in ESRD Patients**  
Yi-Chou Hou,<sup>1</sup> Kuo-Cheng Lu,<sup>2</sup> <sup>1</sup>Cardinal Tien Hospital, New Taipei City, Taiwan; <sup>2</sup>Taipei Tzu Chi Hospital, New Taipei City, Taiwan.

**Background:** Sarcopenia is common in patients with chronic kidney disease (CKD)/end stage kidney disease (ESRD) than in normal patients. Lower handgrip strength, in comparison with sarcopenia, is associated with clinical outcome including cardiovascular mortality and hospitalization in CKD subjects. The study is to elucidate if uremic toxin contributes to the lower handgrip strength in CKD/ESRD patients.

**Methods:** The participants of the study were divided into three groups: control group (estimated glomerular filtration rate [eGFR] ≥ 60 mL/min), advanced CKD (eGFR = 15–60 mL/min), and ESRD (under maintenance renal replacement therapy). All participants received handgrip strength measurement, dual-energy X-ray absorptiometry, blood sampling for myokine and indoxyl sulfate. Sarcopenia was with lower appendicular skeletal muscle index (appendicular skeletal muscle/height<sup>2</sup>) of <7.0 kg/m<sup>2</sup> in men and <5.4 kg/m<sup>2</sup> in women) and lower handgrip strength (handgrip strength of <28 kg in men and <18 kg in women).

**Results:** The ESRD group had the highest number of participants with lower handgrip strength (41.6% vs 25% and 5.85% in the control and CKD groups, respectively, p < 0.05). The percentage of sarcopenia was similar between group (p=0.864). Lower handgrip strength was associated with higher hospitalization within total population (p=0.02) during 600 days of following up. The serum concentration of indoxyl sulfate was higher in the ESRD group (227.29±92.65uM, vs 41.97 ±43.96uM for CKD group and 6.54±3.45uM for control group, p<0.05). Indoxyl sulfate was associative to lower handgrip strength in univariate (OR: 3.485, 95%CI:1.372-8.852, p=0.001) and multivariable logistic regression (OR: 8.525, 95% CI:1.807-40.207, p=0.007).

**Conclusions:** Handgrip strength was lower in the ESRD patients. The lower handgrip strength was predictive to the hospitalization in the total population. Indoxyl sulfate contributed to lower handgrip strength associated with lower handgrip strength and counteract the effect of myokine in CKD patients.

	Univariates (95%CI)	p value	Multivariates	p value

**The Prevalence of Sarcopenia and Its Impact on CV Events and Mortality Among ESKD Patients on Dialysis: A Systematic Review and Meta-Analysis**  
Wannasit Wathanavasin,<sup>1</sup> Athiphat Banjongjit,<sup>2</sup> Yingyos Avihingsanon,<sup>2</sup> Kearkiat Praditpornsilpa,<sup>2</sup> Somchai Eiam-Ong,<sup>2</sup> Paweena Susantitaphong,<sup>2</sup> <sup>1</sup>Charoenkrung Pracharuk Hospital, Bangkok, Thailand; <sup>2</sup>King Chulalongkorn Memorial Hospital, Bangkok, Thailand.

**Background:** Sarcopenia in end stage kidney disease (ESKD) patients requiring dialysis is a frequent complication but remains under-recognized problem. This meta-analysis was conducted to determine the global prevalence of sarcopenia and explore whether it impacts on the clinical outcomes especially cardiovascular events and mortality in dialysis patients.

**Methods:** The eligible studies were searched from PubMed, Scopus and Cochrane Central Register of Controlled trials up to 31 March 2022. We included cross-sectional and cohort studies that reported the prevalence of sarcopenia including low muscle mass and low muscle strength and adverse effects such as cardiovascular events and mortality. The random-effects model was used to calculate pooled prevalence rate. Associations between sarcopenia and clinical outcomes were expressed as odd ratio (OR) and 95% confidence interval (CI). Cochran's Q statistic and I<sup>2</sup> test were used to measure the presence of heterogeneity. Publication bias were also tested by Funnel plot and Egger's test.

**Results:** This meta-analysis included 41 studies with 7,576 patients. The pooled prevalence of sarcopenia in dialysis patients was 25.6% (95% CI 22.1 to 29.4%). Among various diagnostic criteria, the highest prevalence was found in Asian Working Group for Sarcopenia (AWGS) 2019 criteria [36.9%, 95% CI 30.4 to 44.2%]. Sarcopenia was significantly associated with higher mortality risk [adjusted OR 1.83 (95% CI 1.40 to 2.39)] and cardiovascular events [adjusted OR 3.80 (95% CI 1.79 to 8.09)]. Additionally, both low muscle mass and low muscle strength were independently related to increased mortality risk in dialysis patients [OR 1.71; 95% CI (1.20 to 2.44), OR 2.15 (95% CI 1.51 to 3.07), respectively].

**Conclusions:** This meta-analysis revealed that sarcopenia was highly prevalent among dialysis patients and shown to be an important predictor of cardiovascular events and mortality. Future intervention research to alleviate this burden of disease in dialysis patients is needed.

# Palliative Care for Patients With Failing Kidney Allograft: A Mixed Methods Study

Amanda J. Reich,<sup>1</sup> Naoka Murakami,<sup>1</sup> Joshua R. Lakin,<sup>9</sup> Katherine He,<sup>1</sup> Samantha L. Gelfand,<sup>1</sup> Richard E. Leiter,<sup>9</sup> Joel T. Adler,<sup>10</sup> Emily Lu,<sup>6</sup> Song C. Ong,<sup>8</sup> Beatrice P. Concepcion,<sup>2</sup> Neeraj Singh,<sup>3</sup> Haris F. Murad,<sup>5</sup> Prince M. Anand,<sup>7</sup> Sarah Ramer,<sup>11</sup> Darshana M. Dadhania,<sup>12</sup> Krista L. Lentine,<sup>4</sup> Tarek Alhamad,<sup>5</sup> KRAFT workgroup<sup>1</sup> Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Vanderbilt University, Nashville, TN; <sup>3</sup>Willis-Knighton Health System, Shreveport, LA; <sup>4</sup>Saint Louis University, Saint Louis, MO; <sup>5</sup>Washington University in St Louis, St Louis, MO; <sup>6</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>7</sup>Medical University of South Carolina, Charleston, SC; <sup>8</sup>The University of Alabama at Birmingham Montgomery, Montgomery, AL; <sup>9</sup>Dana-Farber Cancer Institute, Boston, MA; <sup>10</sup>The University of Texas at Austin, Austin, TX; <sup>11</sup>James J Peters VA Medical Center, New York, NY; <sup>12</sup>Weill Cornell Medicine, New York, NY.

**Background:** Patients with failing kidney allografts suffer from multiple comorbidities and experience significant symptom burden. Palliative care (PC) in transplant recipients is underutilized and the underlying barriers to PC delivery to renal transplant patients are poorly characterized.

**Methods:** We conducted an explanatory sequential mixed methods study with an online survey followed by semi-structured interviews targeting US transplant clinicians.

**Results:** A total of 149 participants (83 nephrologists, 31 nurses, 15 advanced practice providers, 10 surgeons, 6 social workers, 4 others) from 80 transplant centers completed the survey, of which 19 completed an interview. Most transplant clinicians (68%) have never or rarely referred transplant patients to PC. Participants reported poor patient functional status (86%), cancer diagnosis (76%) and frailty (74%) as the most influential factors for PC referral. Regarding timing of PC referral, most providers disagreed with PC involvement in pre-transplant (68%) or early post-transplant (74%) phases. Some (41%) thought that the goals of transplantation and PC are contradictory, others (60%) agreed with consulting PC only near end-of-life, but 62% also thought that early PC intervention may be beneficial in persistent allograft dysfunction. Barriers to engaging PC included patient/caregivers' unrealistic prognostic expectations (69%) and competing demands for clinicians' time (43%). Interviews revealed institution-level (e.g. narrow PC service scope, overburdened PC services) and clinician-level factors (e.g. lack of relationship between PC and transplant teams, limited understanding of patients' racial, ethnic or cultural background) that lead to the patterns observed in our survey. Additionally, interviews suggested several facilitators to PC care referral: improving awareness of PC services and educations to clinicians and patients/caregivers.

**Conclusions:** This mixed methods study highlights opportunities to improve the engagement of PC for transplant recipients. More attention is needed to optimize the timing, clinical setting and collaborative model to best deliver PC, especially for the diverse populations served by renal transplant teams.

## TH-PO792

# Bioelectrical Impedance Analysis Derived-Phase Angle as an Earlier Predictor of Frailty in Hemodialysis Patients

Ismael A. Gómez Ruiz, Oscar Hernández Apolinar, Samantha Hernandez Espinoza, Geovana Martin-Alemañ, Juan M. Ardavin Ituarte. *Medica Santa Carmen, Ciudad de México, Mexico.*

**Background:** Frailty is highly prevalent in the hemodialysis (HD) patient population (28-60%) and is associated with higher morbidity and mortality. Early frailty identification will allow earlier treatment interventions. The aim of the present study was to study phase angle (PA) measured by bioelectrical impedance analysis (BIA) as a predictor of frailty risk. Secondary aims were: a) evaluate the association between frailty and different factors, b) determine the prevalence of frailty among adult patients on hemodialysis.

**Methods:** prospective cohort study performed between July 2021 and April 2022 in two Mexican HD centers. The Clinical Frailty Scale (CFS) was used to diagnose frailty. Using ROC curves, we determined the best cut-off for PA to predict frailty (Figure A). Pearson's correlation coefficient between PA and CFS score were calculated and univariate logistic regression analysis was performed (Figure B).

**Results:** 78 patients were enrolled in this study. Participants were an average of 63.7 ± 14.3 years old with more male gender (62.8%) than female. 60.2% of participants were categorized as frailty. As expected, patients with frailty were older, had lower PA value and higher CFS score. Frailty was more prevalent in males and smokers. The AUC of PA to predict frailty was 0.87 (p<0.0001). Moderate-to-strong negative correlation was found between PA and CFS score (r=-0.58, p<0.0001). A univariate logistic regression analysis revealed that the factors independently associated with frailty were the following: male (odds ratio [OR] = 3.01, 95% confidence interval [CI] 1.09-8.35), age (OR = 1.04, 95% CI 1.00-1.08) and phase angle (OR = 0.51, 95% CI 0.34-0.75).

**Conclusions:** A simple PA determination (<5.3) by BIA can predict risk of frailty (sensitive 85% and specificity 84%) in HD patients. The use of PA as a screening tool at no extra cost would allow early identification of frailty and referral for geriatric evaluation.

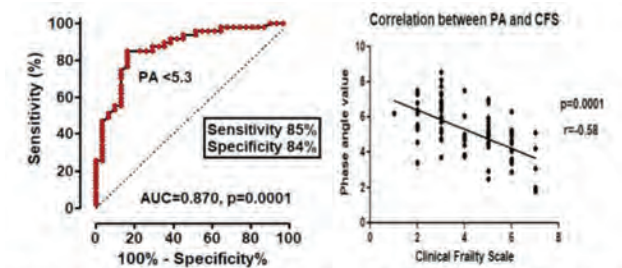

Figure A. ROC curves to predict Frailty.

# Prediction Model for 6-Month Mortality in Incident Older Hemodialysis Patients: Data From the Korean Society of Geriatric Nephrology

Woo Yeong Park,<sup>1</sup> Jang-Hee Cho,<sup>2</sup> Byung chul Yu,<sup>3</sup> Miyeun Han,<sup>4</sup> Sang Heon Song,<sup>5</sup> Gang-Jee Ko,<sup>6</sup> Jae Won Yang,<sup>7</sup> Sungjin Chung,<sup>8</sup> Yu Ah Hong,<sup>9</sup> Young Youl Hyun,<sup>10</sup> Eunjin Bae,<sup>11</sup> In O Sun,<sup>12</sup> Hyunsuk Kim,<sup>13</sup> Won Min Hwang,<sup>14</sup> Sung Joon Shin,<sup>15</sup> Soon hyo Kwon,<sup>16</sup> Kyung Don Yoo.<sup>17</sup> Korean Society of Geriatric Nephrology<sup>1</sup> Keimyung University School of Medicine, Daegu, Republic of Korea; <sup>2</sup>Kyungpook National University School of Medicine, Daegu, Republic of Korea; <sup>3</sup>Soonchunhyang University Hospital Bucheon, Bucheon, Gyeonggi-do, Republic of Korea; <sup>4</sup>National Medical Center, Seoul, Republic of Korea; <sup>5</sup>Pusan National University School of Medicine, Busan, Republic of Korea; <sup>6</sup>Korea University College of Medicine and School of Medicine, Seoul, Republic of Korea; <sup>7</sup>Yonsei University Wonju College of Medicine, Wonju, Gyeonggi-do, Republic of Korea; <sup>8</sup>The Catholic University of Korea, Seoul, Republic of Korea; <sup>9</sup>The Catholic University of Korea, Daejeon, Republic of Korea; <sup>10</sup>Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; <sup>11</sup>Gyeongsang National University Graduate School of Medicine, Changwon, Gyeongsangnam-do, Republic of Korea; <sup>12</sup>Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea; <sup>13</sup>Hallym University College of Medicine, Chuncheon, Gangwon, Republic of Korea; <sup>14</sup>Konyang University Hospital, Daejeon, Republic of Korea; <sup>15</sup>Dongguk University School of Medicine, Goyang, Gyeonggi-do, Republic of Korea; <sup>16</sup>Soonchunhyang University Hospital, Seoul, Republic of Korea; <sup>17</sup>University of Ulsan College of Medicine, Ulsan, Republic of Korea.

**Background:** Early mortality following hemodialysis initiation is a barrier to improving patient survival. We aimed to develop a clinical risk model to predict the early mortality of older hemodialysis patients.

**Methods:** Hemodialysis patients aged >70 years were recruited from a retrospective cohort from the Korean Society of Geriatric Nephrology (KSGN). A prognostic score for 6-month mortality risk after dialysis initiation was developed, named the KSGN score. Multivariate Cox regression analysis was used to select risk factors from 20 clinical variables.  $\beta$ -coefficients were converted to natural logarithms for the final risk score model.

**Results:** Among the 1,967 incident hemodialysis patients, the crude 6-month mortality rate was 15.7% (n=309). In the multivariate Cox analysis, independent risk factors for 6-month mortality and each score were as follows: the body mass index (<18.5 kg/m<sup>2</sup> (0), 18.5 ≤ <23 kg/m<sup>2</sup> (0)), age at dialysis initiation (<80 years (0), ≥85 years (1)), status of malignancy (curative state (0), palliative treatment (1)), hypertension (0), nursing hospital care at dialysis initiation (0), vascular access at dialysis initiation (arteriovenous graft (-1)), vascular access on maintenance dialysis (arteriovenous fistula (-1), arteriovenous graft (-1)), and serum albumin (0)). According to the KSGN score, mortality rate was 4.8%, 8.6%, 32.0%, 60.3%, and 66.7% for -2, -1, 0, 1, and 2 points, respectively. The area under the curve of the KSGN score was significantly higher than that of either the Alberta or United States Renal Data System scores.

**Conclusions:** The KSGN score is a simple tool to predict early mortality after dialysis initiation in older patients with end-stage kidney disease and may be useful to support decision-making and management in older adults starting dialysis.

Comparison of ROC curve between the prognostic models

## TH-PO794

**Dialysis vs. Conservative Management for Patients 65 Years and Older With ESKD: A Propensity-Matched Cohort Study**

Bjoerg Thorsteinsdottir,<sup>1</sup> Kavya Sindhu Swarna,<sup>1</sup> Andrew D. Rule,<sup>1</sup> Runolfur Palsson,<sup>2</sup> Robert C. Albright,<sup>1</sup> Kianoush Kashani,<sup>1</sup> Ann M. O'Hare,<sup>4</sup> LaTonya J. Hickson,<sup>3</sup> <sup>1</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Landspítali, Reykjavik, Iceland; <sup>3</sup>Mayo, Jacksonville, FL; <sup>4</sup>VA Puget Sound Health Care System Seattle Division, Seattle, WA.

**Background:** Several cohort studies have compared survival for older individuals with ESKD who pursue dialysis vs. conservative care. Results have been variable and methodologically challenged by systematic differences in age and comorbidity by treatment. We sought to account for differences in patient characteristics by using propensity score matching among members of a large claims-based database.

**Methods:** All patients in the OptumLabs Data Warehouse over 65 years old with at least one creatinine measure, and six months of coverage were identified. The median eGFR at dialysis start was 9 mL/min/1.73 m<sup>2</sup>. All patients who started dialysis within 3 days of reaching this eGFR threshold were propensity matched with patients with an eGFR in the same range who did not start dialysis. Overall survival was compared for the two groups with Cox regression and the subgroup age >80 years. Sensitivity analysis was performed using eGFR thresholds of 11 and 7 mL/min/1.73 m<sup>2</sup>, (representing the 25<sup>th</sup> and 75<sup>th</sup> percentiles), and excluding patients with an AKI diagnosis.

**Results:** We identified 6017 patients who initiated dialysis during the observation period and 5814 who did not start dialysis. Those who started dialysis were younger (mean age 74.9 vs. 77.3 years), more likely to be men, more likely to be identified as Black or Hispanic and had a higher comorbid burden, especially CKD complications (i.e. anemia), cardiac and pulmonary disease, and less likely to have dementia, cancer and other neurological conditions. In survival comparison before propensity matching, dialysis carried a hazard ratio (HR) of 0.67(CI 0.64-0.71) compared to no dialysis. After propensity matching of 2,566 patients from each group, the overall survival advantage was attenuated (HR 0.77; CI 0.71-0.83) but persisted even for those over 80 years old (HR 0.65; CI 0.57-0.73).

**Conclusions:** Patients who do not receive dialysis are more likely to be older, white and have disabling or life limiting comorbidities. Even after propensity score matching, patients who started dialysis survived longer than those who did not, and this was true even for those aged 80 years or older. However, sicker patients who start dialysis more acutely at higher GFR levels may be underrepresented in our cohort.

**Funding:** NIDDK Support, Other NIH Support - NIAK23AG051679

## TH-PO795

**Validity and Practice Patterns of Mortality Risk Prediction Tools in Dialysis Patients**

Jennifer Bergeron,<sup>1</sup> Christina Damon,<sup>2,1</sup> Sean Meagher,<sup>1</sup> Katharine L. Cheung,<sup>1</sup> <sup>1</sup>University of Vermont, Burlington, VT; <sup>2</sup>Tufts University School of Medicine, Boston, MA.

**Background:** Mortality rates are high among dialysis patients, but much heterogeneity exists, making it difficult to predict patients' outcomes, particularly in older adults. Accurately predicting mortality is essential for prognostication and advance care planning. Although several risk assessment tools have been developed, few have been externally validated. Furthermore, there are no studies assessing nephrologists' ideas and use of these tools.

**Methods:** All 279 of Vermont's dialysis patients' data were input into 3 mortality risk prediction tools: Cohen, Charlson Comorbidity Index, and Couchoud. 6 months later, chart review determined which patients had died, and the c statistic for each tool was calculated via logistic regression and subsequent ROC curve. 80% of nephrology dialysis providers in Vermont underwent a semi-structured interview regarding their experience, use, and ideas of the utility of mortality risk prediction tools. The interviews were transcribed, and common themes were identified independently by 2 reviewers.

**Results:** Couchoud had the best discrimination in Vermont's dialysis patients with a c statistic of 0.77 compared to Cohen and Charlson (both 0.68). Providers were only aware of 2 tools to predict mortality, 100% knew Cohen's surprise question and 25% knew Charlson. No nephrologists used these tools in their practice. The main barrier to use identified was concern that the tool would not be accurate in their individual patients and providers trusted their own clinical judgement over that of a tool. Most providers were open to using these tools in their prognostication if further evidence for the validity and education about the use of these tools was provided. Providers noted that if a tool with strong discrimination predicted a high mortality, it would change management of the patient- make them more likely to encourage supportive care over dialysis.

**Conclusions:** Our study shows that nephrologists do not routinely use mortality risk prediction tools in practice due to concerns about their external validity and lack of knowledge about how to use them. We also showed that Couchoud had strong discrimination, particularly in Vermont's older population, and could be used for advanced care planning. We are currently conducting further interviews to see if this data specific to their patients changes their ideas and use of prediction tools.

## TH-PO796

**Association of ACR Trajectories With Frailty Worsening or Death in Community-Dwelling Older Adults**

Nina Mielke,<sup>1</sup> Alice Schneider,<sup>1</sup> Natalie Ebert,<sup>1</sup> Markus van der Giet,<sup>1</sup> Doerte Huscher,<sup>1</sup> Martin K. Kuhlmann,<sup>2</sup> Elke Schaeffner.<sup>1</sup> <sup>1</sup>Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>Vivantes Klinikum im Friedrichshain, Berlin, Germany.

**Background:** Elevated Albumin-creatinine-ratio (ACR) has been associated with prevalent and incident frailty. We analyzed the association of ACR trajectories over 6 years and frailty status worsening or death in the successive 2-year follow up window in data of the Berlin Initiative Study (BIS).

**Methods:** Prospective population-based cohort of old adults interviewed biennially with a standardized questionnaire incl. geriatric and physical examination. 6-year ACR trajectories were constructed using either "no albuminuria (A0)" or "albuminuria (A1) (30 – 300 mg/g)" or "A2 (>300 mg/g)" over four study visits. Trajectories were distinguished into "stable A0" or "all other" trajectories of albuminuria incl. incident albuminuria. Frailty was assessed at the 3<sup>rd</sup> (frailty baseline) and 4<sup>th</sup> follow-up. Frailty worsening was defined as the transition from robust to prefrail or frail, or from prefrail to frail within the 2-year period. Association between ACR trajectories and the ordinal outcome of no worsening, frailty worsening, or death was analyzed using partial proportional odds regression.

**Results:** At frailty baseline, mean age was 84 yrs, 46% were male, and 48% were prefrail and 31% frail. Participants with trajectories of albuminuria during the previous 6 years (N=342) were older (86 vs. 84 yrs), were less physically active, had higher prevalence of diabetes (39% vs. 24%) or CVD (83% vs. 66%) and had a lower mean eGFR of 45 compared to 53 mL/min/1.73 m<sup>2</sup> in participants with stable A0 trajectories (N=729). After 2.1 (2.0-2.3) years, 960 (90%) participants had valid information on frailty transition: 187 (17.5%) worsened and 111 (10.3%) died. In the multivariable model<sup>1</sup> the odds of frailty worsening for participants with albuminuria trajectories during the 6 yrs preceding initial frailty assessment were 1.5-fold higher compared to participants with stable A0 trajectories. The odds for death were even higher with albuminuria trajectories.

**Conclusions:** In older adults, albuminuria trajectories are associated with 1.5-fold higher odds for frailty worsening independent of death.

**Funding:** Private Foundation Support

Table: Association of ACR trajectory over 6 years with subsequent frailty worsening or death within 2 years, OR (95%CI)

	Outcome	ACR trajectory	
		stable A0 (N=656)	albuminuria (N=304)
No. of events (%)	frailty worsening	130 (19.8)	57 (18.8)
	death	43 (6.6)	88 (22.4)
crude model	frailty worsening	Reference	1.95 (1.46-2.60)
	death	Reference	4.11 (2.73-6.19)
adjusted model <sup>1</sup>	frailty worsening	Reference	1.53 (1.11-2.10)
	death	Reference	3.17 (2.07-4.86)

ACR – albumin creatinine ratio in mg/g; OR – odds ratio; CI – confidence interval.

<sup>1</sup>adjusted for age, sex, hypertension, diabetes mellitus, physical activity, calve circumference, smoking, body mass index, CRP and any cardiovascular disease

**Effect of Structured Exercise on Biomarkers of Kidney Health in Sedentary Older Adults in the LIFE Study: A Randomized Clinical Trial**

Anoop Sheshadri,<sup>1,2</sup> Mason Lai,<sup>1</sup> Fang-Chi Hsu,<sup>3</sup> Scott R. Bauer,<sup>1,2</sup> Shyh-Huei Chen,<sup>3</sup> Vasantha Jotwani,<sup>1,2</sup> Gregory J. Tranah,<sup>4</sup> Roger A. Fielding,<sup>5</sup> Christine Liu,<sup>6</sup> Joachim H. Ix,<sup>7</sup> Steven G. Coca,<sup>8</sup> Michael Shlipak.<sup>1,2</sup> LIFE-Kidney Investigators <sup>1</sup>University of California San Francisco, San Francisco, CA; <sup>2</sup>San Francisco VA Health Care System, San Francisco, CA; <sup>3</sup>Wake Forest University School of Medicine, Winston-Salem, NC; <sup>4</sup>California Pacific Medical Center, San Francisco, CA; <sup>5</sup>Tufts Medical Center, Boston, MA; <sup>6</sup>Stanford University School of Medicine, Stanford, CA; <sup>7</sup>University of California San Diego, La Jolla, CA; <sup>8</sup>Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** We previously demonstrated among older adults that a structured exercise intervention slowed kidney function decline over two years, *independently of changes in blood pressures and weight*. In an ancillary study to the Lifestyle Interventions and Independence For Elders (LIFE) study, we sought to evaluate mechanisms by which physical activity and exercise might slow kidney decline using biomarkers of kidney health.

**Methods:** Participants in LIFE were 1381 sedentary adults aged 70-89 years who were randomized to a structured exercise intervention or health education (HE). Physical activity was measured by step count (Actigraph wGT3X-B). Blood and urine samples were collected at baseline, year 1 and year 2 of follow-up. We estimated the association of step count and biomarkers of kidney health using mixed effects models. Primary outcomes were changes in 14 blood and urine biomarkers of kidney health categorized by quartiles to allow for comparisons across biomarkers.

**Results:** Participants assigned to the intervention walked a mean 291 more steps/day compared to HE. The intervention was not significantly associated with changes in any biomarkers. However, persons in the highest versus lowest quartile of steps (≥3470 vs. <1568 steps) had statistically significant improvement in biomarkers assessing for glomerular injury, tubular function and repair, tubular injury, generalized inflammation, and tubulointerstitial fibrosis. (Figure).

**Conclusions:** While randomization to a structured exercise program did not result in improvements in biomarkers at a group level, larger increases in step count were associated with improvements in several biomarkers of kidney health.

**Funding:** NIDDK Support, Other NIH Support - National Institute on Aging, FDA, Other U.S. Government Support

Underline represents presenting author.

**Figure: Associations of physical activity (high vs. low quartile) with changes in 14 biomarkers of kidney health (scaled/SD) using mixed effects models in the LIFE trial**

All models are adjusted for intervention, sex, clinical sites, age, BMI, time-varying SBP, race, education, diabetes, CVD, hypertension, visit, and intervention by visit interaction.  
 †Changes in UMOD and EGF are reversed for clarity, higher levels reflect improved kidney health. Lower levels of all other biomarkers reflect better kidney health or systemic inflammation. All urine biomarkers are indexed to urine Cr.  
 \*Biomarker units are mg/L per mg/dL of UCr  
 \*\*Biomarker units are pg/mL per mg/dL of UCr

## TH-PO798

### The Effect of Long-Term High-Intensity Interval Training on CKD Prevention in the Elderly: A Substudy of the Generation-100 Randomized Controlled Trial

Stein I. Hallan,<sup>1,2</sup> Marius A. Øvrehus,<sup>2</sup> Michael Shlipak,<sup>3,4</sup> Joachim H. Ix,<sup>5,6</sup> Dorthe Stensvold,<sup>1</sup> Knut Asbjørn R. Langlo.<sup>1,2</sup> <sup>1</sup>Norges teknisk-naturvitenskapelige universitet, Trondheim, Norway; <sup>2</sup>St Olavs Hospital Universitetssykehuset i Trondheim, Trondheim, Norway; <sup>3</sup>University of California San Francisco, San Francisco, CA; <sup>4</sup>San Francisco VA Health Care System, San Francisco, CA; <sup>5</sup>University of California San Diego, La Jolla, CA; <sup>6</sup>Veterans Affairs San Diego Healthcare, San Diego, CA.

**Background:** Recent trials suggest moderate-intensity exercise may lower CKD incidence in older adults. Whether or not there is a dose response relationship regarding intensity of exercise and CKD risk is unknown. High-intensity interval training (HIIT) has shown very encouraging results on cardiorespiratory capacity, endothelial function and other key aspects of cardiovascular as well as kidney health.

**Methods:** All inhabitants of Trondheim, Norway, aged 70-77 years were invited to participate in the Generation 100 study. Main exclusion criteria were uncontrolled hypertension, unstable angina, heart failure or symptomatic valvular disease, dementia, cancer or other diseases or disabilities that precluded exercise. Participants were randomized to supervised physical training consisting of 10-minute warm-up followed by 4x4-minute high-intensity interval training (HIIT) at ~90% of peak heart rate or 50 minutes of moderate-intensity continuous training (MICT) at ~70% of peak heart rate twice/week for five years. Peak oxygen uptake ( $\text{VO}_2$  peak) and blood samples were obtained at baseline and at one, three, and five years. Incident CKD was defined as a >25% eGFR decline to a new level <60ml/min/1.73m<sup>2</sup> based on the CKD-EPI Cystatin C equation.

**Results:** The 787 participants had mean (1 SD) age 72 (2) years, 51% were males, and 6% had diabetes. Baseline blood pressure was 134 (18) / 75 (9) mmHg, and eGFR was 91 (16) ml/min/1.73m<sup>2</sup>. In total, 400 subjects were randomized to the HIIT group and 387 to the MICT groups. After one year, mean  $\text{VO}_2$  peak had increased from 28.9 (6.4) to 32.2 (6.7) ml/kg/min in the HIIT group and from 28.6 (6.6) to 30.9 (6.8) ml/kg/min in the MICT group. During the five-year training period, there were 13 new CKD cases in the HIIT group (3.4%) and 25 cases in the MICT group (6.7%) for a relative risk reduction of 0.47 (95% CI 0.24, 0.93, p=0.030). There was no interaction between the HIIT treatment effect and baseline levels of  $\text{VO}_2$  peak or eGFR.

**Conclusions:** Among older persons, compared to moderate-intensity continuous training, high-intensity interval training reduced the risk of incident CKD.

**Funding:** Government Support - Non-U.S.

### Lower Functional Status and Perceived Health Status Are Associated With Poorer Quality of Life in Older People With ESKD

Amarpreet K. Thind,<sup>1,2</sup> Michelle Willicombe,<sup>1,2</sup> Edwina A. Brown.<sup>2,1</sup> KTOP Study Investigator Group <sup>1</sup>Imperial College London, London, United Kingdom; <sup>2</sup>Hammersmith Hospital, London, United Kingdom.

**Background:** Frailty is under-recognised in end-stage kidney disease (ESKD) including in those eligible for transplantation. Understanding which frailty components are associated with quality of life outcomes (QoL) allows for focused intervention and counselling of older people with ESKD.

**Methods:** The Kidney Transplantation in Older People: impact of frailty on outcomes (KTOP) study explores frailty, cognition, and QoL changes in older people (≥60) whilst waiting for and after a transplant. Frailty was assessed using the Edmonton Frailty Scale which gives total scores and scores for different frailty components. We present QoL scores from 5 measures at recruitment, their variation by frailty status, and their association with frailty components.

**Results:** 210 patients have been recruited; 118(63.4%) were identified as not frail, 38(20.4%) were vulnerable, and 30(16.2%) were frail. Frailty and QoL scores were available for 164-167 patients. Progressively lower QoL scores in all measures were observed in the vulnerable and frail groups (figure 1, p<0.0001). Table 1 shows the association between frailty components and QOL scores (p<0.05 on adjusted linear regression). Poor functional status and general health status were associated with lower QoL scores across all measures.

**Conclusions:** Frailty and vulnerability to frailty is not uncommon in older people considered eligible for transplantation and is associated with worsening reported QoL. Functional dependence and general health status were associated with poorer QoL scores throughout all questionnaires. This is invaluable for giving a holistic depiction of ESKD in older people and allows for more targeted management.

Association of Plant-Based Protein Intake With Cognitive Function in Adults With CKD

Luis M. Perez, Zhiying You, Jessica B. Kendrick. *University of Colorado Denver School of Medicine, Aurora, CO.*

**Background:** Patients with chronic kidney disease (CKD) have accelerated cognitive aging and cognitive function worsens as kidney function declines. Diets higher in plant-based proteins are associated with better survival in patients with CKD. Whether diets high in plant-based proteins are associated with cognitive function in adults with CKD is unclear.

**Methods:** Using NHANES 2011-2012 data, we included participants aged 60 years and older with cognitive and dietary data available. We calculated plant-based protein intake from dietary records by linking food database codes with standard references. CKD was defined as urine albumin:creatinine  $\geq 30$ mg/g and/or eGFR  $< 60$  mL/min. Plant protein intake was examined categorically with high vs. low intake defined by median levels. Primary cognitive outcomes included: 1) Consortium to Establish a Registry for Alzheimer’s disease (CERAD); 2) the Animal Fluency test (AFT); and 3) the Digit Symbol Substitution test (DSST). Regression analysis models were used to examine the association between plant-based protein intake and cognition.

**Results:** We included 322 participants with CKD. The mean age and eGFR were  $72 \pm 7$  years and  $60.5 \pm 22.4$  mL/min/1.73m<sup>2</sup>, respectively. Over half of the participants were male (52%) and the majority were Non-Hispanic White (47%). Median (IQR) plant protein intake was 19 (13-27)g. Higher plant-based protein intake was significantly associated with higher cognitive scores on CERAD and AFT in the fully adjusted model (Table). Higher plant-based protein intake was not associated with DSST in the fully adjusted model.

**Conclusions:** Plant-based protein appears to be a significant predictor of cognitive score measures in adults with CKD. It is possible that plant-based protein intake represents lower dietary acid load or other healthy habits that may improve cognitive performance or be associated with increased cognitive function.

**Funding:** NIDDK Support

Phosphorus Content and Phosphorus-to-Protein Ratio Among Plant-Based Protein Products

Kendal M. Burstad,<sup>1</sup> Alexandria Fons,<sup>1</sup> Kathleen M. Hill Gallant.<sup>1,2</sup> *<sup>1</sup>University of Minnesota Twin Cities, Minneapolis, MN; <sup>2</sup>Indiana University School of Medicine, Indianapolis, IN.*

**Background:** Plant-based eating is of growing interest in management of CKD due to several reasons, including the proposed lower P bioavailability from plant sources. However, few data are available on the P content of emerging plant-based products. In this study, we aimed to quantify P in several popular food categories of plant-based foods (soy or other pulse-based) and compared to their animal protein counterparts. Our results for plant-based dairy and ground beef alternatives were presented at the National Kidney Foundation Spring Clinical Meeting 2022 and overall showed that P content and P-to-protein ratio were lower in soy- compared to pulse-based products, and soy products were comparable to their animal protein counterparts.

**Methods:** Here, we present results for plant-based chicken/turkey, sausage/bacon, yogurt/cheese, and other popular soy/pulse products. Products were prepared according to package directions, freeze-dried, ashed and analyzed for P content using MP-AES.

**Results:** Analyzed P content ranged from 116-196 mg P/100g, 80-293 mg P/100g, and 5-346 mg P/100g for plant-based chicken/turkey, bacon/sausage, and yogurt/cheese products, respectively. For comparison, P content from animal sources in the categories of chicken/turkey, bacon/sausage, and yogurt/cheese ranged from 125-273 mg P/100g, 122-237 mg P/100g, and 105-1223 mg P/100g. Analyzed P content of other soy products (i.e., tofu, tempeh, etc.) ranged from 145-571 mg P/100g and of other pulse products (i.e., chickpea, green lentils, etc.) ranged from 52-166 mg P/100g. Nine of the 40 products analyzed had least one inorganic phosphate additive listed on the label. Total P content of plant-based chicken/turkey alternatives was lowest in pulse-based products, but the P-to-protein ratio was lowest in a soy-based chicken product (3.8 mg/g). Total P content of soy-based cheese products was lower than pulse- or animal-based. However, these soy-based cheeses contained no protein, and animal- and pulse-based cheese products had the highest P-to-protein ratios of all food studied, 85.6 mg/g and 103.6 mg/g.

**Conclusions:** These data show the wide variation in P content and P-to-protein ratio of both plant-based products and their animal-based counterparts. Further quantification and reporting of P content in emerging plant-based products is needed for appropriate recommendations for patients with CKD.

TH-PO802

Therapeutic Strategies for Reversing the Negative Health Effects of a High Phosphate Diet in Mice

Uma D. Alappan,<sup>1</sup> Jamie Arnst,<sup>1</sup> Manjula Viggeswarapu,<sup>2</sup> George R. Beck.<sup>1,2</sup> *<sup>1</sup>Emory University School of Medicine, Atlanta, GA; <sup>2</sup>VA Medical Center Atlanta, Decatur, GA.*

**Background:** Dietary inorganic phosphorus (Pi) regulation is crucial for treating CKD patients as excess serum Pi can lead to comorbidities. Studies show high +Pi may negatively impact those with clinically normal renal function via partly understood mechanisms like increased Pi-responsive factors (PTH, osteopontin [OPN], FGF23), kidney damage, and decreased bone volume. Clinicians commonly administer Lanthanum Carbonate (LaC) Pi-binder to reduce serum Pi, Vitamin D (VitD) to increase bone strength, Cinacalcet (CNC) to suppress PTH, and Zoledronate (Zol) to prevent bone loss. Our study investigates these pharmacologic strategies compared to a low Pi diet to reduce excess Pi’s negative health consequences.

**Methods:** Healthy 10-Week-old, female C57BL/6J mice were fed diets with Normal Pi (NPD, 0.6% Pi) or High Pi (HPD, 1.8% Pi). All diets contained 0.6% Calcium, 2.2IU VitD, similar protein, Kcals, and fat%. Strategies to control systemic effects of high Pi included: low Pi diet (LPD, 0.2%), HPD + LaC (3%), VitD (10IU) or CNC (100mg/kg) incorporated into the feed, and Zol (100µg/kg ip). Serum FGF23, OPN, PTH were measured by ELISA, bone volume by micro-computed tomography, and kidney gene expression by quantitative real-time (qRT) PCR.

**Results:** Therapeutic strategies to control Pi-responsive factors were generally as expected with LaC reducing HPD-induced increase in FGF23 and CNC lowering PTH in response to HPD. VitD did not produce an effect and surprisingly Zol somewhat exacerbated response to HPD. Though some strategies controlled systemic, high Pi-related effects, all were generally ineffective at blunting bone loss—except Zol. Changes in kidney-related gene expression—i.e. Klotho, Pi transporters, Lipocalin-2—were influenced by dietary Pi and at least partially corrected with Pi-normalizing strategies. Reducing Pi consumption (LPD) lowered systemic Pi factors and improved bone volume over NPD.

**Conclusions:** Though individually existing, clinically used therapies are generally effective at correcting some aspects of systemic phosphate dysbiosis in mice, they generally do not correct negative consequences on bone volume. This suggests that the negative health consequences of dysregulated phosphate homeostasis, even in the context of normal renal function, are multifactorial and cannot be fully alleviated with existing clinically used therapies.

Low Sodium Intake, Low Protein Intake, and Excess Mortality: Findings in the Lifelines-MINUTHE Study

Niek Hessels,<sup>1</sup> Yinjie Zhu,<sup>1</sup> Martin H. De Borst,<sup>1</sup> Stephan J. Bakker,<sup>1</sup> Gerjan Navis,<sup>1</sup> Ineke J. Riphagen.<sup>1,2</sup> *<sup>1</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>2</sup>Certe Medical Diagnostics and Advice, Leeuwarden, Netherlands.*

**Background:** Several observational studies reported on a U-shaped association between sodium intake and mortality, which raises questions about the safety of low sodium intake and hampers widespread acceptance of public health campaigns and dietary guidelines. We investigated whether concomitant low protein intake explained the lower part of this U-shaped association between sodium intake and all-cause mortality.

**Methods:** We investigated the associations between sodium intake (24 h sodium excretion) and all-cause mortality, including the interaction with protein intake (Maroni formula), using multivariable Cox regression in a gender and socioeconomic status balanced Lifelines cohort.

**Results:** A total of 1603 individuals aged between 60 and 75 years was included. After a median follow-up of 8.9 years, 125 (7.8%) deaths occurred. Both the highest (Q4,  $> 4.7$  g/day; HR 1.74 [95%CI 1.03-2.95]) and the lowest quartile of sodium intake (Q1, 0.7-2.8 g/day; 2.05 [1.16-3.62];  $p=0.01$ ) were associated with increased risk of all-cause mortality compared with the third quartile of sodium intake (Q3, 3.6-4.7 g/day), independent of potential confounders. A significant interaction with protein intake (P-interaction=0.006) was found, with the increased risk of low sodium intake being reversed to reduced risk by concomitant high protein intake, while the increased risk was magnified by concomitant low protein intake (see figure 1).

**Conclusions:** We found that both high and low levels of sodium intake were associated with increased all-cause mortality. However, higher protein intake annihilated the excess mortality observed in subjects on low sodium intake. A joint low intake of sodium and protein is associated with a particularly high mortality risk, allegedly due to a poor nutritional status. This backs up guidelines advocating to lower sodium intake while also highlighting the importance of recognizing overall nutritional status.

TH-PO804

**Effectiveness of Short-Term, Home-Delivered, Low Sodium Meals to Sustain Long-Term Changes in Dietary Behavior in Hemodialysis Patient**  
Shu H. Kwan,<sup>1</sup> Alexis King,<sup>2</sup> Hsin-Yu Fang,<sup>2</sup> Kenneth R. Wilund.<sup>2</sup> <sup>1</sup>University of Illinois Urbana-Champaign College of Agricultural Consumer and Environmental Sciences, Urbana, IL; <sup>2</sup>University of Illinois Urbana-Champaign, Urbana, IL.

**Background:** Reducing dietary sodium intake (SI) in hemodialysis (HD) patients can reduce volume overload and risk of cardiovascular complications. However, previous studies indicated that dietary education alone is ineffective in reducing SI in HD patients. A 4-week-study in our lab found that short-term low-sodium home-delivered meals provision could reduce SI, interdialytic weight gain (IDWG), and blood pressure (BP) of HD patients. However, it is not known if changes from short-term meal feeding can be sustained long-term. The purpose of this study is to determine if short-term feeding of low-sodium meals can “prime” changes in long-term dietary behavior and lead to sustained reductions in IDWG and BP in HD patients.

**Methods:** To date, we have recruited 11 subjects (61±11 years, BMI 35.6±11.9 kg/m<sup>2</sup>) from a HD clinic in central IL. Subjects were randomized into a control (CON) or intervention group (INT). CON subjects received standard care for the first 5 months, followed by 2 months of low-sodium meals (2 meals/day in Month 6 and 1 meal/day in Month 7) and dietary education. INT subjects received low-sodium meals (2 meals/day in Month 1 and 1 meal/day in Month 2) and dietary education for the first 2 months, followed by 3-month continued dietary education. We collected monthly IDWG, BP, and 3 days of dietary recalls at baseline (0M), 1 month (1M), 2 month (2M), and 5 month (5M).

**Results:** SI, IDWG, systolic blood pressure (SBP), and diastolic blood pressure (DBP) were significantly reduced after 1 month of low-sodium meal feeding (p < 0.05), but these changes were not sustained long-term (Table). SI, IDWG, and DBP increased starting 2M.

**Conclusions:** Short-term low-sodium home-meal delivery can reduce SI, IDWG, and BP in HD patients. However, these changes are not sustained after patients’ resumption of meal responsibility. This suggests that extended meal feeding and/or more intensive low-sodium counseling strategies may be needed to sustain long-term behavior change.

**Funding:** Commercial Support - Renal Research Institute

**Urinary Sodium, Potassium, and Kidney Function in West Africans**  
Titilayo O. Ilori,<sup>1</sup> Temitayo M. Adebile,<sup>1</sup> Adaobi Solarin,<sup>2</sup> Manmak Mamven,<sup>3</sup> Bolanle A. Omotoso,<sup>4</sup> Yemi R. Raji,<sup>5</sup> Ifeoma I. Ulasi,<sup>6</sup> Runqi Zhao,<sup>1</sup> Rasheed A. Gbadegesin,<sup>7</sup> Rulan S. Parekh,<sup>8</sup> Babatunde L. Salako,<sup>9</sup> Dwomoa Adu,<sup>10</sup> Cheryl A. Anderson,<sup>11</sup> Akinlolu Ojo,<sup>12</sup> Christiana O. Amira,<sup>13</sup> Sushrut S. Waikar.<sup>1</sup> <sup>1</sup>Boston University School of Medicine, Boston, MA; <sup>2</sup>Lagos State University Teaching Hospital, Lagos, Nigeria; <sup>3</sup>University of Abuja, Abuja, Nigeria; <sup>4</sup>Obafemi Awolowo University Teaching Hospital Complex, Ile-Ife, Nigeria; <sup>5</sup>University College Hospital Ibadan, Ibadan, Nigeria; <sup>6</sup>University of Nigeria, Nsukka, Nigeria; <sup>7</sup>Duke University School of Medicine, Durham, NC; <sup>8</sup>Women’s College Hospital, Toronto, ON, Canada; <sup>9</sup>University of Ibadan, Ibadan, Nigeria; <sup>10</sup>University of Ghana Medical Centre, Accra, Ghana; <sup>11</sup>University of California San Diego, La Jolla, CA; <sup>12</sup>University of Kansas School of Medicine, Kansas City, KS; <sup>13</sup>Lagos University Teaching Hospital, Surulere, Nigeria.

**Background:** Dietary intake of sodium (Na) and potassium (K) may impact kidney function and outcomes, but data are conflicting. Our goal was to examine associations of 24hr urine K and Na (as proxies for dietary intake) with kidney function in Africans with CKD and compare our findings to a U.S.-based CKD cohort, the Chronic Renal Insufficiency (CRIC) study.

**Methods:** We included participants in the Diet, CKD and ApolipoproteinL1 study (DCA, n=619) ancillary to the Human Hereditary and Health in Africa Kidney Disease study. The exposures were calibrated, log transformed 24hr -UNa, UK and Na/K ratio. Outcomes were calculated eGFR and 24hr-urine protein (Uprotein). We utilized generalized linear regression with a random intercept for clinical center to estimate crude and adjusted beta coefficients and 95% CI. We performed similar analyses in 3,459 participants in CRIC.

**Results:** Median UNa excretion was lower in DCA than in CRIC [134 (104-175) vs. 160 (118-215) mmol/24hr, p <0.001]. Median UK excretion was lower in DCA than in CRIC [36 (28-48) vs 55 (40-74) mmol/24hr (p <0.001)]. Findings on the associations of UNa and UK with eGFR and Uprotein were directionally consistent. Higher UK was associated with higher eGFR in DCA and CRIC participants. Higher 24hr-UNa was associated with higher Uprotein excretion but not eGFR in both cohorts. The UNa/UK<sub>ratio</sub> was associated with lower eGFR and higher Uprotein in both cohorts (see figure).

**Conclusions:** Cross-sectional associations with eGFR and proteinuria were similar in West Africans and Americans, with evidence for associations of higher UK with higher eGFR, and higher UNa with higher proteinuria.

**Funding:** NIDDK Support

UNa, UK, EGFR and Proteinuria

## Urinary Sodium and Potassium and Blood Pressure in African and US Cohorts With CKD

Titilayo O. Ilori,<sup>1</sup> Manmak Mamven,<sup>2</sup> Adaobi Solarin,<sup>3</sup> Temitayo M. Adebile,<sup>1</sup> Yemi R. Raji,<sup>4</sup> Bolanle A. Omotoso,<sup>5</sup> Ifeoma I. Ulasi,<sup>6</sup> Rulan S. Parekh,<sup>7</sup> Rasheed A. Gbadegesin,<sup>8</sup> Runqi Zhao,<sup>1</sup> Christiana O. Amira,<sup>9</sup> Dwomoa Adu,<sup>10</sup> Cheryl A. Anderson,<sup>11</sup> Akinlolu Ojo,<sup>12</sup> Sushrut S. Waikar.<sup>1</sup> <sup>1</sup>Boston University School of Medicine, Boston, MA; <sup>2</sup>University of Abuja, Abuja, Nigeria; <sup>3</sup>Lagos State University College of Medicine, Ojo, Nigeria; <sup>4</sup>University College Hospital Ibadan, Ibadan, Nigeria; <sup>5</sup>Obafemi Awolowo University College of Health Sciences, Ile-Ife, Nigeria; <sup>6</sup>University of Nigeria, Nsukka, Nigeria; <sup>7</sup>Women's College Hospital, Toronto, ON, Canada; <sup>8</sup>Duke University School of Medicine, Durham, NC; <sup>9</sup>Lagos University Teaching Hospital, Surulere, Nigeria; <sup>10</sup>University of Ghana Medical Centre, Accra, Ghana; <sup>11</sup>University of California San Diego, La Jolla, CA; <sup>12</sup>The University of Kansas Medical Center, Kansas City, KS.

**Background:** Higher dietary sodium (Na) and lower potassium (K) are associated with increased blood pressure and cardiovascular disease risk. In individuals with CKD, there are conflicting results on the associations of dietary Na and K with kidney function. We examined associations of 24hr-urine Na and K, with systolic and diastolic blood pressure (SBP and DBP) and pulse pressure (PP) in Africans and Americans with CKD.

**Methods:** We analyzed 619 participants enrolled in an ancillary study to the Human Hereditary and Health in Africa Kidney Disease Network. Calibrated log transformed 24-hr urinary sodium (UNa), potassium (UK) and sodium/potassium ratio (UNa/UK) were analyzed centrally. Using generalized linear regression with a random intercept for clinical center, we calculated crude and adjusted (adjusting for covariates)  $\beta$  coefficients and 95% CI with each blood pressure parameter. Similar cross-sectional analyses were performed in the Chronic Renal Insufficiency Cohort (n=3459).

**Results:** Median UNa excretion was lower in West Africans vs Americans [134 (104-175) vs. 160 (118-215) mmol/24hr,  $p < 0.001$ ]. Median UK excretion was lower in West Africans vs Americans [36 (28-48) vs 55 (40-74) mmol/24hr ( $p < 0.001$ )]. Higher UNa excretion was associated with higher SBP in both cohorts (**Fig 1**). Higher UK was associated with lower SBP, and significantly associated with lower DBP in both cohorts.

**Conclusions:** Cross-sectionally, higher urinary Na excretion, lower urinary K excretion and higher Na/K ratio are associated with higher blood pressure and is consistent among West Africans and Americans with CKD.

**Funding:** NIDDK Support

$\beta$  Coefficients and 95% CI of UNa and K and Blood pressure

## TH-PO807

## Estimated 24-Hour Urinary Sodium Excretion and the Risk of ESKD

Xiaoyan Huang, Peking University Shenzhen Hospital, Shenzhen, China.

**Background:** Sodium reduction lowers blood pressure and albuminuria, but the association between sodium intake and long-term kidney hard endpoints is debated and yet to be proven. We investigated linear and nonlinear associations of estimated 24-h urinary sodium excretion, reflecting daily sodium intake, with the incidence of ESKD.

**Methods:** This was a population-based cohort study including 444,375 community-dwelling volunteers (mean age, 56.2 years; 54% females) from the UK Biobank. The participants were followed for a median of 12.7 years. Estimated 24-h urinary sodium excretion was calculated based on spot urinary biomarkers at baseline. A repeated measurement after an average of 4.3 years in a subsample of 17,205 participants was used to correct for regression dilution bias. The outcome of interest was incident ESKD, ascertained by linking to electronic health records. We constructed Cox proportional hazards models and restricted cubic splines to access both linear and nonlinear relationships.

**Results:** The mean estimated 24-h urinary sodium excretion was 3.3 g. During follow-up, 865 (0.2%) ESKD events occurred. For every 1 g increment in estimated 24-h urinary sodium excretion, multivariable-adjusted HRs (95% CIs) for incident ESKD were 1.07 (0.95 - 1.21) and 1.09 (0.94 - 1.26) before and after regression dilution adjustment, respectively. Similar null results were observed when estimated 24-h urinary sodium excretion was treated as binary ( $< 2$  g vs.  $\geq 2$  g) or multicategorical. Nonlinear associations were not detected with restricted cubic splines. The null findings were confirmed by a series of sensitivity analyses, which attenuated potential bias from measurement errors of the exposure, reverse causality, and competing risks.

**Conclusions:** In individuals at low- or intermediate-risk, estimated 24-h urinary sodium excretion is neither linearly nor nonlinearly associated with the incidence of ESKD.

**Funding:** Government Support - Non-U.S.

Restricted cubic splines for the incidence of ESKD.

The analyses were adjusted for potential confounders. Each point of the curve is the pointwise average HR. Shaded areas represent 95% CIs.

## TH-PO808

## Investigating the Kidney-Gut-Brain Axis in CKD: Effects of High Amino Acids Diet With/Without Antibiotic Therapy

Yitong Zhao, Han Liu, Tiffany Tran, Mark Fisher, Wei Ling Lau. University of California Irvine, Irvine, CA.

**Background:** Chronic kidney disease (CKD) has been associated with increased brain microhemorrhages in humans and in animal models. The altered gut microbiome in CKD contributes to the accumulation of uremic toxins such as p-cresyl sulfate (pCS), indoxyl sulfate (IS) and trimethylamine N-oxide (TMAO), which are derived from amino acid catabolism. We hypothesize that these vascular toxins increase brain microhemorrhages, and that suppression of the gut microbiome with broad-spectrum antibiotics in drinking water (Abx) will modify this outcome.

**Methods:** Male C57Bl/6J mice were randomized to control or CKD groups. CKD was induced with 0.2% adenine diet. Subgroups of mice were fed a high amino acids diet (HAA: 1.26% tryptophan, 2.88% phenylalanine & 0.6% choline) with/without Abx (ampicillin 1g/L, vancomycin 500 mg/L, neomycin sulfate 1g/L & metronidazole 1g/L). Levels of creatinine, cystatin C and uremic toxins were measured in serum samples. Microhemorrhage quantification was done via brain histology with Prussian blue staining, and stool was analyzed for microbial diversity. Data were analyzed using ANOVA.

**Results:** Levels of creatinine and cystatin C were significantly increased in CKD vs control animals and were decreased with Abx water consumption in CKD mice. Consumption of Abx changed the composition of microbiota in the stool samples. More Lactobacillus was observed in CKD and CKD+HAA mice compared to controls. There was an increased abundance of Akkermansia on the HAA diet, and Abx treatment markedly increased gut Enterobacter while suppressing other bacterial taxa. Levels of the uremic toxins pCS, IS and TMAO were significantly increased in CKD groups compared to controls, and TMAO was further increased on the HAA diet. Consumption of Abx in drinking water significantly reduced levels of all 3 toxins and the number of brain microhemorrhages (see table).

**Conclusions:** Broad-spectrum oral antibiotics treatment altered the gut microbiome, suppressed serum uremic toxins, and reduced brain microhemorrhage development in CKD mice.

**Funding:** Other NIH Support - NINDS

Table 1. Serum metabolites and cerebral microhemorrhage counts in control (CTL) and chronic kidney disease (CKD) groups. HAA: high amino acid diet; Abx: antibiotics in drinking water.				
	CTL n=8	CKD n=16	CKD+HAA n=16	CKD+HAA+Abx n=16
Creatinine (mg/dL)	0.046 ± 0.001	0.243 ± 0.011*	0.160 ± 0.003**	0.141 ± 0.008**

TH-PO809

**Association Between Dietary Protein Sources and Gut-Derived Uremic Toxins in Patients on Long-Term Hemodialysis**  
Yoko Narasaki, Connie Rhee, Yitong Zhao, Kamyar Kalantar-Zadeh, Wei Ling Lau. *University of California Irvine, Irvine, CA.*

**Background:** Gut-derived uremic toxins derived from bacterial catabolism of amino acids include indoxyl sulfate (IS), p-cresyl sulfate (PCS) and trimethylamine N-oxide (TMAO). These vascular toxins have been associated with increased risk of cardiovascular events and mortality in chronic kidney disease (CKD). In this study, we examined the association between dietary protein sources and gut-derived uremic toxins in chronic hemodialysis patients using an existing biorepository from the “Malnutrition, Diet and Racial Disparities in CKD” (MADRAD) study.

**Methods:** Dietary intake was assessed using the Block Food Frequency Questionnaire (FFQ). Serum samples collected within 1 year of FFQ survey date were analyzed for uremic toxins using mass spectrometry. Cross-sectional associations were examined using linear regression models.

**Results:** Participant age was 54±15 years (mean±SD) and 54% were male, n=154. Dialysis vintage was 4.1±3.3 years, and serum was analyzed 2.7±5.8 months from time of FFQ survey. Caloric intake averaged 985 kcal/day [interquartile range (IQR) 569, 1400] and total protein intake was 42 g/day [IQR 24, 64] with 70% from animal sources [IQR 60, 76]. Average serum toxin levels for IS, PCS and TMAO were 10.6±7.1, 79.5±74.9 and 6.6±4.3 ug/mL respectively, as compared to 0, 1.4 and 1 ug/mL in healthy controls. On unadjusted linear regression analysis, there was a positive association between %plant-based protein intake and higher IS levels (beta coefficient, B = 0.074 with 95% confidence interval [CI] 0.005, 0.143; P=0.03) as well as dietary fiber intake from vegetables/fruits and IS levels (B = 0.677 with 95% CI: 0.215, 1.138; P<0.01). There was a negative association between dairy intake and TMAO (B = -1.473 with 95% CI: -2.620, 0.326; P=0.01) and between total animal protein intake and TMAO (B = -0.022 with 95% CI: -0.043, -0.002; P=0.04). Percent plant vs animal protein intake was not associated with PCS levels.

**Conclusions:** This hemodialysis cohort study revealed unexpected associations between higher plant-based protein intake and higher levels of circulating uremic toxins. More work is needed to elucidate the dietary sources of gut-derived toxins in the dialysis population.

TH-PO810

**The Dietary Fiber Inulin Beneficially Alters the Gut Microbiota and Microbially-Derived Metabolites in a Rat Model of Progressive CKD**  
Annabel Biruete,<sup>1,2</sup> Shruthi Srinivasan,<sup>2</sup> Kalisha O’Neill,<sup>2</sup> Henriette De Ioor,<sup>3</sup> Pieter Evenepoel,<sup>3</sup> Kelly Swanson,<sup>4</sup> Neal X. Chen,<sup>2</sup> Sharon M. Moe.<sup>2</sup> <sup>1</sup>*Indiana University Purdue University Indianapolis, Indianapolis, IN;* <sup>2</sup>*Indiana University School of Medicine, Indianapolis, IN;* <sup>3</sup>*Katholieke Universiteit Leuven, Leuven, Belgium;* <sup>4</sup>*University of Illinois Urbana-Champaign, Urbana, IL.*

**Background:** Inulin is a fermentable dietary fiber that may be able to improve uremic dysbiosis. Our objective was to evaluate if inulin impacts the gut microbiota and derived metabolites in a rat model of CKD-MBD.

**Methods:** The Cy/+ rats, a model of progressive CKD, were fed a grain-based diet until 22 weeks of age and then changed to a casein-based diet with either inulin (CKD+IN) or cellulose (non-fermentable fiber; CKD+CE) for 10 weeks (until the CKD animals had a GFR ~ 15% or normal) to test the hypothesis that fiber type affects the cecal microbiota and derived metabolites, including uremic toxins. NL littermates were treated with a casein-based diet with cellulose (NL). Cecal microbiota, cecal and serum butyrate, and microbially-derived serum uremic toxins were analyzed.

**Results:** There was no difference in CKD progression in the CKD animals with the two types of fiber. The a-diversity, or diversity within a sample, was lower with CKD+IN treatment across different metrics (p<0.03) than CKD+CE and NL. B-diversity, or diversity between samples, was also different in CKD+IN vs. CKD+CE or NL (PERMANOVA q=0.03). At the genera-level, CKD+IN (vs. CKD+CE or NL) had a higher

relative abundance of *Allobaculum*, *Bacteroides*, *Parabacteroides*, *Bifidobacterium*, and *Sutterella*, and lower *Clostridium*, unclassified *Peptostreptococcaceae*, *U. Desulfovibrionaceae*, *U. Ruminococcaceae*, and *Oscillospira* (p<0.05). Fecal and serum butyrate, a short-chain fatty acid produced by the microbiota, were increased in the CKD+IN by 3- and 7-fold, respectively, vs. NL and CKD+CE (p<0.03). CKD+IN lowered the elevated levels of indoxyl sulfate and p-cresyl sulfate found in the CKD+CE group (p<0.0008) to concentrations similar to the NL rats despite no difference in kidney function between CKD+CE and CKD+IN.

**Conclusions:** In our rat model of CKD-MBD, the fermentable fiber inulin, compared to non-fermentable fiber cellulose, improved the gut microbiota composition and the microbially-derived metabolites, including butyrate and uremic toxins. This suggests that adequate dietary fiber substrates can improve uremic dysbiosis and reduce toxin production.

**Funding:** NIDDK Support

TH-PO811

**Plasma Metabolites and Physical Function in Patients Undergoing Dialysis**  
Keith G. Avin,<sup>1,2</sup> Ranjani N. Moorthi,<sup>2</sup> Sharon M. Moe,<sup>2</sup> Thomas Oconnell,<sup>2</sup> Stephanie Dickinson,<sup>3</sup> Sahir Kalim,<sup>4</sup> Clary B. Clish,<sup>5</sup> Tariq Shafi,<sup>6</sup> Eugene P. Rhee.<sup>4</sup> <sup>1</sup>*Indiana University Purdue University Indianapolis, Indianapolis, IN;* <sup>2</sup>*Indiana University School of Medicine, Indianapolis, IN;* <sup>3</sup>*Indiana University Bloomington, Bloomington, IN;* <sup>4</sup>*Massachusetts General Hospital, Boston, MA;* <sup>5</sup>*Broad Institute, Cambridge, MA;* <sup>6</sup>*University of Mississippi School of Medicine, Jackson, MS.*

**Background:** Impaired physical function contributes to falls, fractures, and mortality among patients undergoing dialysis. Using a metabolomic approach, we identified metabolite alterations and composite scores associated with measures of impaired physical function (gait speed and grip strength).

**Methods:** In 108 subjects incident to dialysis, targeted plasma metabolomics via liquid chromatography-mass spectrometry and physical function (i.e., 4m walk, handgrip strength) were measured. Gait speed and grip strength were categorized as above/ below median, with grip utilizing sex-based medians. Metabolites significant between gait speed and grip strength groups (Wilcoxon p<0.05) and effect sizes >0.40 were used to develop composite scores. Receiver operating characteristic analyses tested whether scores differentiated between high and low function groups.

**Results:** Participants were 54% male, 77.4% Black and 53.4 ± 13.9 y. Median (IQR) grip strength was 35.5 (11.1) kg (males) and 20 (8.4) kg (females); median gait speed was 0.82 (0.34) m/s. Of 246 measured metabolites, 30 and 20 metabolites were different between grip strength and gait speed groups respectively with three common metabolites (C7 carnitine, phosphocholine isomer, valine). Composite scores were composed of 22 and 12 metabolites that differentiated grip strength and gait speed, respectively. Area under the curve for metabolite composite was 0.88 (gait) and 0.911 (grip).

**Conclusions:** n this study, we developed a composite score that represents physical function with metabolites unique for each measure of gait speed and grip strength in patients who are incident to dialysis. We included 22 key metabolites for grip strength and 12 metabolites for gait speed in the composite score, with alterations in fatty acid oxidation and protein synthesis observed in both measures. Given the complexity of the systems involved in physical function, the use of panels of metabolites associated with physical function offers a fresh opportunity to both predict changes over time and offer insight into pathophysiology for those with CKD.

TH-PO812

**Selenium Concentration and Kidney Function: A Mendelian Randomization Study**  
Schoon Park, Yong Chul Kim, Seung Seok Han, Hajeong Lee, Yon Su Kim, Dong Ki Kim. *Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

**Background:** Selenium is one of the trace minerals that is commonly included in micronutrient supplements, although the supplementation is associated with some adverse side effects. The effect of selenium on kidney function remains unclear. A genetically predicted micronutrient and its’ association between eGFR can be used to assess the causal estimates towards kidney function by Mendelian randomization (MR).

**Methods:** In this MR study, we instrumented 11 genetic variants associated with blood or toenail selenium level with genome-wide significance from a previous large-scale genome-wide association study (GWAS). The association between genetically predicted selenium concentration and eGFR was first assessed by summary-level MR in the CKDGen GWAS meta-analysis summary statistics including 567,460 European samples. Replication analysis was performed with individual-level UK Biobank data including 337,318 white British ancestry individuals.

**Results:** Summary-level MR analysis by inverse variance weighted method indicated that a genetically predicted one standard deviation increase in selenium concentration was significantly associated with low eGFR [-1.05 (-1.28, -0.82) %]. The results were similarly reproduced by pleiotropy-robust MR analysis including MR-Egger and weighted median method. In the UK Biobank data, genetically predicted high selenium concentration was also significantly associated with low eGFR [-0.36 (-0.52, -0.20) %],

and the results were similar when body mass index, hypertension, and diabetes mellitus covariates were adjusted [-0.33 (-0.50, -0.17) %].

**Conclusions:** This MR study suggests higher concentration of selenium may possibly decrease eGFR for a small degree. Selenium should be carefully supplemented for those at risk of kidney function impairment.

#### TH-PO813

##### Underweight Status and Development of ESKD: A Nationwide Population-Based Study

Chang Seong Kim,<sup>1,2</sup> Tae ryom Oh,<sup>2</sup> Sang Heon Suh,<sup>2</sup> Hong sang Choi,<sup>1,2</sup> Eun Hui Bae,<sup>1,2</sup> Seong Kwon Ma,<sup>1,2</sup> Soo Wan Kim.<sup>1,2</sup> <sup>1</sup>Chonnam National University Medical School, Gwangju, Republic of Korea; <sup>2</sup>Chonnam National University Hospital, Gwangju, Republic of Korea.

**Background:** An underweight status increases the risk of cardiovascular disease and mortality in the general population. However, whether an underweight status is associated with an increased risk of developing end-stage kidney disease (ESKD) is unknown.

**Methods:** A total of 9,845,420 participants aged  $\geq 20$  years who underwent health checkups were identified from the Korean National Health Insurance Service database and were analyzed in this study. Individuals with underweight (body mass index [BMI]  $< 18.5$  kg/m<sup>2</sup>) and obesity (BMI  $\geq 25$  kg/m<sup>2</sup>) were categorized according to the World Health Organization recommendations for Asian populations.

**Results:** During a mean follow-up period of  $9.2 \pm 1.1$  years, 26,406 participants were diagnosed with ESKD. After fully adjusting for other potential predictors of ESKD, the severe underweight group (BMI  $< 16.5$  kg/m<sup>2</sup>) had a significantly higher risk of ESKD than the reference (normal) weight group (adjusted hazard ratio [HR], 1.531; 95% confidence interval [CI], 1.243–1.884), whereas the obesity group had a lower risk of ESKD (adjusted HR, 0.661; 95% CI, 0.642–0.681). Compared with the reference BMI group (BMI 24–25 kg/m<sup>2</sup>), the adjusted HRs for ESKD increased as BMI decreased by 1 kg/m<sup>2</sup>. In the sensitivity analysis, sustained underweight or progression to an underweight status over two repeated health checkups had a higher HR for ESKD, even after fully adjusting for other potential predictors.

**Conclusions:** An underweight status is associated with an increased risk of ESKD, and this association gradually becomes stronger as BMI decreases.

#### TH-PO814

##### Strategies to Improve Self-Management in CKD From the Patient Perspective

Sarah J. Schrauben,<sup>1</sup> Eleanor Rivera,<sup>3</sup> Diane Park,<sup>1</sup> Sandra Amaral,<sup>2</sup> Harold I. Feldman,<sup>1</sup> Laura M. Dember,<sup>1</sup> Frances K. Barg.<sup>1</sup> <sup>1</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>2</sup>The Children's Hospital of Philadelphia, Philadelphia, PA; <sup>3</sup>University of Illinois Chicago, Chicago, IL.

**Background:** Self-management is integral for the treatment of chronic kidney disease (CKD). Despite low adherence to self-management behaviors, few studies provide insight into ways to improve self-management. This current study aimed to describe factors needed to self-manage CKD and suggestions to improve self-management from the patient perspective.

**Methods:** Semi-structured interviews were conducted with 30 participants who were purposively recruited for representation by CKD stage (3 or 4), age ( $<65$ ,  $\geq 65$  yrs), race (white, non-white), and sex. Interviews focused on patient experiences with CKD and its management, and to identify resources necessary to manage CKD. They were recorded, transcribed, and entered into NVivo 12.0 for coding and analysis. Transcripts were coded inductively and analyzed thematically.

**Results:** Two themes described components necessary for self-management from the patient perspective. The first was “getting in the right mindset”, which included acceptance of the CKD diagnosis, being open-minded, and expecting lifestyle changes. The second theme was “supports of self-management”, which included educational resources, social/peer support, and a good patient-provider relationship. Almost all participants shared they wanted to be educated “on their level” about CKD. Participants shared that “having people who are in the same situation is very valuable”, especially for emotional support. Another shared that “you have to have open lines of communication with your doctor”. Participants also provided actionable suggestions for enhancing the supports of self-management, which included 1) creating a repository of trustworthy educational resources in laymen's terms, 2) establishing peer support groups, and 3) encouraging shared-decision making by providing example questions to patients that are important to ask doctors.

**Conclusions:** Participants with CKD in this study endorsed several key themes to promote their self-management, across different levels of the healthcare model. At an individual level, they endorsed the need to accept their disease and be ready to change, at a community-level, they emphasized benefits of social or peer support and at an institutional level, they stressed the need for education to be at the patient's level of health literacy and for shared-decision making in disease management.

**Funding:** NIDDK Support

#### TH-PO815

##### Using Formative Research to Develop a Healthy Lifestyle Program for Recent Kidney Transplant Recipients

Cheryl Gibson,<sup>1</sup> Aditi Gupta,<sup>1</sup> Abhijit S. Naik,<sup>2</sup> Debra K. Sullivan,<sup>6</sup> Mona D. Doshi,<sup>2</sup> Jaehoon Lee,<sup>4</sup> James M. Backes,<sup>5</sup> Susan P. Harvey,<sup>3</sup> Kelly Shaffer,<sup>2</sup> Rebecca Mount,<sup>1</sup> Heather Valentine.<sup>1</sup> <sup>1</sup>University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS; <sup>2</sup>University of Michigan Medical School, Ann Arbor, MI; <sup>3</sup>University of Kansas, Lawrence, KS; <sup>4</sup>Texas Tech University, Lubbock, TX; <sup>5</sup>University of Kansas School of Pharmacy, Lawrence, KS; <sup>6</sup>University of Kansas Medical Center Department of Nutrition and Dietetics, Kansas City, KS.

**Background:** A significant number of kidney transplant recipients experience weight gain in the first year after transplantation. Post-transplantation weight gain is associated with higher rates of cardiovascular disease, new-onset diabetes, metabolic syndrome and loss of graft function. The objective of this formative research project was to gather data to inform intervention design and implementation of a healthy lifestyle program to counter unnecessary weight gain.

**Methods:** Recent kidney transplant recipients at the University of Kansas Health System and the University of Michigan Transplant Center were invited to participate in an online survey. Survey items included sociodemographic information, current medications, health conditions, weight change post-transplant, diet behaviors, physical activity participation, and desired features of a healthy lifestyle program.

**Results:** Fifty-three (38 KS; 15 MI) participants, average age  $58 \pm 12$  years, primarily male, completed surveys. Forty percent gained weight post-transplantation with 19% gaining 10+ pounds. Most indicated struggling with their diet after transplantation, with ratings of current eating habits fair to poor (e.g., too few fruits and vegetables, too much sodium, fat and added sugars). Physical activity (PA) stayed the same (17%) or decreased (40%) post-transplantation with most not regularly participating in PA or resistance training. Many participants (41.5%) indicated they would very likely or definitely participate in a healthy lifestyle program of 6 to 12 months in length. Most wanted online PA and nutrition sessions to meet once or twice weekly with several suggestions about what kinds of information and activities to make part of the program, including healthy eating strategies (e.g., how to eat healthfully at restaurants, grocery shopping tips, recipes), resources for at-home physical activities, access to healthy cooking classes and apps to track both physical activity and food intake.

**Conclusions:** Gathered information will be used to inform and tailor the healthy lifestyle program for recent kidney transplant recipients. Identifying features of a program for the prevention of unnecessary weight gain with patients' input is essential for promoting healthy behaviors.

### Occupational Prolonged Sitting Increased the Risk Across the Spectrum of Kidney Disease: Results From a Cohort of a Half-Million Asian Adults

Min Kuang Tsai, Chi pang Wen. *National Health Research Institutes, Zhunan, Taiwan.*

**Background:** Kidney diseases were viewed as continuously progressing from microalbuminuria, chronic kidney disease (CKD), end-stage renal disease (ESRD), and deaths. The report of the association between prolonged sitting and kidney diseases is limited.

**Methods:** We examined a cohort of 455,506 participants in a screening program in Taiwan conducted between 1996 and 2017. Data on occupational sedentary behavior and physical activity were collected with a standardized questionnaire. The outcomes of ESRD and death were identified by linking with the Registry of Dialysis and Cause of Death Data. The association between prolonged sitting and CKD, the incident of ESRD, and death were assessed using a logistic regression model to compute odds ratios (ORs) and Cox proportional hazards model for hazard ratios (HRs).

**Results:** More than half of the participants, 265,948 (58.4%), were categorized as “prolonged sitting” during their work. During the median 13 years of follow-up, we identified 2,227 individuals undergoing dialysis and 25,671 deaths. Occupational prolonged sitting was significantly associated with a higher risk of CKD (OR: 1.26, 95% confidence interval: 1.21, 1.31), ESRD (HR: 1.19, 95% CI: 1.03, 1.38), and kidney-specific mortality (HR: 1.43, 95% CI: 1.07, 1.91) compared to mostly standing participants after controlling for physical activity and other risk factors. Inactive prolonged sitting carries a significantly higher risk of ESRD than physically active, mostly standing participants (HR: 1.34, 1.04, 1.73). However, active prolonged sitting decreased ESRD risk (HR: 1.03, 95% CI: 0.79, 1.34) compared to inactive prolonged sitting.

**Conclusions:** The results suggest that prolonged sitting is associated with a greater risk of kidney diseases, independent of physical activity. Given the pervasive nature of prolonged sitting, especially during the COVID-19 pandemic, decreasing the amount of time spent sitting can be a modifiable behavior to lower the risk of kidney diseases.

## TH-PO817

### Prehabilitative Virtual Reality Mindfulness and Personalized Physical Activity for Hemodialysis Patients With Depressive Symptoms: A Feasibility Study

Brett Burrows, Alexis King, Ashley Morgan, Kenneth R. Wilund. *University of Illinois Urbana-Champaign, Urbana, IL.*

**Background:** Historically, exercise-related trials in hemodialysis (HD) patients have suffered from low exercise adherence, possibly due to a lack of personalization and/or high rates of depression in HD patients. Therefore, our aim was to assess the feasibility and initial efficacy of applying a novel virtual reality (VR) mindfulness program as a prehabilitation to a personalized activity prescription (PARx) in HD patients with elevated depressive symptoms.

**Methods:** HD patients (n=10) with elevated depressive symptoms were randomized into a treatment (VR mindfulness + PARx) or control (PARx only) group. The intervention began with 2 weeks of prehabilitation, in which the treatment group was exposed to our VR-based mindfulness program and the control group received usual care. Directly following, both groups participated in 8 weeks of our PARx program. Feasibility was assessed through recruitment, retention, adherence, acceptability, and adaption (assessed by the Modified Health Care Climate Questionnaire). Initial efficacy was measured using metrics of depression, mindfulness, fatigue, and physical activity (PA) energy expenditure.

**Results:** Recruitment rate was 25%, with a 90% retention rate. Mean age was 59.60 ( $\pm$  13.66) years; 70% female; and 60% Black. 100% and 90% of the participants liked or strongly liked our VR mindfulness program and PARx, respectively. PARx demonstrated high levels of perceived autonomy support ( $M = 27.6 \pm 2.1$ ). Following the prehabilitation, the treatment group showed significant between-group improvement in mindfulness ( $p = 0.02$ ) and trended towards significance in depressive symptoms ( $p = 0.07$ ). Both groups saw an increase in PA energy expenditure from week 1 to week 8 of PARx (treatment: 824 to 2835 kcal/wk and control 792 to 1740 kcal/wk), though no between-group difference was evident. The treatment group did, however, have a significant within-group increase in PA energy expenditure ( $p < 0.01$ ).

**Conclusions:** The current pilot study demonstrated that our novel VR-based mindfulness program and PARx program are both feasible and potentially efficacious for in-center HD patients. Future trials should examine a larger sample size and expand the intervention duration to validate these findings.

### A Novel Exercise Intervention, Home-Based and Video-Supervised, Improved Cardiorespiratory Fitness and Physical Performance in CKD

Gwenaëlle Begue,<sup>1</sup> Alina Nicorici,<sup>2</sup> Nargies Ghafar,<sup>2</sup> Radhika Batra,<sup>2</sup> Harshanna Badhesha,<sup>2</sup> Chenoa R. Vargas,<sup>2</sup> Tae Youn Kim,<sup>2</sup> Hiba Hamdan,<sup>2</sup> Thomas Jue,<sup>2</sup> Jorge Gamboa,<sup>3</sup> Baback Roshanravan.<sup>2</sup> <sup>1</sup>California State University Sacramento, Sacramento, CA; <sup>2</sup>University of California Davis, Davis, CA; <sup>3</sup>Vanderbilt University Medical Center, Nashville, TN.

**Background:** Sarcopenia is a prevalent complication in chronic kidney disease (CKD) and a central component of the frailty phenotype associated with adverse clinical outcomes. In the era of COVID, there is a critical need for practical, safe, interactive, and personalized home-based exercise targeting improvements in physical function in vulnerable patients living with CKD.

**Methods:** The ESTEEM-VIDA CKD pilot randomized clinical trial tests the efficacy of a home-based, video-supervised, and personalized exercise program on cardiorespiratory fitness (CRF) and physical performance in patients with moderate-severe CKD. Exercise (EX, n=12) consisted of 30-40min exercise sessions, thrice a week for 12 weeks: high-intensity interval training, strength training, and moderate intensity walking. One week of video-supervised exercise alternates with one week of self-directed exercise. Each one-week video-supervised session was conducted by exercise trainers using a videoconference tool, while self-directed exercise weeks used pre-recorded exercise videos. Controls (CTL, n=5) received diet and exercise counseling at baseline. Pre- and post-intervention CRF (VO2peak) and total work were measured using a graded cycle ergometer test and physical performance was assessed by the 6-minutes walking distance (6MWT) test. The effect of exercise on change in CRF and 6MWT using linear mixed effects models was tested.

**Results:** Mean age was 62  $\pm$  10y with 47% females and 53% with diabetes. Mean eGFR was 34.4 $\pm$ 11.8 ml/min per 1.73m<sup>2</sup>. Mean total work and 6MWT at baseline were 31.7  $\pm$  17kJ and 494  $\pm$  51m, respectively. EX was associated with a 6.9kJ increase in total work (95% CI 2, 12;  $p = 0.008$ ) compared to CTL independent of change in VO2peak, suggesting improved muscular efficiency following training. EX was associated with a 43m increase in 6MWT (95% CI 11, 75;  $p = 0.008$ ) compared to CTL. VO2peak did not differ between groups ( $p = 0.99$ ).

**Conclusions:** Preliminary findings suggest a home-based, video supervised, personalized exercise program is feasible and efficacious in improving muscular and physical performance in CKD. It provides a tool for studying metabolic and molecular health and may shed new light on the pathophysiology of sarcopenia in CKD.

**Funding:** NIDDK Support, Private Foundation Support

## TH-PO819

### Relationship Between Serum Klotho Levels and Physical Function in a Community-Based Cohort

Elliott Arroyo,<sup>1</sup> Gayatri Narayanan,<sup>1</sup> Andrew R. Coggan,<sup>2</sup> Sharon M. Moe,<sup>1</sup> Kenneth Lim.<sup>1</sup> <sup>1</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>2</sup>Indiana University Purdue University Indianapolis, Indianapolis, IN.

**Background:** Sarcopenia is a degenerative skeletal muscle disease involving the loss of muscle mass and function that can progress into decreased physical function. Beyond exercise and physical activity interventions, there are limited options for the treatment of sarcopenia. Therefore, identifying potential modifiable targets for the treatment of sarcopenia is critically important. Emerging data indicates that the anti-aging protein Klotho may play a key role in regulating sarcopenia and physical function. Herein, we sought to examine the relationship between serum Klotho levels and physical function in a well-validated community-based cohort.

**Methods:** We conducted an exploratory analysis utilizing data from the “Musculoskeletal Function, Imaging and Tissue Resource Core (FIT Core) study” cohort that enrolled ambulatory men and women in Central Indiana aged 5 years and over. All patients underwent comprehensive physical performance assessment and self-reported physical activity questionnaire.

**Results:** A total of 80 healthy participants (age=49 [18] years) were stratified into four age groups (n=20, 10 [50%] men per group): 20-35 years, 35-50 years, 50-65 years, and  $\geq$ 65 years. Subjects were further grouped into Low and High performers based on the z-scores for grip strength and number of chair stands completed in 30 seconds. Klotho levels were significantly lower in the  $\geq$ 65 years group (703.0 $\pm$ 189.3 pg/mL) compared to 20-35 years group (916.1 $\pm$ 284.8 pg/mL;  $p = 0.03$ ). Despite significantly higher grip strength, number of chair stands completed in 30 seconds, gait speed, distance walked in 6 minutes, and self-reported physical function (SF-36 and PROMIS PF CAT), no significant differences were observed in Klotho levels between the Low and High performers in any age group.

**Conclusions:** Our findings suggest that Klotho levels decline with increasing age but are not associated with declines in physical function in a healthy community-based cohort. Studies evaluating the relationship between impaired physical function and Klotho levels in patients with chronic kidney disease (CKD), a known state of Klotho deficiency, are warranted.

**Funding:** Other NIH Support - National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS)

## TH-PO820

### Objective Physical Activity Is Associated With Glycemic Variability in Patients With CKD

John Mowrey, Zaneb Mehmood, Harshanna Badhesha, Radhika Batra, Hiba Hamdan, Tae Youn Kim, Baback Roshanravan. *University of California Davis, Sacramento, CA.*

**Background:** Sedentary behavior is highly prevalent in patients with Chronic Kidney Disease (CKD) and strongly associated with adverse metabolic and clinical outcomes across populations. However, associations of objective and self-reported physical activity with clinically relevant measures of glycemic variability in patients with CKD remain unknown.

**Methods:** We performed a cross-sectional study in 25 patients with moderate-severe CKD simultaneously wearing an ActivPAL 4 accelerometer and Abbott Freestyle Libre Pro continuous glucose monitor (CGM) for 2 weeks. Self-reported physical activity was evaluated using the Human Activities Profile (HAP), divided into maximal and adjusted activity scores. Linear regression was used to test associations of measures of physical activity and CGM.

**Results:** Mean eGFR of our sample was  $35.72 \pm 11.54$  ml/min with 48% female, and 56% with diabetes. Average sitting time in the cohort was  $527 \pm 168$  min/day. We observed that greater sitting time correlates with worsening glucose control including higher average glucose ( $P=0.04$ ), decreased time in target ( $p=0.04$ ), and increased time above target ( $p=0.007$ ). Each 1-SD increase in sitting time was associated with a 0.77SD lower (95% CI 0.65SD, 2.11SD lower;  $p=0.001$ ) time in target range (70-140mg/dL) independent of diabetes status, sex, and BMI. We did not see any meaningful or significant association of impact on self-reported physical activity on CGM readings.

**Conclusions:** Objective measurement of sitting time is strongly associated with worse glycemic control in patients with CKD. Future intervention studies are needed to determine if physical activity interventions improve glycemic control in CKD patients with, and without diabetes.

##### The Impact of Home-Based Exercise on Skeletal Muscle Mitochondria in CKD

Jennifer E. Norman,<sup>1</sup> Jesse Gipe,<sup>1</sup> Béatrice Chabi,<sup>2</sup> Radhika Batra,<sup>1</sup> Harshanna Badhesha,<sup>1</sup> Chenoa R. Vargas,<sup>1</sup> Armin Ahmadi,<sup>1</sup> Tae Youn Kim,<sup>1</sup> Thomas Jue,<sup>1</sup> Jorge Gamboa,<sup>3</sup> Gwenaëlle Begue,<sup>4</sup> Baback Roshanravan.<sup>1</sup> <sup>1</sup>University of California Davis, Davis, CA; <sup>2</sup>DMEM, Université de Montpellier, INRAE, Montpellier, France; <sup>3</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>4</sup>California State University Sacramento, Sacramento, CA.

**Background:** Mitochondrial dysfunction in patients with chronic kidney disease (CKD) contributes to the development of sarcopenia, central to the frailty phenotype. The impact of exercise on muscle mitochondrial energetics in patients with CKD is unknown.

**Methods:** We performed an interim analysis of the ESTEEM-VIDA CKD study, a pilot randomized trial of a 12 week, home-based, video-supervised exercise intervention in CKD patients. Vastus lateralis biopsy samples were analyzed by high resolution respirometry (Oroboros O2k) pre and post intervention. Two protocols were run: 1) muscle tissue was homogenized using the PBI Shredder and the  $O_2$  consumption and hydrogen peroxide production were measured simultaneously (using Amplex UltraRed) and 2)  $O_2$  consumption was measured on permeabilized muscle fibers in a more comprehensive protocol, including measurements with sub-saturating ADP concentrations. We used paired t-tests to test for differences in mitochondrial respiration rates pre and post exercise intervention.

**Results:** Respirometry rates were compared pre and post exercise intervention for 11 participants. Protocol 1 demonstrated an increase in succinate supported leak (53% increase,  $p=0.005$ ) and pyruvate and succinate supported OXPHOS (57% increase,  $p=0.0114$ ). There was a decrease in hydrogen peroxide production relative to  $O_2$  consumption in the succinate supported leak state (20% decrease,  $p=0.0326$ ). In protocol 2, pyruvate and malate supported OXPHOS with 31.25  $\mu$ M ADP (44% increase,  $p=0.0435$ ) and 62.5  $\mu$ M ADP (55% increase,  $p=0.0485$ ) were significantly increased after exercise, while no statistical differences were observed between pre and post exercise intervention for OXPHOS with saturating ADP.

**Conclusions:** Exercise increased leak and OXPHOS respiratory rates measured on skeletal muscle homogenate (protocol 1), but changes in respiratory rates measured on permeabilized fibers with saturating ADP were not evident. The lack of agreement between the protocols may be attributed to greater sample variability between permeabilized fiber bundles, requiring a greater number of samples to detect a change in respiration rates. Further, our data may indicate increased sensitivity to changes in respiration with sub-saturating levels of ADP.

##### Exercise in CKD Patients Reduces Collagen Crosslinking but Not Total Collagen in Quadriceps Muscle

Sarah E. Brashear,<sup>1</sup> Armin Ahmadi,<sup>1</sup> Tae Youn Kim,<sup>1</sup> Jorge Gamboa,<sup>2</sup> Baback Roshanravan,<sup>1</sup> Lucas R. Smith.<sup>1</sup> <sup>1</sup>University of California Davis, Davis, CA; <sup>2</sup>Vanderbilt University, Nashville, TN.

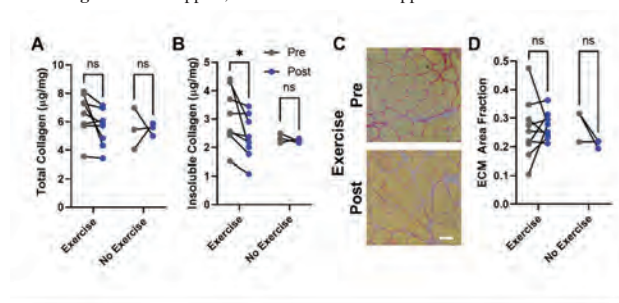

**Background:** Muscles in CKD become fibrotic, containing excess extracellular matrix (ECM), particularly collagen, that contribute to muscle dysfunction. Collagen is crosslinked in the ECM with crosslinking associated with fibrosis, stiffness, and reduced ECM remodeling. However, it is not known how exercise in CKD may impact the extent of collagen crosslinking or fibrosis.

**Methods:** We studied 12 patients with non-dialysis CKD (eGFR < 60 ml/min per  $1.73m^2$ ) enrolled in the ESTEEM-VIDA CKD pilot randomized clinical trial who underwent muscle biopsy. Participants were randomized to home-based exercise ( $n=9$ ) or no exercise ( $n=3$ ). Exercise consisted of 30-40 min sessions, thrice weekly for 12 weeks. Vastus lateralis biopsies were obtained pre and post 12 weeks. Biochemical analysis used tissue powdered and separated into a pepsin and acidic acid soluble and insoluble fraction before applying a hydroxyproline assay. The insoluble fraction represents the more crosslinked collagen. For histology tissue frozen in liquid nitrogen cooled isopentane was cut in  $10\mu$ m thick sections and stained with Picrosirius Red.

**Results:** The overall amount of collagen was not altered in either group (Fig. 1A). However, the amount of heavily crosslinked collagen associated with fibrosis was significantly decreased in the exercise cohort (Fig. 1B). Picrosirius red stained sections did not reveal a change in ECM area with exercise (Fig. 1C/D).

**Conclusions:** This study shows that while overall collagen was not influenced by exercise, the extent of crosslinked collagen was decreased with exercise in CKD patients. This is indicative of improved muscle health as collagen crosslinking is associated with fibrosis, increased muscle stiffness, and decreased ECM remodeling.

**Funding:** NIDDK Support, Private Foundation Support

**Figure 1:** Skeletal muscle collagen. A) Total collagen content and B) crosslinked collagen measured biochemically pre- and post- exercise intervention. C) Representative sirius red stained sections labeling ECM in red from a CKD subject pre- and post- exercise intervention. D) Quantification of ECM area fraction. Scale bar = 50  $\mu$ m.

#### TH-PO823

##### Exercise Training Reduces Maximal Peripheral Blood Mononuclear Cell Mitochondrial Respiration While Increasing Anti-Inflammatory IL-10 in Patients With CKD

Armin Ahmadi,<sup>1</sup> Jennifer E. Norman,<sup>1</sup> Radhika Batra,<sup>1</sup> Harshanna Badhesha,<sup>1</sup> Jesse Gipe,<sup>1</sup> Chenoa R. Vargas,<sup>1</sup> Béatrice Chabi,<sup>2</sup> Tae Youn Kim,<sup>1</sup> Thomas Jue,<sup>1</sup> Gwenaëlle Begue,<sup>3</sup> Jorge Gamboa,<sup>4</sup> Baback Roshanravan.<sup>1</sup> <sup>1</sup>University of California Davis, Davis, CA; <sup>2</sup>Université de Montpellier, Montpellier, France; <sup>3</sup>California State University Sacramento, Sacramento, CA; <sup>4</sup>Vanderbilt University, Nashville, TN.

**Background:** Patients with CKD suffer from impaired physical performance. Exercise has been shown to improve physical performance in CKD, but its impact on immune cell mitochondrial function is unknown. We tested the impact of exercise on peripheral blood mononuclear cell (PBMC) mitochondrial function and their link with inflammatory biomarkers.

**Methods:** We performed an interim analysis of pilot randomized trial of 12 weeks of home-based, video supervised exercise intervention in CKD. Intact PBMC bioenergetics were measured using the high resolution respirometry (Oroboros O2k). We estimated basal, maximal respiration (MR) and reserve capacity (RC). Plasma IL-10 concentrations were measured using ELISA. Two-way ANOVA was used to evaluate the impact of exercise on PBMC bioenergetics. Spearman correlation was calculated for changes in log-transformed MR and IL-10 concentrations in exercise responders defined with >5% improvement in total work measured by cycle ergometry testing.

**Results:** Twelve participants ( $60.6 \pm 11.1$  yrs) were randomized to the exercise (EX) group and 5 ( $64.5 \pm 8.1$  yrs) were randomized to the non-exercise control (CTL) group. The mean EX eGFR was  $33.3 \pm 14.1$  compared to eGFR of  $37 \pm 3.1$  of CTL. The mean MR was 10.9 (3.8) and mean RC was 8.57 (2.8). EX was associated with a marked reduction in MR and RC compared to CTL ( $p=0.03$  and  $p=0.02$ , respectively) (Figure 1A). The change in PBMC MR inversely correlated with changes in plasma IL-10 concentration among EX responders ( $n=9$ ,  $r=-0.83$ ,  $p=0.008$ ) (Figure 1B).

**Conclusions:** A decrease in PBMC MR is associated with an increase in anti-inflammatory IL-10 levels which suggest that exercise alters PBMC mitochondrial energetics in CKD. Future studies will focus on the impact of exercise on immune cell metabolic health and its immunomodulatory effects in CKD

**Funding:** NIDDK Support, Private Foundation Support

## TH-PO824

### Association of Mitochondrial Respiration in Peripheral Blood Mononuclear Cells With Fatigue in Persons With CKD

Tae Youn Kim,<sup>1</sup> Harshanna Badheshia,<sup>1</sup> Radhika Batra,<sup>1</sup> Jesse Gipe,<sup>1</sup> Armin Ahmadi,<sup>1</sup> Chenoa R. Vargas,<sup>1</sup> Jennifer E. Norman,<sup>1</sup> Thomas Jue,<sup>1</sup> Gwenaelle Begue,<sup>3</sup> Jorge Gamboa,<sup>2</sup> Baback Roshanravan.<sup>1</sup> <sup>1</sup>University of California Davis, Sacramento, CA; <sup>2</sup>Vanderbilt University, Nashville, TN; <sup>3</sup>California State University Sacramento, Sacramento, CA.

**Background:** Increased physical frailty and fatigue are prevalent in persons with chronic kidney disease (CKD), contributing to poor quality of life and increased morbidity and mortality risk. Impaired mitochondrial function adversely impacts energy metabolism and may contribute to increased fatigue. While patient-reported fatigue is a complex syndrome involving physiological and psychological mechanisms, little is known about the relevance of PBMC mitochondrial bioenergetics to fatigue in CKD.

**Methods:** We performed a cross-sectional analysis of the association of PBMC mitochondrial energetics and patient reported fatigue in 27 persons. PBMC basal respiration (BR) and maximal uncoupled respiration (MR) were measured using the high resolution respirometry (Oroboros O2k). Fatigue and depression were measured using the 8-item PROMIS® Fatigue and Depression scales respectively. A higher PROMIS score indicates having more fatigue or depressive mood. Linear regression with robust standard errors was used to test associations adjusting for sex, age, and depression.

**Results:** Fifty-two percent of the sample were male and diabetes with a mean age of 63±10 years and mean eGFR of 37±12ml/min per 1.73m<sup>2</sup>. The mean depression and fatigue scores were 47±8.3 and 50±8.5 respectively. The mean PBMC BR and MR were 2.2±0.8 and 9.3±3.3 pmol O<sub>2</sub>/min/10K cells respectively. Spearman's correlation coefficient was -.43 (p=.025) between BR and fatigue and -.46 (p=.015) between MR and fatigue. The elevated BR was associated with less fatigability after adjustment of sex and age. Each 1 standard deviation greater BR was associated with a 8.7-point (95%CI [-16.0, -1.3], p=.023) reduction in fatigue. Further adjustment for depression minimally attenuated the estimated association (8.5 points, 95%CI [-14.6, -2.4], p=.0008), suggesting a potential role of PBMC mitochondrial energetics in explaining the variation in fatigability.

**Conclusions:** In a cross-sectional analysis, greater PBMC mitochondrial respiration was associated with improved patient-reported outcomes. Further research is needed to examine longitudinal impact of improving PBMC mitochondrial function on patient outcomes such as fatigue and quality of life in a larger cohort of CKD.

**Funding:** NIDDK Support, Private Foundation Support

## TH-PO825

### Association Between Cardiorespiratory Fitness and Muscle Strength in Maintenance Hemodialysis Patients

Kun Zhang, Zhang-Yi Zhu, Xin Li, Chen Yu. Tongji University, Shanghai, China.

**Background:** Cardiovascular disease (CVD) is one of the most common complications in patients with maintenance hemodialysis (MHD). Cardiopulmonary fitness (CRF) was strongly associated with the incidence of CVD and the risk of all-cause death. MHD patients always have muscle wasting because of chronic inflammation, oxidative stress, dietary restrictions and other factors, but there is still a lack of relevant research between CRF and muscle strength in MHD patients. We aimed to investigate the association between cardiorespiratory fitness and muscle strength in maintenance hemodialysis (MHD) patients.

**Methods:** In this Cross-Sectional Study, patients who were ≥18 years old and were treated with regular MHD ≥3 months in MHD center from September 2020 to December 2020 were recruited. Cardiopulmonary exercise test (CPET) was used to test cardiorespiratory fitness (CRF) of MHD patients. Baseline data including body circumference, exercise capacity, upper and lower extremity muscle strength as well as clinical and biochemical data were collected. Correlation and hierarchical regression analysis was performed on the corresponding indicators to explore the influencing factors of CRF and the relationship between CRF and muscle strength.

**Results:** A total of 48 patients were enrolled in our study, of whom 34 were male (70.8%), the age was (60.31±10.44) years old, and the median dialysis vintage was 48(15,84) months. Furthermore, CRF was positively correlated with lower extremity muscle strength (r = 0.322, P = 0.026) and 6MWT (r = 0.307, P = 0.034), was negatively correlated with age (r = -0.300, P = 0.038). Multivariate linear regression analysis demonstrated that age (β=-0.235) and lower extremity muscle strength (β=0.241) were the influencing factor for peak VO<sub>2</sub>/kg.

**Conclusions:** Cardiorespiratory fitness were at an extremely low level, which is closely related to the lower extremity muscle strength in MHD patients.

## TH-PO826

### Mitochondrial Quality Control Mechanisms and Fatty Acid Metabolism in Renal Cortex During the Normoalbuminuric Stage of Diabetes Mellitus

Naohito Ishii,<sup>1</sup> Pamela K. Carmines,<sup>2</sup> Yoshifumi Kurosaki,<sup>1</sup> Akemi Imoto,<sup>1</sup> Taro Sugase,<sup>4</sup> Hiroyuki Takahashi,<sup>1</sup> Masanori Yokoba,<sup>1</sup> Takafumi Ichikawa,<sup>1</sup> Tsuneo Takenaka,<sup>3</sup> Masato Katagiri.<sup>1</sup> <sup>1</sup>Kitasato University, Sgamihara, Japan; <sup>2</sup>University of Nebraska Medical Center, Omaha, NE; <sup>3</sup>International University of Health & Welfare, Minato-ku, Japan; <sup>4</sup>Seikai Medica Clinic, Tochigi, Japan.

**Background:** Oxidative stress during the normoalbuminuric stage of type 1 diabetes mellitus (DM) damages renal cortical mitochondria; hence, we aimed to determine if oxidative stress in DM triggers 1) mitochondrial fission or fusion, 2) mitophagy, and/or 3) increased fatty acid (FA) metabolism.

**Methods:** Rats receiving streptozotocin (STZ, 65 mg/kg i.p.) or vehicle (Sham) were left untreated or treated with telmisartan (TLM, an angiotensin receptor blocker; 10 mg/kg/d). Two weeks later, blood glucose (BG), blood pressure (BP), glomerular filtration rate (GFR), and urinary excretion of albumin (U<sub>alb</sub>V) and N-acetyl-β-D-glucosaminidase (U<sub>NAG</sub>V) were measured, and the renal cortex was harvested for the following assays: HPLC was used to detect 3-NT (oxidative stress marker). Fission-, fusion-, and mitophagy-related proteins were quantified by Western blot. Levels of acylcarnitine (transports FA into mitochondria for β-oxidation) were calculated as total-minus-free carnitine levels measured by the enzymatic cycling method. GC was used to quantify ω3 FAs (α-linolenic acid, EPA & DHA) and ω6 FAs (linoleic acid & AA).

**Results:** BP, U<sub>alb</sub>V, and U<sub>NAG</sub>V did not differ among groups. STZ rats displayed elevated BP and GFR that were unaffected by TLM. Renal cortical samples yielded the following: The ω3/ω6 FA ratio (corrected for FA intake) and 3-NT levels were increased in STZ rats (both P<0.05 vs Sham), effects that were prevented by TLM. Acylcarnitine levels in STZ rats were higher than in Sham and were further elevated in STZ+TLM (P<0.05 vs STZ alone). STZ rats displayed TLM-sensitive increases in the mitophagy-related proteins LC3-II and PINK1 (all P<0.05), but not BNIP3 dimer or p62. Drp1 (fission marker) was 3-fold higher in STZ than in Sham, with intermediate values in STZ+TLM. Mfn2 (fusion marker) did not differ among groups.

**Conclusions:** During the normoalbuminuric stage of DM, renal cortical mitochondria undergo enhanced fission and mitophagy, as well as increased FA metabolism with a shift toward ω3 FAs (antioxidant & vasoprotective) relative to ω6 FAs. As these effects are blunted by TLM jointly with its antioxidant effect, they are likely quality control mechanisms triggered by oxidative damage.

## TH-PO827

### Appropriate Evaluation of Sarcopenia Among Hemodialysis Patients: Impact of Different Indices of Muscle Mass and Myokines

Donghwan Oh,<sup>1</sup> Hae Yeul Park,<sup>1</sup> Jong Hyun Jhee,<sup>1</sup> Jung eun Lee,<sup>2</sup> Hoon Young Choi,<sup>1</sup> Hyeong cheon Park.<sup>1</sup> <sup>1</sup>Gangnam Severance Hospital, Seoul, Republic of Korea; <sup>2</sup>Yongin Severance Hospital, Yongin, Republic of Korea.

**Background:** No consensus exists for appropriate adjustment methods and cutoff values for the diagnosis of sarcopenia in hemodialysis (HD) patients. The aim of study was to investigate proper method for normalizing skeletal muscle mass to define low muscle mass (LMM) and assess myokines as potential biomarkers for sarcopenia.

**Methods:** We conducted a cross-sectional observational study in a cohort of 139 Korean HD patients. All patients underwent bioelectrical impedance analysis (BIA) to measure muscle mass after HD session. Appendicular skeletal muscle mass (ASM) was indexed to height-squared (HT<sup>2</sup>), body surface area (BSA), body mass index (BMI), and body weight (BW). Handgrip strength (HGS) and muscle function were evaluated using a handgrip dynamometer and a gait speed test, respectively. Serum myostatin was measured by enzyme-linked immunosorbent assay kit.

**Results:** The mean age of participants was 63.9±13.1 years, and 49.6% was male. Depending on the equation used to standardize ASM, the prevalence of LMM ranged from 17.3 to 29.5% and the prevalence of sarcopenia ranged from 11.5 to 20.9%. The prevalence of LMM adjusted for HT<sup>2</sup> and BW was not constant, in contrast no significant difference in LMM indexed to BSA and BMI was observed among the different BMI groups (normal: BMI<23kg/m<sup>2</sup>, overweight: 23kg/m<sup>2</sup>≤BMI<25kg/m<sup>2</sup>, obese: BMI>25 kg/m<sup>2</sup>). Muscle strength was positively correlated with muscle mass normalized by HT<sup>2</sup>, BSA, and BMI (r=0.63, 0.62 and 0.60, P<0.001, respectively), but the association was less robust in muscle mass indexed to BW (r=0.49, P<0.001). In term of the correlation between muscle mass and performance, there were significant direct correlations with all muscle mass indices, although the correlation was less robust. Patients with LMM by all definitions, especially BSA, were more likely to have muscle weakness compared to those

with normal muscle mass (OR 3.07, 95% CI 1.19-7.91,  $P=0.021$ ). Serum myostatin level was proportional to muscle mass ( $r=0.417$ ,  $P<0.001$ ) and was positively correlated with muscle strength ( $r=0.527$ ,  $P<0.001$ ) and performance ( $r=0.343$ ,  $P<0.001$ ).

**Conclusions:** Muscle mass index adjusted to BSA and BMI is superior to height or weight alone in terms of diagnosis of sarcopenia in HD patients. Moreover, serum myostatin may act as an adjunct biomarker for sarcopenia in HD patients.

## TH-PO828

### Molecular Mechanisms Underpinning Muscle Atrophy in CKD

Limy Wong,<sup>1,2</sup> Rachel Kenny,<sup>1</sup> Jennifer L. Howard,<sup>2</sup> Lawrence P. McMahon,<sup>1,2</sup>  
<sup>1</sup>Monash University Eastern Health Clinical School, Box Hill, VIC, Australia;  
<sup>2</sup>Eastern Health Foundation, Box Hill, VIC, Australia.

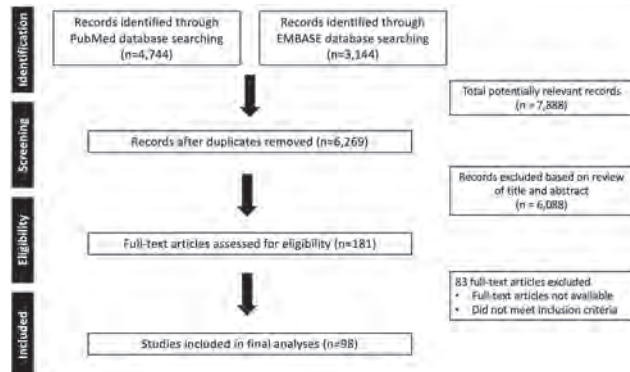

**Background:** Sarcopenia is prevalent in patients with chronic kidney disease (CKD). Emerging evidence reports the association of sarcopenia with poor outcomes. The underlying molecular pathogenesis has yet to be fully elucidated. The aim of this systematic review is to summarise the current evidence on molecular mechanisms underpinning muscle atrophy in CKD and to assess the strength of such evidence.

**Methods:** The PubMed and EMBASE databases were searched using 3 main themes: mRNA/protein/microRNA expression, skeletal muscle and CKD. This study was conducted in accordance with the PRISMA standards (Figure 1) and was registered with PROSPERO (CRD42021257292).

**Results:** Ninety-eight studies were included in the systematic review, comprising 26 prospective human clinical studies, 4 human and rodent studies, and 68 rodent-only studies (32 mouse and 36 rat models respectively). The sample sizes of human studies were predominantly small (40% of studies had  $\leq 20$  participants). Qualitative polymerase chain reaction (qPCR) was the most commonly used method for gene expression. None of the studies fulfilled the Minimum Information for Publication of qPCR Experiments (MIQE) criteria for quality assessment. Most studies investigated only a few genes or a specific signalling pathway. *FBXO32*, *TRIM63*, *MSTN*, *IL6*, *TNF* and *IGF1* were the most studied genes. The identified differentially expressed genes and proteins belonged to 8 major pathways, including apoptosis, autophagy, inflammation, insulin/insulin-like growth factor 1 signalling, lipid metabolism, mitochondrial function, muscle cell growth and differentiation, and protein degradation, similar to other chronic disease states.

**Conclusions:** The current evidence for molecular mechanisms of muscle atrophy in CKD is largely derived from small and heterogeneous studies. Nonetheless, comparable modifications in the major biological pathways between CKD and other chronic diseases supports shared deleterious molecular mechanisms producing muscle atrophy, irrespective of the underlying chronic disease.

**Funding:** Private Foundation Support

## TH-PO829

### RNA Sequencing Analysis of Skeletal Muscle in Moderate to Advanced CKD

Jorge Gamboa,<sup>1</sup> Javier Jaramillo Morales,<sup>1</sup> Armin Ahmadi,<sup>2</sup> Gwenaelle Begue,<sup>3</sup> Tae Youn Kim,<sup>2</sup> Lucas R. Smith,<sup>2</sup> Baback Roshanravan,<sup>2</sup> Talat Alp Ikizler,<sup>1</sup>  
<sup>1</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>2</sup>University of California Davis, Davis, CA; <sup>3</sup>California State University Sacramento, Sacramento, CA.

**Background:** Patients with moderate to advanced kidney disease suffer a higher prevalence of sarcopenia and frailty. We hypothesized that the RNA expression profiling in skeletal muscle from patients with CKD will provide mechanistic insight into these abnormalities.

**Methods:** In a cross-sectional study, we performed RNA sequencing analysis and pathway analysis in skeletal muscle biopsies from three groups (matched for gender, body mass index, and history of diabetes); controls (n=13), patients with CKD 3-5 not yet on hemodialysis (n=13), and patients on maintenance hemodialysis (MHD, n=10). Total RNA was extracted and used to construct libraries for small and total RNA sequencing using Illumina NovaSeq 6000 system. Differentially expressed genes (DEGs) were identified with a false discovery rate (FDR)  $<0.05$  and fold change  $>2$ . Gene Set Enrichment Analysis (GSEA) was performed using WebGestaltR v0.4.4 to analyze RNA sequencing results and to identify the overrepresentation of cellular components and biological pathways.

**Results:** We identified 256 DEGs between controls and MHD groups, and 261 DEGs between CKD 3-5 and MHD groups (Figure 1). Notably, there were only 3 DEGs between controls and patients with CKD 3-5. GSEA showed that there is an enrichment of cellular components related to the extracellular matrix [18 DEGs (with enrichment ratio (ER) of 8.1, FDR  $<1 \times 10^{-7}$ ) in control vs MHD; and 24 DEGs (ER 10.1, FDR  $<1 \times 10^{-7}$ ) in CKD 3-5 vs. MHD] and collagen-containing extracellular matrix [14 DEGs (ER 8.5, FDR  $=4 \times 10^{-7}$ ) in control vs MHD; and 22 DEGs (ER 12.6, FDR  $<1 \times 10^{-7}$ ) in CKD 3-5 vs. MHD].

**Conclusions:** Our results suggest that there is altered remodeling of the extracellular matrix in moderate to advanced CKD. This may be associated with the progressive loss of muscle mass in CKD, which is replaced by adipose and/or fibrotic tissue through the differentiation of fibroadipogenic progenitors. Further studies should identify specific molecular and cellular pathways to prevent sarcopenia and frailty in CKD.

**Funding:** NIDDK Support

## TH-PO830

### Effect of IV-Iron on Markers of Skeletal Muscle Health in Iron Deficient CKD Patients: Initial Findings From the Iron and Muscle Study

Luke A. Baker,<sup>1,2</sup> Benjamin A. Oliveira,<sup>3</sup> Nicola Parker,<sup>1</sup> Kate Bramham,<sup>4</sup> Sharlene A. Greenwood,<sup>4</sup> Iain C. Macdougall,<sup>4</sup> Darlington Okonko,<sup>3</sup> Alice C. Smith,<sup>1,2</sup> Emma L. Watson,<sup>1,2</sup> <sup>1</sup>University of Leicester College of Life Sciences, Leicester, United Kingdom; <sup>2</sup>NIHR Leicester Biomedical Research Centre, Leicester, United Kingdom; <sup>3</sup>King's College London, London, United Kingdom; <sup>4</sup>King's College Hospital NHS Foundation Trust, London, United Kingdom.

**Background:** Many people with chronic kidney disease (CKD) present with non-anaemic iron deficiency but are not routinely offered intravenous iron (IV) supplementation. With this population known to present with impaired muscle health, and previous studies showing a cardiovascular benefit of IV-iron usage, the Iron & Muscle study investigated the effect of 4-weeks IV iron on skeletal muscle function and health; we now report initial results from a mechanistic muscle biopsy sub-study.

**Methods:** This was a prospective, double-blind multicentre randomised controlled trial in 75 non-dialysis CKD patients with non-anaemic iron deficiency, of which 29 provided samples for the sub-study. Patients were randomly assigned to either: IV-Iron or placebo. and muscle biopsy samples were taken pre and 4 weeks post-intervention. This initial analysis involved mRNA expression analysis of indicators of mitochondrial biogenesis, protein turnover and inflammation. Baseline samples were also collected from healthy volunteers (HV, n=6) and non-iron deficient CKD controls (CKD, n=8) to allow for cohort comparisons.

**Results:** At baseline, significantly higher mRNA expression of several markers was seen in ID-CKD compared to CKD and HV cohorts: SOD2 (vs. HV  $p=0.021$ ; vs. CKD  $p=0.016$ ); Parkin (vs. HV  $p<0.001$ ; vs. CKD  $p<0.001$ ); TNF $\alpha$  (vs. HV  $p=0.032$ ; vs. CKD  $p=0.012$ ). A significant reduction in Murf-1 was noted in the CKD cohort in relation to both the ID-CKD cohort ( $p=0.001$ ) as well as the HV cohort ( $p=0.011$ ). No further differences were noted in relation to other markers of mitochondrial biogenesis, oxidative stress, or inflammation. Initial analysis of the effect of 4-weeks of IV-Iron in our ID-CKD cohort showed no significant change in any of our panel of markers related to mitochondrial biogenesis, inflammation, or oxidative stress.

**Conclusions:** This preliminary analysis suggests that skeletal muscle in those with ID-CKD have elevated levels of oxidative stress, mitophagy and inflammation in comparison to those without ID and HV. The use of 4-week IV-Iron does not influence any of these markers at the transcriptional level. Subsequent analysis will seek to examine whether IV-Iron produces beneficial effects on the translational & structural, components of skeletal muscle.

## TH-PO831

### Intradialytic Oral Nutrition on Clinical Outcomes in Malnourished ESRD on Hemodialysis Patients: A Randomized Controlled Trial

Tanin Apiyangkool, Paramat Thimachai, Pamela Tasanavipas, Narongrit Siri Wattanasit, Pitchamon Inkong, Narittaya Varothai, Amnart Chairprasert, Naowanit Nata, Theerasak Tangwonglert, Wisit Kaewput, Ouppatham Supasyndh, Bancha Satirapoj. Phramongkutklao College of Medicine, Bangkok, Thailand.

**Background:** Oral nutritional supplementation (ONS) is recommended for malnourished hemodialysis patients when nutritional intake remains inadequate to meet energy and protein requirements. Hemodialysis induces a negative nitrogen balance, hence oral intradialytic supplements might be an option for well-nourished patients, compensating for the loss of proteins during hemodialysis sessions. The study aimed to

evaluate intradialytic ONS supplements (INTRA-ONS) compared with interdialytic ONS supplements (INTER-ONS) on nutritional status in patients on hemodialysis.

**Methods:** Patients were randomized in two groups; INTRA-ONS group (N=16) received specific renal formula 370 kcal/day three time per weeks during each hemodialysis session and INTER-ONS group (N=16) received same ONS three time per weeks on day without hemodialysis for 12 weeks. All patients were counseled by the same registered dietitian during the study. The nutritional status was evaluated using malnutrition inflammation score (MIS) assessment, serum albumin, and anthropometric measurements at baseline and 12 weeks.

**Results:** Total MIS decreased significantly among patients in the INTRA-ONS (-6.12, 95%CI -8.26 to -3.96) and INTER-ONS group (-3.50, 95%CI - 5.65 to -1.35), while a significant difference in changes of MIS was found among the two groups (-3.06%, 95% -5.94 to -0.17, P=0.038). Additionally, serum albumin (0.31 g/dL, 95%CI 0.14 to 0.47) and body weight (1.05 kg, 95%CI 0.36 to1.74) increased significantly in the INTRA-ONS group, whereas no significant change was found in the INTER-ONS group. No significant change was observed between groups by treatment effects regarding anthropometric measurements, body weight or physical function. No serious adverse effects were reported in any group.

**Conclusions:** Dietary advice combined with oral nutritional supplementation given during hemodialysis improves malnutrition inflammation score among malnourished ESRD patients undergoing maintenance hemodialysis.

TH-PO832

The Effects of Brazilian Green Propolis Extract on Inflammation in CKD on Peritoneal Dialysis (PD): A Randomized Double-Blind Controlled Clinical Trial

Denise Mafra,<sup>1,2</sup> Beatriz G. Baptista,<sup>1</sup> Ludmila F. Cardozo,<sup>1</sup> Marcelo Ribeiro-Alves,<sup>3</sup> Marcia M. Ribeiro,<sup>2</sup> Susane Fanton,<sup>1</sup> Livia D. Alvarenga,<sup>1</sup> Bruna R. de Paiva,<sup>1</sup> Paul G. Shiels,<sup>5</sup> Andresa Berretta,<sup>4</sup> Renal Nutrition - UFF <sup>1</sup>Universidade Federal Fluminense, Niteroi, Brazil; <sup>2</sup>Universidade Federal do Rio de Janeiro Centro de Ciencias da Saude, Rio de Janeiro, Brazil; <sup>3</sup>Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil; <sup>4</sup>Apis Flora, São Paulo, Brazil; <sup>5</sup>University of Glasgow, Glasgow, United Kingdom.

**Background:** Chronic kidney disease (CKD) patients on dialysis display a low-grade systemic inflammatory burden. Nutritional interventions designed to activate the cytoprotective nuclear factor Nrf2, and inhibit nuclear NF-κB have been proposed to mitigate this burden. Several bioactive compounds have been investigated to achieve this, including propolis, a resin produced by *Apis mellifera* bees. The aim of the study was to evaluate the effects of propolis supplementation on inflammatory markers in patients with CKD on PD.

**Methods:** CKD patients were randomized into two groups: propolis (4 capsules of 100 mg/day containing concentrated and standardized dry EPP-AF® Brazilian green propolis extract) or placebo for two months. The plasma levels of TNF-α and IL-6 were evaluated by ELISA. Quantitative real-time PCR analyses were performed to evaluate the expression of Nrf2 and NF-κB in peripheral blood mononuclear cells. Plasma malondialdehyde (MDA) levels and routine biochemical markers were analyzed. Carotid Intima-Media Thickness (CIMT) was measured with a doppler ultrasonography device.

**Results:** A total of 19 patients completed the study, ten patients in the propolis group (54 ± 1.0 years, five men, 7.2 ± 5.1 months on PD) and nine in the placebo group (47.5 ± 15.2 years, three men, 10.8 ± 24.3 months on PD). There were no differences in baseline values in both groups (Table 1). The plasma levels of TNF-α reduced significantly (p=0.02), and mRNA expression of Nrf2 showed a trend to increase (p=0.07) after propolis supplementation.

**Conclusions:** EPP-AF® Green Propolis extract (400 mg/day) supplementation for two months mitigated inflammation by reducing TNF-α levels in CKD patients on PD.

**Funding:** Government Support - Non-U.S.

Inflammation markers, biochemical parameters, and CIMT values in placebo and propolis groups at the baseline.

Inflammation markers	Overall	Placebo Group	Propolis Group	p-values
Ultrasonal (mm)	0.7 (0.2)	0.6 (0.2)	0.7 (0.1)	0.892
MDA (nmol/mL)	0.80 (0.6)	0.87 (1.6)	0.64 (0.5)	0.131
TNF-α (pg/mL)	48.1 (13.9)	53.7 (17.5)	47.5 (11.8)	0.820
CRP (mg/mL)	7.9 (9.7)	5.8 (10)	8.3 (9.3)	0.594
NF-κB (a.u.)	0.87 (0.6)	0.95 (0.5)	0.79 (0.6)	0.518
Nrf2 (a.u.)	1.04 (0.6)	1.05 (0.3)	0.85 (0.5)	0.351

TH-PO833

Effects of Curcumin Supplementation on mRNA Expression of NLRP3 Inflammasome, IL-1β, and NF-κB in Hemodialysis Patients

Denise Mafra,<sup>1</sup> Livia D. Alvarenga,<sup>1</sup> Marcelo Ribeiro-Alves,<sup>2</sup> Ludmila F. Cardozo,<sup>1</sup> <sup>1</sup>Universidade Federal Fluminense, Niteroi, Brazil; <sup>2</sup>Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil.

**Background:** Chronic Kidney Disease (CKD) patients have many complications associated with inflammation and oxidative stress. Inflammasomes are multimeric protein complexes that can be activated by the nuclear factor kappa-B (NF-κB). When the NLRP3 is activated, pro-Interleukin 1β (IL-1β) is cleaved to IL-1β, inducing the inflammatory response. Curcumin may mitigate the inflammatory process.

**Methods:** Thirty-one patients with CKD on HD were randomized into two groups: "Curcumin" and "Control." The curcumin group received 100 mL of orange juice with

12 g of carrots and 2.5 g of turmeric three times a week for three months. The control group received the juice with the same composition (without curcumin). The mRNA expression of NF-κB, NLRP3, and IL-1β was measured by real-time polymerase chain reaction (RT-qPCR) on PBMC.

**Results:** Twenty-eight patients concluded the study, 14 patients in the control group [50% men, 51.5 (IQR=15.5) years, HD time 36 (IQR=38.75) months], and 14 patients in the curcumin group [50% men, 56.5 (IQR=20) years, HD time 45 (IQR=85) months]. After three months of supplementation with curcumin, the patients showed a significant reduction in mRNA expression of IL-1β (p=0.05) (Figure 1).

**Conclusions:** Curcumin supplementation showed to mitigate inflammation in CKD patients on HD by decreasing mRNA IL-1β expression.

**Funding:** Government Support - Non-U.S.

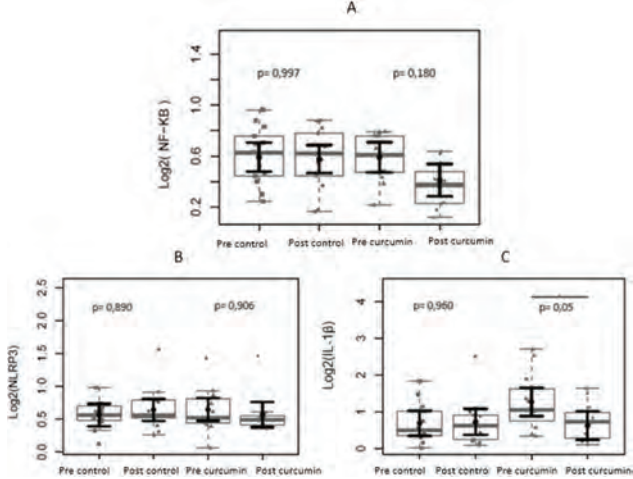

Figure 1. Comparison of mRNA of the factors of evolution of the inflammatory pathway before and after three months of intervention

TH-PO834

Curcumin: A Nutritional Strategy to Control Oxidative Stress in Patients Undergoing Peritoneal Dialysis

Denise Mafra,<sup>1</sup> Drielly Cristhiny M. Reis,<sup>1</sup> Beatriz G. Baptista,<sup>1</sup> Ludmila F. Cardozo,<sup>1</sup> Marcelo Ribeiro-Alves,<sup>2</sup> Bruna R. de Paiva,<sup>1</sup> Livia D. Alvarenga,<sup>1</sup> Denis Fouque,<sup>3</sup> Maurilo Leite,<sup>4</sup> <sup>1</sup>Universidade Federal Fluminense, Niteroi, Brazil; <sup>2</sup>Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil; <sup>3</sup>Universite Claude Bernard Lyon 1, Villeurbanne, France; <sup>4</sup>Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil.

**Background:** Patients with chronic kidney disease (CKD) on peritoneal dialysis (PD) present a high production of reactive oxygen species (ROS) that lead to oxidative stress and inflammation. Bioactive compounds such as curcumin (from turmeric) have been tested as nutritional strategies to mitigate both complications. The aim of this study was to evaluate the effect of curcumin supplementation on lipid peroxidation and inflammatory markers in patients with CKD on PD.

**Methods:** In this longitudinal, randomized, single-blind, placebo-controlled trial, 42 patients were randomized into two groups: curcumin (1.5g/d with 98.42% of curcuminoids) or placebo for 3 months. The malondialdehyde (MDA) plasma levels (lipid peroxidation marker) and TNF-α and IL-6 were measured before and after the intervention.

**Results:** Twenty-four patients completed the study, 10 in the curcumin group (54 yr, 3 men) and 14 in the placebo group (52 yr, 5 men). MDA plasma levels were significantly reduced after three months of curcumin supplementation (Figure 1), whereas remained unchanged in the placebo group. The inflammation markers did not change after intervention in both groups.

**Conclusions:** Curcumin supplementation may be a good strategy to reduce oxidative stress in patients undergoing PD.

**Funding:** Government Support - Non-U.S.

## TH-PO835

### Use of Parenteral Vitamins and Trace Elements for Critically Ill Patients: A Survey of Practice in the United Kingdom

Lynda K. Cameron,<sup>1,3</sup> Nuttha Lumlertgul,<sup>1,2</sup> Marlies Ostermann,<sup>1,3</sup> <sup>1</sup>Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; <sup>2</sup>King Chulalongkorn Memorial Hospital, Bangkok, Thailand; <sup>3</sup>King's College London, London, United Kingdom.

**Background:** Micronutrient products, including parenteral vitamins and trace elements, are prescribed commonly to critically ill patients in the UK for different reasons. Our aim was to explore clinical practice of prescribing micronutrients in the absence of clear evidence or consensus practice guidelines. We were particularly interested in prescribing practice in patients receiving renal replacement therapy (RRT) for acute kidney injury (AKI).

**Methods:** A 12-question survey was designed and distributed through professional networks of clinicians (physicians, nurses, pharmacists and dietitians) working in UK intensive care in late 2019 – early 2020.

**Results:** A total of 217 responses to the survey were received from physicians (58%), nurses (16%), pharmacists (15%) and dietitians (11%). Table 1 shows the proportion of respondents who stated they would prescribe/recommend micronutrient products for renal indications in the ICU. The reasons underpinning prescribing decisions for patients receiving RRT were variable: to replace water soluble vitamins lost via the filter circuit (20%), to treat concurrent disease states (8%), to both replace losses and treat an underlying condition (24%), unsure (18%), for another reason (6%) and declined to answer (24%).

**Conclusions:** These results show heterogeneity in reported prescribing practice. Only 1 in 5 respondents considered AKI in critical illness (whether receiving RRT or not) to be an indication for parenteral micronutrient administration, despite altered micronutrient status being reported in this cohort. A decision to prescribe micronutrients to patients on RRT may be based on the loss of water soluble substances in RRT effluent (which has been demonstrated for some micronutrients), a potential treatment effect of micronutrients, or a combination of both. As the evidence base and cost-benefit ratio in this population is uncertain, further research is needed to better define their place in therapy.

#### Renal indications for prescribing micronutrients in ICU

Primary indication	Would prescribe/recommend parenteral vitamins	Would prescribe/recommend parenteral trace elements
RRT for any indication	43 (19.8%)	27 (12.4%)
AKI requiring RRT	41 (18.9%)	33 (15.2%)
AKI not requiring RRT	4 (1.8%)	4 (1.8%)
Known ESRD	7 (3.2%)	9 (4.1%)

AKI = acute kidney injury; ESRD = end stage renal disease; RRT = renal replacement therapy

## TH-PO836

### Severe Hyperparathyroidism Is Associated With Nutritional Impairment in Maintenance Hemodialysis Patients

Sinee Disthabanchong, Mahidol University Faculty of Medicine Ramathibodi Hospital Department of Medicine, Bangkok, Thailand.

**Background:** Severe hyperparathyroidism predicts poor outcomes and parathyroidectomy is associated with improved survival in patients with kidney failure. Mechanisms underlying these observations have not been clearly elucidated. The issues regarding nutritional impairment in severe hyperparathyroidism have rarely been addressed. The present study examined nutritional status among maintenance hemodialysis (MHD) patients with different degree of hyperparathyroidism.

**Methods:** Seven hundred forty-five patients were categorized into four groups according to PTH levels: group 0, PTH<200; group 1, PTH=200-599; group 2, PTH=600-1499; and group 3, PTH≥1500 pg/mL. Group 0 was excluded because low PTH level was linked to

older age and malnutrition. Patients in groups 1 and 2 were matched to group 3 by propensity score yielding 410 patients in the final analysis. Nutritional parameters at baseline (Year 0) and the preceding 1 and 2 years (Year -1 and Year -2) were analyzed.

**Results:** At baseline, lower serum albumin ( $P<0.001$ ), creatinine ( $P<0.001$ ), height in female ( $P=0.001$ ), creatinine/body surface area (Cr/BSA) ( $P=0.001$ ) and higher number of patients with serum albumin  $<38$  g/L ( $P<0.001$ ) were observed in group 3 compared to groups 1 and 2. Higher PTH level was independently associated with serum albumin  $<38$  g/L ( $P<0.001$ ) and serum Cr/BSA  $<380$   $\mu\text{mol/L/m}^2$  ( $P=0.001$ ). Lower serum albumin, creatinine and Cr/BSA and higher number of patients with serum albumin  $<38$  g/L were observed at Year 0 compared to Year -1 and Year -2 among patients in group 3. Between group comparisons confirmed a significant difference in serum albumin, the number of patients with serum albumin  $<38$  g/L, serum creatinine and Cr/BSA between baseline and the preceding 1 and 2 years in group 3 compared to groups 1 and 2. The number of patients with Cr/BSA  $<380$   $\mu\text{mol/L/m}^2$  was also significantly different between baseline and the preceding 1 and 2 years in group 3 compared to group 1. Weight loss was more substantial in group 3 compared to group 2 ( $P=0.03$ ) and the number of patients with  $\geq 5\%$  weight loss was higher in group 3 compared to groups 1 ( $P=0.005$ ) and 2 ( $P=0.03$ ).

**Conclusions:** MHD patients with severe hyperparathyroidism had deterioration of nutritional status compared to patients with moderate hyperparathyroidism and patients with PTH level within the recommended range.

## TH-PO837

### Higher 25-Hydroxyvitamin D Associates With Gastrointestinal Bleeding Events

John W. Larkin,<sup>1</sup> Yue Jiao,<sup>1</sup> Suman K. Lama,<sup>1</sup> Sheetal Chaudhuri,<sup>1</sup> Joanna Willetts,<sup>1</sup> Anke Winter,<sup>2</sup> Manuela Stauss-Grabo,<sup>2</sup> Len A. Usvyat,<sup>1</sup> Jeffrey L. Hymes,<sup>1</sup> Franklin W. Maddux,<sup>4</sup> Peter Stenvinkel,<sup>5</sup> Jürgen Floege,<sup>3</sup> on behalf of the INSPIRE Core Group <sup>1</sup>Fresenius Medical Care, Global Medical Office, Waltham, MA; <sup>2</sup>Fresenius Medical Care, Global Medical Office, Bad Homburg, Germany; <sup>3</sup>University Hospital Aachen, Division of Nephrology and Clinical Immunology, Aachen, Germany; <sup>4</sup>Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany; <sup>5</sup>Karolinska Institutet, Stockholm, Sweden.

**Background:** In an effort within the INSPIRE collaboration, we built a gastrointestinal (GI) bleed hospitalization risk model and unexpectedly found higher serum 25 hydroxyvitamin D concentration (25OH Vit D) was one of the most predictive factors in hemodialysis (HD). To investigate this signal, we assessed all-cause and GI bleed hospitalization rates by 25OH Vit D levels.

**Methods:** We used data from adult HD patients in the United States with  $\geq 1$  25OH Vit D lab during Jan 2016-Dec 2020. We calculated % patients with  $\geq 1$  all-cause or GI bleed admission within 180 days after a 25OH Vit D lab by groups ( $<15$ ,  $\geq 15$  to  $<30$ ,  $\geq 30$  to  $<50$ ,  $\geq 50$  to  $<60$ ,  $\geq 60$  ng/mL).

**Results:** Among 225,459 patients (mean age 63.1 years, 57.4% male, 56.2% white race & HD vintage 3.3 years), those with 25OH Vit D  $<15$  ng/mL had the highest all-cause, yet the lowest GI bleed, admission rates (Figure 1). Patients with 25OH Vit D  $\geq 30$  to  $<50$  and  $\geq 50$  to  $<60$  ng/mL had the lowest all-cause and highest GI bleed admission rates. Patients with 25OH Vit D  $>60$  ng/mL had a higher all-cause admission rate than the  $\geq 30$  to  $<50$  and  $\geq 50$  to  $<60$  ng/mL groups, and a GI bleed admission rate slightly lower than the  $\geq 30$  to  $<50$  ng/mL group.

**Conclusions:** We found an inverse association between all-cause and GI bleed admission rates based on 25OH Vit D levels. It appears 25OH Vit D  $>30$  ng/mL may associate with GI bleeding events in HD patients, with the highest event rates at  $\geq 50$  to  $<60$  ng/mL, which is consistent with findings at in warfarin users without kidney failure (Keskin U, 2019). Albeit hypothetical, extremely high 25OH Vit D  $>60$  ng/mL might be representative of specific comorbidities that explain the all-cause admission rates in this group. Given the higher recommendations for 25OH Vit D in kidney disease ( $\geq 30$  ng/mL) versus general population ( $\geq 20$  to  $<30$  ng/mL), further adjusted analysis accounting for competing risks are needed.

**Funding:** Commercial Support - Fresenius Medical Care

## TH-PO838

## Subjective Global Assessment Scores and Survival in a Multi-Center Prospective Hemodialysis Cohort

Ji Hoon Yoon,<sup>1</sup> Yoko Narasaki,<sup>1</sup> Amy S. You,<sup>1</sup> Silvina Torres Rivera,<sup>1</sup> Lisa Le,<sup>1</sup> Anyssa K. Dang,<sup>1</sup> Matthew D. Nguyen,<sup>1</sup> Arjun Marwaha,<sup>2</sup> Danh V. Nguyen,<sup>1</sup> Kamyar Kalantar-Zadeh,<sup>1</sup> Connie Rhee.<sup>1</sup> <sup>1</sup>University of California Irvine, Irvine, CA; <sup>2</sup>University of Pennsylvania, Philadelphia, PA.

**Background:** Protein-energy wasting (PEW) is highly prevalent in end-stage kidney disease (ESKD) patients receiving hemodialysis (HD), and is a potent predictor of survival in this population. We sought to conduct Subjective Global Assessment (SGA) surveys, a simple yet validated nutritional assessment instrument, in a prospective cohort of HD patients in order to assess the relationship between PEW and survival in this population.

**Methods:** In a multi-center prospective cohort of 1018 HD patients from the NIH "Malnutrition, Diet, and Racial Disparities in Kidney Disease (MADRAD)" Study recruited from 18 dialysis clinics who underwent protocolized SGA surveys every 6 months, we examined the relationship between baseline and time-dependent SGA scores with all-cause mortality using multivariable Cox models.

**Results:** The median (IQR) and min-max of baseline SGA scores were 1 (0, 2) and 0-13, respectively (**Fig A**). In analyses of baseline SGA scores categorized as quartiles, we observed that incrementally higher SGA quartiles were associated with increasingly higher mortality risk: HRs (95%CI) 1.37 (1.01, 1.86), 1.65 (1.17, 2.33), and 2.02 (1.55, 2.64) for the second lowest, second highest, and highest quartiles of SGA scores, respectively, in expanded case-mix+laboratory models (**Fig B**). Analyses of time-dependent SGA scores showed a similar pattern of findings: HRs (95%CI) 1.27 (0.92, 1.76), 1.53 (1.08, 2.16), and 2.58 (1.98, 3.36) for the second lowest, second highest, and highest quartiles of SGA scores, respectively, in expanded case-mix+laboratory models (**Fig C**).

**Conclusions:** In a prospective multi-center cohort of HD patients, increasing severity of PEW ascertained by SGA surveys were associated with incrementally higher death risk. These findings underscore the importance of using the SGA as a practical nutritional assessment tool that can be conveniently applied at the bedside in order to identify HD patients with inadequate dietary intake who may benefit from earlier implementation of nutrition interventions.

**Funding:** NIDDK Support

## TH-PO839

## Case Studies of Intradialytic Total Parenteral Nutrition in Nocturnal Home Hemodialysis

Sachin V. Pasricha,<sup>1,2</sup> Khaled A. Alqarni,<sup>1,2</sup> Michael Davis,<sup>1,2</sup> Christopher T. Chan.<sup>1,2</sup> <sup>1</sup>University of Toronto, Toronto, ON, Canada; <sup>2</sup>University Health Network, Toronto, ON, Canada.

**Introduction:** Malnutrition occurs in 30-50% of dialysis patients. If unable to meet caloric intake requirements, intradialytic parenteral nutrition (IDPN) may be considered. Standard IDPN occurs thrice weekly with intermittent hemodialysis (IHD), but has yielded heterogeneous clinical results. Nocturnal home hemodialysis (NHD) occurs at a median of 5 nights/week with 8 hours/session. Through longer duration and increased frequency, prescribing IDPN with NHD augments IDPN dose. We present a series of four NHD patients who required intradialytic total parenteral nutrition (IDTPN) as their primary source of caloric intake.

**Case Description:** 1. A 25-year old woman with ANCA-vasculitis on Peritoneal Dialysis (PD) developed encapsulating peritoneal sclerosis (EPS) and a small bowel obstruction (SBO). 2. A 60-year old woman with amyloidosis on NHD had weight loss from amyloidosis. 3. A 46-year old man with cryoglobulinemic vasculitis on NHD needed IDTPN twice for GI symptoms and suboptimal intake. 4. A 59-year old man with IgA-nephropathy on PD developed an EPS-related SBO. **Outcomes:** Our patients received 1200-1590 kCal with each IDTPN session and achieved a significant increase in weight, albumin, and BMI (Table 1) ( $p < 0.05$  using a Wilcoxon signed rank test). Metabolic complications resembled those with TPN (cramping, hypertriglyceridemia, transaminitis, and fluid overload), and other complications resembled those of the dialysis population (three hospitalizations and one line infection).

**Discussion:** IDTPN significantly improved nutrition without significant side effects. Our cases are the first example of IDPN being used as the primary source of caloric intake (i.e. IDTPN), which was enabled by longer ( $\leq 8$  hours) and more frequent ( $\leq 7$ /week) sessions. Our study is novel in its focus on NHD, whereas prior IDPN studies have focused on IHD. We highlight this because NHD enables diet liberalization and enhances quality of life, both relevant to malnourished patients. Finally, NHD with IDTPN may be particularly useful for PD patients with EPS, as they need to switch dialysis modality and start parenteral nutrition, but presumably prefer to dialyze at home.

Table 1: Summary of IDTPN outcomes

Patient	Pre-IDTPN			On IDTPN		
	Albumin (mmol/L)	Weight	BMI	Albumin (mmol/L)	Weight	BMI
1	26	47.2 kg	18.4	41	50.5 kg	19.7
2	32	44.0 kg	15.3	29 (note worsening liver amyloid)	53.9 kg	18.7
3 (Time 1)	26	58.5 kg	19.5	36	66.6 kg	22.3
3 (Time 2)	23	57.0 kg	19	36	69.7 kg	23.3
4	28	67.1 kg	22.4	39	74.2 kg	24.5

## TH-PO840

## DASH Diet Mechanism Dissected by Urinary Extracellular Vesicles

Dana Bielopolski,<sup>1</sup> Luca Musante,<sup>2</sup> Douglas Barrows,<sup>1</sup> Tom S. Carroll,<sup>1</sup> Jonathan N. Tobin,<sup>1,4</sup> Uta Erdbruegger.<sup>3</sup> <sup>1</sup>The Rockefeller University, New York, NY; <sup>2</sup>The Pennsylvania State University - University Park Campus, University Park, PA; <sup>3</sup>University of Virginia, Charlottesville, VA; <sup>4</sup>Clinical Directors Network Inc, New York, NY.

**Background:** The DASH (Dietary Approach to Stop Hypertension) diet is a proven intervention in lowering blood pressure, yet its mechanism has never been elucidated. We sought to characterize changes in urine exosome protein abundance pattern shifting from Western style diet to DASH diet.

**Methods:** 9 volunteers were admitted for 14 days to the Rockefeller hospitalization unit, during which they transitioned from American style diet to DASH diet. blood and urine for electrolytes were collected daily and aldosterone was sampled four times. Urine was centrifuged to discard cell debris at low speed and then the supernatant was centrifuged at 21,000g, the pellet was termed P20. P20 was treated with TCEP to discard of Uromodulin. The supernatant was further centrifuged at 164,000g, and the pellet termed P100. P100 was fractionated with size exclusion chromatography to discard of Uromodulin, and the first two fractions that were positive for TSG101 and negative for Uromodulin were used for further analysis.

**Results:** A total of 1,593 proteins were identified in P20+P100. 240 were uniquely expressed in P100 and 759 were uniquely expressed in P20. According to DAVID annotation tool both fractions were enriched for exosomes (P20 with 95% and P100 with 97.4% of proteins involved P-value of 7.0E-51). Due to this differential expression we chose to unite the two fractions of P100 and P20 for mass spectrometry analysis of the DASH samples. 1800 proteins were identified and 226 crossed the significance threshold of change between trial days. 22 proteins were with upregulated and 25 were down regulated from day 0 to days 5 and 11. Both groups were enriched for extracellular Exosomes pathway p-value= 3.8E-14 including SLC12A3 (NCC) in the upregulated and Aquaporin 2 (AQP2) in the downregulated.

**Conclusions:** Following DASH diet implementation, the prevalence of NCC symporter increases and the prevalence of AQP2 decreases in uEV's. This leads to increased urine output and salt wasting similar to Gitelman syndrome. prolonged thiazide treatment increases NCC abundance in urinary extracellular vesicles of essential hypertensive patients, as well as in uEVs isolated from mice fed a high potassium diet. The increased abundance following the two stimuli may be a compensatory effect to counteract reduced NCC activity as a result of inhibition.

## Abstract Withdrawn

## TH-PO842

## Enteric Hyperoxaluria With Recurrent Oxalate Nephropathy

Himesh Sheth,<sup>1</sup> Tammy Yu, Jie Tang. Brown University Warren Alpert Medical School, Providence, RI.

**Introduction:** Enteric hyperoxaluria (EH) can lead to acute kidney injury (AKI), end-stage renal disease (ESRD) and represents therapeutic challenge. Here we present a case of recurrent oxalate nephropathy in a kidney transplant recipient, illustrating the potential aggressive nature of EH and the challenges in treating this condition

**Case Description:** 77-year-old Caucasian lady with hypertension, diabetes, and obesity, developed AKI three years after her Roux-en-Y gastric bypass, with serum creatinine (sCr) rose to of 7 mg/dl from a baseline of 0.7 mg/dl. Kidney biopsy at the time showed extensive tubular injury with numerous calcium oxalate (CaO) inclusions superimposed on moderate interstitial fibrosis and tubular atrophy. Patient ultimately started on hemodialysis four months later and underwent living unrelated kidney transplant 12 months after the onset of AKI, with sCr improved to 0.7 mg/dl. However, six months later, patient developed AKI again following a bout of diarrhea, sCr rose to 3 mg/dl with urine sediment showing features of tubular injury. Due to concern for graft rejection, patient underwent allograft biopsy which again showed intratubular CaO inclusions without signs of rejection. 24-hour urine collection revealed an elevated oxalate level (62 mg), low citric acid (<20mg) pH of 5.1, urine calcium of 70 mg. Her diarrhea resolved after the adjustment of her immunosuppressive regimen. But AKI persisted with 24hr urine oxalate unexpectedly worsened to 92 mg. Patient was then started on potassium citrate (KC) to alkalinize urine and to prevent CaO crystallization. Calcium carbonate with meals to reduce oxalate absorption from the gastrointestinal tract in addition to dietary oxalate restriction. She responded well initially, sCr improved to 1.37 mg/dl, along with a reduction in 24-hour urine oxalate and rises in urine citric acid and pH (7.1). Unfortunately, sCr worsened again to 1.7 mg/dl 6 weeks later. Iatrogenic

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

milk alkali syndrome was suspected. Calcium carbonate was stopped, and patient continued dietary oxalate restriction and KC supplementation. Her sCr improved again to 1.3 mg/dl 4 months later and repeat 24-hour urine showed oxalate 55 mg, citric acid 102 mg, Ca <20 mg, pH 5.55.

**Discussion:** Enteric oxalate nephropathy is often under recognized, and, if left untreated, can lead to ESRD and allograft injury. Current treatment options are limited although several promising medications are on the horizon.

## TH-PO843

### Adenine Phosphoribosyl Transferase Deficiency Caused Obstructive Nephropathy: A Case Report

Jonathan Sung, Lili Tong, Tiane Dai. Harbor-UCLA Medical Center, Torrance, CA.

**Introduction:** Adenine phosphoribosyl transferase deficiency (APRTD) is a rare autosomal recessive metabolic disorder. It causes excessive production and renal excretion of 2,8-dihydroxyadenine (DHA), which leads to nephrolithiasis. Characterized by radiolucency, which is similar to uric acid stones, they are often misdiagnosed or missed, which can often lead to progressive renal failure, even in transplanted patients. We report a case of APRTD in a woman with an incidental finding of unilateral hydronephrosis from ureteral stone.

**Case Description:** A 57 year-old Mexican female, with known medical history of hypertension and extensive peripheral arterial disease requiring multiple interventions including aortobifemoral bypasses, was referred to urology for incidentally noted persistent right-sided severe hydronephrosis from an obstructive right mid ureteral stone. Patient underwent ureteroscopy with stone extraction and laser lithotripsy of the right ureteral stone. Stone analysis revealed a 2,8-dihydroxyadenine stone. She was subsequently referred to nephrology for management and Human Genetics for genetic testing/counseling. Patient was asymptomatic. Patient was started on allopurinol 300mg daily, which inhibits xanthine oxidoreductase and results in adenine urinary excretion instead of 2,8-dihydroxyadenine, and hydration. She has continued to have relatively stable renal function without known recurrence of nephrolithiasis. She had APRT gene sequencing, and the results revealed homozygous pathogenic variant in APRT gene, c.294G>A (p. Trp98Ter).

**Discussion:** APRTD is characterized by a mutation on chromosome 16q24, affecting the gene for adenine phosphoribosyltransferase resulting in accumulation of the insoluble purine 2,8-dihydroxyadenine in the kidneys. This can result in crystalluria and nephrolithiasis, which can lead to hydronephrosis and chronic, progressive renal disease. Generally, two different types of mutations have been described. Type I APRT deficiency has virtually absent enzyme activity whereas Type II deficiency has functionally decreased activity. 2, 8-dihydroxyadenine stones are similar to uric stones as they are both radiolucent and have identical chemical reactivity. The treatment is allopurinol and hydration. Stone retrieval and stone analysis play pivotal roles in the diagnosis of APRTD induced nephrolithiasis and guide further management.

## TH-PO844

### Marginal Structural Model (MSM) Analysis to Investigate the Causal Relationship of XOR Inhibitors With Outcomes in Hemodialysis

Takeo Ishii,<sup>1,2</sup> Masataka Taguri,<sup>3</sup> Hiromichi Wakui,<sup>2</sup> Kouichi Tamura.<sup>2</sup> Department of Medical Science and Cardiorenal Medicine, Yokohama City University School of Medicine <sup>1</sup>Yokohama Daiichi Hospital, Yokohama, Japan; <sup>2</sup>Department of Medical Science and Cardiorenal Medicine, Yokohama City University School of Medicine, Yokohama, Japan; <sup>3</sup>Department of Health Data Science, Tokyo Medical University, Shinjuku, Japan.

**Background:** Randomized trial of allopurinol and febuxostat has been performed in hyperuricemic patients to inhibit XOR and reduce uric acid levels. Nonetheless, the protective effect for CVD events and mortality is insufficient in dialysis patients. Furthermore, febuxostat(FEB) is also known to be a potent ATP binding cassette transporter subfamily G member2 (ABCG2) inhibitor that promotes the accumulation of uremic toxins by reduced excretion from the gut. We investigated the preventative effect of XOR inhibitors on outcomes under observation.

**Methods:** We observed 6791 maintenance dialysis patients from April 2016 to March 2019. Outcomes were all-cause mortality and CVD events, using longitudinal data. Baseline uric acid and outcome was examined using Cox Hazard analysis. Causal associations for outcomes of allopurinol (ALLO) or FEB were analyzed using 3 years of longitudinal data, including concomitant drugs, using MSM, which is weighted analysis that examined the causal effect of ALLO or FEB versus control at each visit.

**Results:** MSM indicated that ALLO estimated HR 0.35 for all-cause mortality versus un treatment (p<0.001), also indicated that FEB estimated HR 0.42 (p<0.001). In CVD events, ALLO demonstrated a preventative effect of HR 0.81 versus control (p<0.001). However, FEB did not show a preventative effect of HR 0.98 (95% CI: 0.91–1.04). ALLO versus FEB for CVD events was HR 0.83(95% CI 0.75–0.92).

**Conclusions:** FEB failed to demonstrate a preventative effect for CVD events compared with ALLO and the control but did not increase the risk of all-cause mortality or CVD events. Attenuated effect of FEB was considered to be the result of uremic toxin accumulation evoked by ABCG2 dysfunction.

CKD events

## TH-PO845

### Associations of Reduced Rank Regression (RRR)-Based Dietary Patterns With Kidney Health

Giulia Barbieri,<sup>1,2</sup> Vanessa Garcia-Larsen,<sup>4</sup> Ryosuke Fujii,<sup>1,3</sup> Roberto Melotti,<sup>1</sup> Lucia Cazzoletti,<sup>2</sup> Peter Paul Pramstaller,<sup>1</sup> Maria E. Zanolini,<sup>2</sup> Cristian Pattaro,<sup>1</sup> Essi V. Hantikainen,<sup>1</sup> <sup>1</sup>Accademia Europea, Bolzano, Italy; <sup>2</sup>Università degli Studi di Verona, Verona, Italy; <sup>3</sup>Fujita Ika Daigaku Daigakuin Igaku Kenkyu-ka Seikei Geka, Toyoko, Japan; <sup>4</sup>Johns Hopkins University, Baltimore, MD.

**Background:** A healthy diet is key to chronic kidney disease (CKD) prevention; however, which specific dietary components are more beneficial is still unclear. We identified dietary patterns (DPs) analytically through selected risk factors of CKD.

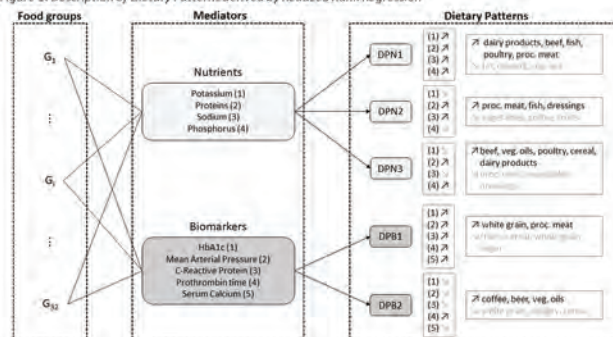

**Methods:** We included 6215 Cooperative Health Research In South Tyrol (CHRIS) study participants without known kidney disease, hypertension or diabetes. We obtained serum creatinine-based estimated glomerular filtration rate (eGFR) with the 2021 CKD-EPI equation and defined CKD as eGFR<60 ml/min/1.73m<sup>2</sup>. Dietary intake was estimated based on the self-administered internationally validated GA2LEN food frequency questionnaire (FFQ). We estimated DPs using RRR, selecting two groups of mediators (Figure 1): the FFQ-derived nutrients (DPN) and selected biomarkers (DPB). Factor loading-based scores, either as continuous or stratified into tertiles (T1-T2-T3), were included in multiply-adjusted regression models for eGFR and CKD. Sex-specific DPs and models were also implemented.

**Results:** We identified 3 DPN and 2 DPB scores (Figure 1). DPN1 was characterized by high intake of all nutrients and associated with lower eGFR (linear p<0.001, T3vsT2 p=0.042). The T3 of DPN3 (low intakes of potassium and sodium; high intakes of proteins and phosphorus) was protective against CKD risk (T3vsT2 p=0.017). DPB1 reflected the impact of higher levels of all risk biomarkers and was associated with lower eGFR (linear p=0.027). Other DPs showed no evidence of association with eGFR or CKD. Sex-stratified analyses led to similar DPs, and effects on eGFR and CKD differed to some extent between males and females.

**Conclusions:** In addition to confirming known relationships between nutrient-based DPs and kidney health, biomarker-based DPs highlighted additional food groups related with specific CKD risk factors. Integrating both nutrients and biomarkers risk factors as mediators adds value to the investigation of diet effects on kidney function.

Figure 1: Description of Dietary Patterns derived by Reduced Rank Regression

## TH-PO846

# Coffee Consumption and Risk of Kidney Function Decline in a Dutch Population-Based Cohort

**Qingqing Cai,<sup>1,2</sup> Anniek V. Westing,<sup>3</sup> Stephan J. Bakker,<sup>1</sup> Gerjan Navis,<sup>1</sup> Johanna M. Geleijnse,<sup>3</sup> Martin H. De Borst.<sup>1</sup>** <sup>1</sup>*Universiteit Groningen Faculteit Medische Wetenschappen, Groningen, Netherlands;* <sup>2</sup>*Southern Medical University Nanfang Hospital, Guangzhou, China;* <sup>3</sup>*Wageningen University, Wageningen, Netherlands.*

**Background:** Coffee consumption has been associated with beneficial outcomes in various disease domains, including chronic kidney disease (CKD). Whether coffee consumption is associated with kidney function decline in the general population is unclear. We investigated the association of coffee consumption with kidney function decline or incident chronic kidney disease (CKD) in the Dutch population.

**Methods:** This study was performed in 78,346 participants free of CKD in the prospective population-based Lifelines cohort from Northern Netherlands. Coffee consumption (daily cups) was assessed at baseline using food frequency questionnaires. Incident CKD was defined as eGFR <60 mL/min/1.73 m<sup>2</sup> (CKD-EPI equation). Multivariable logistic regression analyses were used to evaluate the associations of daily coffee consumption with annual change in estimated glomerular filtration rate (eGFR) or a composite kidney outcome (incident CKD and/or >20% eGFR decline).

**Results:** Participants with higher daily coffee intakes were more often men, older, lower-educated, and current smoker. They were less physically active and had higher BMI, higher alcohol intake, and lower tea intake. They also had less often diabetes and cardiovascular disease and more often gastrointestinal disease. During a mean (SD) follow-up of 3.6(±0.9) years, 8 735 events (11.1%) of the composite kidney outcome occurred. The median (IQR) annual change in eGFR was -2.23 (-3.69, -0.80) mL/min/1.73 m<sup>2</sup>. Coffee intake was inversely associated with annual eGFR decline (B [95%CI] for 1-2 cups, 0.13 [0.06,-0.21]; 3-4 cups, 0.15 [0.08, 0.23]; 5-6 cups, 0.19 [0.11, 0.27]; and >6 cups, 0.23 [0.14, 0.33], vs non-coffee drinkers, P<sub>trend</sub> <0.001). Similar dose-response relationships were observed for composite kidney outcome. Coffee intake (continuously, per cup/d) was related to a lower risk of the composite kidney outcome (OR [95%CI], 0.98 [0.97,0.99], P=0.02).

**Conclusions:** Daily coffee consumption was inversely associated with kidney function decline and CKD risk in a dose-response manner in Dutch population-based cohort. Intervention studies are needed to address whether increasing coffee consumption protects against kidney function loss.

**Funding:** Government Support - Non-U.S.

## TH-PO847

### Measured GFR Adjusted Metabolic Changes Following Bariatric Surgery

Benjamin J. Apple,<sup>1</sup> Jingsha Chen,<sup>2</sup> Tooraj Mirshahi,<sup>3</sup> Andrew S. Levey,<sup>4</sup> Lesley A. Inker,<sup>4</sup> Morgan Grams,<sup>5</sup> Josef Coresh,<sup>2</sup> Alex R. Chang,<sup>3</sup> <sup>1</sup>*Geisinger Commonwealth School of Medicine, Scranton, PA;* <sup>2</sup>*Johns Hopkins University Welch Center for Prevention Epidemiology and Clinical Research, Baltimore, MD;* <sup>3</sup>*Geisinger Medical Center, Danville, PA;* <sup>4</sup>*Tufts Medical Center, Boston, MA;* <sup>5</sup>*New York University Grossman School of Medicine, New York, NY.*

**Background:** Bariatric surgery reduces glomerular hyperfiltration in the short term and is associated with a reduced risk of end-stage kidney disease during long-term follow-up. Assessing surgery-induced changes in serum metabolites may be useful to understand the salutary metabolic changes that occur after bariatric surgery.

**Methods:** In a prospective, single-center research cohort of 27 adults with severe obesity who underwent bariatric surgery, we measured serum metabolites using untargeted ultrahigh-performance liquid chromatography-tandem mass spectrometry and measured glomerular filtration rate (mGFR) by iohexol clearance approximately 1-3 months prior and 6 months after bariatric surgery. Generalized estimated equations (GEE) were used to examine changes in serum metabolites after surgery.

**Results:** Bariatric surgery was significantly associated with 223 serum metabolites after adjustment for age, sex, and log(mGFR) at a Bonferroni-corrected *p*-value <4.85E-05. Following bariatric surgery, the levels of many metabolites associated with insulin resistance and inflammation decreased, such as branch-chain amino acids (tiglyl carnitine, isovaleryl carnitine, alpha-hydroxyisovalerate), kynurenine pathway (kynurenine, xanthurenate, 8-methoxkyunurenate, quinolinate), sphingomyelin metabolites (behenoyl dihydrosphingomyelin, sphingomyelin, tricosanoyl sphingomyelin). Additionally, creatinine decreased following surgery independent of mGFR. Increases in metabolite levels occurred for insulin sensitivity-promoting primary bile acid metabolites (cholic acid glucuronide, cholate, glycol-beta-muricholate), antioxidant plasmalogen metabolites (1-2-oleoyl-GPC, 1-2-palmitoleyl-GPC), and microbiome-derived acetylated peptide metabolites (phenylacetylglutamate, phenylacetylglutamine).

**Conclusions:** After adjustment for mGFR, we confirm several metabolic changes after bariatric surgery, which could have favorable renal benefits.

### High-Fat Diet Increases Gadolinium Retention in Mice

**Brent Wagner**<sup>1,2</sup> G. P. Escobar,<sup>2,1</sup> Joshua Deaguero,<sup>2,1</sup> Abdul Mehdi S. Ali,<sup>3</sup> Karol Dokladny,<sup>2,1</sup> Kidney Institute of New Mexico <sup>1</sup>New Mexico VA Health Care System, Albuquerque, NM; <sup>2</sup>University of New Mexico Health Sciences Center, Albuquerque, NM; <sup>3</sup>University of New Mexico Department of Earth & Planetary Sciences, Albuquerque, NM.

**Background:** Gadolinium is a heavy/rare earth (lanthanoid) metal extensively used in modern diagnostic medicine as an enhancer of magnetic resonance imaging (MRI) procedures. Exposure to gadolinium-based contrast agents can cause ‘nephrogenic’ systemic fibrosis (NSF), a medical condition characterized by skin fibrosis associated with severe pain, burning, and itching leading to inhibition or loss of joint flexibility and movement. Our team has shown that gadolinium is detectable in symptomatic and asymptomatic patients in the urine, hair, and nails after MRI contrast exposure. We have also pioneered mechanistic studies showing that C-C chemokine receptor 2-dependent activated myeloid cells and fibroblasts mediates NSF. It has been shown that the kidney is a reservoir for gadolinium-based contrast even days after a single dose. However, relative gadolinium retention in obese animals has not been examined.

**Methods:** Mice were randomized to a 60 kcal% fat diet (n=14) ad libitum (20 kcal% protein and 20 kcal% carbohydrates; Research Diets, Inc; D12492j) or control chow (19% protein, carbohydrates 47%, and fat 6.5 %; Teklad Diets; 2020x; n=8) for 18-20 weeks. Then, the groups were sub-divided into untreated (n=8) and gadolinium-based contrast agent-treated (Omniscan 2.5 mM) (n=14) subgroups 5 days a week for 4 weeks. Tissues were excised and snap-frozen in liquid nitrogen. On average, 15 mg of tissue were digested and gadolinium concentrations were quantified using PerkinElmer NexION 300D Inductively Coupled Plasma Mass Spectrometry (ICP/MS) with a detection limit of 0.01 ppb.

**Results:** We observed gadolinium retention in the kidney and liver of animals exposed to Omniscan. Interestingly, HFD increased gadolinium accumulation in tested organs in males and females. Similarly, tungsten retention was increased in animals (regardless of sex) treated with gadolinium. HFD exacerbated gadolinium retention. In the kidneys of males, Ca and P retention was augmented by HFD regardless of Omniscan treatment. Zn accumulation was not influenced by either Omniscan or HFD treatment.

**Conclusions:** Our data indicate that obesity promotes gadolinium retention in the kidney and liver. Future studies are needed to delineate the cellular mechanisms leading to augmented gadolinium accumulation in obese animals and demonstrate associated pathological consequences.

## TH-P0849

## The 10-Year Effects of Lifestyle Modifications on Kidney Outcomes

Linda-Marie U. Lavenburg, Jordana B. Cohen, Douglas E. Schaubel, Peter P. Reese. Renal-Electrolyte and Hypertension, University of Pennsylvania *University of Pennsylvania, Philadelphia, PA.*

**Background:** Obesity is a global epidemic associated with risk factors for chronic kidney disease (CKD). The Action for Health in Diabetes (Look AHEAD) trial showed greater weight loss after exposure to intensive lifestyle intervention compared to diabetes support and education (i.e., usual care). Weight loss interventions can improve short-term kidney outcomes, but larger longitudinal studies on non-surgical obesity treatments are needed. We investigated the effects of weight loss from lifestyle modifications on kidney function over ten years.

**Methods:** We performed a retrospective cohort study of 4,901 individuals with type 2 diabetes and BMI  $\geq 25\text{kg/m}^2$  using the Look AHEAD dataset which was collected between 2001-2015. We used linear mixed effect models to evaluate for within-individual changes of mean values and slope of estimated glomerular filtration rate (eGFR) (primary

outcome) and urine albumin to creatinine ratio (UACR) (secondary outcome) between randomization arms. We evaluated for effect modification by baseline kidney function and visit year using the Wald test and a two-sided significance level of 0.05.

**Results:** At baseline, mean eGFR in both randomization arms was 89ml/min/1.73m<sup>2</sup> and 83% of participants had normal albuminuria. Over 10 years, the intervention arm had a slightly higher mean eGFR compared to the usual care arm (beta-coefficient (B): 0.5, p=0.04). The intervention improved loss of eGFR after year two (B: 0.78, p<sub>interaction</sub>=0.001). The magnitude of the intervention's effect differed by year with the slowest decline in eGFR by 1.20ml/min/1.73m<sup>2</sup> (p=0.002) at year 3. Among individuals with a baseline eGFR <80ml/min/1.73m<sup>2</sup>, the mean eGFR in the intervention arm was 1.25ml/min/1.73m<sup>2</sup> (p=0.02) higher than the usual care arm. However, there was no difference in mean UACR (B: -0.001, p=0.94) or slope of UACR (B: 0.0002, p=0.80) between arms.

**Conclusions:** Among individuals at high risk for CKD, exposure to intensive lifestyle intervention resulted in slower eGFR loss by year 2 and slightly higher kidney function over 10 years compared to usual care. Individuals with lower kidney function had greater benefit from the intervention than those with higher kidney function. Participation in a lifestyle modification program is recommended for individuals with excess body weight and can slow progression to CKD in at risk populations.

**Funding:** Other NIH Support - T32

## TH-PO850

### Individualized and Technology-Assisted Ketogenic Diet on Metabolic and Kidney Health in Overweight or Obese Adults

Christiane L. Meireles,<sup>1</sup> Yan Du,<sup>1</sup> Shiyu Li,<sup>1</sup> Brittany Dennis,<sup>1</sup> Nicholas S. Niazi,<sup>2</sup> Darpan I. Patel,<sup>1</sup> Jonathan A. Gelfond,<sup>4</sup> Chengdong Li,<sup>3</sup> Hongping Ye,<sup>2</sup> Richard Montellano,<sup>2</sup> Anthony J. Franzoni,<sup>2</sup> Jing Wang,<sup>3</sup> Kumar Sharma.<sup>2</sup> <sup>1</sup>School of Nursing, UT Health San Antonio, San Antonio, TX; <sup>2</sup>Center for Precision Medicine, School of Medicine, UT Health San Antonio, San Antonio, TX; <sup>3</sup>Florida State University College of Nursing, Tallahassee, FL; <sup>4</sup>Department of Population Health Sciences, School of Medicine, UT Health San Antonio, San Antonio, TX.

**Background:** Obesity is a major public health concern, as it is associated with a variety of chronic conditions, including kidney and cardiovascular dysfunction. The ketogenic diet has drawn much scientific and public attention to improve health however implementation is challenging. We therefore designed a study to assess the effects of a technology-assisted ketogenic diet on metabolic and kidney health, and report the results of the 3-month data collection point of the overall 6-month study.

**Methods:** Sixty overweight/obese adults (20 without type 2 diabetes and chronic kidney disease (CKD), 20 with type 2 diabetes and without CKD, and 20 with CKD) were randomized to a ketogenic diet (n=30) or a low-fat diet (n=30) group. Both groups received individual in-person educational sessions, digital educational sessions, and devices for self-monitoring lifestyle behaviors and health indicators (e.g., physical activity, diet, ketone levels). The data of 34 participants who finished the 3-month data collection by May 2022 were analyzed (n=17 in the ketogenic diet group, mean age 55.5 ± 12.4, 47% without diabetes and/or CKD; n=17 in the low-fat diet group, mean age 50.2 ± 11.3, 47% without diabetes and/or CKD). An intention to treat analysis was used. Paired t-tests and independent t-tests were conducted to assess within and between group differences in kidney and metabolic health from baseline to 3 months, respectively.

**Results:** Body weight, body mass index (BMI), and triglycerides were found to be significantly reduced in both the ketogenic diet and the low-fat diet groups; BMI reduction in the ketogenic diet group was significantly greater compared to the low-fat group. Reductions in hemoglobin A1c (HbA1c) (p=0.006), and systolic (p=0.010) and mean arterial pressure (MAP, p=0.003) were only found in the ketogenic diet group. No significant changes in urine albumin to creatinine ratio and estimated glomerular filtration rate were found in either group at 3 months compared to baseline.

**Conclusions:** At three months, a ketogenic diet-based lifestyle intervention has favorable effects on weight control, HbA1c, triglycerides, and systolic and mean arterial pressure in overweight/obese adults with or without diabetes and/or CKD.

## TH-PO851

### Need to Think Outside the Box: Clinical Presentation and Outcome of Tuberculosis in Patients With CKD

Mohan P. Patel,<sup>1</sup> Jitendra Goswami.<sup>2</sup> <sup>1</sup>Apollo Specialty Hospitals Pvt Ltd, Nashik, India; <sup>2</sup>Manipal Hospitals, Jaipur, India.

**Background:** Tuberculosis (TB) is still an important public health problem in Indian subcontinent and limited literature on TB among chronic kidney disease (CKD) population. Additionally, the diagnosis of TB in CKD patients is challenging because of suboptimal performance of screening and diagnostic tests. The present study aimed to investigate the clinical profile and outcome of TB in CKD patients and further assisting the complications during the treatment and recovery of the patients.

**Methods:** A prospective observational study was conducted in patients with CKD stage III - V, diagnosed with TB between January 2014 and December 2021. Demographic characteristics and clinical findings were recorded. Treatment with anti-TB drugs, adverse events and the outcome of patients were also noted.

**Results:** A total of 63 CKD patients with mean (SD) age 49.2 (18.3) years, clinically diagnosed with TB were enrolled in the study. About 72% of patients were male and 76.2% of patients (n=48) with TB had advanced CKD stage V. At the time of diagnosis of TB, 39 (81.25%) and 9 (18.75%) patients were on hemodialysis and peritoneal dialysis, respectively with mean (SD) dialysis duration was 9.2 (7.4) months. At the time of TB

diagnosis, twenty-nine patients (46%) were already diagnosed to have Diabetes Mellitus. The diagnosis of TB in 58.73% patients was on the basis of microbiological/histological reports and only on clinical grounds in rest of the 41.27% patients. The majority of the patients (n=41, 65%) had extrapulmonary TB. Pleuro-pulmonary (38.09%), lymph node (26.6%), peritoneum (17.46%) and genitourinary tract (6%) were common sites for TB. About 7.9% patients had joint TB and one patient (2%) had disseminated TB. Twenty-four patients (39.68%) had adverse events related to anti-TB drugs like rifampicin induced hypertension (n=11), isoniazid induced rash (n=2) isoniazid induced cerebellitis (n=3) and hepatitis (n=9). About 69.8% of the patients in the study were survived and 30.2% died.

**Conclusions:** As the clinical presentations of TB in CKD patients are mostly nonspecific, leading to delay in diagnosis and treatment along with poor patient outcomes. Hence, we need to think outside the box in patients with CKD as extrapulmonary presentations are more common. Adverse events related to anti-TB drugs frequently complicate the treatment, therefore vigilance is needed.

## TH-PO852

### Association of Bicarbonate Therapy With Incident CKD

Hanwen Wang,<sup>1</sup> Elani Streja,<sup>2</sup> Keiichi Sumida,<sup>3</sup> Fridtjof Thomas,<sup>3</sup> Csaba P. Kovessdy,<sup>3</sup> Kamyar Kalantar-Zadeh.<sup>2</sup> <sup>1</sup>University of California Los Angeles, Los Angeles, CA; <sup>2</sup>University of California Irvine Medical Center, Orange, CA; <sup>3</sup>The University of Tennessee Health Science Center, Memphis, TN.

**Background:** Sodium bicarbonate is used to treat metabolic acidosis and may delay deterioration of kidney function in patients with chronic kidney disease (CKD), but its effects on end-stage kidney disease (ESKD), incident CKD, and death in patients with normal kidney function are unclear.

**Methods:** We examined a national cohort of 238,313 US veterans with normal baseline kidney function (eGFR ≥60 ml/min/1.73m<sup>2</sup> and UACR <30 mg/g). We examined the association of de novo prescription of bicarbonate with ESKD, incident CKD (defined as two eGFR values <60 ml/min/1.73m<sup>2</sup> at least 90 days apart), and all-cause mortality, over a follow-up of up to 14 years. Associations were examined in Cox models and competing risk analyses adjusted for demographics, major comorbidities, baseline eGFR, and serum bicarbonate level. We also analyzed associations in a propensity score (PS)-matched cohort.

**Results:** We identified 2,992 Veterans who were incident bicarbonate users. Overall, patients had a mean age of 58 ± 12 years, with 7% female, 18% Black, and 7.7% Hispanic. Bicarbonate users (vs non-users) had a 1.7-fold higher risk of ESKD (SHR: 1.71, 95%CI: 0.69, 4.21), a 2-fold higher risk of incident CKD (SHR: 2.04, 95%CI: 1.87, 2.23), and a 3.3-fold higher risk of death (HR: 3.33, 95%CI: 3.15, 3.51) (Table). Results were consistent in a PS-matched cohort.

**Conclusions:** In this cohort of veterans with normal baseline kidney function, sodium bicarbonate use was associated with higher risks of ESKD, incident CKD, and mortality. Additional research is needed to determine if bicarbonate treatment is a surrogate of disease conditions associated with a higher risk of CKD, or if it causes deleterious outcomes directly.

**Funding:** NIDDK Support, Veterans Affairs Support

Table. Association of bicarbonate therapy with A) ESKD, B) Incident CKD and C) Death across models in 238,313 US veterans with normal baseline kidney function.

Event	Overall cohort (n=238,313)				PS matched cohort (n=5,968)	
	Crude (un-adjusted) model		Adjusted model		HR (95%CI)	P-value
	HR/SHR (95%CI)	P-value	HR/SHR (95%CI)	P-value		
ESKD	1.51 (0.62, 3.66)	0.3624	1.71 (0.69, 4.21)	0.2450	5.82 (0.80, 58.46)	0.0797
Incident CKD	1.96 (1.81, 2.13)	<0.0001	2.04 (1.87, 2.23)	<0.0001	2.82 (2.48, 3.20)	<0.0001
Death	5.22 (4.95, 5.51)	<0.0001	3.33 (3.15, 3.51)	<0.0001	2.31 (2.12, 2.53)	<0.0001

PS, propensity score; HR, hazard ratio; SHR, subhazard ratio; eGFR, estimated glomerular filtration rate; ESKD, end-stage kidney disease.

## TH-PO853

### Association of Fibrate Therapy and Incident CKD

Diana Tran,<sup>1</sup> Csaba P. Kovessdy,<sup>2</sup> Shaun M. Whitecavage,<sup>1</sup> Keiichi Sumida,<sup>2</sup> Fridtjof Thomas,<sup>2</sup> Kamyar Kalantar-Zadeh,<sup>1</sup> Elani Streja.<sup>1</sup> <sup>1</sup>University of California Irvine Medical Center, Orange, CA; <sup>2</sup>The University of Tennessee Health Science Center, Memphis, TN.

**Background:** Fibrate therapy can result in an acute increase in serum creatinine, which makes the assessment of kidney outcomes associated with fibrates difficult in studies with short follow-up times. We aimed to examine the association of fibrate therapy with incident CKD in a large national cohort of US Veterans with long follow-up.

**Methods:** In a nationwide cohort of 688,382 US Veterans with an eGFR ≥60 mL/min/1.73m<sup>2</sup> and available data on albuminuria in 2004-2006, we examined the association of de novo prescription of fibrate medications during the baseline period with incident CKD (defined as an eGFR <60 mL/min/1.73m<sup>2</sup> measured at least twice and separated by at least 90 days) over 14 years. Associations were examined in hazard models adjusted for demographics, major comorbidities, labs, baseline eGFR, and albuminuria.

**Results:** We identified 58,773 incident new fibrate users. Overall mean (SD) age was 59 (13) years, with 6.6% female, 17.9% Black, and 7.0% Hispanic. Fibrate users were more likely to be male, White, current smokers, and had higher frequencies of comorbidities. There were 139,360 cases of incident CKD (event rate 2.64/100PY, 95% CI: 2.63-2.66) with median follow-up of 8.5 years. Fibrate use (vs. non-use) was associated with higher

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

risk of incident CKD in crude (HR: 1.52, 95% CI: 1.50-1.55, model 1; Figure) and in multivariable adjusted models (HR: 1.33, 95% CI: 1.31-1.36, model 5).

**Conclusions:** In this large national cohort of US Veterans with long follow-up time, fibrinolytic therapy was associated with a higher risk of incident CKD. Further studies are needed to corroborate these findings by examining alternative kidney end points.

**Funding:** NIDDK Support, Veterans Affairs Support

## TH-PO854

### Changing Patterns of Antihypertensive Treatment Among CKD Patients: The CKD-REIN Cohort Study

Margaux Costes-Albrespic,<sup>1</sup> Solene M. Laville,<sup>4</sup> Sophie Liabeuf,<sup>4</sup> Christian Jacquelinet,<sup>5</sup> Christian Combe,<sup>6</sup> Denis Fouque,<sup>7</sup> Maurice Laville,<sup>8</sup> Carole Ayav,<sup>3</sup> Ziad Massy,<sup>1</sup> Roberto Pecoits-Filho,<sup>9</sup> Benedicte Stengel,<sup>1</sup> Benedicte Sautenet,<sup>2</sup> Natalia Alencar de Pinho,<sup>1</sup> <sup>1</sup>Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; <sup>2</sup>Centre Hospitalier Regional Universitaire de Tours, Tours, France; <sup>3</sup>Centre hospitalier regional universitaire de Nancy, Nancy, France; <sup>4</sup>Centre Hospitalier Universitaire Amiens-Picardie, Amiens, France; <sup>5</sup>Agence de la biomedecine, La Plaine Saint-Denis, France; <sup>6</sup>Centre Hospitalier Universitaire de Bordeaux Groupe hospitalier Pellegrin, Bordeaux, France; <sup>7</sup>Hospices Civils de Lyon, Lyon, France; <sup>8</sup>Universite Claude Bernard Lyon 1, Lyon, France; <sup>9</sup>Arbor Research Collaborative for Health, Ann Arbor, MI.

**Background:** Blood pressure (BP) control is one of the cornerstones for preventing cardiovascular complications in chronic kidney disease (CKD). Yet, despite a wide range of treatments, a majority of patients remain off-target. We aimed at describing changes in antihypertensive treatment regimens in this population.

**Methods:** We collected drug prescriptions over 5 years among 2,755 hypertensive patients with CKD stages 3 and 4 recruited from a nationally representative sample of 40 nephrology clinics in France. Using the international Anatomic Therapeutic and Chemical codes, we classified antihypertensive drugs into 14 mutually exclusive classes, and assessed time-dependent prescription status until death, kidney replacement therapy, or censoring.

**Results:** At baseline, 81% of the patients (mean age, 67; 66% men; mean eGFR 33 mL/min/1.73 m<sup>2</sup>) had BP ≥130/80 mmHg. We identified 257 distinct antihypertensive drug class regimens. The most prescribed class were RAS inhibitors (78%), and the most frequent combination, RAS inhibitors with diuretics (9%). BP level did not significantly differ according to the number of antihypertensive drugs. Over a median of 5 years of follow-up (IQR 4.5; 5.1), half of the patients changed their treatment regimen. These changes included adding-on, withdrawing or changing a drug class in 22%, 19%, and 10% of cases, respectively, and resulted in virtually no progression in the number of prescribed drug classes per patient at the end of follow-up (Figure). Analyses by drug classes revealed highest rates of regimen increments for β-blockers (46%) and for diuretics in addition with drug classes other than RAS inhibitors (35%).

**Conclusions:** This study highlights substantial heterogeneity of antihypertensive drug prescriptions among CKD patients under nephrology care. Greater knowledge of the evolving patterns of antihypertensive treatment regimens is a first, but key step in the understanding of the determinants of BP control in CKD.

**Funding:** Government Support - Non-U.S.

### Early Dapagliflozin Utilization for CKD Treatment in the United States

Eric T. Wittbrodt,<sup>1</sup> Jason M. Wright,<sup>3</sup> Juan Jose Garcia Sanchez,<sup>4</sup> Matthew Arnold,<sup>4</sup> Cassandra Nan,<sup>2</sup> <sup>1</sup>AstraZeneca R&D Gaithersburg, Gaithersburg, MD; <sup>2</sup>AstraZeneca AB, Mölndal, Sweden; <sup>3</sup>AstraZeneca Pharmaceuticals LP, Wilmington, DE; <sup>4</sup>AstraZeneca UK Ltd, Cambridge, United Kingdom.

**Background:** In 2021, dapagliflozin was approved for the treatment of adults with chronic kidney disease (CKD) in the United States (US). OPTIMISE-CKD is a multinational, observational, secondary data study program describing dapagliflozin treatment for CKD in routine clinical practice, contextualized by contemporary CKD management. This first observational analysis aims to describe early dapagliflozin utilization under the approved CKD indication in the US.

**Methods:** Adult patients with CKD in administrative claims data linked with electronic medical records in the OPTUM Market Clarity database from 30 March 2020 - 30 June 2021 were included. Criteria for CKD included any of the following: ≥1 UACR ≥30 mg/g, 2 eGFR ≥90 days apart of which the second was ≤75 mL/min/1.73m<sup>2</sup>, or a CKD diagnosis code. Patients with type 1 diabetes, gestational diabetes or <365 days continuous enrolment were excluded. Patients were dapagliflozin eligible if they met the CKD indication after 30 April 2021 and did not have a previous prescription for dapagliflozin 10 mg. Dapagliflozin CKD initiators had a recorded prescription for dapagliflozin 10 mg within 90 days of dapagliflozin eligibility.

**Results:** A total of 583 patients met the study criteria and had initiated dapagliflozin during the first 2 months since approval. The median age was 69 years (interquartile range; IQR 59-77) and 46% were female. For the 316 initiators with known CKD stage, the distribution was as follows: 4% stage 1, 16% stage 2, 28% stage 3a, 38% stage 3b, 13% stage 4 and 1% stage 5 (non-dialysis). The most common comorbidities were hypertension (91%), heart failure (44%) and type 2 diabetes (82%). Lipid lowering drugs (61%), diuretics (58%), renin-angiotensin-aldosterone system inhibitors (57%) and angiotensin receptor/neprilysin inhibitor (9%) were commonly prescribed. Similar patterns were found among patients who were not treated with dapagliflozin.

**Conclusions:** Early use of dapagliflozin in the US was observed in a broad range of patients with CKD with respect to baseline characteristics and was representative of treatment-eligible patients overall. Further analyses across more patients and countries in the OPTIMISE-CKD program will provide additional insight into the real-world experience of novel treatments for CKD and facilitate optimized CKD management.

### Fracture Risk in Association With Use of Anticoagulants for Atrial Fibrillation in Patients With CKD

Nazleen Khan, Seoyoung C. Kim, Su Been Lee, Katsiaryna Bykov, Julie M. Paik. Brigham and Women's Hospital Department of Medicine, Boston, MA.

**Background:** Direct oral anticoagulant (DOAC) use has been associated with better safety outcomes relative to warfarin in patients with atrial fibrillation. However, little is known about the safety and effectiveness of anticoagulant therapy in patients with chronic kidney disease (CKD), who are predisposed to fractures and other adverse outcomes.

**Methods:** We conducted a new user, active comparator cohort study in a large US commercial insurance database (2013-2020). Individuals were required to have at least 365 days of continuous enrollment prior to anticoagulant initiation and at least one International Classification of Diseases (ICD) diagnosis code for CKD, stages 3-5, and atrial fibrillation during the baseline period. The primary outcome was non-vertebral fracture defined using a previously validated algorithm of ICD diagnosis and procedure codes. Primary analyses quantified fracture risk in patients initiating DOACs (apixaban or rivaroxaban) or warfarin using a 1:1 propensity score-matched design with adjustment for 82 covariates. Cox proportional hazards regression and modified generalized linear models were used to obtain adjusted hazard ratios (HRs) and rate differences and 95% confidence intervals (CIs) of fracture in the 365 days following anticoagulant initiation. Secondary analyses evaluated comparative risks of all-cause mortality and hip fracture.

**Results:** The matched population included 14,394 initiators of DOACs and warfarin, respectively. The mean age was 77 years (standard deviation 8), and 45% were female. The rate of fracture events per 1,000 person-years was 32.53 for DOAC users and 29.89 for warfarin users. The adjusted HR of fracture comparing DOACs to warfarin was 1.09 (95% CI 0.92 to 1.29), and the rate difference was 2.64 events per 1,000 person-years.

(95% CI -2.56 to 7.83). In secondary analyses, the adjusted HR comparing DOACs to warfarin was 0.87 (95% CI 0.81 to 0.93) for all-cause mortality and 1.23 (95% CI 0.91 to 1.65) for hip fracture.

**Conclusions:** In our study of CKD patients with atrial fibrillation, we did not observe a difference in the rates of fracture between DOACs and warfarin initiators; however, the use of DOACs was associated with a lower risk of all-cause mortality.

## TH-PO857

### Leukotriene Antagonist Use Is Associated With Less Albuminuria and Lower Systolic Blood Pressure in Adults

Jennifer M. Lai,<sup>1</sup> Seth B. Furgeson,<sup>1</sup> Petter Bjornstad,<sup>1,2</sup> Zhiying You,<sup>1</sup> Kalie L. Tommerdahl,<sup>1,2</sup> Jessica B. Kendrick,<sup>1</sup> <sup>1</sup>University of Colorado Denver School of Medicine, Aurora, CO; <sup>2</sup>Children's Hospital Colorado, Aurora, CO.

**Background:** Proinflammatory mediators known as leukotrienes have been implicated in the development of both chronic kidney disease (CKD) and cardiovascular disease (CVD). Leukotrienes cause endothelial dysfunction which increases glomerular permeability to albumin and causes vascular dysfunction leading to CVD. We hypothesized that the use of montelukast in adults would associate with less albuminuria and lower systolic blood pressure (SBP).

**Methods:** Participant data from a total of 51,111 adults was extracted from NHANES 1999-2018 and stratified by montelukast prescription status. We evaluated baseline urine albumin to creatinine ratio (ACR) (mg/g), estimated glomerular filtration rate (eGFR) (mL/min/1.73m<sup>2</sup>), CKD (defined as urine ACR >30 mg/g or eGFR <60 mL/min/1.73m<sup>2</sup>), and SBP (mmHg) in participants taking montelukast vs. participants not taking montelukast. Urine ACR was log transformed prior to analysis due to positive skew. Regression analyses were used to examine the association between montelukast use and outcomes.

**Results:** We identified participants taking montelukast (N=434) and compared them to participants not taking montelukast (N=50,677). The mean age and eGFR were 47.2 ± 19 years and 96.6 ± 23.2 mL/min/1.73m<sup>2</sup>, respectively. Participants taking montelukast were older, had a higher prevalence of diabetes and hypertension, and had a lower eGFR. After adjustment for demographics, diabetes status, hypertension, body mass index (BMI), eGFR, and use of an ACE inhibitor or angiotensin receptor blocker, montelukast use associated with lower urine ACR (Table). Montelukast use did not associate with eGFR or CKD. After adjustment for demographics, diabetes status, BMI, hypertension, eGFR, urine ACR and use of anti-hypertensive medications, montelukast use associated with lower SBP.

**Conclusions:** Participants taking montelukast had significantly lower albuminuria and SBP compared to participants not taking montelukast. Leukotriene inhibition may represent a promising avenue for future treatment of CKD and CVD.

**Funding:** NIDDK Support

Montelukast Use vs. No Use	$\beta$ -estimate (95% CI)	P-value
Urine ACR	-0.13 (-0.22 to -0.04)	0.005
eGFR	-0.50 (-2.1 to 1.05)	0.51
SBP	-1.98 (-3.82 to -0.11)	0.038
	Odds Ratio (95% CI)	P-value
CKD	0.89 (0.66 to 1.21)	0.45

### Nephrologists Survey to Learn Prescribing Patterns of Sodium-Glucose Cotransporter 2 Inhibitors (SGLT2i)

Tripti Singh,<sup>1</sup> Tingting Li,<sup>2</sup> Didier A. Mandelbrot,<sup>1</sup> Ali Poyan-Mehr,<sup>3</sup> <sup>1</sup>University of Wisconsin-Madison, Madison, WI; <sup>2</sup>Washington University in St Louis, St Louis, MO; <sup>3</sup>Kaiser Permanente, Oakland, CA.

**Background:** SGLT2i decrease proteinuria and slow the progression of CKD. KDIGO recommends using SGLT2i in all diabetic CKD patients (1A recommendation). However, only 10% of diabetic CKD patients are prescribed SGLT2i. Here we surveyed SGLT2i prescribing patterns among nephrologists globally and identify barriers to SGLT2i prescribing.

**Methods:** We developed a nine-item online questionnaire to understand the causes of SGLT2i underutilization. We collected the responses of the anonymous survey via Qualtrics from nephrologists through the Glomerular Disease Study and Trial Consortium's (GlomCon) email distribution list, and via Twitter, Facebook, and Instagram.

**Results:** We received responses from 153 survey participants. Forty-nine percent of responders were nephrology fellows or recent graduates of past five years and 51% had been practicing for more than five years. 42% of respondents were from the US, and 58% were outside the US. 52% of respondents worked at a university hospital, and 48% were in private practice. 86% of respondents said they spend >50% of their time in clinical practice. 64% of total respondents and 68% of trainees or recent graduates said that they knew the indications for SGLT2i very well. 53% of respondents from the US vs. 80% of respondents outside the US responded that they knew indications of SGLT2i very well (P 0.001). 33.6% of respondents said that they prescribe SGLT2i to >50% of their patients meeting requirements for SGLT2i. There was no difference based on recent graduates vs. practicing nephrologists >5 years or US nephrologists vs. non-US nephrologists. The most common barriers to prescribing SGLT2i were the cost of the medication or high co-pay (34%), lack of experience or comfort in prescribing SGLT2i (29%), and lack of time and personnel to manage the side effects (11%). Professional guidelines (29%), readily available medical knowledge through social media (26%), and participation in professional conferences (18%) were identified as the mechanisms that have helped the most in prescribing SGLT2i

**Conclusions:** SGLT2i prescribing remains low among nephrologists. Major barriers to prescribing SGLT2i include unfamiliarity with drug indication among nephrologists and cost of medication.

## TH-PO859

### Novel Phosphate Binder Lanthanum Dioxycarbonate Does Not Demonstrate Clastogenic or Mutagenic Potential

Pramod Gupta, Atul Khare. *Unicycive Therapeutics, Inc, Los Altos, CA.*

**Background:** Lanthanum dioxycarbonate, RENAZORB (LDC), is a novel nanotechnology product that combines lanthanum, which has the highest binding capacity vs. other P binders, with a potentially smaller pill size that is swallowed with water rather than chewed. We present studies assessing the clastogenic and mutagenic potential of LDC.

**Methods:** The clastogenic and mutagenic potential of LDC was tested using chromosome aberration assays and bacterial reverse mutation assays, respectively. For the chromosome aberration assays, Chinese hamster ovary cells were harvested 20 hours after treatment initiation. Cell growth and mitotic inhibition relative to control were evaluated. Statistical analysis was performed using the Fisher's Exact test. Bacterial reverse mutation assays (Ames Test) consisted of two phases (initial toxicity mutation and confirmatory mutagenicity) and used *Salmonella typhimurium* and *Escherichia coli* tester strains with and without Aroclor-induced rat liver S9. Dose levels tested were 1.5, 5.0, 15, 50, 150, 500, 1500, and 5000 µg for the first phase and 50, 150, 500, 1500, and 5000 µg for the second phase.

**Results:** In the non-activated 4-hour exposure group, there was no increase in the proportion of cells with structural or numerical aberrations relative to control at any dose level (p>0.05). In the non-activated 20-hour exposure group, increases in the proportion of cells with numerical aberrations were not significant at any dose level (p>0.05). In the initial toxicity-mutation assay, precipitate was observed beginning at 500 µg per plate, and no background lawn toxicity was observed. No positive mutagenic responses were observed with any of the tester strains with or without S9 activation. In the confirmatory mutagenicity assay, no appreciable toxicity or positive mutagenic responses were observed.

**Conclusions:** Lanthanum dioxycarbonate did not induce structural and numerical chromosome aberrations. LDC was negative in bacterial reverse mutation assay. These data support that LDC is safe and should be tested in the target population of patients with ESKD on dialysis with hyperphosphatemia. If approved, LDC would offer a small, swallowable phosphate binder option that could improve patient quality of life and potentially adherence.

### Simulated Impact of SGLT2 Inhibitors on US Dialysis Census

Alhaji Cherif,<sup>1</sup> Peter Kotanko,<sup>1,2</sup> Nina L. Muellers,<sup>4</sup> Zdenek Cerman,<sup>4</sup> Julian Dreisemeier,<sup>4</sup> Robert J. Kossman,<sup>3</sup> Franklin W. Maddux,<sup>3</sup> <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>3</sup>Fresenius Medical Care North America, Waltham, MA; <sup>4</sup>Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany.

**Background:** Diabetes (DM) is common in CKD patients and associated with excess cardiovascular (CV) mortality. Sodium-glucose cotransporter 2 inhibitors (SGLT2i) have beneficial effects on morbidity and mortality of patients with DM, CV, and CKD. This study aims to predict the impact of SGLT2i use on dialysis census.

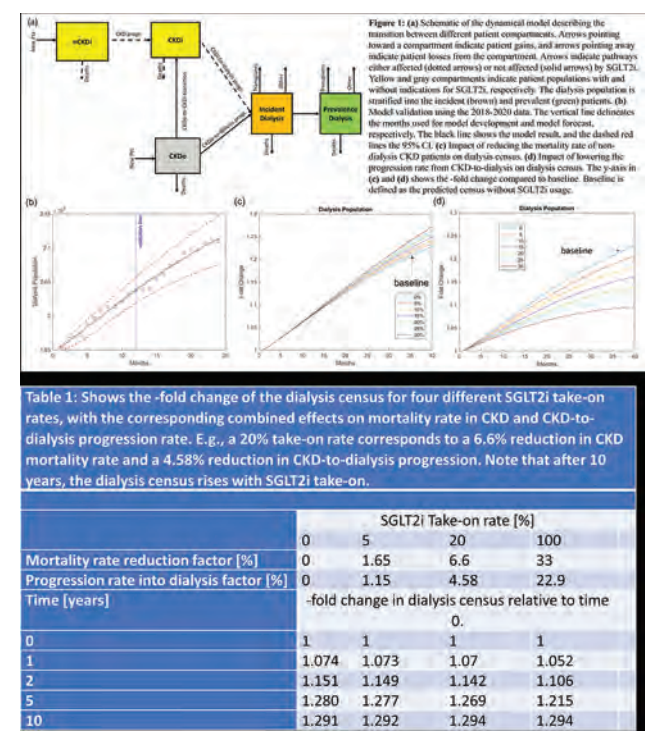

**Methods:** The patient population was divided into 5 groups: (1) non-CKD (nCKDi) and (2) CKD patients with indications for SGLT2i use (CKDi); (3) CKD patients without SGLT2i indication (CKDo); (4) incident and (5) prevalent dialysis patients. The model describes the transitions between different groups with the respective influx/efflux rates, e.g., mortality and CKD-to-dialysis progression (Fig.1a). The model was validated using Fresenius Kidney Care data from 1/2018 to 1/2020.

**Results:** The model predicted dialysis census between 1/2019 and 1/2020 (Fig.1b). Sensitivity analysis identified 4 SGLT2i-related parameters that affect dialysis census: mortality rate of CKD patients and CKD-to-dialysis progression exert a significant effect, while nCKDi mortality rates and progression to CKD have marginal impacts. **Figs. 1c-d** show the forecasted dialysis census over 40 months when CKDi mortality and CKD-to-dialysis progression rates are reduced by 30%. **Table 1** shows that a 20% SGLT2i take-on rate among CKDi reduces the dialysis census from 1.280 to 1.269 -fold change at year 5. Within ≤9 years, SGLT2i reduces the dialysis census based on the drug take-on rate. But, this trend is reversed after 10 years, resulting in a rising dialysis census.

**Conclusions:** SGLT2i use affects dialysis census dynamically. In the first 9 years, the dialysis census is reduced; then followed by an increase. Further research is needed to understand the effect of time-varying SGLT2i take-on rates on dialysis census.

**Association Between Urine Uromodulin and Interstitial Fibrosis**  
Alexander L. Bullen,<sup>1,2</sup> Joachim H. Ix,<sup>1,2</sup> Dena E. Rifkin,<sup>1,2</sup> Pranav S. Garimella,<sup>1</sup>  
<sup>1</sup>University of California San Diego, La Jolla, CA; <sup>2</sup>VA San Diego Healthcare System, San Diego, CA.

**Background:** Tubular atrophy and interstitial fibrosis are common findings in virtually all forms of chronic kidney disease. The severity of tubular atrophy and fibrosis on kidney biopsy is strongly predictive of progression to kidney failure; however, this damage is poorly correlated with either eGFR or albuminuria. The only form to identify interstitial fibrosis is with a kidney biopsy. Identifying interstitial fibrosis in a noninvasive manner would be of extreme value. Urine uromodulin (uMOD) is a marker of the renal reserve, and low concentrations of uMOD have been associated with chronic kidney disease progression. The association between uMOD and tubulointerstitial fibrosis is uncertain.

**Methods:** Among 52 individuals who underwent kidney biopsy for clinical reasons, we measured uMOD. The percentage of fibrosis was determined by morphometry technique. Due to skewed distribution, we log-transformed uMOD. We used linear regression to evaluate the association between uMOD and fibrosis, adjusting for age, sex, urine creatinine, obesity, diabetes, hypertension, baseline eGFR, and albuminuria.

**Results:** Among the 52 study participants, the mean age was 42 years, 48% were women, 23% had diabetes, and the mean eGFR was 64 mL/min/1.73m<sup>2</sup>. The mean uMOD was 5.1 mcg/mL. Participants in the lowest tertile of uMOD had more hypertension and diabetes mellitus and lower eGFR. Each doubling of urine uromodulin was associated with 1.88% decrease in fibrosis greater or equal to 25% (moderate or severe) after adjusting for all the covariates, including baseline eGFR and albuminuria.

**Conclusions:** Assessment of tubule function by measurement of uMOD provides information on interstitial fibrosis, independent of eGFR and albuminuria.

**Funding:** Veterans Affairs Support

TH-PO862

**Circulating Proteins Improve Prediction of Short-Term Kidney Disease Progression**  
Carolina Lopez-Silva,<sup>1</sup> Aditya L. Surapaneni,<sup>2</sup> Josef Coresh,<sup>1</sup> Teresa K. Chen,<sup>1</sup> Morgan Grams,<sup>2</sup> <sup>1</sup>Johns Hopkins University School of Medicine, Baltimore, MD; <sup>2</sup>New York University Grossman School of Medicine, New York, NY.

**Background:** Chronic kidney disease (CKD) progression may be preventable with early medical intervention, but few tools reliably identify high-risk patients in early disease. The proteins KIM-1, TNFRSF1A, and TNFRSF1B have been proposed as promising early markers of CKD progression.

**Methods:** Using participants from ARIC visit 2 (mean age 57 years, 56% women, mean eGFR 98 mL/min/1.73m<sup>2</sup>), ARIC visit 5 (mean 76 years, 76% women, mean eGFR 69 mL/min/1.73m<sup>2</sup>) and AASK (mean age 55 years, 39% women, mean eGFR 46 mL/min/1.73m<sup>2</sup>) studies, we compared the performance of three clinical models: model 1 (age, sex, GFR, race and center/randomized group), model 2 (model 1 + albuminuria),

model 3 (model 2 + diabetes, systolic BP, hypertension medication, smoking status) with those incorporating KIM-1, TNFRSF1A and TNFRSF1B. Individuals were stratified by diabetes status and eGFR level.

**Results:** The baseline clinical models had strong risk discrimination for 3-year 40% eGFR decline (C-statistic range for model 3: 0.73-0.89). Baseline levels of KIM-1, TNFRSF1A and TNFRSF1B improved risk prediction among 9,605 ARIC visit 2 participants (where albuminuria was not obtained). Among 2,935 ARIC visit 5 participants, the biomarkers enhanced risk prediction over model 1, except in patients without diabetes. Finally, among 557 AASK participants, the biomarkers added discrimination to model 1 but not to models 2 or 3 (Table 1).

**Conclusions:** Inclusion of KIM-1, TNFRSF1A and TNFRSF1B in clinical models resulted in small but significant improvements in risk prediction for short-term 40% eGFR decline in subgroups of patients at various levels of risk. Model improvement for 40% eGFR decline was more consistent among patients with diabetes and eGFR<60 mL/min/1.73 m<sup>2</sup>, and before inclusion of albuminuria.

**Funding:** Other NIH Support - R01 DK124399, K24 HL155861

**Lifestyle, Work, Clinical Parameters, and Kidney Function Decline in a Prospective Cohort With CKD of Uncertain Etiology in Sri Lanka**  
Edison Lee,<sup>1</sup> Pasan M. Hewavitharane,<sup>2</sup> Sai Liu,<sup>1</sup> Kaitlin E. Harold,<sup>1</sup> Santhushya Hewapathirane,<sup>3</sup> Shuchi Anand,<sup>1</sup> Maria E. Montez-Rath,<sup>1</sup> Stephen L. Schensul,<sup>4</sup> Penny Vlahos,<sup>5</sup> Nishantha Nanayakkara,<sup>2</sup> <sup>1</sup>Stanford University, Stanford, CA; <sup>2</sup>Kandy Teaching Hospital, Kandy, Sri Lanka; <sup>3</sup>University of Peradeniya, Peradeniya, Sri Lanka; <sup>4</sup>University of Connecticut School of Medicine, Farmington, CT; <sup>5</sup>University of Connecticut College of Liberal Arts and Sciences, Storrs, CT.

**Background:** Chronic kidney disease of unknown origin is a leading cause of death for adults living in the dry region of Sri Lanka and in other hotspots throughout the world.

**Methods:** In 2018, we initiated the Kidney Progression Project to prospectively follow 292 persons with CKDu and with CKD-EPI eGFR 20-60mL/min. Using data from 3 years of follow-up, we assessed the rate of kidney function decline by sex, and the association of rapid kidney function decline (>3mL/min annual decline) with baseline lifestyle, residence and clinical parameters.

**Results:** Median eGFR at enrollment was 28mL/min/1.73m<sup>2</sup> among 71 women and 30mL/min/1.73m<sup>2</sup> among 221 men; 91-99% had trace or no proteinuria during follow up. Among women, median serum Na was 143meq/L, uric acid was 6.3mg/dL, and K was 4.5meq/L. Among men, median serum Na was 143, uric acid was 6.9, and K was 4.3. Overall slope of decline was -0.5 [SD 4.9] mL/min/year; 30% of women and 17% of men experienced >3mL/min annual decline. Figure 1 depicts Kaplan-Meier curves for the composite outcome of 30% reduction in eGFR, eGFR<15% and death, stratified by sex. Self-reported hypertension was associated with rapid kidney function decline among men (OR 4.03 (1.81-8.95)); no other variables, e.g., family CKD history, tobacco use, farm work hours, agrochemical application, or serum sodium, were consistently associated with rapid kidney function decline.

**Conclusions:** Overall rate of kidney function decline was slow in this CKDu cohort, similar to other non albuminuric CKD (e.g., in CRIC cohort). Men and women had similar event rates, highlighting the need to re-examine the current understanding of CKDu as disproportionately affecting men. Many exposures were ubiquitous, and thus we could not identify distinct correlates of rapid kidney function loss, implying the need for control populations.

**Metabolic Biomarkers and Risk of CKD: A Prospective Cohort Study**  
Tingting Geng, Junxiang Chen, Yan-Feng Zhou, Gang Liu, An Pan. *Huazhong University of Science and Technology Tongji Medical College, Wuhan, China.*

**Background:** The prospective associations between nuclear magnetic resonance (NMR)-based metabolic biomarkers and chronic kidney disease (CKD) have not been scrutinized, which is crucial for understanding the etiological pathways and paving the way toward novel prevention and treatment strategies of CKD. We aimed to examine the associations of NMR-based metabolic biomarkers with risk of CKD using data from the UK Biobank study.

**Methods:** A total of 91,534 participants (mean age 55.3 years, 42.8% men) without CKD and lipid-lowering therapy were followed for a median of 11.5 years. NMR spectroscopy was used to quantify 249 metabolic biomarkers, including routine lipids, lipid concentrations and composition within 14 lipoprotein subclasses, as well as other metabolites. Multivariable-adjusted Cox regression models were used to compute the hazard ratios. We also estimated the predictive performance for the 10-year CKD risk using the selected metabolites by the least absolute shrinkage and selection operator (LASSO) regression.

**Results:** A total of 1846 incident CKD were identified. In general, very-low-density lipoprotein (VLDL) particles were associated with a higher risk of CKD whereas high-density lipoprotein (HDL) particles were associated with a lower risk of CKD. Similar patterns of cholesterol, lipids, and phospholipids in VLDL and HDL with risk of CKD were observed. Triglycerides within all lipoproteins, including all HDL particles were associated with a higher risk of CKD. However, we did not observe significant associations of LDL particles or lipids measures, except for triglycerides and free cholesterol in LDL, with risk of CKD. Adding metabolic biomarkers selected by LASSO, including histidine, isoleucine, albumin, glucose, omega-3 fatty acids to total fatty acids percentage, docosahexaenoic acid to total fatty acids percentage, glycoprotein acetyls, phospholipids to total lipids in very small VLDL percentage, and triglycerides to total lipids in large LDL percentage to the clinical variable-based model improved discrimination (C-statistic from 0.820 to 0.831, P<0.001) for prediction of 10-year CKD incidence.

**Conclusions:** Circulating lipids, lipoprotein and metabolites were associated with risk of CKD, suggesting that these metabolites may be involved in the pathogenesis of CKD. Selected NMR-based biomarkers could enhance the prediction of CKD.

TH-PO865

**Mitochondrial DNA Haplotypes and Risk of CKD and AKI**  
Vasanth Jotwani,<sup>1</sup> Mark J. Sarnak,<sup>3</sup> Heather Thiessen Philbrook,<sup>2</sup> Ronit Katz,<sup>4</sup> Joachim H. Ix,<sup>5</sup> Sushrut S. Waikar,<sup>6</sup> Chirag R. Parikh,<sup>2</sup> Gregory J. Tranah,<sup>8</sup> Samir M. Parikh,<sup>7</sup> Michael Shlipak,<sup>1</sup> Dan Arking.<sup>2</sup> <sup>1</sup>*University of California San Francisco, San Francisco, CA;* <sup>2</sup>*Johns Hopkins University, Baltimore, MD;* <sup>3</sup>*Tufts University, Medford, MA;* <sup>4</sup>*University of Washington, Seattle, WA;* <sup>5</sup>*University of California San Diego, La Jolla, CA;* <sup>6</sup>*Boston University, Boston, MA;* <sup>7</sup>*The University of Texas Southwestern Medical Center, Dallas, TX;* <sup>8</sup>*California Pacific Medical Center, San Francisco, CA.*

**Background:** Experimental models suggest an important role for mitochondrial dysfunction in the pathogenesis of chronic kidney disease (CKD) and acute kidney injury (AKI), but little is known regarding the impact of mitochondrial genetic variation on kidney health. We evaluated associations of inherited mitochondrial DNA (mtDNA) haplotypes with risk of CKD and AKI in a large population-based cohort.

**Methods:** Among UK Biobank participants who self-identified as white, we tested eight distinct mtDNA haplotypes (N=379,432) with minor allele frequency >0.5% that were previously identified based on associations with traits associated with mtDNA copy number. Individuals with prevalent end-stage kidney disease were excluded. We used linear and logistic regression models to evaluate associations of these mtDNA haplotypes with estimated glomerular filtration rate by serum creatinine and cystatin C (eGFR, N=362,802), AKI defined by diagnostic codes (N=14,170 cases), and urine albumin/creatinine ratio (ACR, N=114,662).

**Results:** The mean age was 57±8 years and the mean eGFR was 90±14 ml/min/1.73m<sup>2</sup>. MtDNA haplotype was significantly associated with eGFR (p= 2.84E-12), but not with risk of AKI (p=0.256) or urine ACR (p=0.538). The association of mtDNA haplotype with eGFR remained significant after adjustment for diabetes mellitus and hypertension (p=1.20E-10). When compared to the reference haplotype, mtDNA haplotypes I, IV, and V were each associated with higher eGFR (Table).

**Conclusions:** Among self-identified white UK Biobank participants, mtDNA haplotype was associated with eGFR, but not with AKI risk or albuminuria.

**Funding:** NIDDK Support, Other NIH Support - NIA 2R01AG027002

Table: Associations of mitochondrial DNA haplotypes with eGFR (mL/min/1.73m<sup>2</sup>) among UK Biobank participants

mtDNA haplotype	N (%)	β Coefficient	P-Value

**MR Imaging-Based Kidney Parameters in the Population-Based German National Cohort Study**  
Peggy Sekula, Jan Lipovsek, Elias Kellner, Anna Kottgen. on behalf of the Project Team Medical Center - University of Freiburg, Freiburg, Germany.

**Background:** Chronic kidney disease (CKD) affects around 10% of adults worldwide. Imaging is an emerging and complementary approach to derive markers of kidney function, CKD and CKD progression. The goal of our project was to derive novel imaging markers of the kidneys through automated kidney segmentation from whole-body MR images of a subgroup of participants of the large, population-based German National Cohort (NAKO/GNC) study, and to examine their distributions and associations with other characteristics.

**Methods:** Using MR images of 11207 GNC participants and functionalities of the imaging platform NORA (www.nora-imaging.org), a workflow to train a convolutional neural network was developed to automatically segment different kidney compartments (cortex, hilus, medulla). Volumetric parameters (mL) for compartments and total kidney volume (TKV) were normalised to body-surface-area (BSA, m<sup>2</sup>) and related to demographic variables and estimated glomerular filtration rate (eGFR) based on serum creatinine and cystatin C.

**Results:** Quality control left data of 9955 participants for analysis. The mean (SD) TKV was 339 (+/-56) mL for men and 276 (+/-46) mL for women. On average, right kidneys were 5% smaller than left kidneys. The compartment volumes showed different patterns across age, with medullary volume decreasing and hilus increasing. In multivariable linear regression analyses (Table), BSA-corrected TKV was positively associated with age, sex, height and body mass index (BMI). The inclusion of eGFR strongly improved the proportion of explained variance in BSA-corrected TKV and compartments (R<sup>2</sup>=33-36%). For example, per 1 mL/min/1.73m<sup>2</sup> higher eGFR, the BSA-corrected TKV was higher by 0.99 mL/m<sup>2</sup>.

**Conclusions:** The developed framework allows for robust segmentation of kidneys from MR images of a large cohort study. TKV and compartment volumes of the kidney show correlations with various participants' characteristics that are consistent with prior knowledge and with eGFR.

**Funding:** Government Support - Non-U.S.

**New Surrogate Marker of CKD Progression and Mortality in Medical Word Virtual Space: Prospective Cohort Study**  
Eiichiro Kanda,<sup>1</sup> Bogdan I. Epureanu,<sup>2</sup> Taiji Adachi,<sup>3</sup> Naoki Kashihara.<sup>1</sup> <sup>1</sup>*Kawasaki Ika Daigaku, Kurashiki, Japan;* <sup>2</sup>*University of Michigan, Ann Arbor, MI;* <sup>3</sup>*Kyoto Daigaku, Kyoto, Japan.*

**Background:** Chronic kidney disease (CKD) leads to end-stage renal disease (ESRD) or death. A new surrogate marker reflecting its pathophysiology has been needed for CKD therapy.

**Methods:** In this study, we developed a virtual space unifying data in the medical literature and that of actual CKD patients and created a surrogate marker of CKD progression and mortality using natural language processing.

**Results:** A virtual space of medical words was constructed from the CKD-related literature (n=165,271) using natural language processing, in which CKD-related words (n=106,612) composed a network (Figure 1). The data of CKD patients of a prospective cohort study for three years (n=26,433) were transformed into the space and linked with the network on the basis of information-geometry theory. We let the relationship between a patient and the outcome (ESRD or death) in the network be a surrogate marker of the outcome. The network satisfied the definitions of vector keeping their medical meanings. Riemannian metrics highly accurately predicted the primary outcomes; C-statistics, 0.911. Cox proportional hazards models with spline showed that the high Riemannian metrics were associated with high hazard ratio of the primary outcomes ( $p < 0.0001$ ). Moreover, the risk of the primary outcome in high-Riemannian-metric group was 21.92 (95% CI: 14.77, 32.51) times higher than that in the low-Riemannian-metric group.

**Conclusions:** The medical-word virtual space reflects the real-world patient data. And the Riemannian metrics between a patient and the outcome is a new surrogate marker for CKD therapy.

#### Plasma KIM-1, MCP-1, suPAR, TNFR1, and TNFR2 Are Associated With Incident CKD in Individuals Without Diabetes

Dustin Le. Chronic Kidney Disease Biomarkers Consortium Johns Hopkins Medicine, Baltimore, MD.

**Background:** Numerous kidney biomarkers related to tubular injury, inflammation, and repair have been associated with kidney disease progression in patients with diabetes and underlying chronic kidney disease (CKD). Whether these markers are associated with incident CKD in a general population without diabetes is not well established.

**Methods:** In a nested case-cohort study within the Atherosclerosis Risk in Communities (ARIC) study, we evaluated the association of plasma biomarkers related to tubular injury (kidney injury molecule-1 [KIM-1]), inflammation (monocyte chemoattractant protein-1 [MCP-1]), soluble urokinase plasminogen activator receptor [suPAR], tumor necrosis factor receptor 1 [TNFR-1], tumor necrosis factor receptor 2 [TNFR-2]), and repair (human cartilage glycoprotein-39 [YKL-40]) and risk of incident CKD among individuals with baseline eGFR  $\geq 60$  mL/min and no diabetes. Biomarkers were measured at visit 4 (1996-1998). Incident CKD was defined as eGFR  $< 60$  mL/min per 1.73 m<sup>2</sup> and  $\geq 40\%$  eGFR decline at visit 5 (2011-2013) or end stage kidney disease through linkage with the USRDS registry.

**Results:** There were 523 incident CKD cases (38 being ESRD) and 425 non-cases. Mean age was 62 years, 59% were women, and 20% were black. Mean baseline eGFR was 88 (5<sup>th</sup>-95<sup>th</sup> percentile: 66 - 108). In multivariable analyses, there was a higher risk of incident CKD per two-fold higher concentration of KIM-1 (HR 1.35, 95% CI: 1.22 - 1.50), MCP-1 (HR 1.36, 95% CI: 1.12 - 1.65), suPAR (HR 1.69, 95% CI: 1.37 - 2.08), TNFR-1 (HR 1.54, 95% CI: 1.32 - 1.80), and TNFR-2 (HR 1.69, 95% CI: 1.35 - 2.11). See Figure for results by biomarker quartile. YKL-40 was not significant.

**Conclusions:** Higher plasma levels of KIM-1, MCP-1, suPAR, TNFR-1, and TNFR-2 were associated with increased risk of incident CKD in a general population study.

#### The Associations of Kidney Functional Magnetic Resonance Imaging Biomarkers of Oxygenation and Fibrosis With Inflammatory Biomarkers in Individuals With Advanced CKD

Jacquelyn Trujillo,<sup>1</sup> Manal Alotaibi,<sup>1</sup> Nay Seif,<sup>1</sup> Xuan Cai,<sup>1</sup> Brett Larive,<sup>2</sup> Jennifer J. Gassman,<sup>2</sup> Kalani L. Raphael,<sup>3</sup> Dominic S. Raj,<sup>4</sup> Linda F. Fried,<sup>5</sup> Stuart M. Sprague,<sup>6</sup> Geoffrey A. Block,<sup>10</sup> Michel Chonchol,<sup>7</sup> John P. Middleton,<sup>8</sup> Myles Wolf,<sup>8</sup> Joachim H. Ix,<sup>9</sup> Pottumarthi V. Prasad,<sup>6</sup> Tamara Isakova,<sup>1</sup> Anand Srivastava.<sup>1</sup> <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>Cleveland Clinic, Cleveland, OH; <sup>3</sup>Oregon Health & Science University, Portland, OR; <sup>4</sup>The George Washington University School of Medicine and Health Sciences, Washington, DC; <sup>5</sup>University of Pittsburgh School of Medicine, Pittsburgh, PA; <sup>6</sup>NorthShore University HealthSystem, Evanston, IL; <sup>7</sup>University of Colorado Denver School of Medicine, Aurora, CO; <sup>8</sup>Duke University School of Medicine, Durham, NC; <sup>9</sup>University of California San Diego School of Medicine, La Jolla, CA; <sup>10</sup>US Renal Care, Dallas, TX.

**Background:** Chronic kidney hypoxia and tubulointerstitial fibrosis promote chronic inflammation, which may lead to worsening CKD progression. There is limited data on the associations between non-invasive markers of kidney oxygenation and fibrosis with inflammation.

**Methods:** We evaluated the association of baseline kidney functional magnetic resonance imaging (fMRI) biomarkers of oxygenation and fibrosis with interleukin-6 (IL-6) and C-reactive protein (CRP) in 127 participants from the COMBINE trial, which was a randomized, 12-month study of nicotinamide and lanthanum carbonate vs. placebo in individuals with CKD stages 3-4. Higher cortical relaxation rate (R2\*) on BOLD MRI may represent decreased oxygenation. Lower cortical apparent diffusion coefficient (ADC) on diffusion-weighted MRI may indicate greater fibrosis. Multivariable linear regression models tested the associations between kidney fMRI and inflammatory biomarkers at baseline. Linear mixed effects models tested the association of baseline kidney fMRI biomarkers with change in inflammatory biomarkers over time.

**Results:** At baseline, mean  $\pm$  SD eGFR, R2\*, and ADC was 32.2  $\pm$  8.7 mL/min/1.73m<sup>2</sup>, 20.3  $\pm$  3.1 s<sup>-1</sup>, 1.46  $\pm$  0.17 mm<sup>2</sup>/s, respectively. Median [IQR] IL-6 and CRP was 3.7 [2.4-4.9] pg/mL and 2.8 [1.2-6.3] mg/L. At baseline, cortical R2\* did not have a significant association with IL-6 or CRP, but higher ADC was associated with lower IL-6 and CRP (Figure 1A). Mean annual IL-6 and CRP slope were 0.98 (95% CI 0.85-1.12) pg/mL per year and 0.91 (95% CI 0.79-1.06) mg/L per year, respectively. Cortical ADC and R2\* did not have significant associations with change in IL-6 or CRP over time (Figure 1B).

**Conclusions:** In individuals with advanced CKD, higher cortical ADC, suggestive of less cortical fibrosis, was associated with lower inflammation, as assessed by IL-6 and CRP. Kidney fMRI biomarkers did not associate with change in inflammatory biomarkers over time.

**Funding:** NIDDK Support

**Figure 1B.** Associations of baseline kidney fMRI biomarkers with change in serum IL-6 and CRP over time.

	$\beta$	SE	P
<b>IL-6</b>			
ADC <sup>+</sup> Time	-0.001	0.009	0.395
R2 <sup>+</sup> Time	0.006	0.008	0.449
<b>CRP</b>			
ADC <sup>+</sup> Time	-0.002	0.01	0.363
R2 <sup>+</sup> Time	0.007	0.009	0.414

Each model is adjusted for age, sex, race, diabetes status, treatment group, study center, baseline log transformed UACR, baseline eGFR, and respective log<sub>2</sub> transformed inflammation biomarker. The  $\beta$  estimate is the difference in each respective mean annual inflammation biomarker slope per 1 SD increase in the MRI biomarker of interest from the respective MRI biomarker  $\times$  time interaction term.

## TH-PO871

Yoko Narasaki,<sup>1</sup> Connie Rhee,<sup>1</sup> Susan T. Crowley,<sup>2</sup> Csaba P. Kovacs,<sup>3</sup> Dana B. Mukamel,<sup>1</sup> Amy S. You,<sup>1</sup> Ji Hoon Yoon,<sup>1</sup> Danh V. Nguyen,<sup>1</sup> Kamyar Kalantar-Zadeh.<sup>1</sup> <sup>1</sup>University of California Irvine, Irvine, CA; <sup>2</sup>Yale University, New Haven, CT; <sup>3</sup>The University of Tennessee Health Science Center, Memphis, TN.

**Methods:** In a national cohort of US Veterans, we examined patients with advanced CKD ( $\geq 2$  eGFRs  $< 25$  ml/min/1.73m<sup>2</sup> separated by  $\geq 90$  days from 10/2010-9/2019). Using linked USRDS and Medicare (CMS) data, we compared comorbidity trends among patients categorized according to receipt of CM, defined as those who did not receive dialysis within 2-years of the index eGFR (1<sup>st</sup> eGFR  $< 25$ ), vs. receipt of dialysis within 2-years of the index eGFR.

**Results:** Among 106,089 advanced CKD patients who met eligibility, 25% and 75% were treated with dialysis vs. CM, respectively. Compared to the dialysis group, CM patients tended to be younger; were more likely to be White; and less likely to be Black or Hispanic. Median (IQR) Charlson Comorbidity Index (CCI) scores in the dialysis vs. CM groups were 7 (6, 9) and 7 (5, 9), respectively (Fig A). Using CMS Chronic Conditions Data Warehouse algorithms, the most prevalent comorbidities in the dialysis group were diabetes (77%), CHF (65%), PVD (50%), CVD (36%), and history of MI (35%) (Fig B). Among the CM group, the most common comorbidities were diabetes (65%), CHF (58%), COPD (50%), PVD (46%), and CVD (37%).

**Conclusions:** Among US Veterans with advanced CKD, while there were socio-demographic differences among the dialysis vs. CM groups, comorbidity burden defined by CCI score and types of comorbidities were similar. Further studies are needed to identify the clinical phenotype of patients who will most benefit from dialysis vs. CM.

**Background:** In patients with atrial fibrillation (AF), the risk of stroke and mortality increases with worsening estimated glomerular filtration rate (eGFR). The purpose of this systematic review was to study the independent associations of eGFR and albuminuria with incident AF.

**Methods:** MEDLINE, EMBASE and CENTRAL databases were searched for cohort studies and randomized controlled trials that reported incident AF in adults according to baseline measurements of eGFR or albuminuria. From cohort studies, multivariable-adjusted risk ratios (RR) were extracted. For each trial, RRs and 95% CIs for eGFR and albuminuria categories were derived from meta-analysis using reported event data. The outcome of incident AF was analyzed separately among patients with decreased eGFR and increased albuminuria using random effects meta-analysis. If studies reported more than one estimate of the association for different eGFR and albuminuria categories, a

within-study summary risk estimate was obtained. Subgroup analyses according to eGFR and albuminuria categories were conducted to explore sources of heterogeneity.

**Results:** Thirty-five studies involving 26,840,893 participants with 436,304 incident AF cases were included. Compared to participants with eGFR  $\geq 60$  and  $\geq 90$  mL/min/1.73 m<sup>2</sup>, the risk of incident AF was increased among participants with eGFR  $\leq 59$  mL/min/1.73m<sup>2</sup> (16 studies, RR 1.56, 95% CI 1.34 – 1.81, I<sup>2</sup>= 70%), and eGFR  $\leq 89$  mL/min/1.73m<sup>2</sup> (11 studies, RR 1.49, 95% CI 1.28 – 1.74, I<sup>2</sup>=67%), respectively. Compared to participants with no albuminuria, the risk of incident AF was greater among participants with albuminuria (3 studies, RR 1.37, 95% CI 1.18 – 1.60, I<sup>2</sup>=0%). Compared to those with normal to mildly increased albuminuria, risk of incident AF was greater for participants with moderately- to severely-increased albuminuria (6 studies, RR 1.67, 95% CI 1.28 – 2.17, I<sup>2</sup>=75%). Subgroup analyses showed that incident AF risk increased progressively at lower eGFR and higher albuminuria categories.

**Conclusions:** Lower eGFR and higher albuminuria are independent risk factors for incident AF. Additional studies are required to evaluate whether systematic screening for AF leads to improved outcomes in patients with chronic kidney disease.

## TH-PO873

### Association Between Dietary Magnesium Intake and Incident CKD

Hee Byung Koh, Ga Young Heo, Hyo Jeong Kim, Ye Eun Ko, Shin-Wook Kang, Jung Tak Park. *Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

**Background:** Recent studies suggest a close association between low serum magnesium levels and kidney injury. However, whether dietary magnesium intake relates with kidney function is not well known. In this study, the relationship of dietary magnesium intake with the development of chronic kidney disease (CKD) was evaluated.

**Methods:** This observational study screened 210,984 European adults aged 40-70 who underwent dietary questionnaires from April 2009 to June 2012 in the UK Biobank cohort. Participants with underlying CKD (baseline eGFR < 60 mL/min/1.73 m<sup>2</sup> or urine albumin-to-creatinine ratio >30mg/g/Cr) or dietary energy intake <500 kcal or >6000 kcal were excluded. Dietary magnesium intake was assessed through online 24-hour recall dietary questionnaire and adjusted for energy intake using residual method. The participants were categorized into quartiles according to energy-adjusted dietary magnesium intake. Primary outcome was incident CKD diagnosed through ICD-10 and OPCS-4 codes. Sensitivity analysis was performed with outcome of CKD defined as eGFR <60 mL/min/1.73 m<sup>2</sup>.

**Results:** A total of 144,408 participants were included in the final analysis. The mean age was 55.8  $\pm$  8.0 years and 51.8 % were female. Average magnesium intake amount per person was 352.0  $\pm$  118.7 mg/day. During a 1431716.4 person-year follow-up, CKD outcome occurred in 4,438 patients. Incidence of CKD was progressively lower in patients with higher magnesium intake (3.5%, 3.1%, 2.9%, and 2.7% in Q1-4, respectively). Cox regression analysis revealed that the hazard ratios (HRs) for incident CKD decreased in a stepwise manner towards higher magnesium intake quartiles (1Q: HR, 0.90; 95% CI, 0.83-0.97; 2Q: HR, 0.83; 95% CI, 0.77-0.90; 3Q: HR, 0.80; 95% CI, 0.74-0.87) relative to 4Q (*P* for trend <0.001). This association was maintained even after adjustments were made for confounding factors. Similar results were observed with eGFR-defined CKD outcome (1Q: adjusted HR [AHR], 0.93; 95% CI, 0.84-1.04; 2Q: AHR, 0.86; 95% CI, 0.76-0.96; 3Q: AHR, 0.83; 95% CI, 0.74-0.94) relative to 4Q (*P* for trend =0.002).

**Conclusions:** Higher intake of dietary magnesium may relate with lower risk of kidney function decline in adults with normal kidney function.

### Patterns of Gut Microbiota and Metabolites in CKD: The CRIC Study

Amanda H. Anderson,<sup>1,2</sup> Robin L. Baudier,<sup>1</sup> Scott G. Daniel,<sup>4</sup> Lillian Chau,<sup>2</sup> Lisa C. Nessel,<sup>2</sup> James P. Lash,<sup>3</sup> Anne Frydrych,<sup>3</sup> Harold I. Feldman,<sup>2</sup> Kyle Bittinger,<sup>4</sup> Tanika Kelly,<sup>1</sup> Jiang He,<sup>1</sup> Gary Wu.<sup>2</sup> The CRIC Study <sup>1</sup>Tulane University, New Orleans, LA; <sup>2</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>3</sup>University of Illinois Chicago, Chicago, IL; <sup>4</sup>The Children's Hospital of Philadelphia, Philadelphia, PA.

**Background:** The gut microbiome is altered in numerous disease conditions but its importance in the setting of moderate chronic kidney disease (CKD) remains to be elucidated.

**Methods:** Among 291 men and women with CKD (58% with diabetes; mean estimated glomerular filtration rate (eGFR): 56 mL/min/1.73m<sup>2</sup>; 56 repeat stool collections) enrolled in the Chronic Renal Insufficiency Cohort (CRIC) Study, shotgun metagenomic sequencing and targeted fecal metabolite assays were performed. For genera associations, 148 genera present in  $\geq 5\%$  of samples that comprised  $\geq 0.01\%$  of total reads were included.

**Results:** Beta diversity (Euclidean distance, Bray Curtis dissimilarity and unweighted Jaccard similarity index) was related to eGFR and its change over time using the Optimal Microbiome Regression-based Kernel Association Test (Figure 1; each *P*  $\leq 0.001$ ). Nearly all fecal measures of amino acids, bile acids, short-chain fatty acids and urea were significantly associated with beta diversity at a false discovery rate (FDR) <0.05. eGFR was inversely correlated with alpha diversity (ACE: each *P* <0.001). Five genera including *Lawsonella* (phylum: Actinobacteria), *Hymenobacter* (phylum: Bacteroidetes), *Neisseria* and *Halomonas* (phylum: Proteobacteria), and *Methanospaera* (phylum: Euryarchaeota), as well as caproic acid levels were associated with eGFR by linear regression independent of age, sex, race, diabetes, and systolic blood pressure at an FDR <0.05. Twenty-six genera were independently associated with eGFR change prior to FDR adjustment. Various genera were independently associated with amino (Figure 2) and bile acids (not shown) at an FDR threshold of <0.05 by tobit regression.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** These findings suggest possible pathways through which CKD may influence health.

**Funding:** NIDDK Support

Figure 2. Heatmap of genera independently associated with amino acids related to Beta Diversity.

## TH-PO875

### Peri and Para-Renal Fat Tissue and Risk of CKD in Morbid Obese Patients

Natasha Smiliansky, Sofia San Román, Gabriela Ottati, Gustavo Bruno, Mariela Garau, Oscar A. Noboa, Veronica Etcheagoimberly. *UDELAR, Hospital de Clinicas, Montevideo, Uruguay.*

**Background:** Obesity is known as a global pandemic. Multiple studies had determined obesity as an independent risk factor to the initiation and progression of CKD. The measurement of peri and para-renal fat thickness could reflect the visceral fat accumulation associated with kidney function impairment. The aim of this study is to determine the association of para and peri-renal ultrasonographic fat thickness (PUFT) with some cardiovascular and kidney damage markers in morbid obese patients.

**Methods:** This study was performed with morbid obese patients in bariatric surgery preoperative evaluation. The sonograms were performed by a single technician, to decrease the inter operator variability. It was measured the perirenal fat thickness from the inner side of the abdominal wall to the external edge of each kidney with a convex transducer (3-5 MHz), this measurement was taken twice to insure results. The average of the sonographic measurements to both sides was defined as PUFT

**Results:** 44 patients were analyzed, 86.4% of the population studied were women, with a mean age of 45 ( $\pm 11.2$ ) years. 65.9% of the patients were hypertensive and 36.4% diabetic. The average BMI was 50.4 ( $\pm 8.1$ ) in a range between 35 and 71.6 kilogram square meter. The PUFT was correlated with BMI (*p*=0.007) and with visceral fat thickness (*p*<0.001) with a significance level of 0.05. Albuminuria and PUFT were correlated (*p*=0.006) even in non-diabetic patients (*p*=0.018). Estimated glomerular filtration rate (eGFR) was no correlated with PUFT (*p*=0.735), but when categorizing individuals according to eGFR (< 60 mL/min, between 60-120 mL/min, >120 mL/min), there was a correlation between hyperfiltration patients and PUFT (*p*=0.0039). Spearman correlation was performed. When correlating uricemia and PUFT through Pearson's *r* coefficient, the value was 0.316, (*p*=0.047), indicating that there is a weak association. The PUFT did not show association with TC, LDL, HDL or TG.

**Conclusions:** The sonographic perirenal fat thickness (PUFT) measurements could be considered as an accessible and least invasive method to predict kidney damage in morbid obese patients. It has an equivalence to BMI and other traditional anthropometric indexes as an accurate parameter of visceral fat thickness

## TH-PO876

### Association Between Family History of CKD and Incidence and Progression of CKD: A Nationwide Family Cohort Study in South Korea

Jae Young Kim,<sup>1,2</sup> Tae ik Chang.<sup>1</sup> <sup>1</sup>National Health Insurance Service Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; <sup>2</sup>Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.

**Background:** It is suggested that family clustering plays a crucial role in the development of kidney diseases with the effect of both genetic factor and shared environment. However, it is not well documented that if chronic kidney disease (CKD) aggregates in Asian families.

**Methods:** We aimed to estimate the familial aggregation of kidney diseases using a national database of Korean population with detailed longitudinal data. A total of 881,453 patients with incident CKD diagnosed between 2004-2017 were matched to control by age and sex on a 1:1 basis. Primary outcome of interest was the risk for incident CKD in the general population and the disease progression to kidney failure among CKD patients having first-degree relatives affected with end stage renal disease (ESRD).

**Results:** Multivariable logistic regression analysis showed that individuals with an affected first-degree relative with CKD were found to have 46% higher risks for incident CKD than that in the general population, which was independent of age, sex, residential area, income levels, and comorbid conditions including hypertension and diabetes (adjusted OR 1.46; 95% CI, 1.43-1.49). Furthermore, during 3,207,497 person-years of follow-up (mean 3.9 years), multivariable-adjusted Cox proportional hazards models revealed that having an affected first-degree relative with ESRD was associated with an increased risk for the development of ESRD (adjusted HR 1.22; 95% CI, 1.17-1.26). Not only in related kinship, higher risks were observed in those with an unrelated affected spouse.

**Conclusions:** In this large national study of Korean population, individuals having first-degree relatives affected with kidney diseases had higher risks for incident CKD and the disease progression to kidney failure.

TH-PO877

**Association of Low-Grade Albuminuria With CKD Progression in Individuals With CKD**  
Ashish Verma,<sup>1</sup> Insa M. Schmidt,<sup>1</sup> Ragnar Palsson,<sup>2</sup> Sushrut S. Waikar,<sup>1</sup> Anand Srivastava,<sup>3</sup> <sup>1</sup>*Boston University School of Medicine, Boston, MA;* <sup>2</sup>*Massachusetts General Hospital, Boston, MA;* <sup>3</sup>*Northwestern University Feinberg School of Medicine, Chicago, IL.*

**Background:** By convention, albuminuria, a major risk factor for CKD progression, is classified as moderately (30-300 mg/g) or severely (>300 mg/g) increased. However, the relationship of low-grade albuminuria (<30 mg/g) with CKD progression has not been well-studied among individuals with CKD.

**Methods:** We examined the association of urine albumin to creatinine ratio (UACR) with CKD progression (defined as eGFR decline ≥50% or incident ESKD) in 1629 participants with UACR <30 mg/g enrolled in the Chronic Renal Insufficiency Cohort (CRIC) Study. Multivariable-adjusted Cox-proportional hazard models tested the association of CKD progression with UACR modeled as a continuous variable (log base 2) and in tertiles.

**Results:** Mean ± SD age was 60.2 ± 9.6 years, 847 (52%) participants were women, mean eGFR was 49.6 ± 14.7 mL/min/1.73m<sup>2</sup>, and median [IQR] UACR was 6.9 [4.0, 14.2] mg/g. Over a median follow-up of 9.8 years, 182 participants developed CKD progression. In fully adjusted models, UACR had a linear association with CKD progression (**Figure 1A**). Each doubling of UACR was associated with 56% increased risk of CKD progression (HR 1.56, 95% CI 1.33-1.83) (**Figure 1B**). Individuals in the highest tertile of UACR had a 2.64-fold increased risk of CKD progression (HR 2.64, 95% CI 1.72-4.05) compared to individuals in the lowest tertile (**Figure 1B**).

**Conclusions:** Low levels of urine albumin excretion, well below the threshold set in the current CKD staging system, were independently associated with CKD progression. Future studies are needed to determine the optimal threshold for initiation of treatment with anti-proteinuric agents and whether the further reduction in albuminuria may improve adverse clinical outcomes in individuals with CKD.

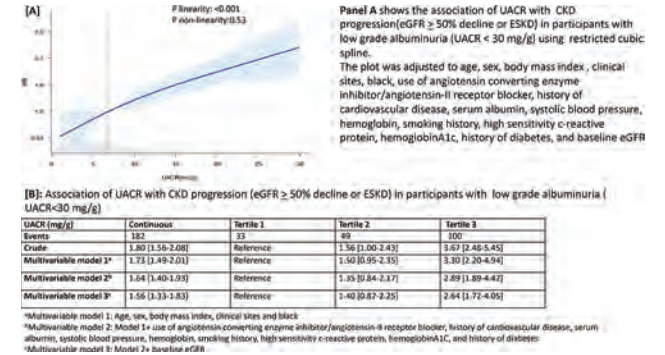

FIGURE 1: Association of UACR with CKD progression using co-proportional hazard and cubic restricted spline models.

TH-PO878

**Association of Race-Based vs. Race-Free eGFR With Nutritional Status, Mortality, and ESKD in African Americans With CKD**  
Sahar Amin,<sup>1</sup> Atif Ibrahim,<sup>1</sup> Barry M. Wall,<sup>1,2</sup> Csaba P. Kovcsy.<sup>1,2</sup> <sup>1</sup>*The University of Tennessee Health Science Center College of Medicine, Memphis, TN;* <sup>2</sup>*VA Memphis Medical Center, Memphis, TN.*

**Background:** Severity of CKD is associated with malnutrition and higher risk of death and kidney failure. As a result of the elimination of race from equations estimating GFR (eGFR), the eGFR value of African American patients was revised downward to variable extent, depending on the equation used. It is unclear if the different levels of eGFR and the resultant differences in CKD stages affects the association of kidney function with clinical outcomes such as nutritional status, mortality and ESKD.

**Methods:** We examined a cohort of 461 African American US veterans with stage 3-5 CKD followed at a single institution. We used the original CKD-EPI equation with and without the inclusion of the race correction factor and the revised 2021 race-free CKD EPI formula to estimate GFR and to determine CKD stages. We examined the association of

the different eGFR values and CKD stages with dietary protein intake (g/day, estimated from spot urine urea nitrogen/creatinine) in linear regression models and with all-cause mortality and ESKD incidence in Cox models.

**Results:** Patients were 66±11 years old, 96% were male, and 60% were diabetic. The race-free equations yielded lower eGFR values and a higher proportion of patients with more advanced stages of CKD, with the lowest eGFR values seen with the race-free old CKD-EPI equation (Table). There were 154 ESKD events (event rate, 82.3/1000 PY; 95%CI, 70.3-96.3) and 250 deaths (133.6/1000PY, 95%CI: 118.0-151.2) over a median follow-up of 4.0 years. Lower eGFR was associated with lower protein intake and higher risk of death and ESKD irrespective of the eGFR formula (Table).

**Conclusions:** Elimination of race from the GFR estimation formulas results in lower estimated GFR values and a higher proportion of African American patients categorized into more advanced stages of CKD. While subjective decisions using eGFR cutoffs may be influenced by such differences, the association of eGFR with objective clinical outcomes was similar across the different formulas used to estimate GFR.

**Funding:** Veterans Affairs Support

	Mean (SD) eGFR value: (ml/min/1.73m2)	CKD stages 2, 3a, 3b, 4 and 5 (%)	Dietary protein intake per 10 ml/min/1.73m2 lower eGFR in g/day (95%CI)	Hazard ratio (95%CI) of death (per 10 ml/min/1.73m2 lower eGFR)	Hazard ratio (95%CI) of ESKD (per 10 ml/min/1.73m2 lower eGFR)

TH-PO879

**Changes in CKD Prevalence With and Without eGFR Indexing to the Median Body Surface Area in the United States**  
Elani Streja,<sup>1</sup> Maria Clarissa Tio,<sup>2</sup> Aliba Syed,<sup>1</sup> Yoshitsugu Obi,<sup>2</sup> Michael Hall,<sup>2</sup> Kamyar Kalantar-Zadeh,<sup>1</sup> Tariq Shafi.<sup>2</sup> <sup>1</sup>*University of California Irvine, Irvine, CA;* <sup>2</sup>*University of Mississippi Medical Center, Jackson, MS.*

**Background:** The eGFR is reported indexed to a body surface area (BSA) of 1.73m<sup>2</sup>, the estimated BSA of 25-year-olds in 1912. However, the contemporary median BSA of the US population is higher than 1.73 and arbitrarily indexing eGFR to a lower BSA may systematically overcalculate CKD prevalence, particularly Stage G3A A1. We assessed the changes in the U.S. CKD prevalence using eGFR indexed to the median BSA of the U.S. population (mL/min/medianBSA), with particular emphasis on CKD G3A.

**Methods:** We analyzed the 2017-2020 National Health and Nutrition Examination Survey (NHANES; N=8,016). eGFR was calculated using the CKD-EPI 2021 race-free equation while individual BSA was calculated from the DuBois & DuBois formula. We used reclassification tables to determine the changes in CKD prevalence when eGFR is indexed to 1.73m<sup>2</sup> (eGFR/1.73) vs. indexed to median BSA in the US (eGFR/Median). We defined CKD as eGFR <60 or ACR ≥30 mg/g.

**Results:** The median US BSA was 1.91m<sup>2</sup> (2.0m<sup>2</sup> in males and 1.78m<sup>2</sup> in females). The BSA of 1.73 corresponded to the 26th percentile for the US population (6.4<sup>th</sup> percentile in males and 39.6<sup>th</sup> percentile in females). The median eGFRs of the US population was 108 mL/min/1.73m<sup>2</sup> and 109.2 mL/min/1.91m<sup>2</sup>. Using eGFR/Median instead of eGFR/1.73, 3.7 million (12%) US adults with CKD (eGFR<60 mL/min/1.73m<sup>2</sup> or ACR ≥30 mg/g) were no longer classified as CKD (Table 1). All of those reclassified as no CKD were in CKD 3a A1 (ACR <30) and comprised 54% of the US population with CKD 3a A1.

**Conclusions:** Our data suggest overdiagnosis of CKD using only eGFR with arbitrary selection of BSA-indexing to 1.73m<sup>2</sup> and that using the outdated BSA for eGFR indexing leads to an 11.8% higher CKD prevalence in the US.

**Funding:** Other NIH Support - NIGMS

Table 1: Changes in CKD Prevalence when eGFR is Indexed to 1.73m <sup>2</sup> vs. 1.91m <sup>2</sup> .				
eGFR/1.73m <sup>2</sup>	eGFR/1.91m <sup>2</sup>			
	Not CKD	CKD	TOTAL	
	196.4 million (100.0%)	27.5 million (86.2%)	196.4 million	
eGFR/1.73m <sup>2</sup>	3.7 million (11.8%)	27.5 million (86.2%)	31.1 million	
	200.0 million	27.5 million	227.5 million

## Cognitive Patterns in Patients With CKD: The CKD-REIN Cohort Study

Hélène Levassort,<sup>1,3</sup> Ziad Massy,<sup>2,3</sup> Oriane Lambert,<sup>3</sup> Christian Combe,<sup>4,3</sup> Denis Fouque,<sup>5,3</sup> Maurice Laville,<sup>6,3</sup> Carole Ayav,<sup>7,3</sup> Christian Jacquelinet,<sup>8,3</sup> Benedicte Stengel,<sup>3</sup> Marion Pépin.<sup>1,3</sup> Center for research in Epidemiology and Population Health (CESP), Clinical Epidemiology Team, Paris-Saclay University, Versailles Saint-Quentin-en-Yvelines University, National Institute of Health and Medical Research, Villejuif, France; <sup>1</sup>Clinique Ambroise Pare Service de Court Séjour Geriatrique, Boulogne-Billancourt, France; <sup>2</sup>Hopital Ambroise-Pare Service de Nephrologie Dialyse, Boulogne-Billancourt, France; <sup>3</sup>Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; <sup>4</sup>Centre Hospitalier Universitaire de Bordeaux, Bordeaux, France; <sup>5</sup>Universite Claude Bernard Lyon 1, Villeurbanne, France; <sup>6</sup>Universite de Lyon, Lyon, France; <sup>7</sup>Centre hospitalier regional universitaire de Nancy, Nancy, France; <sup>8</sup>Agence de la biomédecine, La Plaine Saint-Denis, France.

**Background:** Chronic kidney disease (CKD) is associated with an increased risk of neurocognitive disorders (NCD). The global Mini Mental State Examination (MMSE) is often used to screen for cognitive impairment in patients with CKD, but the relative impact of CKD on the different cognitive domains of MMSE remains unexplored.

**Methods:** We used the MMSE to assess orientation, memory, attention and calculation, language and praxis, scores among 3033 patients (mean age, 66.82±12.87; 65.3% men) with all types of CKD and an estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73 m<sup>2</sup> included in the CKD-Renal Epidemiology and Information Network (CKD-REIN) cohort. Adjusted associations of patient characteristics with the global and domain-specific MMSE scores were estimated using linear regression models.

**Results:** The mean global MMSE score was 26.8/30 and the median score was 28/30. Two cognitive domains were significantly lower at lower eGFR level: orientation and praxis. After adjusting for age, sex, education, depressive symptoms, polymedication, psychoactive drug use, cerebrovascular disease, heart failure, history of depression and urinary albumin/creatinine ratio, low eGFR (expressed as 10 mL/min/1.73 m<sup>2</sup>), the orientation score was significantly lower, by 0.03 points [0.003, 0.05] for every 10 mL/min/1.73 m<sup>2</sup> drop in eGFR ( $p=0.03$ ), and praxis, by 0.01 points [0.002, 0.02] ( $p=0.01$ ).

**Conclusions:** This study shows that orientation and praxis domains may be affected before the occurrence of clinically evident NCD, in patients with nondialysis CKD. This highlights the importance of screening individual cognitive domains in this population.

**Funding:** Other NIH Support - CKD-REIN

## TH-PO881

## Comparison Between the Profile of Patients Defined by Age-Adapted and Fixed-Threshold CKD Criteria: A National-Wide, Cross-Sectional Study

Yixin Ma, Jianfeng Lin, Peng Xia, Hua Zheng, Peili Ji, Guangjin Zhu, Ling Qiu, Limeng Chen. Peking Union Medical College Hospital, Dongcheng-qu, China.

**Background:** Kidney function declines with advancing age, an age-adapted eGFR threshold has been proposed instead of the fixed cutoff for CKD definition. The study aims to describe and compare the profile of CKD patients defined by these two criteria in a Chinese population.

**Methods:** We recruited the adult participants with selected biochemical tests from the Chinese Physiological Constant and Health Condition (CPCHC) survey conducted from 2007 to 2011, with the GFR estimated by the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula. The age-adapted threshold of eGFR was 75, 60, and 45 mL/min/1.73 m<sup>2</sup> for the population under 40 years old, 40 to 64 years old, and above 64 years, respectively. The fixed threshold is 60 mL/min/1.73 m<sup>2</sup> for all ages.

**Results:** Among the recruited 23,438 participants, 480 participants were diagnosed with CKD by fixed-threshold criteria, 391 participants by age-adapted criteria. We found that the CKD patients defined by age-adapted criteria matched well with the 2.5th percentile of eGFR in the Chinese individuals. When compared with their age- and gender-matched controls, patients included by age-adapted criteria but excluded by fixed-threshold criteria had a significantly higher prevalence of hypertension (23.2% vs. 7.7%,  $p<0.001$ ) and hyperuricemia (25.0% vs. 5.5%,  $p<0.001$ ), while patients included only by the fixed-threshold criteria were not significantly different in CVD risk factors and CKD related disturbance except for hyperuricemia (41.2% vs. 14.0%,  $p<0.001$ ).

**Conclusions:** An age-adapted criterion is more closely associated with CVD risk factors and CKD-related disturbance compared to fixed-threshold criteria.

**Funding:** Government Support - Non-U.S.

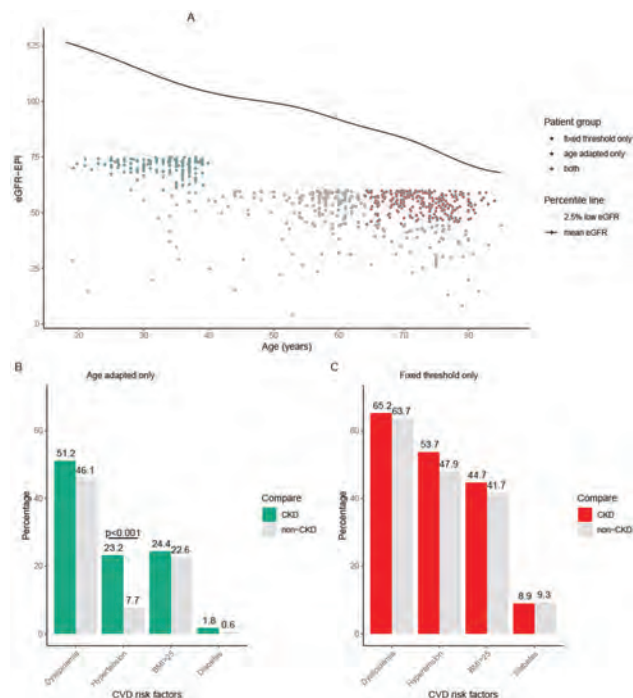

Figure 1. Illustration of age and eGFR distribution and the CVD risk profile of patients

## TH-PO882

## Diagnostic Validity of Claims Data Diagnoses for CKD With Data From the Berlin Initiative Study (BIS)

Tim Bothe,<sup>1,2</sup> Elke Schaeffner,<sup>1</sup> Nina Mielke,<sup>1</sup> Alice Schneider,<sup>1</sup> Antonios Douros,<sup>3</sup> Muhammad Barghouth,<sup>1</sup> Markus van der Giet,<sup>1</sup> Martin K. Kuhlmann,<sup>4</sup> Natalie Ebert.<sup>1</sup> <sup>1</sup>Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>InGef - Institut für angewandte Gesundheitsforschung Berlin GmbH, Berlin, Germany; <sup>3</sup>McGill University, Montreal, QC, Canada; <sup>4</sup>Vivantes Klinikum im Friedrichshagen, Berlin, Germany.

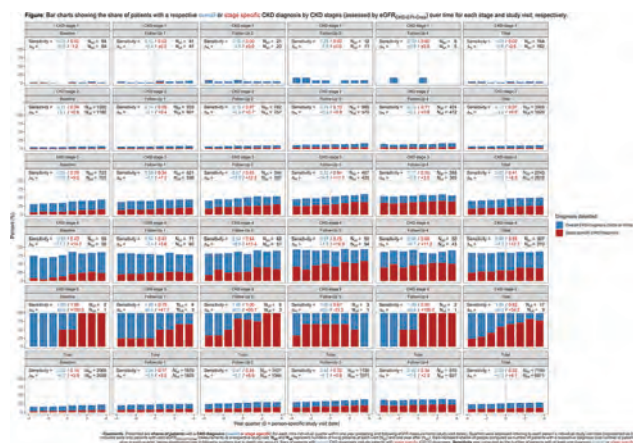

**Background:** Information on diagnostic validity of kidney disease within claims data is scarce. Thus, we aimed to estimate the validity of diagnostic codes of chronic kidney disease (CKD) in German claims data using estimated glomerular filtration rate (eGFR) as the gold standard.

**Methods:** We used data of the Berlin Initiative Study (BIS), a community-dwelling cohort of 2,069 persons aged 70 or older, for whom primary clinical data linked with claims data are available. After baseline assessment (2010–2011), 4 follow-up visits were conducted biennially over a total observation period of 8 years. Correspondence of overall and stage-specific CKD ICD-10 diagnoses in claims data with CKD stages assessed by the creatinine-based CKD-EPI equation ( $eGFR_{CKD-EPI-Crea}$ ) was evaluated over time (cross-sectionally and longitudinally) and for each stage, respectively.

**Results:** The sensitivity of claims data diagnoses increases with CKD stages (Figure). For stages 3 and 4, stage-specific sensitivity increases from baseline to follow-up 4 (0.29/0.42 vs. 0.55/0.68 for stage 3/4) as well as longitudinally through  $\pm 1$  year ( $\Delta_{95\%} = +3.6 - +12.5 / +3.6 - +17.4$  for stage 3/4). Still, false-negative rates are high, as many patients do not receive diagnoses corresponding with the respective CKD stage (e.g., 1-sensitivity<sub>total</sub> = 0.91/0.83 for stage 1/2). Over all measures and stages, sensitivity is low (0.38 for overall and 0.22 for stage-specific diagnoses).

**Conclusions:** Correspondence of claims data diagnoses with eGFR measurements can be interpreted as acceptable for CKD stages 5 and 4, limited for stage 3, and low for stages 2 and 1. Stage-specific sensitivity is lower than overall. Over time (cross-sectionally as well as longitudinally), correspondence seems to increase. Over all measures and stages, diagnostic validity of CKD diagnoses in claims data should be interpreted as restricted.

## TH-PO883

### Impact of Urinary Protein Examination on Early Diagnosis of CKD: A Nationwide Hospital-Based Observational Study in Japan, REAL-CKD

Shoichi Maruyama,<sup>1</sup> Tetsuhiro Tanaka,<sup>2</sup> Masayoshi Takeda,<sup>3</sup> Naru Morita,<sup>3</sup> Toshitaka Yajima.<sup>3</sup> <sup>1</sup>Dep. of Neph, Nagoya Univ., Aichi, Japan; <sup>2</sup>Dep. of Neph, Tohoku Univ., Miyagi, Japan; <sup>3</sup>AstraZeneca K.K., Osaka, Japan.

**Background:** Early diagnosis and active management can slow disease progression of CKD. However, diagnosis rate of CKD in stage 3a (G3a) based on eGFR is reported to be very low (around 10%) in a real-world setting. This study assessed the impact of urinary protein examination in combination with eGFR on the improvement of early diagnosis of CKD patients.

**Methods:** REAL-CKD is a hospital-based observational study using RWD database (Real World Data Co., Ltd., Kyoto, Japan) between 2004-2021. Patients aged  $\geq 18$  years with two or more eGFR results of  $<90$  mL/min/1.73m<sup>2</sup> between 90-360 days apart were included. Patients with CKD diagnosis were defined as having an associated CKD diagnosis code any time in 12 months before or 3 months after the second eGFR measurement. Qualitative proteinuria such as urine albumin-to-creatinine ratio (UACR) and urine protein-to-creatinine ratio (UPCR) were utilized for KDIGO risk classification.

**Results:** Of 788,059 eligible patients, qualitative urinary protein records necessary for KDIGO risk classification were available in 54,073 (6.9%) patients. There was no gender difference in the overall CKD population while in A3 category, male rate was high (60.2%). The most frequent comorbidities were diabetes (63.7%), hypertension (51.1%) and heart failure (22.3%) in KDIGO risk classified population. The CKD diagnosis rate increased from A1 towards A3, notably in G2 (A1: 14.5, A2: 24.9, A3: 47.5%) and G3a (A1: 26.2, A2: 36.2, A3: 56.5%) with the total diagnosis rate of 20.2% and 35.4%, respectively (Figure1).

**Conclusions:** While urinary protein examination in combination with eGFR increased early diagnosis rate of CKD, the examination rate was very low and a high proportion of the patients were still not diagnosed properly in the real-world clinical setting. Given recent development of CKD treatment strategies, there is a clear need to increase the early diagnosis rate to improve the clinical outcomes by proactively detecting progressive CKD patients.

**Funding:** Commercial Support - AstraZeneca K.K.

## TH-PO884

### Performance of Machine Learning Compared With Regression Analysis in Predicting Albuminuria

Ali Haider Arsiwala,<sup>1</sup> Marcella Mathew,<sup>2</sup> Johannes B. Scheppach,<sup>2</sup> Dr. Vasantrao Pawar Medical College, Hospital & Research Centre, Nashik, India; <sup>2</sup>Charité Universitätsmedizin Berlin, Berlin, Germany.

**Background:** Albuminuria is a marker of kidney disease and an independent risk factor for cardiovascular events, cognitive decline, and all-cause mortality. Machine learning (ML) algorithms are increasingly used for risk prediction in medical science, given their proficiency in identifying patterns in large datasets and modeling non-linear interactions, surpassing the capacity of traditional statistical approaches. We compared the predictive performance of three ML models with a regression model in correctly classifying participants as with or without albuminuria.

**Methods:** We studied 18,117 participants aged 20 to 80 years from the National Health and Nutrition Examination Survey (NHANES) between 2005 and 2018. Synthetic minority oversampling technique was used to correct the class imbalances in the data resulting from the oversampling recruitment strategy applied by NHANES. Self-reported variables like age, sex, ethnicity, education status, blood pressure, diabetes status, and modified frailty phenotype were used to predict albuminuria, defined as a Urine Albumin-Creatinine Ratio  $> 30$  mg/g. Participants were randomly grouped into a training dataset (n=13,587) and a testing dataset (n=4,530). A logistic regression model, a gradient boosting classifier model, a k-nearest neighbor model, and an artificial neural network (ANN) were used for classification. To compare classification results, accuracy, sensitivity, and specificity were computed.

**Results:** Out of all prediction models, the ANN had the highest accuracy (0.89; 95% Confidence Interval: [0.88, 0.90]) and highest sensitivity (0.99 [0.97, 1.00]). For comparison, the logistic regression model showed an accuracy of (0.86 [0.85, 0.87]) and a sensitivity of (0.90 [0.89, 0.92]). However, the specificity of the ANN (0.77 [0.75, 0.80]) was lower than that of the logistic regression model (0.83 [0.81, 0.85]).

**Conclusions:** Using ML algorithms for the prediction of albuminuria showed an advantage in performance with higher accuracy and sensitivity over traditional regression analysis. Artificial intelligence-based screening tools for albuminuria developed from self-reported data could offer diagnostic and economic advantages in the early detection and prevention of chronic kidney disease.

## TH-PO885

### Predictors of CKD Awareness in Middle-Aged and Older Community-Dwelling Japanese Adults

Keiko Kabasawa, Yumi Ito, Kazutoshi Nakamura, Junta Tanaka, Ichiei Narita. Niigata University, Niigata, Japan.

**Background:** Despite global efforts in public health campaigns on chronic kidney disease (CKD), CKD awareness, which is a key to improving health outcomes through patient engagement, remains low. Predictors of CKD awareness may help identify effective ways to raise awareness but are not yet clear. In this study, we aimed to determine clinical and socio-demographic characteristics associated with CKD awareness.

**Methods:** Using the 5-year longitudinal framework of the Uonuma cohort study, we analyzed data of 5,932 Japanese adults (median age at baseline, 61 years; range, 40-92 years; 50.7% women) who participated in the baseline (2012-2014) and 5-year surveys and in a health checkup at the study's 5-year follow-up. CKD awareness was defined as answering the question "Have you ever been told by a doctor that you have chronic kidney disease (abnormal urinalysis or kidney dysfunction)?" with "Yes, I was told within the past 5 years." A self-administered questionnaire collected clinical history, socio-demographic characteristics, and family history of CKD. At the 5-year health checkup, CKD was diagnosed based on eGFR  $<60$  mL/min/1.73 m<sup>2</sup> or  $\geq 1+$  dipstick urine protein.

**Results:** At the 5-year follow-up, there were 1,232 participants (20.8%) who had CKD, with mean eGFR of 73.6 (standard deviation 15.0) mL/min/1.73 m<sup>2</sup>. The sensitivity and specificity of the CKD awareness question were respectively 15.4% and 97.7% in men and 9.3% and 99.1% in women. In demographic-adjusted logistic regression analysis, family history of CKD and history of heart disease, stroke, hypertension, diabetes, and hyperuricemia were significantly associated with CKD awareness, but these associations were not significant in multivariable logistic regression analysis with further adjustment for eGFR. In the multivariable logistic regression model, independent predictors of CKD awareness were history of urinary tract stone (adjusted odds ratio [95% confidence interval], 2.08 [1.33-3.25]), female sex (0.47 [0.35-0.64]), and married status (0.62 [0.45-0.87]).

**Conclusions:** The results of this study suggest that known risk factors for CKD did not predict CKD awareness independently of kidney function and that a sex-dependent approach may help to improve CKD awareness.

**Funding:** Government Support - Non-U.S.

## TH-PO886

### Lutetic Nephropathy: An Underrecognized Etiology of Nephropathy

Umair Khan,<sup>1</sup> Divya Mounisha R. Thimmareddygar,<sup>1</sup> Fatima Z. Warraich,<sup>2</sup> Ujjwala Murari,<sup>1</sup> Heather R. Lefkowitz.<sup>1</sup> <sup>1</sup>Newark Beth Israel Medical Center, Newark, NJ; <sup>2</sup>Baystate Medical Center, Springfield, MA.

**Introduction:** Syphilis is an underrecognized cause of nephropathy. Most cases of syphilis are diagnosed in individuals with HIV, Hepatitis B and/or C and hence nephropathy may wrongly be attributed to them. Here we present an unusual case of lutetic nephropathy presenting as crescentic glomerulonephritis.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Case Description:** A 80-year-old female with a history of hypertension and Parkinson's disease was evaluated for lower extremity swelling, facial edema, and elevated serum creatinine. Workup revealed creatinine of 1.5 mg/dL (baseline of 1.01 mg/dL), proteinuria with a urine protein-creatinine ratio of 507 mg/g, mild hematuria without any casts or sediments. Serological panel was positive for antiproteinase 3 (PR-3-ANCA) however was negative for cytoplasmic (C-ANCA), perinuclear (P-ANCA), HIV, HBV, HCV, with normal complements (C3/C4). Lupus, scleroderma, GBM, Sjogren's, Group A strep and primary membranous nephropathy workup was negative. Drug-associated glomerulonephritis was excluded clinically. Infectious work-up revealed a Rapid Plasma Reagin level of 1:1 and positive Treponemal antibody. A diagnostic kidney biopsy showed fibrous crescents consistent with crescentic glomerulonephritis and chronic interstitial inflammation with eosinophils without features of necrotizing arteritis. In our case, biopsy findings of crescentic glomerulonephritis with positive syphilis serologies highly suggested luetic nephropathy and hence was then started on penicillin therapy.

**Discussion:** Syphilis-associated renal disease (luetic nephropathy), is an uncommon disease with a wide variety of manifestations. It presents as a nephrotic syndrome with varying degrees of proteinuria [1,2]. It is now known that deposition of IgG against treponema pallidum in the renal mesangium incites the onset of nephropathy [2]. Walker et al reported a case of secondary syphilis associated with crescentic glomerulonephritis [3]. Syphilis-associated glomerulonephritis is part of the infection-related glomerulonephritis whose main treatment is infection resolution. The implementation of steroid in such cases is unclear but may aid in reducing irreversible glomerular scarring. KDIGO guidelines do not advise to screen for syphilis however given its increased prevalence, luetic nephropathy should be kept in mind to while evaluating patients with renal dysfunction.

**Prevalence of CKD: Comparison of Real-World Data (RWD) Sources to the US National Health and Nutrition Examination Survey (NHANES)**  
Joseph Stavas,<sup>1</sup> Emily L. Butler,<sup>1</sup> Debra E. Irwin,<sup>2</sup> Rohan J. Shah,<sup>2</sup> Helen Latimer,<sup>2</sup> Alberto Sepulveda,<sup>5</sup> Sandy D. Balkin,<sup>5</sup> Katherine R. Tuttle.<sup>3,4</sup>  
<sup>1</sup>ProKidney, Raleigh, NC; <sup>2</sup>Aetion, New York, NY; <sup>3</sup>Providence Health System, Spokane, WA; <sup>4</sup>University of Washington, Seattle, WA; <sup>5</sup>Royalty Pharma, New York, NY.

**Background:** NHANES is a common source of CKD prevalence data in the USA, where CKD stage is based on one eGFR estimate using the KDIGO categories. We estimated the prevalence of CKD stage  $\geq 3$  using RWD and compared it to NHANES estimates.

**Methods:** RWD was extracted from HealthVerity PrivateSource20 closed claims and linked to Veradigm Health Insights Electronic Health Record (EHR). Adults,  $\geq 20$  years old, continuously enrolled in the claims data and active in the EHR were evaluated during 2018. eGFR values were used to determine the CKD stage. The prevalence of CKD stage  $\geq 3$  was projected to the USA population (standardized on age, gender, and geographic region using USA census data) and compared to the NHANES 2015-2018 report.

**Results:** The prevalence of all CKD stage  $\geq 3$  estimated in RWD was significantly lower than NHANES reports (see table). This finding translates into 22.5 million individuals estimated from NHANES and 5.2 million from RWD. The absolute differences between the two groups were less for higher categories.

**Conclusions:** Prevalence estimates from our RWD sources included those who have continuous health insurance, sought healthcare, and were diagnosed with CKD. In contrast, NHANES sampled a more diverse population likely to be covered by various forms of insurance including the uninsured. This work supports the unmet need for early identification of CKD and demonstrates necessity for methodological clarity when reporting prevalence estimates.

**Funding:** Commercial Support - ProKidney, LLC

## Prevalence of CKD stages

## TH-PO888

**REVEAL CKD: Estimated Glomerular Filtration Rate (eGFR) Decline Before and After a CKD Diagnosis Among Patients With CKD Stage 3**  
Navdeep Tangri,<sup>1</sup> Stefan Franzén,<sup>2</sup> Emily J. Peach,<sup>3</sup> Salvatore Barone,<sup>5</sup> Pam R. Kushner.<sup>4</sup>  
<sup>1</sup>University of Manitoba Department of Internal Medicine, Winnipeg, MB, Canada; <sup>2</sup>Medical/Payer Evidence Statistics, BioPharmaceuticals Medical, AstraZeneca, Gothenburg, Sweden; <sup>3</sup>Cardiovascular, Renal and Metabolism Epidemiology, BioPharmaceuticals Medical, AstraZeneca, Cambridge, United Kingdom; <sup>4</sup>Department of Family Medicine, University of California Irvine, Irvine, CA; <sup>5</sup>Global Medical Affairs, BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD.

**Background:** Studies have shown considerably high rates of undiagnosed early-stage CKD despite guidelines recommending that CKD should be diagnosed and managed as soon as possible to slow progression and prevent complications. However, the benefit of an early diagnosis is not yet fully understood. The aim of this analysis was to describe the potential change in slope of eGFR before and after a CKD diagnosis using data from the REVEAL-CKD study program.

**Methods:** Data were extracted from the US TriNetX database for patients aged  $\geq 18$  years with two consecutive eGFR records  $\geq 30$  and  $< 60$  mL/min/1.73m<sup>2</sup> recorded 91-730 days apart from 2015-2020 with an ICD-9/ICD-10 code for CKD after  $\geq 6$  months of follow-up. The eGFR decline was estimated before and after CKD diagnosis by fitting an individual linear regression model with time to diagnosis as the only independent variable for the 2-year period before, and up to 2-year period after CKD diagnosis. Estimated slopes were summarized using medians and compared before and after diagnosis using the Wilcoxon rank sum test. The eGFR trajectories over time were estimated by applying a generalized additive model (GAM).

**Results:** The study cohort included 26,851 patients with diagnosed CKD stage 3. In the 2-year period before CKD diagnosis, the median eGFR decline was -4.12 (95% CI: -4.23, -4.02), and median eGFR decline was -0.30 (95% CI: -0.44, -0.14) in the 2-year period after diagnosis (p<0.001). The decline in eGFR slope before and after CKD diagnosis is shown in Figure 1.

**Conclusions:** A significant slowing in eGFR decline was observed after a CKD stage 3 diagnosis. This finding may be partially explained by the natural course of renal function decline, and also improved care post-diagnosis given the marked difference around the time of diagnosis. Future analyses will explore initiation of targeted monitoring and treatment in response to a formal diagnosis.

**Funding:** Commercial Support - AstraZeneca

## TH-PO889

**REVEAL-CKD: Management and Monitoring of Patients With CKD Stage 3 in France, Germany, Italy, Japan, and the United States**

Navdeep Tangri,<sup>1</sup> Toshiki Moriyama,<sup>9</sup> Markus P. Schneider,<sup>6</sup> Jean Blaise J. Virgitti,<sup>8</sup> Luca De Nicola,<sup>7</sup> Emily J. Peach,<sup>3</sup> Salvatore Barone,<sup>11</sup> Matthew Arnold,<sup>10</sup> Hungta (tony) Chen,<sup>4</sup> Krister Järbrink,<sup>5</sup> Pam R. Kushner.<sup>2</sup>  
<sup>1</sup>University of Manitoba Department of Internal Medicine, Winnipeg, MB, Canada; <sup>2</sup>University of California Irvine, Irvine, CA; <sup>3</sup>Cardiovascular, Renal and Metabolism Epidemiology, BioPharmaceuticals Medical, AstraZeneca, Cambridge, United Kingdom; <sup>4</sup>Medical/Payer Evidence Statistics, BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD; <sup>5</sup>Cardiovascular, Renal and Metabolism Evidence, BioPharmaceuticals Medical, AstraZeneca, Gothenburg, Sweden; <sup>6</sup>Department of Nephrology and Hypertension, University Hospital Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany; <sup>7</sup>Department of Advanced Medical and Surgical Sciences, Nephrology and Dialysis Unit, Naples, Italy; <sup>8</sup>Cabinet Medical, Orry-La-Ville, France; <sup>9</sup>Osaka Daigaku, Suita, Japan; <sup>10</sup>Real World Evidence Data & Analytics, BioPharmaceuticals Medical, AstraZeneca, Cambridge, United Kingdom; <sup>11</sup>Global Medical Affairs, BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD.

**Background:** Chronic kidney disease (CKD) is vastly under-recognised yet affects 11.1% of the global population. Early diagnosis and active management can slow disease progression. This study assessed CKD management and monitoring in patients with CKD stage 3.

**Methods:** REVEAL-CKD is a multi-national, observational study, using medical record and claims data from the general population. Data were extracted from six databases from France, Germany, Italy, Japan, and the USA. Included patients were aged  $\geq 18$  years with 2 consecutive eGFR values  $\geq 30$  and  $< 60$  mL/min/1.73m<sup>2</sup> recorded 91-730 days apart between 2015-2020. The date of the second qualifying eGFR was the index date. Patients with no CKD diagnosis code before and up to 6 months after index were considered undiagnosed. Data on selected quality indicators were extracted from 6-months post-index and the proportion of diagnosed and undiagnosed patients meeting these indicators was calculated.

**Results:** Across the six databases cohort sizes were 20,012-250,879 patients with mean ages of 71-80 years; 41.9-52.9% were male, and median index eGFR was 49-52 mL/min/1.73m<sup>2</sup>. Prevalence of undiagnosed CKD ranged from 61.6 to 95.5%. UACR monitoring and treatment with SGLT2i was low across databases; UACR was notably 3-fold higher for patients with diagnosed CKD in Japan. Across all countries,

blood pressure monitoring, and treatment with ACEi/ARB and statins was greater in patients with diagnosed CKD (Image 1).

**Conclusions:** In five countries, a large proportion of patients with CKD stage 3 are undiagnosed and do not receive timely CKD management and monitoring, however, a greater proportion of patients meet care quality indicators when they have a CKD diagnosis. There is a clear need to proactively diagnose early-stage CKD so that patients can receive guideline-directed monitoring and treatments to improve outcomes.

## TH-PO890

### Risk Prediction: CKD Staging Is the Beginning, Not the End

**Morgan Grams,**<sup>1,2</sup> Yingying Sang,<sup>1</sup> Shoshana Ballew,<sup>1</sup> Kunihiro Matsushita,<sup>1</sup> Andrew S. Levey,<sup>3</sup> Josef Coresh.<sup>1</sup> <sup>1</sup>Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; <sup>2</sup>NYU Langone Health, New York, NY; <sup>3</sup>Tufts Medical Center, Boston, MA.

**Background:** The stages of chronic kidney disease reflect risk of subsequent adverse kidney outcomes. The heterogeneity of risk within each GFR and ACR stage is yet uncertain.

**Methods:** Using deidentified electronic health record data from Optum Labs Data Warehouse on patients with eGFR and albuminuria (urine ACR, PCR, or dipstick protein) within a two-year window. Albuminuria was harmonized to ACR levels for A-staging (ckdpcrisk.org/per2acr). We used the kidney-failure risk equation (ckdpcrisk.org/kidneyfailure-risk) to estimate the 2-year risk of kidney failure in 350,232 patients with eGFR <60 ml/min/1.73m<sup>2</sup>. We used the 40% eGFR decline calculator (ckdpcrisk.org/gfrdecline40) to estimate the 3-year risk of 40% decline in eGFR in 1,365,272 patients with eGFR ≥15 ml/min/1.73m<sup>2</sup>. We plotted the distribution of predicted risk within each G- and A-stage.

**Results:** The patients in the kidney failure risk population had a mean age 73 (SD 11) years; 39% were men; and there were 13,623 kidney failure events over mean follow-up of 3.4 years. The 40% decline population had a mean age of 58 (SD 15) years; 42% were men; and there were 33,257 events over a mean follow-up of 3 years. Risk of adverse outcomes increased with higher G- and A-stage. Within each stage; however, there was heterogeneity in predicted risk of adverse outcomes. Some stages contained risk distributions that spanned risk thresholds for action. For example, G5A1, G5A2, and G4A3 all contained patients with 2-year kidney failure risk above and below 20%, the suggested threshold for referral for vascular access/transplant evaluation. Risk overlap between stages was even greater when using the 40% decline calculator, with nearly all CKD stages spanning multiple risk categories.

**Conclusions:** CKD staging is useful as an initial tool for estimating risk of adverse outcomes but can be enhanced with use of appropriate risk prediction tools for a more nuanced estimate of future kidney failure and eGFR decline. Some strategies for risk-guided care have been developed and the potential for others should be tested using modeling and outcomes studies.

**Funding:** NIDDK Support, Private Foundation Support

Figure. Predicted risk of kidney failure (panel A) and ≥40% decline in eGFR (panel B) by CKD eGFR (G1 to G5) and ACR (A1 to A3) stage in OLDW. Lines show potential risk thresholds for clinical decisions.

## TH-PO891

### TWEAK-Fn14 Signalling in Mesangial Cells Drives Intrarenal Inflammation During CKD Progression

**Asha Seth,**<sup>1</sup> Barbara Musial,<sup>1</sup> Timo N. Haschler,<sup>1</sup> Hong Wang,<sup>1</sup> Pernille B. Laerkegaard Hansen,<sup>2</sup> <sup>1</sup>AstraZeneca PLC, Cambridge, United Kingdom; <sup>2</sup>AstraZeneca, Gothenburg, Sweden.

**Background:** It is increasingly recognised that inflammation evokes renal injury and promotes chronic kidney disease (CKD) progression. Tumor necrosis factor (TNF)-like weak inducer of apoptosis (TWEAK), a member of the TNF superfamily, is a pleiotropic cytokine, which binds to fibroblast growth factor-inducible-14 (Fn14). TWEAK-Fn14 signalling has been linked with pathogenic processes in the kidney that may contribute to the progression of CKD. However, whether this pathway is a key driver of human disease has yet to be established.

**Methods:** To further explore the relevance of TWEAK-Fn14 signalling in CKD we have used human transcriptomic data sets and IHC to interrogate the expression of both ligand and receptor in kidney disease. We have then used human primary mesangial cells to identify regulators of Fn14 expression and explore the mechanisms regulated by the TWEAK-Fn14 pathway in renal cells. Finally, we have used a neutralising TWEAK antibody in vitro and in vivo to explore the therapeutic potential of intervening in this pathway.

**Results:** Fn14 expression was found to be upregulated in biopsies collected from CKD patients as compared to healthy living donors and was also highly correlated with increased kidney damage. IHC showed in patients with CKD, or in pre-clinical models of CKD, Fn14 was localised to the glomerulus, in a pattern consistent with mesangial expression, and in tubule cells. In primary human mesangial cells, PDGF-BB treatment increased cell surface Fn14 expression 9.6-fold. TWEAK application to mesangial cells dose-dependently induced increases in cell proliferation and the release of IL-8 and MCP-1. These effects were blocked by treatment with a neutralising TWEAK antibody. We further tested the beneficial effects of TWEAK neutralization in a murine model of rapid progressive glomerulonephritis induced by administration of nephrotoxic serum. We found that anti-TWEAK treatment significantly decreased MCP-1 transcript expression in the kidney and reduced the level of urinary MCP-1 indicating a reduction in intrarenal inflammation.

**Conclusions:** Fn14 is regulated in human CKD and is highly correlated with disease severity in CKD. In human primary mesangial cells Fn14 activation leads chemokines release. In vivo, TWEAK neutralisation translates into a decrease in the level of kidney MCP-1.

**Funding:** Commercial Support - AstraZeneca

## TH-PO892

### Factors Associated With Influenza Non-Vaccination Among Patients With CKD Under Nephrology Care

**Junichi Ishigami,**<sup>1</sup> Bernard G. Jaar,<sup>1</sup> James P. Lash,<sup>2</sup> Julia Brown,<sup>2</sup> Jing Chen,<sup>3</sup> Katherine T. Mills,<sup>3</sup> Jonathan J. Taliercio,<sup>4</sup> Jeanne Charleston,<sup>1</sup> Sheru Kansal,<sup>5</sup> Deidra C. Crews,<sup>1</sup> Kristin Rieker,<sup>1</sup> David W. Dowdy,<sup>1</sup> Lawrence J. Appel,<sup>1</sup> Kunihiro Matsushita.<sup>1</sup> <sup>1</sup>Johns Hopkins University, Baltimore, MD; <sup>2</sup>University of Illinois Chicago, Chicago, IL; <sup>3</sup>Tulane University, New Orleans, LA; <sup>4</sup>Cleveland Clinic, Cleveland, OH; <sup>5</sup>University Hospitals, Cleveland, OH.

**Background:** Influenza vaccines are strongly recommended in patients with CKD due to their high risk of poor outcomes. Identifying risk factors for not receiving an influenza vaccine ("non-vaccination") could inform strategies for improving vaccine uptake in this population.

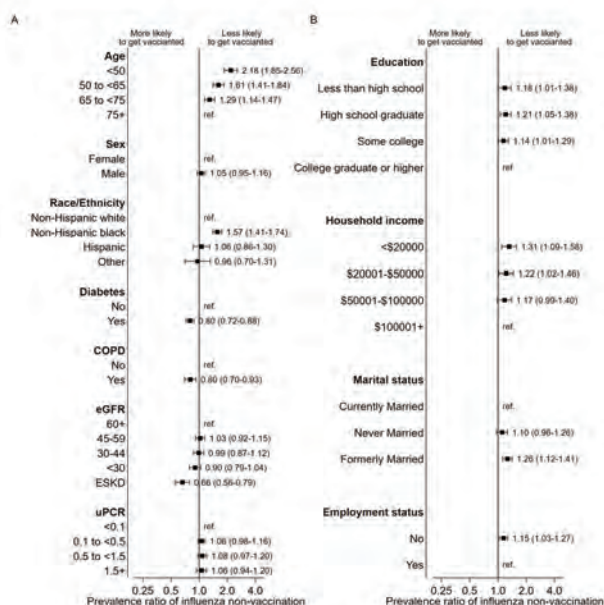

**Methods:** We explored factors associated with influenza non-vaccination in 3522 CRIC participants (mean age 66 years, 43% female, 44% Black). Receipt of influenza vaccine was asked during annual clinic visits in 2008-2020 (median, 4 times per person) if participants were seen by a nephrologist, and assessed along with age, sex, race, diabetes, COPD, eGFR, urine protein-to-creatinine ratio, education, household income, marital status, employment status. We used mixed-effects Poisson models to estimate adjusted prevalence ratios (aPRs) for association with non-vaccination.

**Results:** The overall vaccine uptake was 72%. Factors significantly associated with influenza non-vaccination were younger age (aPR, 2.18 [95%CI, 1.85-2.56] for <50 vs. 75+ years), Black race (1.57 [1.41-1.74] vs. White), lower education, lower annual household income, formerly married status, and non-employed status (Figure). Participants with diabetes (0.80 [0.72-0.88]) and COPD (0.80 [0.70-0.93]) were more likely to receive vaccination than those without. Those with ESKD were more likely to receive vaccination (0.66 [0.56-0.79] vs. eGFR 60+ ml/min/1.73m<sup>2</sup>).

**Conclusions:** Despite nephrology care, influenza vaccines were underutilized for CKD patients, particularly younger adults, Black individuals, and those with low socioeconomic status. Strategies to improve vaccine uptake through nephrology care should be explored in future studies.

**Funding:** NIDDK Support

**Figure: Prevalence ratios (PRs) of not receiving an influenza vaccine: CRIC Study.** PRs (95%CI) for not receiving an influenza vaccine were estimated using mixed-effects Poisson models with robust variance to account for multiple records per person. All estimates are adjusted for age, sex, race, enrollment phase, study center, diabetes, hypertension, history of CVD, COPD, cancer, eGFR, and uPCR.

## TH-PO893

### Impact of Caring for Individuals With CKD in the United States: A Systematic Literature Review

Katherine M. Osenko,<sup>1</sup> Satadbi Chatterjee,<sup>2</sup> Saurabh Ray,<sup>2</sup> Tina Li,<sup>1</sup> Bonnie M. Donato.<sup>2</sup> *Broadstreet HEOR, Vancouver, BC, Canada; <sup>2</sup>Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT.*

**Background:** Individuals with chronic kidney disease (CKD) often rely upon the support of unpaid caregivers (CGs) who play a critical role in assisting with disease management activities. While the importance of CGs' roles is widely recognized, the impact to CGs is not well characterized, including time required for care duties and negative impacts to CG health and well-being. The objective of this review was to synthesize contemporary estimates of economic, clinical, and humanistic impact among CGs of patients with CKD in the United States (US).

**Methods:** A systematic review was conducted using MEDLINE and Embase to identify studies reporting estimates of CG impact in the US, published between 2016-2021. Study selection and data extraction were performed in duplicate, in accordance with PRISMA guidelines. A grey literature search was conducted for the past 5 years. Characteristics of patients with CKD and their CGs were summarized, as well as estimates of the economic, clinical, and humanistic impact to CGs.

**Results:** From 2,990 abstracts, 8 studies reporting CG burden estimates were included. Mean CG age ranged from 61-63 years; CGs were primarily female (57.9-78.4%) and the patient's spouse/partner (42.1-45.3%). Time spent caregiving ranged from 27-38 hours/week (2 studies) and caregiving duration from 3.7-5.0 years (2 studies). In one study, 69.1% of CGs for those with CKD and anemia made at least one job-related decision due to caregiving, including retiring early, reducing work hours, or quitting their job. Depression was identified in 31.6-36.4% CGs (2 studies), while 31.6- 43.6% had anxiety (2 studies). Although a variety of instruments were used to measure humanistic burden, studies consistently documented the high impact of caregiving for patients with CKD.

**Conclusions:** This review demonstrates the considerable burden of caring for individuals with CKD; however, estimates of CG impact were sparse and heterogeneous. Despite limited data, notable findings include the large amount of time spent caregiving and frequent identification of depression and anxiety among CGs. Future research is needed to better characterize the impact to those caring for individuals with CKD, including economic burden and healthcare resource use, as well as the evaluation of drivers of burden.

## TH-PO894

### Nationwide Implementation of Integrated Renal Palliative Care: A Model for Middle-Income Countries

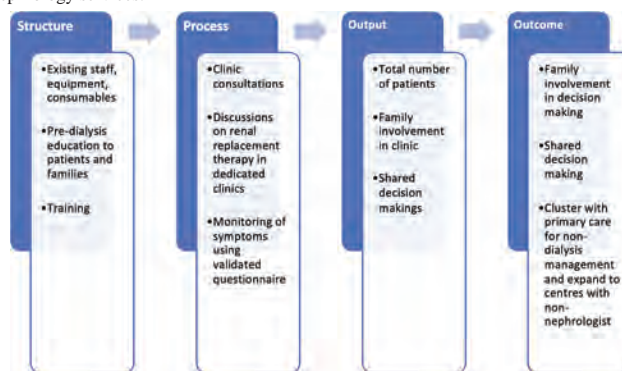

Rafidah Abdullah. *Hospital Putrajaya Malaysia, Putrajaya, Malaysia.*

**Background:** Malaysia is an upper-middle-income country and is categorized as having isolated provisions for palliative care services (Stage 3A). End-stage kidney disease (ESKD) patients have reported palliative care symptoms and their needs are largely unmet. Integration of palliative care into nephrology services will increase access to renal patients.

**Methods:** Comparisons between Malaysia, a middle-income country with a high-income country, United Kingdom were made using Checkland's CATWOE and needs assessment (comparative and corporate approaches). Analysis of current renal services was performed using SWOT analysis.

**Results:** A model of healthcare delivery using four components was designed - structure, process, output, and outcome (Image 1) based on SWOT analysis. The emphasis was put on engagement, capacity, and environmental aspects; in accordance with the findings of the comparative needs assessment. National Palliative Care policy and strategic plan 2019-2030 for Malaysia strongly supported the integration of services. Following this, the integration of renal palliative care into nephrology services was identified as key for nephrology services, a forefront for the 12th National Strategic Plan for Malaysia 2021-2025. A framework for nationwide implementation was designed in four phases. In phase I, the foundation was laid in terms of training, questionnaire, planning, and multi-sectoral engagement. Phase II involved the development of shared decision-making including pre-dialysis education program and training. Phase III includes national implementation, training, audit, and quality improvements. In phase IV, there will be integration with primary care delivering community renal palliative care.

**Conclusions:** A standardized comprehensive ESKD care program will provide holistic healthcare delivery and access to achieve universal health coverage. This framework can be replicated and may be applicable to other middle-income countries. This implementation will achieve advanced integration of palliative care within nephrology services.

## TH-PO895

### HIF-Stabilization Drives Expression of MUC1 Pathogenic Variants in Human Renal Tubular Cells

Stephanie Naas,<sup>1</sup> René Krüger,<sup>1</sup> Karl X. Knaup,<sup>1</sup> Julia Naas,<sup>2</sup> Steffen Grampp,<sup>1</sup> Mario Schiffer,<sup>1</sup> Michael S. Wiesener,<sup>1</sup> Johannes Schödel.<sup>1,1</sup> *Universitätsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany; <sup>2</sup>Center for Integrative Bioinformatics Vienna (CIBIV), Max Perutz Labs, University of Vienna and Medical University of Vienna, Vienna, Austria.*

**Background:** Various genetic alterations in the Mucin1 (*MUC1*) gene predispose to the development of chronic kidney disease. These variations comprise both the frequent GWAS-identified polymorphism rs4072037 that alters splicing of *MUC1* mRNA but also ultra-rare autosomal-dominant inherited mutations which lead to expression of a deleterious frameshift (fs) protein causing autosomal dominant tubulointerstitial kidney disease (ADTKD-*MUC1*). Furthermore, the length of a region with a variable number of tandem repeats (VNTR) within the second exon of the *MUC1* gene is associated with markers of kidney function. Hence, *MUC1* presents a *bona fide* kidney disease gene. However, regulatory mechanisms influencing expression of *MUC1* in the kidney are still poorly defined.

**Methods:** Primary renal tubular cells were isolated from kidneys of a large cohort of patients undergoing tumor nephrectomy or from the urine of ADTKD-*MUC1* patients. Different pharmacological compounds causing stabilization of hypoxia-inducible transcription factors (HIFs) or hypoxia were used to investigate the effect of HIF on the expression of *MUC1* and *MUC1* pathogenic variants. Expression of *MUC1* mRNA including splice variants was analysed by qPCR or RNA-sequencing. Wild-type *MUC1* and fs-protein were detected by Immunoblotting.

**Results:** Using the Assay for Transposase-Accessible Chromatin with high-throughput sequencing and Chromatin Immunoprecipitation DNA-sequencing, we identified a regulatory, hypoxia-responsive element in the promoter-proximal region of *MUC1*, which drives *MUC1* expression upon stabilization of HIF. HIF induces mRNA expression of wild-type *MUC1* but also of the harmful splice-, VNTR-, and frameshift variants when tubular cells were exposed to hypoxia or novel prolyl-hydroxylase inhibitors to stabilize HIF.

**Conclusions:** In this study, we demonstrate a functional link between the regulation of *MUC1* expression and the hypoxia-inducible transcription factor pathway in human renal tubular cells. In the context of the recent introduction of HIF-stabilizing substances for the treatment of renal anemia and the evidence for *MUC1* pathogenic variants in causing kidney disease, our results should be considered when selecting patients for the treatment with novel HIF-stabilizing agents.

TH-PO896

Comparative Safety and Effectiveness of Apixaban Dosing in Patients With Atrial Fibrillation and Severe CKD

Yunwen Xu,<sup>1</sup> Alex R. Chang,<sup>2</sup> Lesley A. Inker,<sup>3</sup> Mara McAdams-DeMarco,<sup>4</sup> Morgan Grams,<sup>4,1</sup> Jung-Im Shin.<sup>1</sup> <sup>1</sup>*Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD;* <sup>2</sup>*Geisinger Health, Danville, PA;* <sup>3</sup>*Tufts Medical Center, Boston, MA;* <sup>4</sup>*New York University Grossman School of Medicine and Langone Health, New York, NY.*

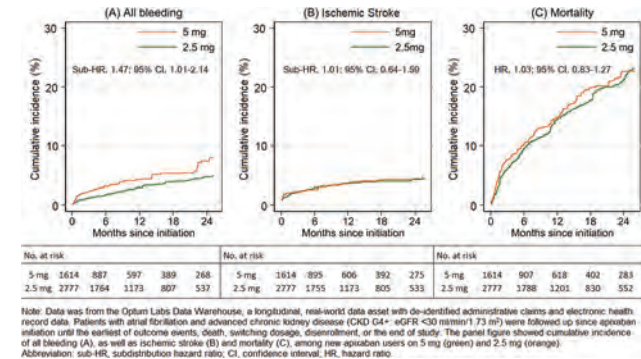

**Background:** The United States Food and Drug Administration (FDA) recommends reduced dose of apixaban in atrial fibrillation (AF) patients with  $\geq 2$  of the following characteristics: age  $\geq 80$  years, weight  $\leq 60$  kg, or serum creatinine  $\geq 1.5$  mg/dL. Thus, the FDA-recommended dose for some patients with severe chronic kidney disease (CKD G4+: eGFR  $< 30$  ml/min/1.73 m<sup>2</sup>) is the standard dose (5 mg twice daily) and for others is the reduced dose (2.5 mg twice daily). On the other hand, the European Medicines Agency (EMA) recommends the reduced dose of apixaban for all patients with severe CKD (creatinine clearance 15-30 ml/min).

**Methods:** Using de-identified electronic health record data from the Optum Labs Data Warehouse, we identified patients with AF and non-dialysis dependent CKD G4+ initiating apixaban in 2013-2021. We compared the risks of bleeding (harm) and ischemic stroke (benefit) by apixaban dose (5 mg vs. 2.5 mg), adjusting for baseline characteristics by inverse probability of treatment weighting (IPTW). We used Fine-Gray subdistribution hazard models to account for the competing risk of death. We also examined the risk of death by apixaban dose using Cox regression.

**Results:** Among 4313 apixaban new users, 1705 (40%) received 5 mg and 2608 (60%) received 2.5 mg. Patients given 5 mg were younger (mean age 72 vs. 80 years), with greater weight (95 vs. 80 kg) and higher serum creatinine level (2.69 vs. 2.47 mg/dL). Mean eGFR was similar between the groups (24 vs. 24 ml/min/1.73 m<sup>2</sup>). In IPTW analyses, apixaban 5 mg (vs. 2.5 mg) was associated with a higher risk of bleeding (incidence rate difference [95% CI], 1.24 [0.19-2.29] per 100 person-years; subdistribution hazard ratio [95% CI], 1.47 [1.01-2.14]) (Figure). The risks for ischemic stroke and death did not differ by apixaban dose.

**Conclusions:** Use of 5 mg apixaban was associated with a higher risk of bleeding in patients with AF and CKD G4+, with a similar risk for ischemic stroke, supporting the current apixaban renal dosing recommendation by EMA.

TH-PO897

Estimating Time to Kidney Failure: Comparison of KFRE and eGFR Thresholds

Chi D. Chu,<sup>1</sup> Charles E. McCulloch,<sup>1</sup> Raymond K. Hsu,<sup>1</sup> Neil R. Powe,<sup>1</sup> Brian Bieber,<sup>2</sup> Bruce M. Robinson,<sup>2</sup> Roberto Pecoito-Filho,<sup>2</sup> Rupesh Raina,<sup>3</sup> Delphine S. Tuot.<sup>1</sup> <sup>1</sup>*University of California San Francisco, San Francisco, CA;* <sup>2</sup>*Arbor Research Collaborative for Health, Ann Arbor, MI;* <sup>3</sup>*Akron Children's Hospital, Akron, OH.*

**Background:** The Kidney Failure Risk Equation (KFRE) is a widely validated model for predicting the risk of ESKD at 2 years among persons with CKD. We examined correspondences between KFRE-predicted risk and time to ESKD and compared them to eGFR thresholds.

**Methods:** In the CKDopps cohort study of patients with CKD G3-G5 recruited from 34 US nephrology practices 2013-2021, the KFRE-predicted 2-year risk of ESKD was computed using age, sex, UACR, and eGFR (2021 CKD-EPI equation without race) and analyzed. For persons missing UACR, we substituted UPCr or urinalysis protein as available, converting to UACR using validated equations. Each participant could contribute multiple risk periods based on updated KFRE predictions calculated at follow up visits. We used accelerated failure time (Weibull) models to estimate median, 25<sup>th</sup>, and 75<sup>th</sup> percentile times to reaching ESKD starting from KFRE values of 10%, 20%, 40% and from eGFR values of 30, 20, and 15 ml/min/1.73m<sup>2</sup>. We additionally examined time to ESKD in subgroups by age, sex, race, diabetes status, and albuminuria. Robust standard errors were used to account for clustering by participant.

**Results:** 1,634 participants (mean age 68 $\pm$ 13 years; 48.7% female; mean eGFR 29 $\pm$ 12 ml/min/1.73m<sup>2</sup>; median UACR 104 [IQR 25, 803] mg/g) were included, contributing 9,886 risk periods. Over a median follow up of 1.6 years (IQR 1.0, 2.5), 266 participants developed ESKD and 178 died. Median time to ESKD was highly

variable across subgroups from eGFR thresholds of 30 and 20 ml/min/1.73m<sup>2</sup> (Figure) and was shorter for Black (versus non-Black), diabetic (versus non-diabetic), younger age, and higher albuminuria subgroups. There was less subgroup variability from an eGFR of 15 ml/min/1.73m<sup>2</sup> and from KFRE thresholds.

**Conclusions:** Compared with eGFR, KFRE thresholds demonstrated less variability across subgroups in time to ESKD and may be advantageous for informing clinical decisions about kidney replacement therapy.

TH-PO898

Discordances Between Creatinine and Cystatin C-Based eGFR and Adverse Clinical Outcomes in Routine Clinical Practice

Edouard Fu,<sup>1,2</sup> Juan J. Carrero,<sup>3</sup> Yingying Sang,<sup>5</sup> Marie Evans,<sup>3</sup> Lesley A. Inker,<sup>4</sup> Andrew S. Levey,<sup>4</sup> Josef Coresh,<sup>5</sup> Morgan Grams.<sup>5</sup> <sup>1</sup>*Brigham and Women's Hospital, Boston, MA;* <sup>2</sup>*Harvard Medical School, Boston, MA;* <sup>3</sup>*Karolinska Institutet, Stockholm, Sweden;* <sup>4</sup>*Tufts Medical Center, Boston, MA;* <sup>5</sup>*Johns Hopkins University, Baltimore, MD.*

**Background:** The 2021 NKF-ASN Task Force recommended increased use of cystatin C-based eGFR equations. Discordances can occur between eGFRcr and eGFRcys, since creatinine and cystatin C have different non-GFR determinants. Currently, it is unknown how common and large these discordances are in routine clinical practice, and whether discordances predict adverse clinical outcomes. In Sweden, routine cystatin C testing has been available for over a decade.

**Methods:** We used data from the SCREAM project, which covers the healthcare of Stockholm region. We identified adults who, during 2011-2018, undertook outpatient tests of IDMS calibrated creatinine and cystatin C on the same day. eGFRcr and eGFRcys were calculated with the 2021 and 2012 CKD-EPI equations. Multivariable Cox proportional hazards regression was used to calculate hazard ratios for quartiles of discordance between eGFRcys and eGFRcr, and the outcomes AKI, kidney failure with replacement therapy (KFRT), major adverse cardiovascular events (MACE) and death.

**Results:** Of 1,570,592 people with eGFRcr, 13% also had routine eGFRcys. We included 158,663 participants (mean age 62 years, 48% women, mean eGFRcr 80 and eGFRcys 73 ml/min/1.73m<sup>2</sup>) with both tests on the same day. Discordances were common, with eGFRcys in most cases being lower than eGFRcr. Patients with lower eGFRcys than eGFRcr were older, and more often female, with hypertension, diabetes or cardiovascular disease. Larger discordances were observed among patients with higher eGFRcr and UACR. Patients whose eGFRcys was lower than eGFRcr were at higher risk of all study outcomes. Conversely, patients whose eGFRcys was higher than their eGFRcr were at lower risks (Table). Similar findings were observed within subgroups of eGFR categories, age, sex, and comorbidities.

**Conclusions:** Integration of cystatin C testing into routine clinical practice in the Stockholm region showed many patients with a discordance between eGFRcys and eGFRcr. Lower eGFRcys than eGFRcr consistently identified patients at higher risk of multiple outcomes.

Table. Adjusted hazard ratios for adverse outcomes associated with quartiles of distribution in discordances between eGFRcys and eGFRcr.

	Percent Difference in eGFR, (eGFRcys-eGFRcr)/eGFRcr * 100%			
	Quartile 1 (-99% to -27%) eGFRcys < eGFRcr	Quartile 2 (-27 to -10%) eGFRcys < eGFRcr	Quartile 3 (-10% to +6%) eGFRcys = eGFRcr	Quartile 4 (+6% to +880%) eGFRcys > eGFRcr
AKI	2.39 (2.11, 2.70)	1.44 (1.27, 1.64)	Reference	0.63 (0.54, 0.75)
KFRT	1.33 (1.14, 1.54)	1.12 (0.97, 1.28)	Reference	0.81 (0.70, 0.94)
MACE	1.67 (1.57, 1.76)	1.25 (1.18, 1.32)	Reference	0.82 (0.76, 0.88)
All-cause death	2.64 (2.55, 2.73)	1.47 (1.41, 1.52)	Reference	0.81 (0.77, 0.85)

Lower quartiles depict situations in which eGFRcys was lower than eGFRcr. Adjusted for age, sex, hypertension, diabetes and history of CVD, eGFRcr splines with knots at 60 and 90, missing indicator of urine albuminuria and logACR (converted from PCR or dipstick if ACR is not available).

## TH-PO899

**Association of Longitudinal B-Type Natriuretic Peptide Monitoring With Kidney Replacement Therapy and Heart Failure in Patients With CKD**  
 Tatsufumi Oka,<sup>1,2</sup> Yusuke Sakaguchi,<sup>3</sup> Koki Hattori,<sup>2</sup> Yuta Asahina,<sup>2</sup> Sachio Kajimoto,<sup>2</sup> Wendy I. McCallum,<sup>1</sup> Hocine Tighiouart,<sup>4,5</sup> Mark J. Sarnak,<sup>1</sup> Jun-Ya Kaimori,<sup>3</sup> Yoshitaka Isaka.<sup>2</sup> <sup>1</sup>*Division of Nephrology, Tufts Medical Center, Boston, MA;* <sup>2</sup>*Department of Nephrology, Osaka University Graduate School of Medicine, Suita, Japan;* <sup>3</sup>*Department of Inter-Organ Communication Research in Kidney Diseases, Osaka University Graduate School of Medicine, Suita, Japan;* <sup>4</sup>*Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA;* <sup>5</sup>*Tufts Clinical and Translational Science Institute, Tufts University, Boston, MA.*

**Background:** Existing evidence suggests that B-type natriuretic peptide (BNP) reflects volume status in patients with chronic kidney disease (CKD). Although longitudinal monitoring of BNP may result in optimal fluid management, including the avoidance of volume overload, potentially leading to better renal prognosis, its clinical benefit remains uncertain.

**Methods:** In this retrospective cohort study, adult CKD outpatients with stages 3–5 not on dialysis referred to an academic hospital between 2005 and 2018 were analyzed. The exposure variable was monitoring of plasma BNP. Study outcomes included kidney replacement therapy (KRT) and heart failure (HF) hospitalization. Applying marginal structural models using inverse probability of weighting (IPW), which created a balanced pseudo-population at each time point, the associations between longitudinal BNP monitoring and outcomes were examined. IPW-weighted pooled logistic regression models were employed to estimate the hazard ratios (HRs). Patient demographics, comorbidities, laboratory data, and medications were considered as potential time-dependent confounders.

**Results:** Among 2998 outpatients, median age and eGFR were 66 years and 38.4 mL/min/1.73 m<sup>2</sup>, respectively. During follow-up (median, 5.9 years), 449 patients required KRT and 236 were hospitalized for HF. After adjustment for time-dependent confounders, longitudinal BNP monitoring was associated with lower risks of KRT (HR, 0.45; 95% confidence interval [CI], 0.21–0.93) and HF hospitalization (HR, 0.37; 95% CI, 0.15–0.94). The association between longitudinal BNP monitoring and KRT was attenuated after additional adjustment for HF hospitalization as a time-dependent covariate.

**Conclusions:** Among patients with CKD not on dialysis, longitudinal BNP monitoring was associated with a lower risk of requirement for KRT, potentially mediated by a reduced risk of HF hospitalization.

## TH-PO900

**An Early Look at the ESRD Treatment Choices (ETC) Payment Model's Impact on Organ Procurement and Transplant Network (OPTN) Medicare Kidney Transplant Waitlist Additions**  
 Andrew Placona, Brittany R. Shean. *United Network for Organ Sharing, Richmond, VA.*

**Background:** Beginning on January 1st, 2021, CMS randomly assigned 30% of Health Referral Regions (HRR) to the ETC payment model. This payment model links dialysis reimbursements to two metrics, home dialysis and the transplant rate. The definition of transplant rate includes the proportion of a dialysis provider's attributed patients on the kidney transplant waitlist. Our objective was to determine if the ESRD Treatment Choices (ETC) payment model was associated with an increased number of Medicare kidney registrations.

**Methods:** We obtained the data for all kidney waitlist additions between 2016 and 2021 from the OPTN database, the participating ETC sites data from CMS, and the zip code to HRR crosswalk from the Dartmouth Atlas. We utilized the archival transplant program-specific report data from the SRTR. We utilized the candidate's reported zip code and the Dartmouth Atlas' zip code to HRR crosswalk to create a panel dataset where the unit of analysis was a HRR for each year from the OPTN registration data. The dependent variable was the logarithmic transformation of the number of Medicare waitlist additions. The dependent variable was regressed on lagged waitlist additions, lagged size of the waitlist, one-year graft survival performance for the dominant transplant center the year prior, and percent Medicare in the HRR utilizing a difference-in-difference design via the first difference estimator.

**Results:** Our sample included 237,850 total additions (106,626 Medicare) between 2016 and 2021. The ETC program was associated with a 6.60% increase in the change of (95 CI: 1.16% to 12.0%, p = .018) Medicare kidney transplant registrations.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**  
 Underline represents presenting author.

**Conclusions:** The first year of ETC program resulted in faster growth in Medicare kidney transplant registrations in areas affected by the new payment policy

## TH-PO901

**Long-Term Effect of COVID-19 Infection on Kidney Function Among COVID-19 Patients Followed in a Post-COVID-19 Recovery Clinic in British Columbia, Canada**

Jordyn R. Thompson,<sup>1</sup> Mohammad Atiquzzaman,<sup>2</sup> Selena Shao,<sup>2</sup> Ognjenka Djurdjev,<sup>2</sup> Adeera Levin,<sup>1</sup> Peter C. Birks.<sup>1</sup> <sup>1</sup>*The University of British Columbia, Vancouver, BC, Canada;* <sup>2</sup>*BC Provincial Renal Agency, Vancouver, BC, Canada.*

**Background:** Recent research suggests that COVID-19 is associated with acute kidney dysfunction. Effect of COVID-19 infection on downstream kidney function is unknown. We investigated this using the BC Interdisciplinary COVID-19 Care Network data.

**Methods:** This retrospective cohort study analyzed a 2,212 COVID-19 patient cohort, aged ≥18 years, referred to the Post COVID-19 Recovery Clinic (PCRC) in BC, Canada between July 9, 2020 & April 21, 2022. COVID-19 diagnosis date was the index date. Patients with history of kidney transplantation or dialysis before index date were excluded. Patients who deceased within 3 months of cohort entry were excluded. eGFR values were retrieved from the Provincial Laboratory Information System. We examined change in eGFR at 3-, 6-, 12-months after COVID-19 infection among the same study individuals using linear mixed model. Subgroup analysis included comparison between hospitalized vs. non-hospitalized, & diabetics vs. non-diabetics.

**Results:** Analytic cohort included 457 patients (median age 59 years, 50% male) for whom eGFR was recorded at 3-, 6-, 12-months from index date. Prevalence of reduced eGFR (≤59mL/min/1.73m<sup>2</sup>) was 16%, 16%, 17% at 3-, 6- and 12- months post-index date, respectively. Median (IQR) eGFR at baseline was 90 (73, 102) that was reduced to 85 (70, 101) at 6-months & remained stable or <previous value at 12 months post-index date, 86 (69, 101). Results from linear mixed model indicated a 0.23 mL/min decrease in eGFR in each month after COVID-19 infection (intercept 85.51, slope -0.23, p-value=0.0003). In subgroup analyses, similar trends of decreasing eGFR over time were observed among diabetic (n=188, intercept 83.08, slope -0.42, p-value=0.0001) & non-diabetic patients (n=269, intercept 87.33, slope -0.12, p-value=0.13). Interestingly, eGFR appeared to improve over time in non-hospitalized patients (n=133, intercept 88.34, slope 0.24, p-value=0.03) compared to a decreasing trend among hospitalized patients (n=324, intercept 83.94, slope -0.41, p-value<0.001).

**Conclusions:** One in 6 COVID-19 patients who were referred to PCRC had reduced eGFR. COVID-19 was associated with a statistically significant decrease in eGFR, particularly in diabetic & hospitalized patients that warrants ongoing monitoring following COVID-19 infection.

## TH-PO902

**COVID-19 Infection Is a Risk Factor for CKD and Glomerulonephritis**

Maria-Eleni Roumelioti, Hamza Mir, Christos Argyropoulos. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

**Background:** The ongoing COVID19 pandemic continues to challenge healthcare systems. While COVID19 disease is associated with Acute Kidney Injury and collapsing glomerulonephritis, little is known about the potential kidney manifestations of PASC (Post-Acute Sequelae of COVID19). In this study we used TrinetX, a large health research network that aggregates data from multiple centers in the United States to analyze the effects of COVID19 on chronic kidney disease (CKD) manifestations of PASC.

**Methods:** We searched TrinetX for patients > 18 years old with a documented SARS-COV-2 PCR test and classified them into 2 cohorts: C19+ve (with a [+] molecular test for SARS-COV-2 or a clinical diagnosis of COVID19 disease) and C19-ve (absence of such findings). We excluded patients who had received any COVID19 vaccine. We collected demographics, comorbidities, diagnoses for up to two years after any COVID19 PCR test (index event). A 1:1 propensity score matching (PSM) using the nearest neighbor method was used to balance the 2 cohorts on age, gender, Hispanic ethnicity, black race, hypertension, diabetes, heart failure and atherosclerosis. Patients with a kidney specific diagnosis prior to their COVID19 PCR test were excluded.

**Results:** We identified 2,780,780 C19+ve and 6,757,849 C19-ve patients. After PSM each group contained 2,775,418 subjects. Mean age was 40.2±23.1, females were 54.7%, blacks were 15.8% & 12.3% were Hispanic or Latinos. COVID19 diagnosis was a strong risk factor for CKD (Relative Risk, RR 2.474, p<0.001), nephritic, nephrotic syndrome and glomerular disorders.

**Conclusions:** COVID19 disease is a major risk factor for incident CKD, nephrotic and nephritic syndrome. These findings should be confirmed in prospective studies. Whether these sequelae represent persistence of the kidney tropic SARS-COV-2 virus, vascular damage from the acute infection or a manifestation of autoimmunity can only be established through targeted mechanistic studies.

## Incident Kidney Specific Diagnosis

Diagnosis (ICD10)	C19+ve	C19-ve	RR	95%CI
CKD (N18)	74,229/2,531,455	31,065/2,620,854	2.474	(2.442, 2.507)
Unspecified kidney failure (N19)	12,286/2,748,570	3,684/2,759,576	3.348	(3.227, 3.474)
Nephritic syndrome (N05)	1,701/2,767,692	1,227/2,767,230	1.386	(1.288, 1.492)
Nephrotic Syndrome (N04)	984/2,771,095	816/2,771,093	1.206	(1.099, 1.323)
Glomerular disease (N00-N06)	3,336/2,757,954	2,879/2,755,818	1.158	(1.102, 1.217)

## TH-PO903

**Vaccination Reduces Risk of CKD Associated With COVID-19 Disease**

Hamza Mir, Maria-Eleni Roumelioti, Christos Argyropoulos. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

**Background:** COVID19 disease has emerged as a major risk factor of chronic health conditions, i.e. PostAcute Sequelae of COVID19 (PASC). With the emergence of more transmissible variants, the global human population will eventually be exposed to the spike protein of SARS-COV-2 either through natural infection or vaccination. It remains unknown whether vaccination may affect the kidney manifestations of PASC.

**Methods:** We searched TrinetX, a large health research network that aggregates data from multiple centers in the United States to analyze the effects of vaccination on CKD manifestations of PASC. We classified patients as C19+ve (with a [+] molecular test for SARS-COV-2 or a clinical diagnosis of COVID19 disease) and Vax7+ve if they had at least one dose of any COVID19 vaccine and did not have a breakthrough infection. We collected demographics, comorbidities, diagnoses for up to 2 years after any COVID19 PCR test (index event). A 1:1 propensity score matching (PSM) using the nearest neighbor method was used to balance the two cohorts on age, gender, Hispanic ethnicity, black race, hypertension, diabetes, heart failure and atherosclerosis. Patients with a kidney specific diagnosis prior to their COVID19 PCR test were excluded.

**Results:** We identified 2,780,576 C19+ve and 735,966 Vax+ve patients. After PSM each group contained 736,034 subjects. Mean age was 51.5±21.4, females were 58.8%, blacks were 14.9% & 9.9% were Hispanic or Latinos. COVID19 vaccination was associated with reduced risk of incident CKD, unspecified kidney failure and the nephritic syndrome, but did not reduce the risk of the nephrotic syndrome or glomerulonephritis relative to COVID19 disease.

**Conclusions:** Vaccination may reduce the risk of CKD associated with PASC. If confirmed in a prospective study, our findings can expand the known benefits of vaccination on the acute disease to PASC manifestations, potentially improving the uptake of the COVID19 vaccines by the population.

## Incident Kidney Specific Diagnosis

Diagnosis (ICD10)	Vax+ve	C19+ve	RR	95%CI
CKD (N18)	16,456/670,266	29,158/632,683	0.933	(0.523, 0.543)
Unspecified kidney failure (N19)	1,409/730,150	5,268/724,675	0.265	(0.250, 0.282)
Nephritic syndrome (N05)	573/732,497	673/733,019	0.852	(0.762, 0.952)
Nephrotic Syndrome (N04)	403/734,394	351/734,500	1.148	(0.995, 1.325)
Glomerular disease (N00-N08)	1,354/727,917	1,290/729,078	1.045	(0.968, 1.127)

## TH-PO904

**The Emergence of CKD After COVID-19 Related AKI**

Thiago Terzian Agadjanian,<sup>1</sup> Vinicius Pereira Leite Nakamura,<sup>1</sup> Beatriz M. Silva,<sup>1</sup> Otavio H. Clemente,<sup>1</sup> Bárbara F. Domingues,<sup>1</sup> Jessica L. Andrade,<sup>1</sup> Adelson Rodrigues,<sup>1</sup> Miguel Angelo Goes.<sup>1,2</sup> <sup>1</sup>Universidade Federal de Sao Paulo, Sao Paulo, Brazil; <sup>2</sup>Universidade Federal de Sao Paulo Hospital do Rim e Hipertensao, Sao Paulo, Brazil.

**Background:** Acute kidney injury (AKI) can eventually progress into chronic kidney disease (CKD) and end-stage kidney disease (ESKD). COVID-19 is a multisystemic disorder that often causes AKI. The purpose of this study is to assess the frequency and association of clinical variables in patients who developed CKD and ESKD after COVID-19-related AKI.

**Methods:** We performed a one-year follow-up study with 182 survivor patients admitted to the ward and intensive care unit (ICU) with COVID-19 between April 2020 and March 2021 at Hospital São Paulo, Brazil. Patients aged ≥ 18 years with COVID-19 confirmed on RT-PCR were included. Patients with ESKD before hospitalization were excluded. AKI and CKD were defined according to the KDIGO criteria. We evaluated the frequency of AKI. After it, we compared some clinical variables and outcomes in two subgroups: CKD after CoV-AKI, and non-CKD after COVID-19. Univariate and multivariate analyses were performed.

**Results:** 137 (75.3%) patients developed AKI. Of these, 56 (30.8%) needed kidney replacement therapy (KRT) in-hospital. There were higher frequencies of diabetes and hypertension with lower eGFR (84.2±24.9, 94.4±29.9 ml/min; p=0.08) and mean arterial pressure (74.9±9.6, 79.1±7.7 mmHg; p=0.03) at baseline in CKD after CoV-AKI group. Hypertension was independently associated with CKD in binary logistic regression [OR: 4.472, 95% CI:1356-13886; p=0.001]. We further observed that all patients who progressed to ESKD (n=7; 3.9%) had non-dialytic CKD exacerbated by COVID-19 requiring KRT.

**Conclusions:** Hypertension was the independent clinical factor associated with progression to CKD after COVID-19-related AKI. All patients who progressed to ESKD had CKD exacerbated by COVID-19 requiring KRT.

## TH-PO905

**Is COVID-19 Infection Associated With the Progression of Kidney Disease? Findings From a Population Based Observational Study From British Columbia, Canada**

Mohammad Atiquzzaman,<sup>1</sup> Ognjenka Djurdjev,<sup>1</sup> Yuyan Zheng,<sup>1</sup> Lee Er,<sup>1</sup> Peter C. Birks,<sup>3</sup> Micheli U. Bevilacqua,<sup>3</sup> Matthew J. Oliver,<sup>2</sup> Adeera Levin.<sup>3</sup> <sup>1</sup>BC Provincial Renal Agency, Vancouver, BC, Canada; <sup>2</sup>Sunnybrook Health Sciences Centre, Toronto, ON, Canada; <sup>3</sup>The University of British Columbia, Vancouver, BC, Canada.

**Background:** Recent research suggests that COVID-19 infection is associated with acute kidney injury (AKI). Together the inflammation caused by the virus in the kidneys and the episodes of AKIs are risk factors for progression of kidney diseases. We investigated the risk of progression to kidney failure among chronic kidney disease (CKD) patients from BC, Canada who were infected with COVID-19.

**Methods:** In this retrospective cohort study, we analyzed a cohort of 22,188 non-dialysis CKD patients aged ≥18 years, with no prior history of ESKD and COVID-19 infection before the cohort entry date between January 27, 2020 & December 15, 2021. The cohort was derived from Patient Records and Outcome Management Information System (PROMIS), a population based integrated registry database for CKD patients under the nephrologist care in BC. Incident COVID-19 cases were iteratively matched without replacement to non-COVID-19 controls (1:3 ratio) based on age, sex, region of residency, diabetes status, eGFR and urine ACR, CKD vintage and COVID-19 vaccination status as of COVID-19 diagnosis date. The primary outcome was a composite of initiation of maintenance dialysis defined by dialysis performed for ≥4 weeks, a sustained decline in eGFR defined by ≥40% decline from baseline that sustained over ≥4 weeks or incident kidney transplantation. Estimated HR and 95% CI using Fine and Gray subdistribution hazard model to account for death as a competing risk.

**Results:** The analytic data included 1,708 patients, 475 (28%) COVID-19 cases and 1,233 (72%) non-COVID-19 controls. Median age was 71 years, 53% was male. Median follow-up was 8.3 months, 70 (4.10%) patients progressed to kidney failure. Among the non-dialysis CKD patients, the risk of developing kidney failure in COVID-19 infected cases was 24% higher compared to matched, non-COVID-19 infected controls. The HR (95% CI) was 1.24 (0.75, 2.06) (p-value: 0.39).

**Conclusions:** COVID-19 infection in non-dialysis CKD patients appeared to be associated with higher risk of progression to kidney failure. Although not statistically significant, the substantial increase in risk estimate warrants close monitoring of kidney function among CKD patients after COVID-19 infection.

**Funding:** Government Support - Non-U.S.

## TH-PO906

**Effect of the COVID-19 Pandemic on Incidence of Glomerular Disease: A Single Centre Report**

Philippa G. Boothroyd, Katie Chu, Sharad C. Sinha, Kazi M. Fardeen, Bhriagu Raj Sood, David Mekanjuola. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

**Background:** Glomerular disease carries a significant burden of morbidity and mortality. There is emerging evidence of the impact of the COVID-19 pandemic and COVID-19 vaccination on glomerular disease. The aim of the study was to retrospectively analyse our experience of the incidence of glomerular disease between 2018 and 2021.

**Methods:** Native renal biopsy results were reviewed to compare the incidence of glomerular disease prior to the COVID-19 pandemic (2018/19); prior to development of COVID-19 vaccination (2020); and after the introduction of COVID-19 vaccines (2021). Biopsy data from January 2018 to October 2021 were collated from pathology records for all glomerular disease patients in our unit. We focused on the incidence of IgA nephropathy, lupus nephritis, minimal change disease, membranous nephropathy and pauci-immune glomerulonephritis.

**Results:** 263 native biopsies were performed; 45 biopsies in 2018, 75 in 2019, 65 in 2020 and 78 in the first ten months of 2021. The proportional incidence of each disease is shown in figure 1. The incidence of membranous nephropathy was noted to be higher in 2021, coinciding with the introduction of the COVID-19 vaccine programme in the UK, from an average of 23% of cases between 2018-2020, to 31% in the first ten months of 2021. The overall incidence of glomerular disease, excluding vasculitis, seemed to have fallen during 2020.

**Conclusions:** The emergence of COVID-19 does not appear to have caused a significant increase in the overall incidence of glomerular disease in our population. We noted an increase in the incidence of membranous nephropathy following the introduction of the COVID-19 vaccination programme in 2021. The relatively lower incidence in 2020 could be related to limited access to primary health care practitioners and consequent reduction in referrals to secondary care at the time.

## Incidence of Glomerular Disease

## TH-PO907

## Kidney Function After SARS-CoV-2 Infection in Patients With and Without AKI During Hospital Admission in Western Mexico

Alejandro García Rivera, Omar H. Sanchez Vazquez, Ríos C. Katia yuritzi, Carlos A. Villavicencio López, Jesus A. Vega Lopez de Nava, Jorge fernando Topete reyes. *Hospital General Regional No 46, Guadalajara, Mexico.*

**Background:** Kidney damage in COVID-19 patients has been of special concern. Kidney function after COVID-19 has not been comprehensively studied, and there is scarce information comparing kidney function among patients with or without AKI during hospital admission.

**Methods:** Retrospective cohort study in a secondary level center in Guadalajara, Mexico. Patients who were admitted due to COVID-19 from April-December 2020 and who survived at discharge and who had at least one follow-up visit in the outpatient clinic 6 months after initial symptoms were included. Information was obtained from outpatient electronic medical files.

**Results:** From a total of 1085 patients, 733 survived at discharge. 113 had AKI during admission and only 33 (29.2%) had any kind of outpatient follow-up. Their mean age was 60.6 years, 63.6% were men, 48.4% had DM and 66.6% had HTN. Mean baseline SCr was 0.82 mg/dL with a mean eGFR of 90.82 ml/min. On follow-up mean stable SCr increased to 1.49 mg/dL, with a mean eGFR of 65.71 ml/min, a mean decrease of 25.11 ml/min. 15 patients (45.45%) developed CKD and 1 patient (3.03%) started RRT. Mean follow-up time was 451 days. 34 patients with no AKI during admission had a follow-up visit; mean age was 58.1 years, 58.8% were men, 47.1% had DM and 70.6% had HTN. Mean baseline SCr was 0.78 mg/dL and mean eGFR was 92.33 ml/min. On follow-up mean stable SCr increased to 0.86 mg/dL, with a mean eGFR of 86.64 ml/min, a mean decrease of 5.69 ml/min. 1 patient (2.94%) developed CKD and none required to start RRT. Mean follow-up time was 468 days.

**Conclusions:** AKI during COVID-19 was associated to a significant decrease in eGFR on follow-up. Those with COVID-19 without AKI during admission also had a small decrease in eGFR on follow-up. Timely and more intense follow-up strategies after COVID-19 and AKI are needed.

## TH-PO908

## No Evidence for Persisting or Progressive Kidney Disease After Non-Severe COVID-19

Christian Schmidt-Lauber,<sup>1</sup> Ammar Alabdo,<sup>1</sup> Elina L. Petersen,<sup>1</sup> Danilo Fliser,<sup>2</sup> Maja Lindenmeyer,<sup>1</sup> Raphael Twerenbold,<sup>3</sup> Thomas Renné,<sup>1</sup> Tobias B. Huber.<sup>1</sup>  
<sup>1</sup>Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany;  
<sup>2</sup>Universitätsklinikum des Saarlandes und Medizinische Fakultät der Universität des Saarlandes, Homburg, Germany; <sup>3</sup>University Heart and Vascular Center, Hamburg, Germany.

**Background:** Diverse abnormal findings have been described after non-severe coronavirus disease 2019 (COVID-19) but kidney outcomes remain largely unknown. Here we analyze various kidney parameters after non-severe COVID-19 to test the hypothesis of a relevant kidney sequela.

**Methods:** This cross-sectional study investigates patients after non-severe COVID-19 and matched control subjects without prior COVID-19. Patients were recruited by the population-based Hamburg City Health Study (HCHS) as well as its associated COVID program. The HCHS is a prospective population-based cohort study on randomly selected residents of the city of Hamburg, Germany. During the COVID-19 pandemic the study also invited patients at least 4 months after a PCR proven severe acute respiratory syndrome coronavirus type 2 (SARS-CoV-2) infection via newspaper announcements and an official COVID-19 test center. All patients had to be between 45 and 74 years of age. Matching was performed by age, sex, and education. Main outcomes were eGFR, albuminuria, Dickkopf3, hematuria, and pyuria. Descriptive analysis and mixed regression models were performed with adjustment for multiple testing by Bonferroni corrections.

**Results:** The non-COVID cohort consisted of 1328 subjects, the post-COVID cohort of 443 patients in median 9 months after SARS-CoV-2 infection. Most patients had mild COVID-19. Only 31 patients were hospitalized with COVID-19 and no patient was treated on an intensive care unit. The risk for chronic kidney disease (CKD), defined by an eGFR < 60 ml/min/1.73m<sup>2</sup>, (OR 0.9, adjusted p=1.000) or severely increased albuminuria (OR 0.79, adj. p=0.893) was not increased in the post-COVID compared to the non-COVID cohort. This also applied for early CKD stages. However, mean eGFR was mildly lower in post-COVID subjects, even after adjusting for known risk factors (beta -1.84, adj. p=0.032). We found no elevation of hematuria, pyuria, and proteinuria for the post-COVID cohort suggesting no systematic ongoing kidney involvement. Urinary Dickkopf3 even tended to be lower in post-COVID patients indicating no risk for ongoing GFR decline in this cohort (beta -72.19, adj. p=0.072).

**Conclusions:** While there is a subclinical eGFR drop after non-severe COVID-19, we found no evidence for a relevant kidney sequela nor ongoing renal involvement.

**Funding:** Government Support - Non-U.S.

## TH-PO909

## Post COVID-19 Sequelae in Kidney Transplant Recipients (KTR): A Single Center Report

Rosy Priya L. Kodiyanplakkal, Gabriel J. Stryniak, Perola Lamba, Thalia Salinas, John R. Lee, Deirdre L. Sawinski, Thangamani Muthukumar, Manikkam Suthanthiran, Darshana M. Dadhania. *Weill Cornell Medicine, New York, NY.*

**Background:** The impact of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), the virus that causes COVID-19, on KTR remains unknown. We aimed to determine the impact of COVID-19 illness on kidney graft function including graft loss and characterize Long COVID (LC) symptoms in KTR.

**Methods:** Clinical data were extracted from an established registry of KTR diagnosed with COVID-19 between February 2020 to April 2022. A LC symptom questionnaire was developed and distributed. KTR that self-reported COVID-19 associated symptoms ≥2 months were considered to have Long COVID (LC).

**Results:** Of the 121 post COVID-19 KTR, 15 (12%) developed graft dysfunction defined as an increase in serum creatinine >0.3 mg/dL. Characteristics of KTR stratified as with and without graft dysfunction are shown in Table 1. Urine albumin/creatinine ratio was higher in the group with dysfunction and 2 (1.6%) KTR lost their allografts as well. Four (18%) reported LC symptoms and the frequency of LC symptoms among the first 22 questionnaire respondents are shown in Figure 1.

**Conclusions:** Both allograft injury and LC symptoms are frequent among KTR. Identification of risk factors for long-term complications post COVID-19 and development of mechanism-based interventions may mitigate post COVID-19 sequelae in KTR.

**Funding:** Other NIH Support - NIAID

Table 1: Characteristics of Kidney Transplant Recipients with and without Allograft Dysfunction* after COVID-19 illness				
Patient Characteristics	Total (N=121)	No Graft Dysfunction (N=106)	Graft Dysfunction* (N=15)	P value
Age at COVID-19 Diagnosis (years), median (IQR)	57 (47-60)	58 (49-65)	56 (42-64)	p=0.09
Sex (male), n (%)	69 (57)	60 (57)	9 (60)	P=0.8
Races, n (%)				P=0.5
Caucasian/White	49 (41)	42 (40)	7 (47)	
Black or African American	51 (42)	29 (27)	4 (27)	
Asian	7 (6)	7 (7)	0	
Other	34 (28)	32 (30)	4 (27)	
Time from Transplant at COVID-19 Diagnosis (months), mean ± standard deviation	64.2 ± 63.2	77.2 ± 39.0	77.2 ± 39.0	P=0.09
Creatinine at baseline, mean ± standard deviation	1.4 ± 0.57	1.49 ± 0.58	2.10 ± 0.80	p=0.001
Creatinine at last clinic visit, mean ± standard deviation	1.4 ± 0.53	1.39 ± 0.60	4.02 ± 5.00	p=0.001
Microalbumin/creatinine ratio at last visit, mean ± standard deviation	2847 ± 15.5	1084 ± 367.3	1084 ± 367.3	p=0.001

## TH-PO910

## Characteristics and Outcomes of Community and Hospital Acquired AKI in Patients With COVID-19

Rolando Claude-Del Granado,<sup>1,2</sup> Leydi M. Oliva-Cadima,<sup>1</sup> Etienne Macedo,<sup>3</sup> Ravindra L. Mehta,<sup>3</sup> <sup>1</sup>Hospital Obrero No 2 - CNS, Cochabamba, Bolivia, Plurinational State of; <sup>2</sup>Universidad Mayor de San Simon, Cochabamba, Bolivia, Plurinational State of; <sup>3</sup>University of California San Diego, La Jolla, CA.

**Background:** Acute kidney injury (AKI) is common in coronavirus disease 2019 (COVID-19). It is unknown if hospital-acquired AKI (HA-AKI) and community-acquired AKI (CA-AKI) convey a distinct prognosis. The study aim was to evaluate the incidence and risk factors associated with both CA-AKI and HA-AKI.

**Methods:** Consecutive patients (>18 years) hospitalized with a positive antigen or RT-PCR result for COVID-19 who meet the criteria for AKI, have known CKD or with kidney transplant were included in this prospective cohort study. Patient information was recorded from the time of diagnosis and renal function was followed up at 48 hours, 7 days, 14 days, at discharge, and at 6 months.

**Results:** From July 1st to May 30th 2021, we included 100 hospitalized patients with AKI, 68% were male and mean age was 68±11. Seventy-two (72%) corresponded to CA-AKI, and 28% to HA-AKI. Compared to patients with HA-AKI, subjects with CA-AKI have higher baseline sCr (1.15±0.46 vs. 1.06±0.26, p<0.001); had more diabetes (14[19.4%] vs. 1[3.6%], p=0.035); and presented to the emergency department with more severe disease. However the presence of ≥2 comorbidities were higher in HA-AKI (27.7% vs. 32.1%, p=0.014). Mortality rates were not different between CA-AKI and HA-AKI (14 [19%] vs. 5 [18%], p=0.856). Complete renal recovery was more frequent in CA-AKI (16[22%] vs. 5[18%], p<0.001) with lower incidence of *de novo* CKD (13 [29%] vs. 13 [65%], p=0.033) or CKD progression (8[18%] vs. 0[0%], p=0.033).

**Conclusions:** CA-AKI and HA-AKI portend an adverse prognosis in COVID-19 patients. Nevertheless, CA-AKI was associated with a higher rate of renal recovery and lower incidence of long term adverse outcomes like *de novo* CKD or CKD progression. HA-AKI is likely part of the multiorgan failure, has a more severe course than CA-AKI, and that kidney injury contributes to worse outcomes.

## TH-PO911

## COVID-19 Pandemic and Its Impact on CKD Patient Care and Clinical Parameters

Fumika Taki, Nozomi Kadota, Kasumi Konishi, Kotaro Shimoyama, Yugo Ito, Takuya Fujimaru, Masahiko Nagahama, Masaaki Nakayama. *St. Luke's International Hospital, Division of Nephrology, Tokyo, Japan.*

**Background:** In CKD management, periodic visit of nephrologist and multiple professions are known to be important. However, with the COVID-19 pandemic from the end of 2019, due to the tightening of medical care resources and intermittent lockdowns, these patients seem to be could not receive the full of nephrology care. We assessed changes of CKD patients care during the COVID-19 Pandemic and evaluated its impact on clinical parameters.

**Methods:** Patients with CKD over stage 4 and who had regularly attended CKD out-patients clinic in St. Luke's International Hospital, Tokyo, Japan, were included. We definite the pre post pandemic periods as: pre-pandemic: Pre-C, from January 2018 to December 2019, and post-pandemic: Post-C, January 2020 to December 2021. The following data was compared between the 2 periods: 1. number of nephrology visits per patient; 2. rate of using telemedicine; 3. rate of receiving multidisciplinary educational support; 4. rate of drop-out patients; 5. Decline rate of GFR and 6. number of initiating renal replacement therapy, newly.

**Results:** 289 individual patients were eligible for the analysis. The baseline data were as follows: mean age 67.9±14 years, 63.5% male, mean eGFR 22.2±5.9 ml/min and 40.2% comorbid DM. The number of nephrology visits and receiving multidisciplinary support was decreased in Post-C periods: Nephrology visits; Pre-C: 9.8±5.1 visits/year, Post-C 7.7±5.2 visits/year, P<0.01, Multidisciplinary support; Pre-C: 78%, Post-C 32%, P<0.01. Multiprofessional educational support was provided mainly for CKD stage 5 patients during the Post-C. More, the rate of using telemedicine and dropout increased in

Post-C. Especially, the dropout rate of elderly patients over 70 years old was significant: 8% in Pre-C and 17% in Post-C, P<0.05. On the other hand, clinical indicators such as delta GFR and RRT initiation rate remained unchanged.

**Conclusions:** Although the frequency of nephrology visits and multidisciplinary educational care has been decreased with COVID-19, there was no difference in the short-term prognosis of CKD patients, from our study. This may be an effect of a kind of triage function, which focused on the more severely ill patients with CKD. On the other hand, the drop out rate in the elderly was increased, the prognosis of these patients needs to be followed up and verified.

## TH-PO912

## Impact of the Risk Perception of COVID-19 Pandemic on Physical

## Activity and Body Weight in CKD Patients

Yae-rim Kim,<sup>1</sup> Jeonghwan Lee,<sup>2</sup> Jae Yoon Park,<sup>3</sup> Jung Nam An,<sup>4</sup> Kyung Don Yoo,<sup>5</sup> Yong Chul Kim,<sup>6</sup> Jin hyuk Paek,<sup>1</sup> Woo Yeong Park,<sup>1</sup> Kyubok Jin,<sup>1</sup> Seungyeup Han,<sup>1</sup> Dong Ki Kim,<sup>6</sup> Jung Pyo Lee.<sup>2</sup> <sup>1</sup>Keimyung University School of Medicine, Daegu, Republic of Korea; <sup>2</sup>Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; <sup>3</sup>Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; <sup>4</sup>Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea; <sup>5</sup>Ulsan University Hospital, Ulsan, Republic of Korea; <sup>6</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.

**Background:** The recent novel coronavirus disease (COVID-19) pandemic has led to restrictions in physical activity. We evaluated the impact of risk perception on physical activity, and its impact on kidney function in chronic kidney disease (CKD) patients during the pandemic.

**Methods:** A population of CKD patients registered in a SKETCH (Study on Kidney disease and Environmental Chemicals, Clinical Trial No. NCT04679168) cohort recruited from June 2020 to October 2020 was included in the study. Patients were followed-up every 3 months for a year. We obtained risk perception and physical activity information by a questionnaire survey. Physical exercise, 3-times/week, was categorized into three groups according to the frequency of positive response during 5 visits: group 1, 0-2; group 2, 3-4; group 3, 5. We used Logistic regression analysis to identify the significance of risk perception to physical activity. The cox-proportional hazard model was used to identify the significance of physical activity for kidney function.

**Results:** A total of 262 patients were included, and the mean age was 60.5±12.8 years old. Mean eGFR was 43.4±20.9 mL/min/1.73 m<sup>2</sup>, and there were 220 (84.0%) with eGFR <60 mL/min/1.73 m<sup>2</sup>. There were 122 (46.6%) of patients who showed higher risk perception for COVID-19 infection. After adjustment with age, sex, comorbidities, and laboratory results, higher risk perception was significantly associated with decreased physical activity (adjusted OR 0.44, 95% CI, 0.23, 0.84). During 364.8±38.6 days, 52 (19.8%) patients showed decreased kidney function with decreasing eGFR ≥30%. Group 1 showed a significantly increased risk for kidney dysfunction (adjusted HR 3.36, 95% CI 1.23, 9.20). This result was prominent in age over 60, male sex, patients with hypertension.

**Conclusions:** Decreased physical activity related to higher risk-perception, and that was significantly increased risk for kidney dysfunction. Healthcare provider needs to consider a new strategy to encourage physical activity irrespective of risk perception.

## TH-PO913

## Outcomes in CKD Patients With COVID-19

Lucas Wang, Victor A. Canela, Manavjot Sidhu. *Methodist Dallas Medical Center, Dallas, TX.*

**Background:** Chronic kidney disease (CKD) and End-stage renal disease patients are at increased risk of severe disease and worse outcomes in coronavirus disease 2019 (COVID-19). In this study, we compared outcomes, including rates of hospital mortality, major adverse cardiovascular events (MACE) and respiratory failure requiring mechanical ventilation in unvaccinated COVID-19 patients with established CKD/ESRD to COVID-19 patients with baseline normal kidney function.

**Methods:** Using an observational database, we analyzed 3183 unvaccinated hospitalized COVID-19 PCR-positive patients at Methodist Health System (Dallas, TX) from March 2020 to December 2020. The primary endpoint was all-cause in-hospital mortality. Severe disease was identified as any patient with a major adverse cardiovascular event (MACE) or respiratory failure requiring mechanical ventilation. A MACE was defined as congestive heart failure (CHF) exacerbation, myocardial infarction, stroke, pulmonary embolism, deep venous thrombosis, or shock. Chi-square (X<sup>2</sup>), Fischer's exact test, and odds ratio tests were used to analyze observed variables.

**Results:** Of the 3183 COVID-19 patients, 476 (15%) had pre-existing kidney disease (either CKD or ESRD), 170 (5.4%) were dialysis-dependent and 279 (8.79%) were CKD KDIGO stages 1-5. Compared to the non-CKD group, the CKD/ESRD group had an increased risk of all-cause in-hospital mortality (OR = 1.41, 95% CI = 1.04-1.83, p<0.04). CKD/ESRD patients also had increased risk of MACE (OR = 1.24, 95% CI = 1.03-1.48, p<0.02), specifically, higher risk of CHF exacerbation (OR = 3.28, 95% CI = 2.16-4.97, p<0.001) and shock (OR = 1.36, 95% CI 1.01-1.84, p<0.04). The risk of respiratory failure requiring mechanical ventilation was comparable between the CKD/ESRD and non-CKD cohorts (OR = 1.06, 95% CI 0.78-1.44, p = 0.70).

**Conclusions:** The COVID-19 pandemic had worldwide devastating outcomes for vulnerable groups such as CKD patients. In our study, we demonstrated that CKD and ESRD is associated with a higher incidence of mortality and MACE in COVID-19. By understanding the clinical course of these patients, clinicians may better anticipate and attempt to improve outcomes during inpatient visits.

## TH-PO914

### Efficacy of COVID-19 Vaccination in Dialysis Patients: A Prospective Multicenter Study

Claudia Ostermaier, Sahana R. Kamalanabhaiah, Christian S. Haas, Christian Keller, Joachim Hoyer. *Philipps-Universität Marburg Fachbereich Medizin, Marburg, Germany.*

**Background:** Dialysis patients are considered to be at increased risk for SARS-CoV-2 infections. Thus, they were prioritized for early vaccination. However, early data suggested that seroconversion rates may be lower in this population, consistent with the reduced response rate to vaccination against hepatitis B, pneumococcus or influenza. The objective of this study was to evaluate the efficacy of COVID-19 vaccines in this cohort with respect to seroconversion, and to identify potential risk factors for nonresponding.

**Methods:** We conducted a prospective, multicenter study in chronic hemodialysis patients at 4 dialysis facilities in central Germany, starting April 2021. Blood samples were taken prior to 1<sup>st</sup> vaccination, before 2<sup>nd</sup> vaccination, 7-14 days after 2<sup>nd</sup> vaccination, as well as 60 and 120 days after full vaccination for long-term follow-up. At any study time point, results of COVID-19 antigen tests and clinical symptoms were assessed. Similarly, data was obtained for 1<sup>st</sup> or 2<sup>nd</sup> booster vaccination. Blood samples for antibody titers were drawn – if applicable – at day 30, 90, 150 and 210 following booster vaccination. To identify potential risk factors, data including underlying condition, comorbidities, lab results, seroresponse to hepatitis B vaccination, immunosuppression and other medication was assessed. Antibody response was defined above a value of 7.1 BAU/l.

**Results:** After 2 vaccinations, 288 individuals were evaluated; of these, 270 (=93%) developed an adequate antibody response. Although the majority of patients had received a mRNA vaccine, there was no significant difference in the alloster response rates compared to vector based vaccines. Age and immunosuppressive medication were found to be significant risk factors for nonresponsiveness to COVID-19 vaccination ( $p < 0.05$ ). Infections dropped following immunization. Of note, 6 months after full vaccination, antibody titers significantly declined. Both, 1<sup>st</sup> and 2<sup>nd</sup> booster doses resulted in an increase of antibody titers: during the omicron wave, no COVID-19 associated hospital admissions were observed.

**Conclusions:** COVID-19 vaccination is effective in hemodialysis patients. Like in the general population, only age and immunosuppression are risk factors for not responding to vaccination, thereby having a potential impact on outcome, especially for the wave to come.

## TH-PO915

### Humoral Responses in the Omicron Era Following a Three-Dose SARS-CoV-2 Vaccine Series in Kidney Transplant Recipients

Caitriona M. McEvoy,<sup>1</sup> Queenie Hu,<sup>4</sup> Kento T. Abe,<sup>4</sup> Kevin Yau,<sup>2</sup> Matthew J. Oliver,<sup>2</sup> Adeera Levin,<sup>3</sup> Anne-Claude Gingras,<sup>4</sup> Michelle A. Hladunewich,<sup>2</sup> Darren A. Yuen.<sup>1</sup> <sup>1</sup>St. Michael's Hospital Keenan Research Centre for Biomedical Science, Unity Health Toronto, Toronto, ON, Canada; <sup>2</sup>Division of Nephrology, Department of Medicine, Sunnybrook Health Sciences Centre, Toronto, ON, Canada; <sup>3</sup>UBC Division of Nephrology, St. Paul's Hospital, Vancouver, BC, Canada; <sup>4</sup>Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada.

**Background:** Kidney transplant recipients (KTR) have a diminished response to SARS-CoV-2 vaccination in comparison to immunocompetent individuals. Deeper understanding of the antibody response in KTRs following third-dose vaccination would enable identification of those who remain unprotected against Omicron and require additional treatment strategies.

**Methods:** We profiled antibody responses in KTRs pre- and at one and three months post-third-dose SARS-CoV2 mRNA-based vaccine. Anti-spike and anti-RBD IgG levels were determined by ELISA. Neutralization against wild-type, Beta, Delta and Omicron (BA.1) variants was determined using a SARS-CoV-2 spike pseudotyped lentivirus assay.

**Results:** 44 KTRs were analysed at 1 and 3 months ( $n = 26$ ) post-third-dose. At one month, the proportion of participants with a robust antibody response had increased significantly from baseline, but Omicron-specific neutralizing antibodies were detected in just 45% of KTRs. Median anti-spike and anti-RBD antibody levels declined at 3 months, but the proportion of KTRs with a robust antibody response was unchanged. 38.5% KTRs maintained Omicron-specific neutralization at 3 months. No clinical variables were significantly associated with detectable Omicron neutralizing antibodies, but anti-RBD titers appeared to identify those with Omicron-specific neutralizing capacity.

**Conclusions:** Over 50% of KTRs lack an Omicron-specific neutralization response 1 month following a third mRNA-vaccine dose. Among responders, binding and neutralizing antibody responses were well preserved at 3 months. Anti-RBD antibody titres may be a useful identifier of patients with detectable Omicron neutralizing antibody response.

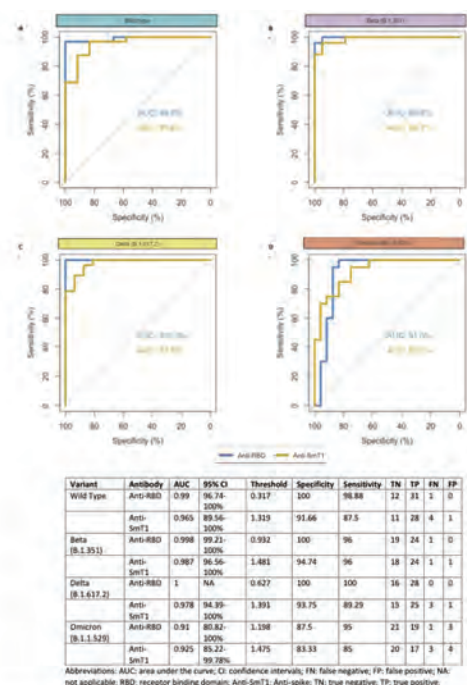

Figure 1: Threshold levels of binding antibody response associated with detectable neutralizing antibody. Receiver operating characteristic (ROC) analysis of anti-RBD and anti-spike antibody levels across A) Wild-type, B) Beta, C) Delta and D) Omicron variants, for classification of the presence or absence of detectable neutralizing antibody (Log10D50 > 0). Areas under the curve (AUC) for anti-spike (yellow) and anti-RBD (blue) are marked. Specific threshold values (expressed as relative ratios to a synthetic mean) are shown in the table.

## TH-PO916

### Factors Associated With Reduced Anti-SARS-CoV-2 Antibody Responses After mRNA Vaccination in Kidney Transplant Recipients on Belatacept

Ayman Al Jurdi,<sup>1</sup> Leela Morena,<sup>1</sup> Jamil R. Azzi,<sup>2</sup> Jay A. Fishman,<sup>1</sup> Leonardo V. Riella.<sup>1</sup> <sup>1</sup>Massachusetts General Hospital, Boston, MA; <sup>2</sup>Brigham and Women's Hospital, Boston, MA.

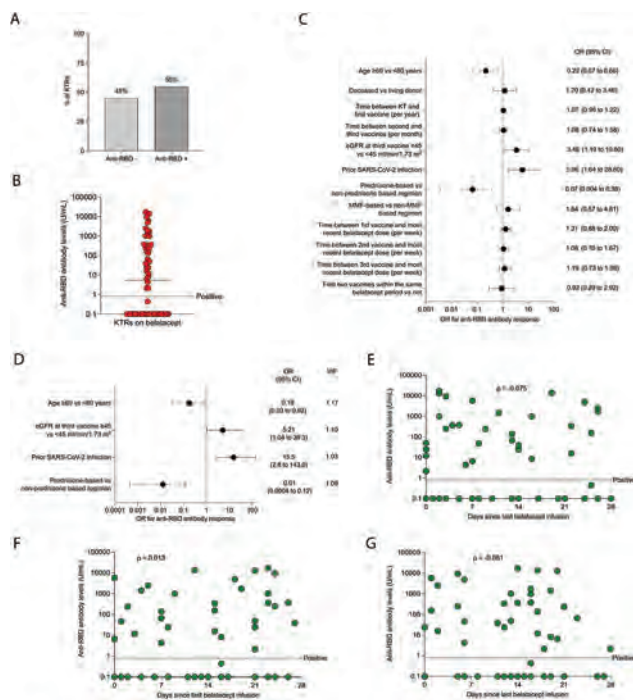

**Background:** Antiviral antibody responses to SARS-CoV-2 vaccines are reduced in kidney transplant recipients (KTRs) on belatacept compared to those not on belatacept. However, factors associated with lower odds of developing antibody responses in KTRs on belatacept are not known.

**Methods:** We conducted a retrospective multicenter cohort study of all KTRs on belatacept who received three mRNA vaccine doses at our institutions, where all KTRs on belatacept had anti-SARS-CoV-2 receptor-binding domain (RBD) antibodies measured by the Roche Elecsys immunoassay. The primary outcome was development of anti-RBD antibodies after the third vaccination.

**Results:** 58 KTRs on belatacept were included. Median age was 62 and 69% were female. 78% were on prednisone, 60% on mycophenolate, 11% on mTOR inhibitors and 9% on azathioprine. After the third vaccine, 32/58 KTRs (55%) developed anti-RBD antibodies (Fig. 1A) with a median level of 3.3U/mL (Fig. 1B). Using univariate logistic regression, we found that age  $\geq 60$ , eGFR  $< 45$  mL/min/1.73m<sup>2</sup>, prednisone use, and no prior SARS-CoV-2 infection were associated with significantly lower odds of developing anti-RBD responses after vaccination (Fig. 1C). These associations remained significant in the adjusted multivariable model (Fig. 1D). We also evaluated correlation between anti-RBD antibody levels and the number of days between vaccination and the most recent belatacept infusion for each vaccination but did not find an association between the two (Fig. 1E-G).

**Conclusions:** Prednisone use, age  $\geq 60$ , eGFR  $< 45$  mL/min/1.73m<sup>2</sup>, and no history of SARS-CoV-2 infection are associated with lower odds of anti-RBD antibody responses after vaccination in KTRs on belatacept.

**Figure 1. Anti-receptor binding domain (RBD) antibody responses in kidney transplant recipients on belatacept after three doses of SARS-CoV-2 mRNA vaccination. (A)**

Percentage of KTRs on belatacept with and without anti-RBD antibody responses after three doses of SARS-CoV-2 of mRNA vaccines (n=58). (B) Total (IgG + IgM + IgA) anti-RBD antibody levels measured by the Roche Elecsys immunoassay. Horizontal line indicates positivity threshold of  $\geq 0.80$  U/mL. (C) Univariate and (D) multivariate logistic regression analysis of factors associated with the odds of developing an anti-RBD antibody response (n=58). (E) Association between anti-RBD antibody levels and days between the most recent belatacept infusion and the first, (F) second and (G) third vaccines (n=57). (E-G) Statistic by Spearman's correlation. KT: kidney transplantation. MMF: mycophenolate mofetil. OR: odds ratio. VIF: variance inflation factor.

## TH-PO917

### Humoral Response 3 Months After the Booster Dose in Patients on Dialysis: The SENCovac Study

Maria Jose Soler,<sup>1</sup> Borja Quiroga,<sup>2</sup> Alberto Ortiz,<sup>3</sup> Patricia de Sequera,<sup>4</sup> SENCovac <sup>1</sup>Hospital Universitari Vall d'Hebron, Barcelona, Spain; <sup>2</sup>IIS-La Princesa. Nephrology Department, Hospital Universitario de la Princesa, Madrid, Spain; <sup>3</sup>Hospital Universitario Fundación Jimenez Diaz Servicio de Neuroradiología Intervencionista, Madrid, Spain; <sup>4</sup>Hospital Infanta Leonor, Madrid, Spain.

**Background:** Patients on hemodialysis are at high-risk for complications derived from coronavirus disease-19 (COVID-19). The present study aims to evaluate the impact of a booster vaccine dose and breakthrough SARS-CoV-2 infections on humoral immunity three months after the booster dose.

**Methods:** This is a multicentric and prospective study assessing anti-Spike antibodies 6 and 9 months after initial SARS-CoV-2 vaccination in patients on hemodialysis that had also received a booster dose before the 6-month assessment (early booster) or between the 6- and 9-month assessments (late booster). The impact of breakthrough infections, type of vaccine, time from the booster and clinical variables were assessed.

**Results:** 711 patients (67% male, 67 [20-89] years) were included. Of them, 545 (77%) patients had received an early booster and 166 (23%) a late booster. At 6 months, 64 (9%) patients had negative humoral response (3% of early booster and 29% of late booster participants,  $p=0.001$ ) and 58 (91%) of them had seroconverted at 9 months, when, 5/545 (0.9%) patients in the early booster cohort and 1/166 (0.6%) in the late booster cohort remained antibody negative ( $p=NS$ ). During follow-up, 35 patients (5%) developed COVID-19. Antibody titers at 9 months were independently associated to lower time from booster (B -0.12,  $p=0.043$ ), COVID-19 (B 2.29,  $p<0.001$ ) and mRNA-1273 booster (B 1.17,  $p=0.001$ ).

**Conclusions:** In hemodialysis patients, higher rates of anti-Spike antibody development were associated to mRNA-1273 booster, lower time from booster and breakthrough SARS-CoV-2 infection.

## TH-PO918

### Phenotype of SARS-CoV-2 Specific T and B Cells in Lymph Nodes of Patients With ESRD

Sophie C. Frölke, Danisha Sri Pathmarajah, Ester B. Remmerswaal, Frederike J. Bemelman. Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.

**Background:** In patients with end-stage renal disease (ESRD), mean antibody concentrations following SARS-CoV-2 vaccination are lower than in the general population, which correlates with the risk of COVID-19 disease. For a high-affinity antibody response, germinal centre responses in lymph nodes (LN) are critical. However, current knowledge on SARS-CoV-2 specific B and T cell responses is almost exclusively based on peripheral blood (PB) mononuclear cells (MNC). Previous studies have shown that LN MNC differ substantially from their PB counterparts. We aim to study the functional and phenotypical differences between PB- and LN-derived SARS-CoV-2 specific B and T cells after vaccination in ESRD patients and compare these with their counterparts after infection.

**Methods:** MNC were isolated from PB and paired non-draining LN of ESRD patients, retrieved during kidney transplantation. Ten patients who received SARS-CoV-2 vaccination and five who suffered COVID-19 disease were included. SARS-CoV-2 spike specific T cells were phenotyped using HLA class I dextramers and for SARS-CoV-2 spike specific B cells spike-tetramers were used. Also, antibody levels and functions like neutralization of infectivity, phagocytosis, antibody-dependent cellular cytotoxicity and complement-mediated lysis of pathogens of infected cells were measured.

**Results:** An example of the SARS-CoV-2 specific T and B cell phenotyping in PB MNC of healthy controls is shown. Whether these cells are detectable in the non-draining LN of ESRD patients after SARS-CoV-2 vaccination or infection and if they functionally and phenotypically correlate with paired PB MNC is yet to be determined.

**Conclusions:** We aim to gain an invaluable insight into the underlying T- and B-cell-centred immunological processes in LN of ESRD patients in order to understand and optimize vaccine response.

SARS-CoV-2 specific T and B cell phenotyping in PB MNC of healthy controls

## TH-PO919

### Adherence to Preventive Measures Before and After Vaccination Against SARS-CoV-2 in Kidney Transplant Recipients

Sophie C. Frölke,<sup>1</sup> Pim Bouwmans,<sup>2</sup> A. L. Messchendorp,<sup>3</sup> Marc H. Hemmelder,<sup>2</sup> Frederike J. Bemelman,<sup>1</sup> Pythia T. Nieuwkerk,<sup>1</sup> Suzanne E. Geerlings,<sup>1</sup> RECOVAC consortium <sup>1</sup>Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; <sup>2</sup>Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands; <sup>3</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands.

**Background:** At the start of the COVID-19 pandemic, kidney transplant recipients (KTR) were warned for a high risk of complications in case of infection. After SARS-CoV-2 vaccination, KTR appeared to still be at risk of fatal COVID-19 disease, especially when they had limited or no antibody formation. The aim of this study was to describe the self-reported change in behavior of KTR before and after SARS-CoV-2 vaccination in groups with different antibody responses.

**Methods:** Questionnaires were sent to 2793 KTR, asking for adherence to preventive measures before vaccination, after vaccination and after receiving their level of antibody response. Adherence was reported on a 5-point Likert scale. From April till June 2021 blood samples were collected measuring anti-spike IgG by ELISA 28 days after full SARS-CoV-2 vaccination. Participants were categorized based on antibody response to vaccination as non-responder ( $\leq 50$  BAU/mL), low-responder ( $>50 \leq 300$  BAU/mL) or responder ( $>300$  BAU/mL), which was shared with the participant as a correlate of protection. Adherence to preventive measures before vaccination was compared with the two time points after vaccination by the Wilcoxon signed rank sum test. The impact of category on adherence was measured by ordinal logistic regression, taking non-responder as reference.

**Results:** The median antibody titer was 7 BAU/mL in the non-(N=1109), 122 BAU/mL in the low-(N=564) and 1751 BAU/mL in the responder cohort (N=1120). Of all preventive measures, adherence to 'keep 1.5 m distance', 'avoid supermarket or shops' and 'rules for visitors or visits' was significantly higher ( $p<0.001$ ) before than after vaccination within all cohorts. Adherence was decreased among participants, with a dose response effect, who were informed of being a (low-) responder compared to KTR with no antibody response.

**Conclusions:** SARS-CoV-2 vaccination in KTR leads to decreased adherence to some, but not all preventive measures, even when the antibody response was absent or low. A greater decrease in adherence was seen in (low-)responders to vaccination.

## Neutralization of the SARS-CoV-2 Delta and Omicron Variants in Previous Non-Responder Kidney Transplant Recipients After Short-Term Withdrawal of Mycophenolic Acid

Louise Benning,<sup>1</sup> Christian Morath,<sup>1</sup> Tessa Kühn,<sup>1</sup> Marie Bartenschlager,<sup>2</sup> Heeyoung Kim,<sup>2</sup> Christian Nussbag,<sup>1</sup> Florian Kälble,<sup>1</sup> Marvin Reineke,<sup>1</sup> Maximilian Töllner,<sup>1</sup> Matthias Schaefer,<sup>1</sup> Katrin Klein,<sup>1</sup> Antje Blank,<sup>3,5</sup> Martin G. Zeier,<sup>1</sup> Caner Süsal,<sup>6</sup> Ralf Bartenschlager,<sup>2,3</sup> Thuong H. Tran,<sup>4</sup> Claudius Speer.<sup>1</sup> <sup>1</sup>Department of Nephrology, University Hospital Heidelberg, Heidelberg, Germany; <sup>2</sup>Department of Infectious Diseases, Molecular Virology, University Hospital Heidelberg, Heidelberg, Germany; <sup>3</sup>German Center for Infection Research, Partner Site Heidelberg, Heidelberg, Germany; <sup>4</sup>Transplantation Immunology, Heidelberg Institute of Immunology, University Hospital Heidelberg, Heidelberg, Germany; <sup>5</sup>Department of Clinical Pharmacology and Pharmacoeconomics, University Hospital Heidelberg, Heidelberg, Germany; <sup>6</sup>Transplant Immunology Research Center of Excellence, Koç University Hospital, Istanbul, Turkey, Istanbul, Turkey.

**Background:** Response to COVID-19 vaccination is significantly impaired in kidney transplant recipients (KTR) even after three doses of an mRNA vaccine. Adaptive immunization strategies are urgently needed to ultimately protect these patients from COVID-19.

**Methods:** We determined the effect of an additional mRNA-1273 vaccine dose in 76 non-responder KTR with at least 3 previous vaccine doses. In 43 KTR with triple immunosuppressive therapy including a calcineurin inhibitor (CNI), mycophenolic acid (MPA), and corticosteroids (CS), MPA was withdrawn to investigate the effect of short-term MPA withdrawal on COVID-19 vaccine immunogenicity. Seroconversion was determined four weeks after vaccination. In addition, neutralization of the delta and omicron variants was determined using a live-virus assay. In patients with temporary MPA withdrawal, donor-specific antibodies (DSA) and donor-derived cell-free DNA (dd-cfDNA) were monitored before MPA withdrawal and at follow-up.

**Results:** After vaccination, 24/69 (35%) KTR showed anti-spike S1 IgG antibodies above the predefined cut-off, excluding 7 breakthrough infections that occurred during follow-up. SARS-CoV-2 specific antibodies were significantly higher in patients where MPA was withdrawn (Figure 1A). Neutralization of the delta variant was significantly better compared to neutralization of the omicron variant (Figure 1B). Higher SARS-CoV-2-specific antibodies were associated with better in-vitro neutralization of the delta and omicron variants (Figure 1C). In KTR with MPA withdrawal, no significant changes in S-creatinine, proteinuria or dd-cfDNA were observed. No acute rejection episode occurred during short-term follow-up. However, resurgence of pre-existing DSA was observed in 7 patients and the development of de novo DSA in one patient.

**Conclusions:** MPA withdrawal seems reasonable to increase immunogenicity of SARS-CoV-2 vaccination. For safety reasons, this may only be offered to patients without current or previous DSA.

**Funding:** Commercial Support - CareDX, Private Foundation Support

## SARS-CoV-2 Anti-Spike IgG Antibody Binding Units and Associated Outcomes in Maintenance Dialysis Patients

Harold J. Manley,<sup>1</sup> Antonia Harford,<sup>1,3</sup> Jill M. Frament,<sup>1</sup> Margaret McNamara,<sup>1</sup> Nien Chen Li,<sup>1</sup> Karen M. Majchrzak,<sup>1</sup> Caroline M. Hsu,<sup>2</sup> Daniel E. Weiner,<sup>2</sup> Dana Miskulin,<sup>2</sup> Doug Johnson,<sup>1</sup> Eduardo K. Lacson.<sup>1,2</sup> <sup>1</sup>Dialysis Clinic Inc, Nashville, TN; <sup>2</sup>Tufts Medical Center, Boston, MA; <sup>3</sup>University of New Mexico Health Sciences Center, Albuquerque, NM.

**Background:** Maintenance dialysis patients' SARS-CoV-2 receptor binding spike antibody (RBD s-Ab) levels decline rapidly in the months following initial vaccination. We describe the association of RBD s-Ab levels with a subsequent diagnosis of COVID-19 and COVID-related hospitalization or death.

**Methods:** We identified all vaccinated adult maintenance dialysis patients at Dialysis Clinic, Inc. who were diagnosed with COVID-19 between June 20, 2021 and May 8, 2022. Descriptive analyses illustrate the association of RBD s-Ab levels assessed 7-45 days prior to COVID-19 diagnosis with COVID-related hospitalization or death.

**Results:** There were 340 maintenance dialysis patients with RBD s-Ab levels assessed at a median 23 [16,40] days prior to COVID diagnosis, with mean age 65±13 years, 51% female, 51% White, 91% HD and vintage 4.3±4.3 years. While COVID-19 diagnosis and COVID-related hospitalization or death events occurred across RBD s-Ab levels (Figure), 74 of 93 (80%) COVID-related hospitalizations and 24 of 25 deaths (96%) occurred at RBD s-Ab level <500 BAU/mL.

**Conclusions:** Maintenance dialysis patients are at risk for serious COVID events when RBD s-Ab < 500 BAU/mL. Routine RBD s-Ab measurement informing personalized vaccination strategies to keep titers above 500 BAU/mL may benefit this high-risk population.

RBD s-Ab levels were converted to WHO standard antibody binding units (BAU) per mL (Freeman J and Conklin J. J Virological Methods 2022)

## TH-PO922

## SARS-CoV-2 Infections and Mortality in Dialysis Patients: A Multicenter Prospective Trial

Sahana R. Kamalanabhaiah, Claudia Ostermaier, Lotte L. Dahmen, Christian S. Haas, Joachim Hoyer, Christian Keller. *Philipps-Universität Marburg Fachbereich Medizin, Marburg, Germany.*

**Background:** Dialysis patients are at great risk for contracting COVID-19 during the pandemic. In need to appear at their dialysis centers on a regular basis they have limited options to self-isolate. They are forced to be in close contact with ambulance or taxi drivers, co-patients and health care workers, setting them at risk of acquiring COVID-19. Disease severity and mortality in dialysis patients seem to be higher than in the general population. The objective of this study was to assess incidence and mortality of SARS-CoV-2 infections in this cohort.

**Methods:** Repetitive PCR testing and antibody blood sampling was performed in a prospective, multicenter study in chronic hemodialysis patients in 12 dialysis centers in central Germany, starting April 2020. Basic data was assessed, means of transportation and kind of residence were evaluated, specifically with regard to risk for infection. COVID-19 associated symptoms were logged, fatalities were counted during the ongoing pandemic with its particular waves of virus variants.

**Results:** 874 patients at a medium age of 69.8±14.2 yrs (62.1% ♂) participated in the study. Taxi or ambulance were the means of transportation in 86.5%, 7.6% lived in a nursing home; 8.8% acquired COVID-19. Demographic data did not differ between diseased and healthy patients except for residency. The odds ratio to get COVID-19 was significantly higher in dialysis patients living in nursing homes compared to those in home care (OR 3.76, 95%CI 2.05-6.87). Like in the general population, the highest infection rate was observed with the alpha variant, whereas the delta variant did not affect the dialysis centers. Omicron on the other hand was highly present. Mortality was highest during the alpha variant wave (29.1%), but was lower in delta (14.2%) and lowest in omicron infections (0.3%). Overall infections and mortality in dialysis patients decreased with immunization status, either through prior infection or vaccination in nursing homes. Of note, mortality in this cohort was barely impacted by COVID-19 associated death.

**Conclusions:** COVID-19 immunization in hemodialysis patients is very effective preventing spreading the virus from nursing homes to dialysis centers. General morbidity status in dialysis patients seems to be more relevant to outcome than intercurrent infections with COVID-19.

## TH-PO923

## Comparing Mortality and Morbidity of COVID-19 Omicron Variant vs. Other Variants in a Hemodialysis Population in Qatar

Musab Elgaali, Mohamed Y. Ali, Mohamad M. Alkadi, Rania A. Ibrahim, Karima Boubaker, Hany E. Ismail, Muftah Othman, Hassan A. Al-Malki, Abdullah I. Hamad. *Hamad Medical Corporation, Doha, Qatar.*

**Background:** Patients on dialysis are more susceptible to COVID-19 infection, with higher mortality and morbidity. In December 2021 the state of Qatar witnessed a surge in COVID 19 cases solely due to omicron variant. We compare the effect of omicron Vs pre-omicron variants COVID infection on hemodialysis patients in terms of incidence, severity and mortality.

**Methods:** This is an observational, analytical, retrospective, nationwide study. COVID-19 PCR was the method of diagnosis. During the Omicron wave, Rapid Antigen Test was accepted by Ministry of Health in Qatar as a diagnostic test. Our study followed patients for duration from 3/2020 to 1/2022. All positive results from 1<sup>st</sup> of December 2021 were assigned to the omicron group as per national genomic surveillance. Cases before that were assigned to the pre-omicron group. Primary outcome was to compare the incidence of omicron infections in haemodialysis patient compared to pre-omicron era. Secondary outcomes were to assess the mortality, ICU admissions, length of stay in ICU and need for ventilatory support in omicron vs pre-omicron phase. Patient demographics and clinical features were collected from a national electronic medical record.

**Results:** 274 haemodialysis patients were diagnosed with COVID-19 during the omicron wave (2 months period) vs 174 patients in the pre-omicron period (21 months). The incidence in omicron wave was 30.3%, which is significantly higher than pre-omicron waves of 18.7% ( $p < 0.001$ ). Omicron variant has lower mortality rate 2.4%, compared to other variants grouped together 15.5% ( $p < 0.001$ ). ICU admissions rate during the omicron wave was significantly less than pre-omicron waves (4.9% Vs 26.4% ( $p < 0.001$ )), and there was less need for ventilatory support (0.01% Vs 0.16% ( $p < 0.001$ )). ICU length of stay was not significantly different (16.7 +/- 8 days Vs 14.2 +/- 17.5 days ( $p = 0.34$ )).

**Conclusions:** This is the 1<sup>st</sup> national study to compare the outcome of omicron vs non-omicron COVID-19 variants infection among hemodialysis patients. The incidence of omicron variant was higher than pre-omicron variants, while mortality and ICU admission were significantly lower in the omicron era compared to pre-omicron era. ICU length of stay was not significantly different.

## TH-PO924

## ChAdOx1 nCoV-19 Immunogenicity and Immunological Response Following COVID-19 Infection in Patients Receiving Maintenance Hemodialysis

Krit Pongpirul,<sup>1,2</sup> Wisit Prasithsirikul,<sup>3</sup> Tanawin Nopsopon,<sup>1</sup> Phanupong Phutrakool,<sup>1</sup> Piyawat Kantagowit,<sup>1</sup> Anan Jongkaewwattana.<sup>4</sup> <sup>1</sup>Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; <sup>2</sup>Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; <sup>3</sup>Bamrasnaradura Infectious Disease Institute, Nonthaburi, Thailand; <sup>4</sup>National Center of Genetic Engineering and Biotechnology, Pathum Thani, Thailand.

**Background:** This study aimed to evaluate the immunogenicity of two doses of ChAdOx1 nCoV-19 and the immune response post-COVID-19 infection in ESRD with HD patients.

**Methods:** The blood samples were obtained at baseline, 1-month, and 3-month follow-up after each shot or recovery. All participants were measured for anti-spike IgG by the ELISA method using Euroimmun.

**Results:** This study found a significant increase in anti-spike IgG after 1 month of two-shot ChAdOx1 nCoV-19 vaccination, followed by a significant decrease after 3 months. On the other hand, the anti-spike IgG was maintained in the post-recovery group. There was no significant difference in the change of anti-spike IgG between one-shot ChAdOx1 nCoV-19 vaccinated and post-recovery groups for both 1-month and 3-month follow-ups. The seroconversion rate for the vaccinated group was 60.32% at one-month after one-shot vaccination and slightly dropped to 58.73% at 3-month follow-up, then was 92.06% at one-month after two-shot vaccination and reduced to 82.26% at 3-month follow-up. For the recovered group, the seroconversion rate was 95.65% at one-month post-recovery and 92.50% at 3-month follow-up.

**Conclusions:** This study established the immunogenicity of two-shot ChAdOx1 nCoV-19 in ESRD patients with HD for humoral immunity. After COVID-19 infection, the humoral immune response was strong and could be maintained for at least three months.

**Funding:** Government Support - Non-U.S.

## Demographic Data of Participants

Characteristics	Total	Vaccinated	Recovered
Participants	109	63	46
Age, year (mean $\pm$ SD)	54.93 $\pm$ 15.28	57.63 $\pm$ 14.83	51.22 $\pm$ 15.26
Hypertension	89 (81.65%)	56 (88.89%)	33 (71.74%)
Diabetes mellitus	49 (44.95%)	33 (52.38%)	16 (34.78%)
Coronary artery disease	4 (3.67%)	3 (4.76%)	1 (2.17%)

Data were presented as counts and percentages if not otherwise specified. SD: standard deviation.

Changes in anti-spike IgG in HD patients who received a single dose of ChAdOx1 and who recovered from COVID-19.

## TH-PO925

## The Safety and Humoral Response to COVID-19 Vaccination in Peritoneal Dialysis Patients

Cheng-Hsu Chen,<sup>1,2</sup> Chia-Yu Shih.<sup>1</sup> <sup>1</sup>Division of Nephrology, Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan; <sup>2</sup>Department of Post-Baccalaureate Medicine, College of Medicine, National Chung Hsing University, Taichung, Taiwan.

**Background:** The battle between human and COVID-19 since 2019, it is highly contagious and fatal disease with poor outcome in dialysis patients. The viral vector AZD1222 is a replication deficient simian adenovirus-vectored vaccine encoding the full length SARS-CoV-2 spike protein. The efficacy and safety of AZD1222 in patients treated with peritoneal dialysis (PD) is still not knowing. We focused their seroresponse of nAb titers against SARS-CoV-2 and their local and systemic adverse effects.

**Methods:** We conducted this study to elucidate the immune response directed against SARS-CoV-2 spike (S) protein antigen and adverse effect to vaccination with AZD1222 in PD patients after their 1st and 2nd shots. There were 205 out of 263 PD patients received the first shot of AZD1222, and 192 of them had the second shot between June 2021 to Oct. 2021.

**Results:** The first and second doses of AZD1222 vaccine 13 (9.1%) and 93 (65.0%) of 143 PD patients seroconverted with anti-SARS-CoV-2 S antibody titers ( $\geq 50$  U/mL), and titers presented with 188.54 U/mL (mean; IQR 54.7-739.6) and significantly increased to 1545.3 U/mL (mean; IQR 52.0-38460), respectively. Pain was the most common local adverse event (AE) (75%). Systemic AEs occurring after the first dose were mostly fatigue (41%) and headache (31%). One severe AE were reported as hearing loss and stroke after the first injection. After the second dose, the most common systemic AEs were fatigue (40.5%), headache (22.5%), joint pain (20%), myalgia (17.5%) and fever (16%), but no severe AE reported. Patients with higher antibody titers after the first dose tended to have higher antibody titers after the second dose ( $p = 1.23 \times 10^{-4}$ ).

**Conclusions:** Our study concludes that significantly increasing humoral responses to AZD1222 vaccination in PD patients are from 9.1% after 1<sup>st</sup> shot and 65% after 2<sup>nd</sup> shot. While acceptable local and systemic adverse events, viral vector AZD1222 is still safe and effective vaccination for PD patients.

## TH-PO926

## Immunogenicity and Safety Outcome of Homologous and Heterologous Prime-Boost of Inactivated Vaccine and Replication-Defective Viral Vectors Vaccine Against SARS-CoV-2 Among Hemodialysis Patients

Phoom Narongkiatikhun, Vuddhichai Ophascharoensuk, Kajohnsak Noppakun. *Maharaj Nakorn Chiang Mai Hospital, Chiang Mai, Thailand.*

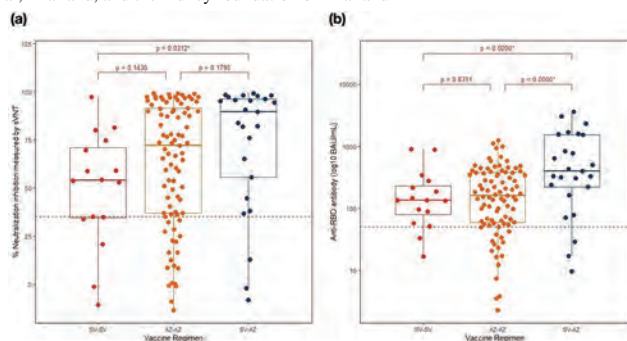

**Background:** Vaccines to prevent SARS-CoV-2 infection are considered as the most promising approach for modulating the pandemic. It is unknown that those vaccines are effectual in maintenance hemodialysis (MHD) patients as demonstrated in healthy people.

**Methods:** We conducted an observational prospective trial involving all MHD patients at Chiang Mai University hospital, Chiang Mai, Thailand. The participants were received homologous Sinovac (SV-SV), homologous AZD1222 (AZ-AZ), or the heterologous prime-boost of SV-AZ. The immunogenicity was assessed by antibodies against the S1 receptor-binding domain (anti-RBD), and SARS-CoV-2 surrogate virus neutralization test (sVNT) at specific timepoints. The primary outcome was the seroconversion rate of sVNT at day 28 after complete vaccination. The secondary outcomes were the seroconversion rate of sVNT after the first dose, the level of sVNT and anti-RBD at specific timepoints, factor associated with seroconversion, and the adverse events of each vaccine regimen.

**Results:** A total of 130 MHD patients were recruited. Among those, 16 (12.31%), 89 (68.46%), and 25 (19.23%) patients were received the SV-SV, AZ-AZ, and SV-AZ regimen, respectively. The seroconversion rate of sVNT at day 28 after the second dose were 68.75%, 78.65%, and 88.0% for SV-SV, AZ-AZ, and SV-AZ, respectively ( $P=0.289$ ). The level of sVNT and anti-RBD was highest among SV-AZ (Figure 1a, b). Age and percent of plasma lymphocyte were associated with seroconversion. There were no serious adverse events reported in any vaccine groups.

**Conclusions:** Immunization with SV-SV, AZ-AZ, and SV-AZ could generate humoral immunity without any serious adverse events among MHD patients. Using the heterologous vaccine prime boost seemed to be more efficacious in term of inducing immunogenicity and further studies should be warranted.

**Funding:** Other NIH Support - Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand, and the kidney foundation of Thailand

**Figure 1** Percentage of sVNT (a) and the level of anti-RBD (b) at day 28 after the second dose of each vaccine regimen.

## TH-PO927

### Frailty and Immunogenicity Following COVID-19 Vaccination Among Patients Undergoing Hemodialysis

Ting-yun Lin. Taipei Tzu Chi Hospital, New Taipei City, Taiwan.

**Background:** Patients with end-stage kidney disease who are undergoing dialysis have reduced immune responses to COVID-19 vaccination. Frailty is extremely common among dialysis patients and may contribute to the impaired immune responses. However, little is known about its effects on the immunogenicity following COVID-19 vaccination in the dialysis population.

**Methods:** Adult hemodialysis patients without prior SARS-CoV-2 infection who received one dose of the ChAdOx1 nCoV-19 vaccine were assessed for eligibility. Participants were categorized as robust, pre-frail, or frail using the Fried frailty criteria. Humoral responses were assessed at 28 days after vaccination by measuring titers of IgG antibody to the receptor-binding domain of SARS-CoV-2 spike protein. Seroconversion was defined as antibody levels  $\geq 50$  AU/mL. Multivariate logistic regression analyses compared humoral responses of frail or pre-frail participants with robust participants.

**Results:** A total of 206 participants were included in the study, of whom 50 (24.3%) were considered frail, 86 (41.7%) pre-frail, and 70 (34.0%) robust. Compared with robust patients, a significantly smaller proportion of pre-frail and frail patients developed anti-spike antibody seroconversion (87.1%, 66.3%, and 40.0%, respectively;  $P<0.001$ ). Frailty was associated with the absence of humoral responses after adjustment for confounders including age, sex, body mass index, diabetes, coronary artery disease, serum albumin, and lymphocyte count (odds ratio, 0.25; 95% CI, 0.08–0.80;  $P$  for trend = 0.025).

**Conclusions:** Frailty is independently associated with impaired humoral responses following COVID-19 vaccination in hemodialysis patients. Whether repeated booster vaccination may improve the immunogenicity in frail hemodialysis patients needs further research.

Association of frailty phenotype with humoral responses to COVID-19 vaccination

## TH-PO928

### Second SARS-CoV-2 Booster Vaccination Significantly Reduces Haemodialysis Patients' Susceptibility to Infection With Omicron Variant

Nadezhda Wall,<sup>1,2</sup> Gemma D. Banham,<sup>1,2</sup> Anna L. Casey,<sup>2</sup> Alex Richter,<sup>1,2</sup> Adam F. Cunningham,<sup>1</sup> Lorraine Harper.<sup>1,2</sup> COVID HD consortium <sup>1</sup>University of Birmingham, Birmingham, United Kingdom; <sup>2</sup>University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.

**Background:** Patients requiring haemodialysis (HD) have disproportionately poorer outcomes from SARS-CoV-2 infection and vaccines afford an opportunity to improve this. However, the efficacy of booster doses on infection with emerging variants remains unclear in this population.

**Methods:** We report the real-world impact of SARS-CoV-2 booster vaccinations in an ethnically diverse urban cohort of 1172 patients receiving in-centre HD who were routinely screened for SARS-CoV-2 infection by weekly nasopharyngeal PCR between 1st December 2021 and 31st March 2022, during dominant UK prevalence of B.1.1.529 variant ("Omicron"). Where possible, genomic sequencing was performed as standard of care.

**Results:** At the start of the observation period, 896 (76.5%) had received 3 doses of SARS-CoV-2 vaccine and only 87 (7.4%) were unvaccinated. By end of study 664 (59.5%) had received 4 vaccine doses. 305 patients had PCR positive SARS-CoV-2 infection, with Omicron variant confirmed in all but one of samples successfully tested. Clinical course of infection was mild: around half of patients asymptomatic, only 1 in 20 hospitalised, case fatality 3%. Three or more vaccine doses significantly associated with reduced risk of SARS-CoV-2 PCR positivity compared to unvaccinated status, together with White ethnicity and lower deprivation index (Cox regression  $p<0.03$ ). However, 2 booster doses further reduced the risk of infection by around a third compared to 1 boost, independent of age, gender and comorbidity.

**Conclusions:** A second SARS-CoV-2 booster vaccine further reduces the risk of Omicron infection in haemodialysis patients. As such, a double-boost policy could significantly reduce the burden and associated spread of SARS-CoV-2 infection in this vulnerable population.

**Funding:** Private Foundation Support

Adjusted proportional hazards model of SARS-CoV-2 infection-free survival in HD patients. Partially vaccinated: 1-2 doses. \*\*\* $p<0.001$ , \* $p<0.05$  (compared to unvaccinated status).

## TH-PO929

### Antibody Response After COVID-19 Vaccination in CKD and Kidney Transplant Patients

Thananda Trakarnvanich. Faculty of Medicine Vajira Hospital, Bangkok, Thailand.

**Background:** Vaccination of patients with chronic kidney disease (CKD) and kidney transplants (KTs) may achieve a less robust immune response. Understanding such immune responses is crucial for guiding current and future vaccine dosing strategies.

**Methods:** This prospective, observational study estimated the immunogenicity of humoral and cellular responses of two SARS-CoV-2 vaccines in different patient groups with CKD compared to controls. Secondary outcomes were adverse events after vaccination and the incidence of COVID-19 breakthrough infection, including illness severity.

**Results:** In total, 212 patients received ChAdOx1 nCoV-19 (89.62%) or inactivated vaccines (10.38%). The antibody response against the S protein was analyzed at T0 (before the first injection), T1 (before the second injection), and T2 (12 weeks after the second injection). Seroconversion occurred in 92.31% of controls at T2 and in 100% of CKD, 42.86% of KT, 80.18% of hemodialysis (HD), and 0% of continuous ambulatory peritoneal dialysis (CAPD) patients at T2 of ChAdOx1 nCoV-19 vaccine. Neutralizing antibody levels were above the protective level at T2 in each group. The KT group had the lowest neutralizing antibody and IFN $\gamma$ . Blood groups O and vaccine type were associated with good immunological responses. After the first dose, 14 individuals (6.6%) out of the total population experienced breakthrough COVID-19 infection.

**Conclusions:** Immunity in patients with CKD and HD after vaccination was strong and comparable to that of healthy controls. Our study suggests that a single dose of the vaccine is not efficacious and delays may result in breakthrough infection. Some blood group and type of vaccine can affect the immune response.

**Funding:** Government Support - Non-U.S.

## TH-PO930

### COVID-19 Infection in Dialysis Patients: Efficacy of Vaccination

Jose E. Navarrete, Jason Cobb, Ibrionke W. Apata, Tahsin Masud, Janice P. Lea. Emory University, Atlanta, GA.

**Background:** End stage kidney disease (ESKD) patients are particularly susceptible to poor outcomes from Covid-19 infection (C19). Vaccination has been the cornerstone of mortality prevention. We examine the efficacy of C19 vaccine in ESKD patients.

**Methods:** All patients dialyzed at Emory dialysis centers from December 1, 2020 until February 2022 represent the study population. Date of completed vaccines series was recorded. Confirmed C19 cases were also registered. Time from vaccination to C19 and from C19 to death was recorded. Mortality risk was compared between vaccinated and unvaccinated patients. Patients that received vaccination after an episode of C19 were excluded from the analysis (n=89).

**Results:** 935 patients received maintenance dialysis during the study period. 68% completed 2 doses of C19 vaccine. 46% of vaccinated patients received a booster dose after 294 days (IQR: 251-273) of completing the primary vaccination series. Non-vaccinated patients were younger (55 vs 60y/o), with shorter dialysis vintage (1.0 vs 2.8 years). The proportion of home and in-center dialysis was similar among vaccinated and unvaccinated patients. The prevalence of diabetes, CHF, PVD, COPD, atrial fibrillation, and previous transplants was also similar. 71 vaccinated patients died during follow up (11%) after 196 days (IQR 122-290), compared to 70 in the non-vaccinated group (24%) after 86 days (IQR 39-166),  $p<0.001$ . Adjusting for age, dialysis vintage, diabetes and CHF, ESKD vaccinated patients had a 78% reduction in mortality risk (A). 73 vaccinated patients (11%) acquired C19 after 250 days (IQR 150-288) compared to 48 unvaccinated patients (16%) who acquired C19 after 64 days (IQR 30-215),  $p<0.001$ . The mortality odds ratio after C19 infection was 3.9 [CI: 1.3-11.9] for unvaccinated patients 30 days post infection, 4.7 [CI: 1.7-14.2] at 60 days and 4.1 [CI: 1.6-11.5] at 90 days (B).

**Conclusions:** Vaccination against C-19 infection resulted in a 78% reduction of mortality risk in patients receiving dialysis. Non-vaccinated patients diagnosed with C19 had higher mortality rates than vaccinated patients (OR 4.1 at 90 days post infection).

## TH-PO931

### The Effect of SARS-CoV-2 Vaccination in a Hemodialysis Population in the Region of Southern Denmark

Anne D. Thuesen,<sup>1</sup> Erik B. Pedersen,<sup>2</sup> Annie R. Knudsen,<sup>1</sup> Rikke Juul-Sandberg,<sup>1</sup> Majbritt Knudsen,<sup>3</sup> Christine Nilsson,<sup>2</sup> Per B. Jensen,<sup>2</sup> Claus Bistrup.<sup>2,4</sup> <sup>1</sup>Sygehus Lillebalt Kolding Sygehus, Kolding, Denmark; <sup>2</sup>Odense Universitetshospital, Odense, Denmark; <sup>3</sup>Sydvestjysk Sygehus, Esbjerg, Denmark; <sup>4</sup>Syddansk Universitet, Odense, Denmark.

**Background:** Hemodialysis patients are a high-risk, immunocompromised population. Therefore, it is expected that vaccination against SARS-CoV-2 will have a reduced efficacy in these patients, who have a high mortality from SARS-CoV-2 infection.

**Methods:** Prospective observational study performed on three dialysis facilities in the Region of Southern Denmark (Kolding Hospital, Odense University Hospital and Sydvestjysk Hospital Esbjerg) in the period March 2021 through March 2023. SARS-CoV-2 anti-S RBD IgG are measured in blood samples collected one, two, five, seventeen and twenty-three month after the second vaccination and furthermore before and one month after the third vaccination see. Anti-S RBD IgG was determined using the SARS-CoV-2 IgG II Quant assay (Abbott Laboratories). Non-responders are defined with anti-S-RBD IgG < 7.1 BAU/mL. All hemodialysis patients received the mRNA vaccine Comirnaty/Pfizer-BioNTech. We have included 249 hemodialysis patients.

**Results:** Below one percent of the hemodialysis population were infected with the Wild type and Delta COVID-19 variant. Significant reduction in the anti-S-RBD level from 4 weeks after the second vaccination (mean = 544 BAU/mL SEM ±82) to 20 weeks after (mean = 102.3 BAU/mL SEM±49.1). There was a significant increase in the anti-S RBD level after the third booster vaccination with a large variation (mean = 2403 BAU/mL SEM ±148.3) compared to four weeks after the second (mean = 544 BAU/mL SEM ±82). The fraction of non-responders were markedly reduced after the third vaccination from 26% to 3%. We will present the latest data on the anti-S-RBD level that we continuously measures until March 2023.

**Conclusions:** Hemodialysis patients seem to lose humoral immunity rapidly after the initial COVID-vaccinations, but gain a significant rise in anti-S RBD antibody levels after the third vaccination. The fraction of non-responders after 3<sup>rd</sup> dose decreased to 3%.

## TH-PO932

### mRNA Vaccines Increase SARS-CoV-2 Antibody Levels Among Dialysis Patients Initially Vaccinated With Adenovirus Vector-Based SARS-CoV-2 Vaccine (Ad26.COV2.S)

Joanna Willets,<sup>1</sup> Linda Ficociello,<sup>1</sup> Curtis D. Johnson,<sup>2</sup> Sandra E. Alexander,<sup>3</sup> Claudy Mullon,<sup>1</sup> Jeffrey L. Hymes.<sup>1</sup> <sup>1</sup>Fresenius Medical Care, Waltham, MA; <sup>2</sup>Spectra Laboratories, Milpitas, CA; <sup>3</sup>Fresenius Medical Care North America, Waltham, MA.

**Background:** Antibody (AB) response to Ad26.COV2.S vaccine (AdV) was observed to be lower than with mRNA vaccines in dialysis patients and additional vaccine doses were recommended. We conducted a quality improvement project in Fresenius Kidney Care clinics to track AB response in dialysis patients initially administered AdV who later received or did not receive additional vaccine doses.

**Methods:** AB response was measured in remnant blood with semiquantitative chemiluminescent assay detecting IgG AB directed against receptor binding domain of S1 subunit of SARS-CoV-2 spike antigen (Siemens); AB index >1 was considered reactive, >7 as adequate, and >750 was maximum detected. All patients who received an AdV, had 2 AB measures after vaccination, and were not Covid-19 positive/suspected cases were included in the analysis. Patients were classified into 4 groups based on vaccine doses received: AdV single dose (n=103); AdV+AdV (n=8); AdV+mRNA (n=329); AdV+mRNA+mRNA (n=14). First AB measurement occurred after initial AdV dose and Last AB measurements occurred after additional vaccine doses.

**Results:** AB was measured, on average, 97 (sd 12) days and 325 (sd 14) days after first AdV dose for First AB and Last AB measurements, respectively. Distribution of AB responses are shown in Figure. At Last AB measurement, AB index ≤ 7 was common for AdV and AdV + AdV groups (43% and 51%, respectively). However, it was rare in AdV+mRNA and AdV+mRNA+mRNA groups (7% and 0%, respectively).

**Conclusions:** Patients who were initially vaccinated with AdV, had improved AB response after one or two mRNA vaccine doses. This response was more pronounced than when patients were administered an additional AdV dose.

**Funding:** Commercial Support - Fresenius Medical Care

## TH-PO933

### SARS-CoV-2 Booster Effect and Waning Immunity in Hemodialysis Patients

Eibhlin S. Goggins,<sup>1</sup> Binu Sharma,<sup>1</sup> Jennie Z. Ma,<sup>1,2</sup> Jitendra K. Gautam,<sup>1</sup> Brendan T. Bowman.<sup>1</sup> <sup>1</sup>University of Virginia School of Medicine, Charlottesville, VA; <sup>2</sup>University of Virginia School of Medicine, Public Health Sciences, Charlottesville, VA.

**Background:** Patients with End Stage Kidney Disease (ESKD) on dialysis are extremely vulnerable to SARS-CoV-2 infection. Antibody levels decline in the months following the standard two-dose vaccination series with Pfizer BioNTech (BNT162b2) mRNA SARS-CoV-2 vaccine in hemodialysis patients. Current guidelines recommend boosters of SARS-CoV-2 mRNA-based vaccines. The aim of this study was to determine the humoral response of hemodialysis patients to a third dose of the BNT162b2 vaccine.

**Methods:** Prospective cohort study measuring the serologic response of hemodialysis patients to a booster dose of BNT162b2 vaccine at an average of 2, 6 and 11 weeks post vaccination. The Anti-SARS-CoV-2 QuantiVac ELISA (IgG) from Euroimmun (EUROIMMUN US, Inc.) was used in all assessments. Differences in antibody levels over time were compared non-parametrically using the Friedman test, then tested pairwise with Bonferroni correction at alpha of < 0.05. A linear mixed model was used to estimate the decline in slope after vaccination.

**Results:** Of 35 hemodialysis patients in the original cohort, 27 (77.1%) received a third dose of BNT162b2. Antibody level significantly increased from pre-booster to 2 weeks post-booster (median (25th, 75th percentile) from 59.94 (29.69, 177.8) to 6216 (3806, 11730)), an average increase of 112 fold. Antibody levels dropped an average of 36.3% to a median of 2654 BAU/mL (1650, 8340) at 6 weeks post-booster. From weeks 6 to 11 post-booster, antibody levels dropped to a median of 1444 BAU/mL (1102, 2020), corresponding to a 52.4% average decrease. Overall, antibody levels declined 47% month to month post-booster. Still, antibody levels at 11 weeks remained an average of 40 fold higher than pre-booster levels. Nine (33%) patients had negative or borderline detectable antibody levels pre-booster and 8 of 9 developed positive (>35.2 BAU/mL) antibody levels post-booster. Those with prior infection had a lower proportional increase

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

in antibody level (51 fold) compared with the median change in COVID naïve patients (144 fold) from pre-booster to 2 weeks post-booster.

**Conclusions:** Following a third dose of the BNT162b2 vaccine, hemodialysis patients obtain a robust humoral response although antibody levels wane over time.

#### TH-PO934

##### Long-Term Humoral Immunity Decline in Hemodialysis Patients Following SARS-CoV-2 Vaccination

Eibhlin S. Goggins,<sup>1</sup> Binu Sharma,<sup>1</sup> Jennie Z. Ma,<sup>1,2</sup> Jitendra K. Gautam,<sup>1</sup> Brendan T. Bowman.<sup>1,1</sup> <sup>1</sup>University of Virginia School of Medicine, Charlottesville, VA; <sup>2</sup>University of Virginia School of Medicine, Public Health Sciences, Charlottesville, VA.

**Background:** Vaccines against SARS-CoV-2 are effective in the general population. Dialysis patients are vulnerable to SARS-CoV-2 infection with high morbidity and mortality. Beginning in January of 2021, the University of Virginia Dialysis Program initiated a program wide vaccination campaign administering Pfizer BioNTech mRNA SARS-CoV-2 (BNT162b2) vaccine. The aim of this study was to characterize the long term time-dependent decline in humoral immunity in hemodialysis patients.

**Methods:** 35 adult hemodialysis patients were recruited to receive two doses of the BNT162b2 vaccine. From 2 to 6 months post vaccination, monthly semi quantitative IgG antibody levels to the SARS-CoV-2 spike protein receptor binding domain were obtained. To analyze the change in antibody levels over time, a linear mixed model with random slope and random intercept was used for longitudinal antibody levels. A multivariable model was used to estimate the slope of antibody levels by adjusting for selected patient characteristics. Based on the estimated intercepts and slopes for each subject from the unadjusted model, 10-month antibody levels were projected.

**Results:** The mean baseline antibody level was 647.59 BAU/mL and 87.88% (29/33) of patients were considered qualitatively positive. Two patients were negative at baseline and an additional two had borderline results. Patient antibody levels declined at an adjusted average rate of 31% per month. At 6 months post vaccination, 40% of patients remaining in the cohort possessed either negative or borderline IgG antibody levels. Immune suppressed patients, on average, had a 65% lower antibody level compared to patients without immune suppression and patients with prior COVID-19 infection had 5 times higher antibody levels than infection naïve patients. Projecting future antibody levels based on the slopes of antibody level decay suggests 65% of the cohort will progress to borderline or negative antibody levels at 10 months post full vaccination if additional doses are not administered.

**Conclusions:** The long term vaccine response of hemodialysis patients vaccinated with the BNT162b2 mRNA vaccine was characterized. Our data demonstrates the decline in humoral immunity over time and emphasizes the crucial need for vaccine boosters in this population.

#### TH-PO935

##### A Single Center Study of SARS-CoV-2 Spike Antibody Response to Vaccination in Renal Transplant Recipients

Debargha Basuli, Bonnie Ross, Kimberly Briley, Hassam Ali, Lorita Rebellato. East Carolina University, Greenville, NC.

**Background:** Kidney transplant recipients are at high risk of mortality and complications related to COVID-19. Vaccination remains the most important strategy to prevent severe disease in this vulnerable population. The goal of this study was to evaluate the antibody response to mRNA vaccines in kidney transplant recipients.

**Methods:** We studied anti-spike IgG response to mRNA vaccines (BNT162b2 and mRNA-1273) against SARS-CoV-2 in adult kidney transplant recipients in a single center. Preserved blood samples of kidney transplant patients undergoing routine monitoring were used. The LABScreen COVID Plus Assay (One Lambda) was used to detect SARS-CoV-2 antibody response. Categorical variables were compared using the Fisher's exact test, and continuous variables were compared using a t-test.

**Results:** Among 120 subjects receiving two doses of vaccines, only 74 (61.7%) elicited a positive response with anti-Spike antibody. After a third dose/first booster vaccine, 35 out of 43 (81.4%) kidney subjects had a positive response. There was no statistically significant difference between the responders and non-responders in terms of age, gender, race, blood group, time since transplant, vaccine type. A third dose vaccine produced statistically significant increase in antibody response compared to 2 doses only. A third dose induced a serological response in 7 out of 8 subjects (87.5%) who did not respond after 2 doses of vaccine. None of the patients developed donor specific HLA antibody in response to COVID-19 infection or the vaccine.

**Conclusions:** In this single center retrospective study, we demonstrated that the antibody response to SARS-CoV-2 mRNA vaccine was most prevalent after 4 months since the second dose. In addition, a third dose induced an antibody response in a larger number of kidney transplant recipients (81.3% vs 61.67%, p value 0.018), suggesting that this patient population may benefit from receiving multiple doses of mRNA vaccines.

#### TH-PO936

##### Undercounting of COVID-19 Vaccinations in Fee-for-Service Medicare Claims

Nicholas S. Roetker,<sup>1</sup> Wendy L. St. Peter,<sup>2</sup> Madison Hoover,<sup>1</sup> James B. Wetmore,<sup>1,3</sup> Kirsten L. Johansen.<sup>1,3</sup> <sup>1</sup>Hennepin Healthcare Research Institute, Minneapolis, MN; <sup>2</sup>University of Minnesota Twin Cities, Minneapolis, MN; <sup>3</sup>Hennepin Healthcare, Minneapolis, MN.

**Background:** Older individuals and those with certain underlying conditions were among the earliest groups offered COVID-19 vaccinations. While patients with ESKD did not initially receive priority, a federal program permitted vaccinations to be administered in dialysis clinics starting in March 2021. We studied early uptake of COVID-19 vaccinations in Medicare fee-for-service beneficiaries with ESKD.

**Methods:** We included beneficiaries aged ≥18 years with ESKD on December 1, 2020 from the US Renal Data System. Vaccinations covered by Medicare were identified using CPT codes. The cumulative monthly incidence of first vaccination dose through June 2021 was compared by modality (HD, PD, transplant) and stratified by age and race/ethnicity. Death was treated as a competing risk.

**Results:** By June 30, 2021, the cumulative incidence of receiving a Medicare-covered first vaccination dose was <40% in patients receiving HD (Figure A), well under the estimate reported by dialysis facilities to the CDC by this date (72%). Although caution is required, some interpretation of the Medicare vaccination data may still be permitted. After the allocation of vaccines to dialysis clinics, Medicare-covered vaccinations surged in patients receiving HD relative to the other modalities. In patients receiving HD, uptake of Medicare-covered vaccinations was initially highest among those aged ≥65 years and then surged in younger patients following the federal vaccine allocation (Figure B).

**Conclusions:** COVID-19 vaccination rates are severely underestimated using Medicare administrative data. It is unclear whether missingness of vaccination data is differential by demographic groups, such as race/ethnicity. Inferences based on these data should be made with caution.

**Funding:** NIDDK Support

**A.** Cumulative incidence of first dose COVID-19 vaccinations covered by Medicare, by ESKD modality, December 2020 – June 2021

**B.** Cumulative incidence of first dose COVID-19 vaccinations covered by Medicare in patients receiving hemodialysis, by age category, December 2020 – June 2021

## TH-PO937

### Humoral Response After Three Doses of SARS-CoV-2 Vaccines in Hemodialysis Patients

Filipa Trigo, Rui A. Duarte, Karina Lopes, Ivan A. Luz, Paulo A. Santos. Centro Hospitalar do Médio Tejo EPE, Torres Novas, Portugal.

**Background:** Hemodialysis patients (HDP) are at higher risk of exposing and developing severe coronavirus disease 2019 (COVID-19). To protect this population, the Portuguese government implemented an early vaccination of these patients in the national COVID-19 immunization plan. Nevertheless, the humoral response to the two doses of BNT162b2 on HDP was lower than the one expected in the general population, leading us to believe that a third dose is of high importance at this group of patients. This study aims to determine the humoral response to the third dose of SARS-CoV-2 mRNA vaccine.

**Methods:** A single center observational prospective study was conducted following HDP receiving SARS-CoV-2 mRNA vaccines in a Portuguese center. Specific anti-Spike IgG quantification 3 weeks after first and second doses, and 3 months after the third dose, was used to determine absolute values and non-responders (NR).

**Results:** A total of 59 patients were enrolled in this study, 33.4% of them were female and the median age was 71.3 years old. About 44% of the patients had COVID-19, all of them after the immunization with two doses of BNT162b2 vaccine. All of them suffered from mild to moderate disease. The median IgG anti-Spike S1 level after the second dose was 43.71AU/mL, with an IQR of 53, whereas 3 months after the third dose was of 473.5AU/mL, with an IQR of 1403.8 (Figure 1). The rate of NR (IgG anti-Spike S1 levels <1AU/mL) also had a high variation with the number of the doses administrated - 14% of the patients after the second dose versus 0% after the third dose. After the last immunization, only 20% of the patients remained weak responders (IgG anti-Spike S1 < 150AU/mL). Age, sex, hemoglobin, ferritin, parathyroid hormone (PTH), C-Reactive Protein (CPR) and albumin did not impact on the response to the vaccine.

**Conclusions:** Most of HDP responded strongly to the third dose of SARS-CoV-2 vaccine, even though the IgG anti-Spike levels were only measured 3 months after the administration. There is no analytical feature that can predict the response to the vaccine. Therefore, every hemodialysis patient would benefit from the administration of a third vaccine dose at least six months after receiving the second one.

## TH-PO938

### Seroresponse to Additional Doses of SARS-CoV-2 Vaccine Among Maintenance Dialysis Patients Over 6 Months

Caroline M. Hsu,<sup>1</sup> Eduardo K. Lacson,<sup>1,2</sup> Harold J. Manley,<sup>2</sup> Gideon N. Aweh,<sup>2</sup> Doug Johnson,<sup>2</sup> Daniel E. Weiner.<sup>1</sup> <sup>1</sup>Tufts Medical Center, Boston, MA; <sup>2</sup>Dialysis Clinic Inc, Nashville, TN.

**Background:** Among patients receiving maintenance dialysis, seroresponse to an initial vaccine series wanes over time. Previously, we showed that additional doses elicit a substantial short-term increase in seroresponse. Here, we assess seroresponse over time in a national sample of maintenance dialysis patients.

**Methods:** Using retrospective clinical data, we assessed seroresponse to additional SARS-CoV-2 vaccine doses over time among maintenance dialysis patients cared for at Dialysis Clinic, Inc (DCI) facilities. Via a clinical protocol available to dialysis providers, antibodies against SARS-CoV-2 spike antigen were assessed monthly alongside routine labwork. Patients with history of COVID-19 prior to additional dose and patients who received Janssen vaccine as an additional dose were excluded. Titers after a second additional dose (i.e., for most, a fourth dose) or after COVID-19 diagnosis were excluded from analysis.

**Results:** Among 1707 patients who had received an additional vaccine dose and had at least one titer level measured after the additional dose, more than 75% had a titer level at the upper limit of the assay in the first month after the additional dose. Titer levels then waned across vaccine types. By Month 6, median [IQR] titer was 68.37 [22.30, ≥100] among Moderna recipients, 59.94 [39.90, 79.97] among Moderna half-dose recipients, and 71.29 [22.46, ≥100] among Pfizer recipients.

**Conclusions:** Among patients receiving maintenance dialysis, anti-spike IgG levels after an additional SARS-CoV-2 vaccine dose wane over time across vaccine types. These results suggest a role for routine antibody monitoring to assess possible need for further re-dosing.

**Funding:** Private Foundation Support

**Figure.** Anti-spike IgG titers by month after receipt of additional SARS-CoV-2 vaccine, comparing by vaccine type. The boxplots are bounded by the upper and lower limits of the assay used. For example, the median [IQR] titer in month 2 was ≥100 [88.91, ≥100] among the Moderna recipients, ≥100 [88.91, ≥100] among the half-dose Moderna recipients, and ≥100 [88.91, ≥100] among the Pfizer recipients. The dots represent outliers, defined as greater than 1.5 IQR above the third quartile or less than 1.5 IQR below the first quartile. Baseline is the last titer prior to the additional dose. The table of N shows the number of titers for each month, by vaccine type.

## TH-PO939

### Persistence of Antibody Response to COVID-19 Vaccine in Peritoneal Dialysis (PD) Patients: A Single Center Study

Shab E Gul Rahim,<sup>1</sup> Sri Lekha Tummalaipalli,<sup>1</sup> Gabriel J. Stryniak,<sup>1</sup> Supriya Gerardine,<sup>1</sup> Vesh Srivastana,<sup>2,1</sup> Weill Cornell Medicine, New York, NY; <sup>2</sup>Rogoin Institute, New York, NY.

**Background:** Published studies on the response to COVID-19 vaccination are primarily focused on hemodialysis. We studied the humoral response to the COVID-19 vaccine in a PD population over a 6 month follow-up period.

**Methods:** In a retrospective single-center study, we assessed response to COVID-19 vaccination in patients on PD at 4 weeks, 3 months and 6 months after completing the full vaccination series. Response was measured via semiquantitative COVID-19 spike protein total antibody (IgG) level using a chemiluminescent sandwich immunoassay. Antibody (Ab) titers <1 were categorized as no response, 1 to <20 as intermediate, and >20 as high response. Chi-squared tests for categorical variables and unadjusted linear regression for continuous variables were used to compare characteristics among responders vs non-responders.

**Results:** Of 119 patients on PD who received COVID-19 vaccine as of December 2021, 108/119 (91%) had a positive Ab response and 11/119 (9%) had no response. A total of 37% had an intermediate and 53.7% had a high response. Positive COVID-19 serology prior to vaccination (p= 0.010) as well as type of vaccine (p=0.032) were associated with higher Ab response in univariate analyses. Other factors were not statistically significantly associated with Ab response. Among the 73 participants with Ab levels at all timepoints, at 4 weeks, 11 (15%) had no Ab response, 19 (26%) intermediate, and 43 (59%) high response. At 3 months, 12 (16%) of participants had no Ab response, 27 (37%) intermediate, and 34 (47%) high response. At 6 months, 12 (16%) of participants had no Ab response, 38 (52%) intermediate, and 23 (32%) high response.

**Conclusions:** Most PD patients developed a positive Ab response to the COVID-19 vaccine. Positive COVID-19 serology prior to vaccination and the type of vaccine received were associated with higher Ab response. Our data suggests promising COVID-19 vaccine response among PD patients.

Characteristic	Total Sample (n = 119)	Never had Antibody Response (<1) to COVID-19 Vaccine (n = 11)	Intermediate Antibody Response (<1 and <20) to COVID-19 Vaccine at any timepoint (n = 44)	Ever had High Antibody Response (≥20) to COVID-19 Vaccine (n = 64)	p-value

Characteristics of Patients Receiving Peritoneal Dialysis by COVID-19 Antibody Response

## TH-PO940

**Antibodies Response in CKD Patients Vaccinated With CoronaVac**  
Catarina Minczuk, Fernando L. Fonseca, Vitor Augusto Q. Mauad, Marcelo R. Bacci. *Faculdade de Medicina do ABC, Santo Andre, Brazil.*

**Background:** Chronic Kidney Disease (CKD) has emerged as one of the major risk factors to a worse outcome in COVID19 (C19) patients. Vaccination became the main prevention policy against virus spread among individuals, apart from other measures, like using face masks and social distancing; however, CKD patients are a sensitive population excluded from many trials when eGFR are below 30 mL/min. C19 pandemic as never before, became possible vaccine development in a record time. CoronaVac, a live inactivated virus vaccine, was the main immunizing agent used in Brazil in the first wave of vaccination. Apart its safety and efficacy, there was no specific dose and regimen to immunosuppressed patients and advanced CKD population. The aim of this study was evaluate the SarsCov2 antibodies response after the full dose regimen of CoronaVac immunizing agent in CKD patients.

**Methods:** It is a cross sectional study conducted in Brazil during C19 second wave. Patients with stage 4 and 5 CKD were included with matched controls. Patients that received a full dosage regimen of CoronaVac, 2 shots of 0.5 mL (600 units of inactivated virus) with a 4 week interval were included. Total Sars-Cov2 antibodies and Spike antibodies were dosed after 12 weeks of the 2 dose CoronaVac regimen received. Siemens ADVIA Centaur® essays were used to determine antibodies levels and a cut off superior to 0.05 U/mL was considered positive. Descriptive analysis were made to show data with their central tendency characteristics. Qualitative data were described with their proportions and to non-normality inference, Mann-Whitney was used. The alpha level accepted was 5%.

**Results:** The study included 41 individuals in total: 19 patients with stage 4 and 5 CKD and 21 matched controls without renal disease. The mean age in the CKD group was 71,68 years (±7,79) and 72,95 years (±9,86) in control group. Male and female individuals were equal among groups. Total SarsCov2 antibodies levels were 4,32 U/mL (±4,16) in CKD group and 6,21 U/mL (±4,51) in controls with no statistical significance (p=0.46). Spike antibodies levels were 10,47 U/mL (±32,41) in CKD group and 10,35 U/mL (±28,34) in controls with a p=0.09 between groups using Mann-Whitney non parametric test.

**Conclusions:** In conclusion, CKD patients developed adequate levels of antibodies against C19 with CoronaVac full dosage regimen in Brazil after a 3 month period.

## TH-PO941

**The Effectiveness of mRNA COVID-19 Vaccine Against SARS-CoV-2 Infection in Hemodialysis Patients: A Case-Control Study**  
Abdullah I. Hamad, Mostafa Elshirbeny, Mohamed Y. Ali, Tarek A. Ghonimi, Rania A. Ibrahim, Fadumo Y. Yasin, Poonam R. Singh, Sahar Aly, Essa Abuhelaiga, Hassan A. Al-Malki, Mohamad M. Alkadi. *Hamad Medical Corporation, Doha, Qatar.*

**Background:** Hemodialysis (HD) patients are at higher risk for SARS-CoV-2 infection and its severe complications compared to the general population. Several studies examined the effectiveness of COVID-19 vaccines in this highly vulnerable population but showed mixed results. The aim of this study was to determine the effectiveness of mRNA vaccines against confirmed SARS-CoV-2 infection in HD patients in the State of Qatar.

**Methods:** We used a test-negative case-control design to determine the effectiveness of vaccination in HD patients > 14 days after the second dose. Ninety-five patients had positive SARS-CoV-2 PCR (cases), while 884 patients had negative PCR (controls). Vaccine effectiveness was determined using the following formula [Vaccine effectiveness = 1 – Odds (T+ [vaccinated]) / Odds (T+ [non-vaccinated])].

**Results:** Thirty out of 691 vaccinated HD patients had positive SARS-CoV-2 PCR versus 65 out of 288 non-vaccinated patients (4% vs. 23%, P<0.0001). Patients were more likely to have positive PCR if they were females (P<0.0001), elderly (P=0.02), or Asians (P=0.03). The overall effectiveness of mRNA COVID-19 vaccines against confirmed SARS-CoV-2 infection was 84.5% (95% CI: 76.5–89.8; Table 1)

**Conclusions:** Our data support the importance of using the mRNA COVID-19 vaccine in HD patients to prevent SARS-CoV-2 infection in such a high-risk population.

Table 1: Vaccine Effectiveness against confirmed infection

Vaccine type	Positive SARS-CoV-2	Negative SARS-CoV-2	Adjusted vaccine effectiveness, %	(95% CI)
mRNA-1273 (Moderna)	1	68	94.9	(79.7 to 99.8)
BNT-162b2 (Pfizer)	29	593	83.3	(74.4 to 89.1)
All vaccinated	30	661	84.5	(76.5 to 89.8)
Non-vaccinated	65	223	Reference	Reference

## TH-PO942

**Improvement in COVID-19 Vaccine Hesitancy Rates Between 2020-2021 in an Inner-City Dialysis Population and Associated Factors**

Edward Bae, Lulu Wei, Judy Lee, Ariel Gidon, Mariana S. Markell. *SUNY Downstate Health Sciences University, Brooklyn, NY.*

**Background:** Studying how vaccination hesitancy has changed since the onset of the pandemic and understanding what changed people's opinions could help improve vaccination rate in susceptible populations with high background refusal rates.

**Methods:** Randomly selected hemodialysis patients in an inner-city Unit were surveyed in 2020 (19 by telephone) and 2021 (31 face to face) about vaccination history and attitudes towards vaccines. In 2020 participants were asked if they would receive a COVID-19 vaccine if available and in 2021 if they had received the vaccine. Respondents who planned to receive the vaccine (2020) or received one or both doses (2021) were counted as VACYES while those who were unsure or refused were classified as VACNO. Respondents were also asked their primary reasons for their choice.

**Results:** The 2021 group had a mean age of 56.1 ± 17.9 yrs., mean time on dialysis was 6.2 ± 7.2 yrs. There were 18 (58%) women and 13 (42%) men, 28 (90%) identified as black. The 2020 and 2021 groups were similar with respect to age, time on dialysis, sex, and race. In 2020, 21% were classified as VACYES compared to 84% of the 2021 sample (p < 0.001). Among VACNO pts the most commonly cited reason was "Safety" (80%). Between vaccinated and unvaccinated patients in 2021, there were no statistically significant differences with respect to age, time on dialysis, sex, race, education, insurance status and presence of diabetes. Among VACYES pts. the three most commonly cited reasons for their choice were "Recommended for people with underlying conditions" (38%), "Trust in healthcare" (45%), and "Safety of the vaccine" (44%).

**Conclusions:** In our inner-city population: 1. Although people in our catchment have a low vaccination rate the majority of the dialysis population studied received the vaccine despite initial hesitancy. 2. Recommendations related to underlying conditions, improved confidence in the safety of the vaccine and trust in healthcare were the most important reasons for acceptance. 3. With vaccine efforts still underway, education programs should continue to focus on stressing the importance in people with underlying conditions, improving patient-provider partnering, and disseminating information regarding vaccine safety in order to improve adherence in our kidney disease patients, in whom almost 20% remain unvaccinated.

## TH-PO943

**Hormone Replacement Therapy and COVID-19 Outcomes in Kidney Transplant Recipients Compared With the General Population**

Amanda J. Vinson,<sup>1</sup> Alfred J. Anzalone,<sup>2</sup> Makayla Schissel,<sup>2</sup> Evan T. French,<sup>3</sup> Amy L. Olex,<sup>3</sup> Roslyn B. Mannon.<sup>2</sup> National Covid Cohort Collaborative (N3C) <sup>1</sup>Dalhousie University, Halifax, NS, Canada; <sup>2</sup>University of Nebraska Medical Center, Omaha, NE; <sup>3</sup>Virginia Commonwealth University, Richmond, VA.

**Background:** In the non-immunosuppressed (non-IS) population, female sex is protective against adverse COVID-19 (C19) outcomes, possibly due to estrogen-related immunity. Sex-based risk is attenuated in IS kidney transplant recipients (KTRs). Exogenous estrogen is associated with reduced C19 mortality in non-IS post-menopausal females. Here, we aimed to study the impact of estrogen or testosterone hormone replacement therapy (HRT) on C19 outcomes in KTRs compared to the general population.

**Methods:** We studied adult (>45 yrs) KTRs from across the US with C19 from 05-01-20 to 05-12-22, using EHR data from the National COVID Cohort Collaborative. Female and male patients were classified as no HRT, or HRT use in the last 6 months (exogenous systemic estrogens for females; testosterone for males). Using MV cox proportional hazards models and logistic regression, we determined the risk of developing a major adverse renal or cardiac event (MARCE), mortality, and other 90-day post-C19 outcomes. We repeated this analysis in a non-IS control group for comparison.

**Results:** Over the study period, 11,498 KTRs and >1.9M non-IS patients were diagnosed with C19. In non-IS, relative to no HRT use, HRT use in the last 6 months was associated with significantly lower risk of MARCE (Hazard Ratio [HR] 0.54, 95% Confidence Interval [CI] 0.51-0.59, for females; 0.63, 0.56-0.70, for males), mortality (HR 0.45, CI 0.40-0.51, for females; 0.55, 0.45-0.66, for males), and all secondary events for males and females (Figure 1). In KTRs, HRT was not associated with any post-C19 outcome in either males or females; there was a trend towards lower risk in males on HRT vs not on HRT, for most outcomes.

**Conclusions:** HRT was protective against adverse C19 outcomes in older non-IS males and females, but not in KTRs. The modifying effects of IS on the benefits of HRT requires further investigation.

**Funding:** Other NIH Support - AO and EF were supported by CTSA award No. UL1TR002649 from the National Center for Advancing Translational Sciences and the data use was supported by NCATS U24 TR002306 and by the National Institute of General Medical Sciences, U54 GM115458, which funds the Great Plains IDEa-CTR Network. ### Treatment With Monoclonal Antibodies Is Safe and Effective for Kidney Transplant Recipients With COVID-19

Yorg Al Azzi, Cindy T. Pynadath, Maria Ajaimy, Luz E. Liriano-Ward, Sanjana Kapoor, Enver Akalin. *Montefiore Medical Center, Bronx, NY.*

**Background:** Monoclonal antibodies have been the mainstay of treatment of COVID-19 in patients at high-risk of mortality from COVID-19. We aimed to study our experience with monoclonal antibodies (mAb) in kidney transplant recipients with COVID-19 at our center.

**Methods:** We reviewed 93 of our kidney transplant recipients who were infected with COVID-19 and received mAb treatment. The mAb infusion received was the one active against the variant that was circulating during that period (39 received either bamlanivimab or casirivimab/imdevimab, 41 received sotrovimab and 13 received bebtelovimab). All patients were on standard immunosuppression with tacrolimus and prednisone, and 88% were on mycophenolate prior to COVID-19 diagnosis, which was subsequently reduced or held for at least 2 weeks.

**Results:** Of the 93 patients, median age was 54 (IQR 44-64), 44% were male, 42% were Hispanic, 36% were African American. 76% have received deceased donor kidney transplant, 94% had history of hypertension, 47% diabetes mellitus, 18% coronary artery disease. All the patients had mild symptoms without initial hypoxia requiring supplemental O<sub>2</sub> and only 5 patients (5.4%) were admitted to the hospital. While 33 patients (35%) were unvaccinated at the time of COVID-19 diagnosis, 60 patients (65%) have received at least 2 doses of COVID vaccination at time of diagnosis and of those 27 patients (29%) have received a third dose. There was only one death (1%) in a patient that was re-hospitalized with severe COVID-19. There was no allograft loss. The rate of re-infection after mAb treatment was 6.5%. There was no serious adverse event related to the mAb infusion.

**Conclusions:** Our experience suggests that monoclonal antibodies are a safe therapeutic to reduce the need for COVID-19 related hospitalization in this high-risk kidney transplant population, while one third of those were unvaccinated at the time of COVID-19 diagnosis.

## TH-PO945

### Decreased Mortality From SARS-CoV-2 in Kidney Transplant Recipients Over the Course of the Pandemic

Yorg Al Azzi, Luz E. Liriano-Ward, Sanjana Kapoor, Maria Ajaimy, Enver Akalin, Cindy T. Pynadath. *Montefiore Medical Center, Bronx, NY.*

**Background:** We aimed to investigate the variation in mortality from SARS-CoV-2 infection in kidney transplant recipients

**Methods:** Between March 16, 2020 and May 4, 2022, 537 patients were diagnosed with SARS-CoV-2 infection by RT-PCR.

**Results:** 59% were male, median age 58 (IQR: 45-67), predominantly Hispanic (51.2%) and African American (29%). 75.4% received a deceased-donor renal transplant, 55% received anti-thymocyte induction. Most patients were on triple immunosuppression (96% on calcineurin inhibitors, 87% on anti-metabolite, and 99% on prednisone). While the mortality rate was 37 % (47/128) during first peak between March 16 and April 30, 2020, it has significantly decreased to 11% (7/61) from May 1, 2020 to end of December 2020 with social distancing and use of facemask. Between January 1, 2021 and November 5, 2021 with use of vaccination and monoclonal antibodies, the mortality rate further decreased to 7.7% (10/129). Between November 6, 2021 till May 4, 2022 which corresponds to the period when the Omicron variant and subvariants are prevalent, the mortality rate was 5.5% (12/219). Among those diagnosed during the period when Omicron was prevalent, 188/219 (85.8%) have received 2 doses of COVID vaccine and 82/219 (37.4%) have received a third dose. Since the beginning of use of monoclonal antibodies, 93 patients received a combination of casirivimab/imdevimab when initial SARS-CoV-2 variants were dominant and sotrovimab then bebtelovimab during the period of Omicron and its subvariants. Only one death occurred in patients who received

monoclonal antibody treatment and that patient was hospitalized for severe COVID-19. We identified 23 re-infections. Most of re-infected patients have already received at least 2 doses of COVID vaccine but only 5 received a third dose. None of the re-infected patients was hospitalized and none of them died.

**Conclusions:** In summary, mortality from SARS-CoV-2 infection in kidney transplant recipients has significantly decreased over time. This could be explained by initial exposure to higher viral load due to lack of personal protection and social distancing. However, since the judicious use of monoclonal antibodies and vaccination, in addition to social distancing protocols and use of facemask, the mortality in kidney transplant recipients has decreased over time.

## TH-PO946

### The Safety Profile and Impact of Remdesivir on Renal Function and Outcome in COVID-19 Infected Renal Allograft Recipients: A Retrospective Cohort Study From a Tertiary Care Hospital in Western India

Mohan P. Patel,<sup>1</sup> Jitendra Goswami,<sup>2</sup> *<sup>1</sup>Apollo Specialty Hospitals Pvt Ltd, Nashik, India; <sup>2</sup>Manipal Hospitals, Jaipur, India.*

**Background:** Severe acute respiratory syndrome coronavirus 2 (SARS-CoV2) infection has extremely impacted the transplant population. Remdesivir (RemD) has shown some promising results in coronavirus disease (COVID-19) pandemic though with low certitude. Literature in kidney transplant recipients (KTR) were still lacking at the time of ongoing pandemic situation.

**Methods:** This was a retrospective cohort of 52 moderate to severe COVID-19 positive KTR in a single center who received RemD as a part of COVID-19 management. No dose adjustments were done. The outcomes were measured as acute kidney injury (AKI) recovery; liver function tests abnormalities, other side effects; graft loss and all-cause mortality.

**Results:** The median (inter-quartile range) age of presentation was 47 (25-56) years. The duration from onset of symptoms to RemD initiation was 5 (4-9) days. Thirty seven (71.2%) cases received RemD on the day of admission. Thirty-nine (75%) cases were on oxygen support upon initiation of RemD. Thirty-two (61.5%) cases had acute kidney injury on admission. The median baseline, admission, and 28-day follow-up serum creatinine of the cohort were 1.5 (1.1-2.0), 2.4 (1.4-3.2), and 1.6 (1.04-2.2) mg/dl, respectively. A total of 12(23%) cases died in the study with 1 (1.9%) graft loss. All those cases that died were on oxygen therapy at the time of initiation of RemD. No significant liver dysfunction or any other major adverse events with the drug were observed.

**Conclusions:** RemD therapy is safe and clinically feasible in renal allograft recipients as seen in our cohort. Larger randomized clinical trials should be conducted to further explore the efficacy in renal allograft recipients.

## TH-PO947

### COVID-19 Outcomes in Kidney Transplant During in the Period of Omicron Predominance

João F. Bernardo, Sara Gonçalves, Natacha Rodrigues, Noélia L. Santos, Joao A. Goncalves, Fernando Abreu, Marta R. Neves, Alice Santana, Jose A. Lopes, Iolanda Godinho. *Centro Hospitalar Universitario Lisboa Norte EPE, Lisboa, Portugal.*

**Background:** In 2022' first trimester the Omicron SARS-COV-2 variant (OV) was the most prevalent in Portugal. OV is associated to greater transmissibility and less severe disease in immunocompetent patients but less is known about the clinical characteristics of the OV in immunosuppressed patients, namely in kidney transplant recipients (KTR). The authors aim to characterize and compare the clinical characteristics of KTR infected during SARSCOV2 Omicron and Delta wave.

**Methods:** Single center retrospective cohort study of KTR (n=675) to analyze the clinical outcomes of SARS-COV-2 infection throughout the epidemic waves: June-November 2021 - Delta predominant wave (DPW); January-March 2022 - Omicron predominant Wave (OPW). Data were collected from electronic clinical records. Continuous variables were compared using t student tests and categorical variables with Chi-square tests.

**Results:** SARSCOV2 infection incidence in the KTR was significantly higher during the OPW than during the DPW (DPW 10.7% vs OPW 3.7%, p<0.001). Most patients had booster of SARSCOV2 vaccine at the time of the diagnosis of SARS-COV-2 infection (DPW 88.8% vs OPW 91.6%, pns). Patients infected during OPW had lower hospitalization rates (OPW 20.8% vs DPW 44.0%, p0.024), less need for invasive ventilation (OPW 4.1% vs DPW 24% p0.003), lower rates of admission to Intensive Care Unit (ICU) (OPW 4.1% vs DPW 24% p0.003) and lower mortality rates (OPW 5.6% vs DPW 24.0%, p0.009). In hospitalized patients, respiratory failure rates were similar between both waves (OPW 81.9% vs DPW 81.8%, pns) and there was similar percentage of lung parenchyma involvement as determined by computed tomography scan (parenchymal involvement> 50%: OPW 53.4% vs DPW 63.5%, pNS). Although not statistically different, there was a higher prevalence of acute kidney graft injury at hospital admission during the OPW (OPW 53.3% vs DPW 18.2%, pns).

**Conclusions:** OV was associated to higher infection rates but less severe respiratory disease, lower admission to the ICU and lower mortality rates than Delta SARSCOV2 in KTR. Nonetheless severe pulmonary involvement occurred in a few cases and mortality seems to be higher than in the general population. Thus, preventive strategies of OV infection in KTR should go beyond vaccination.

## TH-PO948

### Senescent Lymphocyte Subsets Exhibit an Unexpected Advantageous Effect in the Response Against SARS-CoV-2 Vaccination in Dialysis Patients

Georgios Lioulios, Asimina Fylaktou, Ioannis Tsochnikas, Panagiotis Giamalis, Alikis Xochelli, Michalis Christodoulou, Aikaterini A. Papagianni, Maria J. Stangou. *Geniko Nosokomeio Thessalonikes Ippokrateio, Thessaloniki, Greece.*

**Background:** Vaccination against SARS-CoV-2 is a potent preventive tool against Covid-19. However, response to vaccination vary depending on comorbidities. This study evaluates clinical and immunological factors affecting humoral response of End-Stage Renal Disease(ESRD) patients to BNT162b2 Vaccine.

**Methods:** Humoral immunity was evaluated in 54 ESRD patients, by serum levels of anti-receptor-binding-domain (RBD) and neutralizing antibodies (Nab), measured by CLIA, 30 (T1), 60 (T2) and 120 (T3) days, after the second vaccine dose. Results were correlated to baseline patients' T and B-lymphocyte subpopulations as determined by flow cytometry.

**Results:** Proportion of seroconverted patients based on Nab titer was diminished from 83.3%(T1) to 53.7%(T3), in three months. Age was negatively correlated to Nab at T1 and T2 (T1:R=-0.334, p=0.027, T2:R=-0.344, p=0.022). Patients on hemodiafiltration had higher Nab titers at T3. Presence of diabetes was associated with lower response rate, as 9/11 diabetics compared to 16/43 non-diabetics lost seroconversion at T3. Univariate analysis revealed a strong positive correlation of naïve CD4 T-lymphocyte population with RBD at T1(R<sup>2</sup>=0.199, p=0.015) and with Nab titer at T3(R<sup>2</sup>=0.645, p<0.001), while no association was shown with naïve CD8 T-lymphocytes. Nab titers at T3 were significantly correlated with late differentiated CD4 T-lymphocytes(R<sup>2</sup>=0.56, p<0.001) and EMRA CD8 T-lymphocytes(R<sup>2</sup>=0.156, p=0.017). Finally, RBD levels had a significant positive correlation with naïve, and negative with memory B-lymphocyte count at T3(R<sup>2</sup>=0.147, p=0.031, R<sup>2</sup>=0.159, p=0.039, respectively).

**Conclusions:** Age, diabetes mellitus and hemodialysis prescription have a strong impact to response to vaccination. T and B-lymphocytes phenotype are major determinants of humoral response potency to COVID vaccination with BNT162b2, in ESRD patients.

## TH-PO949

### ESKD and Incidence and Outcomes With COVID-19: A 2-Year Review in US Veterans

Mariana Garcia-Touza,<sup>1</sup> Vikas Singh,<sup>1</sup> Aditi Gupta,<sup>2</sup> Varun Chandra Boipelly,<sup>1</sup> Ram Sharma,<sup>1</sup> Rishi Sharma,<sup>3</sup> Dana Hawkinson,<sup>2</sup> Virginia J. Savin,<sup>1</sup> Mukut Sharma,<sup>1</sup> Thomas Wiegmann.<sup>1</sup> VAMC <sup>1</sup>VAMC, Kansas City, MO; <sup>2</sup>KUMC, Kansas City, KS; <sup>3</sup>UMKC, Kansas City, MO.

**Background:** The COVID-19 pandemic has greatly impacted the global community. About 800,000 patients in the United States have ESKD, hence it is important to understand its interaction [WT(1)] with COVID-19.

**Methods:** We used the Veterans Affairs (VA) COVID-19 resource data base to examine the incidence and outcomes of ESKD (CKF2yrs) with COVID-19 in US Veterans. The database included standard hospital data, administrative and clinical records from VA and non-VA sources from March 2020 to April 2022. We examined the effect of basic demographic and common risk factors on all-cause mortality, and other outcomes (Table). Statistical analysis, frequency distributions, ODDs Ratios (OR) used SAS (Enterprise guide 7.1).

**Results:** The total study population consisted of 1,994 533 Veterans, and 27.9% of them (n=557,208) tested positive for COVID-19 (40% Alpha, 20.4 % Delta, 39.6% Omicron). Age, hypertension, diabetes mellitus type 2, Smoking status, Gender or Race had little effect (OR 0.86 – 1.01) while body mass index had moderate effect (OR 1.27) on incidence. ESKD was also increased significantly (OR 1.2). There were 7942 ESKD patients with 7452 on dialysis tested positive for COVID-19. Common risk factors were more prevalent in the ESKD cohort (OR age 5.5, male sex 4.6, hypertension 4.9, and diabetes 7.9) while the effect of BMI was lost (OR 0.63). Propensity matching was used for these conditions to isolate the effect of ESKD on outcomes. ESKD was associated with increased mortality and morbidity (Table). Mortality was reduced by 30% with Omicron.

**Conclusions:** ESKD in Veterans is associated significantly with increased of COVID-19 and its variants, higher rates of ICU admission, ventilator use, oxygen need, ER visits, readmission and all-cause mortality.

**Funding:** Veterans Affairs Support

### Outcomes of Kidney Transplant Recipients in Singapore With COVID-19 Infection With Delta and Omicron Variants

Matthew D'Costa, Hersharan K. Sran, Emmett Tsz Yeung Wong, Anantharaman Vathsala. *National University Hospital, Singapore, Singapore.*

**Background:** Kidney transplant recipients (KTR) are at higher risk for breakthrough COVID-19 infections and progression to severe disease. Herein, we compare the outcomes of KTR infected with the Delta and Omicron variants.

**Methods:** We performed a retrospective, single-centre study of all SARS-CoV-2-infected KTR confirmed by PCR from 17/09/21 to 30/04/22. At diagnosis, anti-metabolite doses were halved with further reductions of immunosuppression with increasing disease severity. Treatment for KTR not requiring supplemental oxygen (SuppO2) on admission was guided by SARS-CoV-2 spike antibody (SpAb), Roche® Cobas SARS-CoV-2-S assay. Sotrovimab 500mg IV was given if SpAb<100 U/mL. With community emergence of Omicron subvariant BA.2, sotrovimab was replaced by tixagevimab/cilgavimab (EVUSHELD™) 600mg IM in KTR with SpAb<250 U/mL or remdesivir if SpAb>250 U/mL. KTR with SuppO2 were treated with dexamethasone +/- remdesivir and immunomodulator therapy (baricitinib or tocilizumab). Characteristics and outcomes between KTR with Delta and Omicron were compared.

**Results:** Clinical characteristics and outcomes are summarized in Table 1. Baseline demographics were similar between groups. Vaccination rates increased over time in concert with government vaccine programs and communications by our team. KTR with Omicron had higher vaccination rates, higher likelihood of SpAb>250 U/mL, and were less likely to have AKI, SuppO2, ICU stay, and mortality (p<0.05 for all). Of 16 KTR with Omicron with SuppO2, 5 were unvaccinated and only 1/16 had SpAb>250 u/mL.

**Conclusions:** Severe disease was less frequent in KTR with Omicron likely due to improved vaccination rates, higher SpAb, and virus characteristics. However, KTR remain at risk for severe disease especially if unvaccinated or if SpAb is low.

Table 1: Baseline Clinical Characteristics and Outcomes for Kidney Transplant Recipients with COVID-19 Infection

Demographics of Study Population		
	Delta N=37	Omicron BA.1 and BA.2 N=164 (2 reinfections)
N (%) or mean $\pm$ SD

\*5 were unvaccinated, 3 received 1 mRNA vaccine

\*\*5 were unvaccinated, 1 received 1 mRNA vaccine, and 5 received 22 inactivated virus vaccines

\*\*\*11 unknown/not obtained at time of infection or were unvaccinated

\*\*\*\* EVUSHELD™ 300mg IM was given as pre-exposure prophylaxis if no prior history of infection or post-exposure prophylaxis if exposed to a household contact with COVID-19.

## TH-PO951

## Characteristics of Vaccinated Kidney Transplant Recipients Requiring Hospitalization for COVID-19 Infection

Ali W. Rizvi, Michael Turk, Laith Alhuneafat, Naman Gupta, Aaisha Shah, Taber Rana, Ramya Gutta, Katherine Barnett, Shane Mealy, Alisha Sharma, Omar Osman, Kalathil K. Sureshkumar. *Allegheny Health Network, Pittsburgh, PA.*

**Background:** Studies have shown suboptimal immunological response to COVID-19 vaccination in kidney transplant recipients (KTRs). We aimed to describe specific characteristics of vaccinated KTRs who required hospitalization for COVID-19 infection.

**Methods:** In this descriptive study utilizing chart review, we identified KTRs who were hospitalized for COVID-19 infection between March 2020 and January 2022 within our integrated health network. Demographic characteristics were identified for KTRs who received  $\geq$  2 COVID-19 vaccine doses prior to hospitalization.

**Results:** Among 114 KTRs admitted to the hospital with COVID-19 infection, 44 (39%) had received 2 or more vaccine doses prior to hospitalization including 35 patients who received 2 vaccines and 9 who received  $>$  2 vaccines. Vaccinated patients requiring hospitalization were generally older with male predominance. Prevalent comorbidities included overweight/obesity, hypertension, and diabetes. Among these patients, 18% required dialysis and 90-day mortality was 20% (Table).

**Conclusions:** Despite receiving at least 2 doses of preventative vaccination, many KTRs developed COVID-19 infection requiring hospitalization. Our findings are consistent with studies showing reduced antibody and cell mediated response to vaccination in KTRs. Every effort should be made to educate and encourage this vulnerable population about measures to prevent infection, especially vaccination with subsequent booster doses.

Baseline Characteristics	Total (n=44)
Age (years)	61.6 $\pm$ 12.2
Body mass index	29.1 $\pm$ 5.2
Sex: Female	19 (43%)
Race: White, Black, Other	29 (66%), 12 (27%), 3 (7%)

## TH-PO952

## Management and Course of the SARS-CoV-2 Pandemic in a German Dialysis Network

Thilo Krueger, Werner Kleophas. *DaVita Clinical Research Deutschland GmbH, Düsseldorf, Germany.*

**Background:** The global Covid-19 pandemic is a particular risk for dialysis patients, the Covid-associated mortality of dialysis patients is known to be higher than that of the general population. From the DaVita network, we present the course of SARS-CoV-2 infections from 65 German centers with around 3,300 active dialysis patients and approximately 1,500 employees.

**Methods:** To reduce the risk of infection, a triage system was introduced, regulating how dialysis patients are treated in the centers. The triage is based on items like clinical symptoms, swab results and contact with confirmed positive individuals and determines further dialysis in isolation. Point-of-care antigen tests were introduced early and routinely used as a screening measure for both dialysis patients and medical staff. Further to general hygiene measures, a traffic light system was implemented depending on the local incidence rate. This provided for further measures such as a ban on visits, cohort isolation, area care and isolated trips to dialysis. The local vaccination status was also recorded in this system.

**Results:** In general, the course of incidences among patients reflects that of the general population. We recorded the peak incidence of SARS-CoV-2 at the end of 2021. The cumulative total number of patients who tested positive is currently 1545 cases, which corresponds to a rate of around 48% of patients (officially 30.4% in Germany as of April 2022). With regard to the infection rate per center, there are marked differences within the network, ranging from 1% to 65%. The mortality rate from SARS-CoV-2 among dialysis patients who tested positive was 10.2% as of April 2022 (158/1545; currently around 0.5% across Germany). Since 2021, a significantly reduced Covid-associated mortality rate was noticed decreasing continuously from around 23% in August 2021 to 1.5% in April 2022. The infection rate of the staff was around 37.1% (587/1583) in the network. The rate of dialysis patients with at least three vaccinations is currently at 84.9%.

**Conclusions:** In summary, the measures taken were able to effectively control for the occurrence of infection within the network. The higher incidence rate of Covid infections amongst patients may be due to more frequent routine testing than in the general population. The markedly decreasing Covid-associated mortality is possibly due to vaccinations and the milder omicron variant.

## TH-PO953

## Worn Face Mask Testing to Diagnose SARS-CoV-2 Infection in Hemodialysis Patients

Xiaoling Wang,<sup>1</sup> Ohnmar Thwin,<sup>1</sup> Zahin S. Haq,<sup>1</sup> Zijun Dong,<sup>1</sup> Lela Tisdale,<sup>1</sup> Lemuel Rivera Fuentes,<sup>1</sup> Nadja Grobe,<sup>1</sup> Peter Kotanko,<sup>1,2</sup> *Renal Research Institute, New York, NY; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY.*

**Background:** Hemodialysis (HD) patients are at increased risk for COVID-19 infection, hospitalization, and mortality. Early COVID-19 diagnosis is thus critical to mitigate SARS-CoV-2 spread and improving patients' health outcomes. Generally, nasopharyngeal (NP) specimens are considered the most sensitive biological samples to diagnose SARS-CoV-2 infections. However, NP swabbing is considered uncomfortable by most patients, and it requires health professionals, thus impacting its cost-effectiveness. In a previous proof-of-principle study, we demonstrated that face masks worn by in-center HD patients can harbor SARS-CoV-2. In this Kidney-X funded study, we determined efficiency of face mask testing by comparing results to saliva specimen collected from same individuals.

**Methods:** Disposable 3-layer masks were provided to each subject at the time of entering the dialysis center. Masks were collected 4 hours after worn. Saliva was collected using Salivette kit at the time of mask collection. RT-PCR based testing were performed using Thermo Fisher COVID-19 Combo Kit (A47814).

**Results:** We collected 179 pairs of saliva/masks, 114 from 42 dialysis staff and patients without recent COVID-19 infection (control group), and 65 from 30 HD patients with COVID-19, diagnosed by NP RT-PCR (COVID-19 group). Patients provided 1 to 7 sample pairs on average 11  $\pm$  8 days (0 to 36) after COVID-19 diagnosis. Thirty-one of the 65 sample pairs were SARS-CoV-2 positive either in the saliva or the mask samples (26 positive saliva; 20 positive masks). Saliva and mask testing sensitivities were 84% and 65% with a mean cycle threshold (CT) of 31.8 and 32.2, respectively. Fifteen pairs tested positive for both worn masks and saliva. Mask and saliva CT values did not differ significantly. Of note, in 5 sample pairs saliva tested negative while masks tested positive. In the control group, all 114 saliva samples tested negative; one mask tested weakly positive, resulting in saliva and mask testing specificities of 100% and 99%, respectively. S gene dropout was observed in all positive samples, indicating Omicron BA.1 infection.

**Conclusions:** While the sensitivity of mask testing is less compared to saliva testing, its operational ease, lack of patient discomfort, seamless repeatability, and lower costs make it a viable option for SARS-CoV-2 screening.

TH-PO954

### Outcomes of COVID-19 in Peritoneal Dialysis: A Multi-Centre Observational Study

Bhamini Guttu, Jyoti B. Baharani. *University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

**Background:** Patients with end stage renal failure are not only at high risk of developing Coronavirus disease 2019 (COVID-19) but there are reports of disproportionately severe impact on dialysis patients, with reported short-term mortality of 20% or higher. The aim of this study was to assess the impact of COVID-19 in patients on peritoneal dialysis (PD).

**Methods:** We conducted a retrospective observational study across four hospitals in West Midlands in United Kingdom. We identified a total of 50 patients on PD, 18 years and over, with a positive SARS-CoV-2 swab from 1st of January 2020 to 31st of December 2020. Data was analysed using IBM SPSS software. We looked at mortality (7 days, 28 days, 3 months), intensive therapy unit (ITU) admission, ventilation requirement, peritonitis and conversion to haemodialysis.

**Results:** The mean age was 63 years, with higher prevalence in men (66%). 54% were of white ethnicity (46% of Black, Asian and minority ethnic groups). 10 out of the 50 patients (20%) had died within 7 days, 17 (34%) had died within 28 days and 19 (38%) were not alive at 3 months. 3 patients (6%) required ITU admission. 4 patients (8%) received non-invasive ventilation, but none required mechanical ventilation. 4 patients (8%) were converted to haemodialysis. 8 patients (16%) had peritonitis.

**Conclusions:** We found a high risk of short-term mortality in our PD patients who acquired COVID-19 infection. However, more studies are required to establish any causal link between COVID-19 infection in PD patients and high short-term mortality.

### Variability in Excess ESKD Patient Mortality Among States During the Pandemic

Eric D. Weinhandl,<sup>1,2</sup> Jiannong Liu,<sup>1</sup> David T. Gilbertson,<sup>1</sup> James B. Wetmore,<sup>1,3</sup> Kirsten L. Johansen.<sup>1,3</sup> <sup>1</sup>Chronic Disease Research Group, Minneapolis, MN; <sup>2</sup>Satellite Healthcare, San Jose, CA; <sup>3</sup>Hennepin Healthcare, Minneapolis, MN.

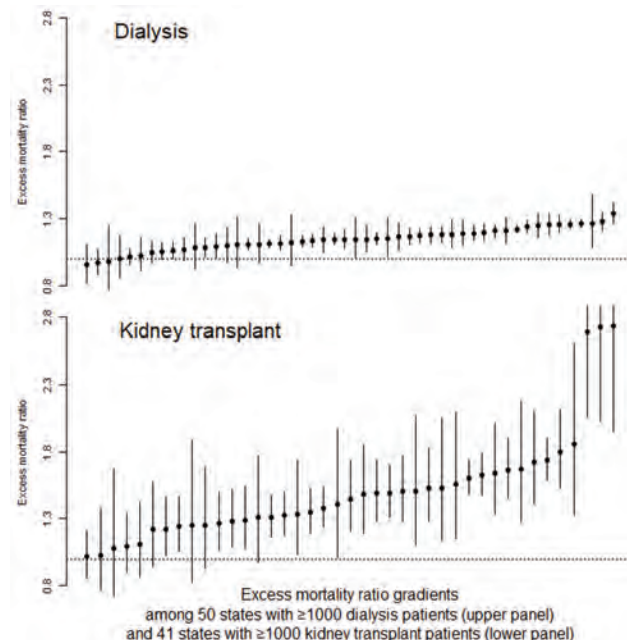

**Background:** The incidence of death among patients with ESKD in the United States has been significantly elevated during the COVID-19 pandemic, relative to recent historical levels. In the general population, individual states have exhibited markedly variable COVID-19 death rates, possibly reflecting policy decisions concerning pandemic management. However, little is known about regional variability in the excess mortality of ESKD patients. We analyzed excess mortality among both prevalent dialysis and kidney transplant (KT) patients between March 15, 2020, and June 30, 2021.

**Methods:** We analyzed national data extracted from the Centers for Medicare and Medicaid Services (CMS) End Stage Quality Reporting System (EQRS). For each epidemiologic week from week 1 of 2018 to week 26 of 2021, we identified prevalent dialysis and KT patients at the beginning of each week, and the incidence of all-cause death among them during the week. For each combination of state and kidney replacement therapy, we estimated excess mortality during the pandemic (definition: week 12 of 2020 and thereafter), using a logistic regression model of death among patient-weeks, with adjustment for age, sex, race.

**Results:** From 732,063 dialysis patients in 50 states, there were 129,095 pandemic-era deaths; and from 238,265 KT patients in 41 states, there were 11,256 pandemic-era deaths. State-level excess mortality ratios in dialysis patients ranged from 0.96 to 1.34, with 40% of states having ratios significantly greater than 1.1. State-level excess mortality ratios in KT patients ranged from 1.02 to 2.73, with 61% of states having ratios significantly greater than 1.1.

**Conclusions:** States exhibited wide variability in excess ESKD patient mortality, with roughly 3-fold wider variability in prevalent KT patients than in dialysis patients.

TH-PO956

### Outcomes in Kidney Transplant Recipients With COVID-19 Illness in the Era of Vaccines

Perola Lamba, Gabriel J. Stryniak, John R. Lee, Thangamani Muthukumar, Thalia Salinas, Deirdre L. Sawinski, Darshana M. Dadhania. *Weill Cornell Medicine, New York, NY.*

**Background:** Kidney transplant recipients (KTRs) are risk for severe complications from COVID-19 illness due to immunosuppression. Predating COVID-19 vaccines our center reported AKI in 39% & death in 13% of KTRs. Here we describe the impact of COVID-19 on allograft & patient outcomes in KTRs with & without COVID-19 vaccination. We also compare outcomes in KTRs with & without response (SARS-CoV2 spike/anti-S antibody) to COVID-19 vaccine.

**Methods:** This is a retrospective cohort analysis of 142 KTRs identified with COVID-19 illness between 7/1/21 and 2/10/22. We collected data on patient demographics, COVID19 vaccine doses, anti-S levels & clinical outcomes including graft dysfunction, hospitalization, ICU admission & death.

**Results:** Of 142 KTRs in our cohort, 113 (80%) were fully vaccinated (+/- booster) and 29 (20%) were un or partially vaccinated. 60 of 113 vaccinated KTRs were tested for anti-S levels between COVID19 vaccination & illness: 68% tested positive and 32% negative for anti-S Ab. Allograft dysfunction & hospitalization were less frequent in fully vaccinated vs unvaccinated KTRs (Fig.1). There was no difference between the two in terms of ICU admission and death (22 vs 18%, p=0.7). Among vaccinated KTRs, there was a trend towards less graft dysfunction in positive vs. negative anti-S (15% vs. 33% p=0.15). No differences were observed between anti-S levels and hospitalization (23% vs 26% p=0.7), ICU admission (11 vs 60% p=0.07) and death (11 vs 20% p=0.65).

**Conclusions:** In our cohort, kidney allograft dysfunction and hospitalization were less common vaccinated vs unvaccinated KTRs with COVID-19. Additionally, there is a trend towards lower graft dysfunction in those with positive anti-S Ab. No significant differences were observed in death and ICU admissions with vaccination or positive anti-S. Vaccination to COVID-19 and maintaining positive anti-S Ab (with boosters or monoclonal Ab) are important in preventing graft dysfunction and hospitalization following COVID-19.

## TH-PO957

**COVID-19 Infection in Patients Receiving Kidney Replacement Therapy Under Universal Health Coverage in Thailand**Siribha Changsirikulchai,<sup>1</sup> Pornpen Sangthawan,<sup>2</sup> Thammasin Ingviya.<sup>3</sup><sup>1</sup>Division of Nephrology, Department of Medicine, Srinakharinwirot University, Nakhonnayok, Thailand; <sup>2</sup>Division of Nephrology, Department of Medicine, Faculty of Medicine, Prince of Songkla University, Songkla, Thailand; <sup>3</sup>Department of Family and Preventive Medicine, Faculty of Medicine, Prince of Songkla University, Songkla, Thailand.

**Background:** The Thai nation has used public health and social health measures to control the spreading of COVID-19 pandemic infection since February 2020. The sample of these measures was identifying the index cases, tracing cases with high-risk contacts, isolating in quarantine sites, vaccination, using face masks, washing hands, and physical distancing. Patients with high mortality risk from COVID-19 would be treated in hospitals. This study aimed to evaluate the incidence and outcomes of COVID-19 infection in patients receiving kidney replacement therapy (KRT) under universal health coverage (UC).

**Methods:** Data of patients who registered with the National Health Security Office Region 4 (NHSO4) to receive peritoneal dialysis (PD), hemodialysis (HD), or kidney transplantation (KT) during January 2020-December 2021 was analyzed. The incidence and mortality rates of COVID-19 in each type of KRT were calculated. The comorbidities and complications which were recorded in the file of the electronic claim to reimburse from the NHSO4 were diagnosed following the ICD-10. The comorbidities and complications which were the risks associated with death in COVID-19 were analyzed. The cost of treatment according to the Diagnosis Related Group (DRG) which was paid back to the hospitals from the NHSO was evaluated.

**Results:** There were 1,744 patients on PD, 1,267 patients on HD, and 35 patients on KT. The incidence, mortality rate, and characteristics of patients with COVID-19 infection in each category of KRT were shown in Table 1.

**Conclusions:** The incidence of COVID-19 infection was highest in patients receiving HD followed by KT and PD respectively. The cost of treatment according to DRG in patients with PD was lower than in those with HD. The mortality was not different among these types of KRT.

Table 1: Incidence, mortality rate, and characteristics of KRT patients with COVID-19 infection

Variable	PD	HD	KT
Total of patients	1744	1267	35
Number (%) of patients with COVID-19	46 (2.6)	132 (10.4)	2 (5.7)
Number (%) of male with COVID-19	27 (58.7)	55 (41.7)	2 (100)
Number (%) of female with COVID-19	19 (41.3)	77 (58.3)	0 (0)
Median (IQR) age at COVID-19 infection	55.2 (22.4)	60.9 (21.5)	53.6 (10.0)
Median (IQR) length of admission (days)	9 (7.8)	12 (7.3)	13.5 (4.5)
Number (%) of death	21 (45.6)	59 (44.7)	1 (50.0)
Number (%) of patients with comorbid diseases			
Diabetes	21 (45.6)	57 (43.2)	1 (50.0)
Cardiovascular disease	8 (17.4)	16 (12.1)	1 (50.0)
Cerebrovascular disease	3 (6.5)	5 (3.8)	0 (0)
Malignancy	0 (0)	2 (1.5)	0 (0)
Airway disease	0 (0)	3 (2.3)	0 (0)
Liver disease	0 (0)	6 (4.5)	0 (0)
HIV infection	0	2 (1.5)	0 (0)
Obesity	0 (0)	2 (1.5)	1 (50)
Psychiatric problem	0	2 (1.5)	0 (0)
Number (%) of patients with complication			
Pneumonia	37 (80.4)	108 (81.8)	2 (100)
Respiratory failure	0	2 (1.5)	0 (0)
Sepsis	7 (15.2)	8 (6.1)	0 (0)
Heart failure	1 (2.2)	8 (6.1)	0 (0)
Fluid overload	0 (0)	4 (3.0)	0 (0)
Median (IQR) cost of treatment according to DRG (not include cost of dialysis) (baht)	13,089.12 (25,099.24)	15,000 (36,962.5)	31,500 (18,000)

## TH-PO958

**Patients With ESKD Are Commonly Hospitalized Early During COVID-19 Illness: An Opportunity for Early Intervention**

Daiana R. Moreno, Ritu Seethapathy, Destiny Harden, Qiyu Wang, Nurit S. Katz, Meghan E. Sise. Massachusetts General Hospital, Boston, MA.

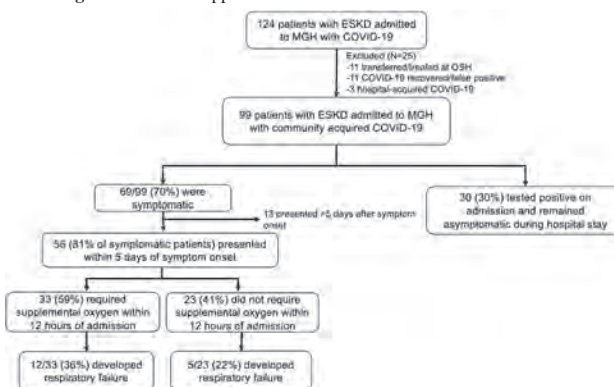

**Background:** Antiviral medications such as remdesivir, molnupiravir, and nirmatrelvir/ritonavir are most effective when used early in the course of COVID-19. These medications are authorized for patients with COVID-19 with mild symptoms who are at high risk for severe disease. ESKD is among the strongest risk factors for mortality from COVID-19. As the ESKD population is highly linked to care, we hypothesized that they are more likely to be admitted to the hospital within five days of symptom onset when antiviral medications are maximally effective.

**Methods:** We identified patients with ESKD on dialysis who were admitted to Massachusetts General Hospital with COVID-19 by using dialysis records and manually extracted the date of symptom onset as shown in the admission note. Primary outcome was the proportion of patients with ESKD admitted within 5 days of symptom onset; secondary outcome was the risk of respiratory failure within 90 days among the early presenters.

**Results:** After implementing the exclusion criteria shown in Figure 1, we included 99 patients with community-acquired COVID-19 admitted between March 2020 and Jan 2022. Thirty patients (30%) remained asymptomatic during their hospitalization. Among patients with symptomatic COVID-19, 56 (81%) were admitted within 5 days of symptom onset; among them, 17 developed respiratory failure within 90 days (30%) and 11 died from respiratory failure (20%). (Figure 1)

**Conclusions:** We found that most patients with ESKD on dialysis admitted for symptomatic COVID-19 presented within 5 days of symptom onset. We conjectured that because of this, inpatient antiviral therapy may be more effective in the ESKD population than in a typical inpatient population with COVID-19 that presents later in the disease course. Given the high risk of respiratory failure in ESKD population who developed COVID-19, improved treatment strategies are urgently needed.

**Funding:** Commercial Support - Gilead

## TH-PO959

**Paradoxical Protection of Keeping an In-Center Short Daily Hemodialysis Schedule During the First 2 Years of COVID-19 Pandemic**

Istenio Pascoal, Adolfo Simon, Luiza Lins, Kelia Xavier, Vilber Bello, Juliane Lauer. Centro Brasileiro de Nefrologia Dialise, Brasilia, Brazil.

**Background:** Covid-19 Pandemic imposed several restrictions to the general population, including stay at home guidance. Most dialysis patients are challenged by mandatory transportation and thrice-weekly long stays in their Units. Home dialysis and/or reduction of hemodialysis frequency have been promoted to mitigate the spread. Notwithstanding, we report the contrasting experience of keeping a long-term in-center short daily hemodialysis program while enforcing protective measures and an unique transportation arrangement.

**Methods:** From March 16, 2020 to March 15, 2022 dialysis patients who were symptomatic, hospitalized for other reasons or had contact with confirmed cases of Covid-19 were tested for Sars-Cov-2 by RT-PCR. We examined outcomes of those who tested positive. Eighty private-insured patients (48M; 62.1±14.3yrs) on in-center short daily hemodialysis (6-7x/wk; 115.4±11.2min; single-use high-flux dialyzer) were studied. Round-trip transportation was provided by a fleet of 12 dedicated minivans. Eating during dialysis was abolished and isolation room for confirmed or suspected cases was adopted. A 3-dose vaccination started in January 2021 and covered all patients and staff members.

**Results:** Forty out of 80 patients (50%) contracted Covid-19 (21M; 60.2±16.8yrs) and four were reinfect. Thirty of the 44 infections were symptomatic (68%) and 14 asymptomatic (32%). Ten of the 40 infected patients were hospitalized (25%), 1 required mechanical ventilation and died, while 39 recovered well (5% fatality rate pre-vaccination, 0% post-vaccination). Over the 2 years dialysis mortality and transplantation rates were 5.6% (9/80 patients). Average dialysis frequency was 5.9 sessions/week. Our 100-member staff presented 33 Covid-19 infections.

**Conclusions:** During the two years of Covid-19 Pandemic we kept our in-center short daily hemodialysis schedule as usual while applied comprehensive transportation and restrictive measures. There was one death attributable to Covid-19, in sharp contrast with the death toll on dialysis population worldwide (20-30% fatality rate). This benign

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

course may reflect a combination of strict prophylactic discipline (limiting transmission among patients and staff) with a potential inflammatory mediators removal by high-frequency high-flux hemodialysis (perhaps preventing cytokine storm).

## TH-PO960

### Opportunistic Infections in Post Renal Transplant Patients Treated With Dexamethasone for COVID-19

Benjamin G. Morrison, Hasan Fattah. *University of Kentucky, Lexington, KY.*

**Background:** Dexamethasone, a common treatment regimen for COVID-19, may mitigate inflammation-mediated lung injury in immunocompromised patients who have COVID-19 with severe disease. However, it comes with the cost of further suppressing the immune system, increasing the risk for opportunistic infections. This study looked at various post renal transplant patients on immunosuppression who contracted COVID-19, their treatment with or without dexamethasone, and their subsequent development of opportunistic infections that necessitated readmission.

**Methods:** We identified index hospitalization for COVID-19 amongst kidney transplant recipients between 2020 and 2022 at our institution. Local electronic medical record review was utilized for demographics, vaccination status, readmissions for opportunistic infections, and dexamethasone treatment characteristics for COVID-19 infection.

**Results:** Of the 33 patients included in the analyses, 14 (42.4%) were readmitted at least once for opportunistic infections. Those readmissions included 5 cases of viral infection, 14 bacterial infection, and 4 fungal infection. For treatment of COVID-19, 18/33 patients (54.5%) received at least 1 dose of dexamethasone. Of the 18 patients given dexamethasone, 8 (44.4%) were found to be among the 14 readmitted patients with opportunistic infection. Of the 33 patients, 25 (75.8%) had received at least one dose of the COVID-19 vaccine at the time of COVID-19 diagnosis. Amongst the 14 readmitted patients, 8 (57.1%) had received at least one dose of COVID-19 vaccine at time of COVID diagnosis and 6 (42.9%) had not received any vaccine.

**Conclusions:** In this single cohort, readmission rate after COVID-19 hospitalization for kidney transplant recipient was 42%, higher than the average rate for all COVID-19 cases readmission rate (12% per CDC, 27% per National Veterans Affairs). Glucocorticoid use should be done with extreme caution in immunocompromised patients due to the increased risk for opportunistic infections. Opportunistic infections were associated with corticosteroids use in 44% of COVID-19 patients in this group. Another risk factor for opportunistic infection following COVID-19 in immunosuppressed patients may be vaccination status at the time of COVID-19 diagnosis.

## TH-PO961

### Diagnostic Value of the COVID-GRAM and 4C Mortality Score in Predicting Critical Events Among ESRD Patients With COVID-19

Kate Nicole T. Yu. *National Kidney and Transplant Institute, Quezon City, Philippines.*

**Background:** Around 800 ESRD patients from March 2021 to July 2021 were affected by COVID-19 in a tertiary specialized hospital in the Philippines, with a case fatality rate of 2.3%. These subset of patients have one of the highest morbidity and mortality among others. That is why numerous tools such as the COVID GRAM and 4C Mortality Score were formulated to predict the critical events in COVID-19 patient and may hopefully be useful for ESRD patients as well.

**Methods:** This is a retrospective cohort design to determine the diagnostic value of COVID GRAM and Mortality 4C score in predicting critical events. Participants were end stage renal disease (ESRD) patients infected with COVID19 seen at the National Kidney and Transplant Institute from March 2020 to July 2021. Chart review was done from August 2021 to October 2021. **Inclusion Criteria:** Age  $\geq 19$  years old Admitted patients for at least 24hrs COVID-19 confirmed via RT PCR or GeneXpert with nasopharyngeal or oropharyngeal swab, provided that: Testing performed in an accredited institution ESRD Filipino patients already on RRT or for RRT initiation **Exclusion Criteria:** Kidney transplant patients Acute kidney injury needing renal replacement therapy Incomplete data on 4C mortality and COVID GRAM

**Results:** This study included a total of 97 patients (41 in the critical group, 56 in non-critical group). Both COVID GRAM and 4C mortality score showed high levels of discriminative ability, accuracy, sensitivity, specificity. The discriminative ability or AUC of both COVID GRAM and 4C Mortality Score were at 0.93 and 0.95, respectively. Overall accuracy was at 93.81% and 96.91%.

**Conclusions:** Even with the advent of vaccination, COVID 19 remains to be a leading cause of morbidity and mortality in our country and has cost the Philippine government \$30.72B. Therefore, proper allocation of the budget and expenses remains to be a priority. With both COVID GRAM and 4C Mortality, these tools can aid physicians in decision making especially for those at high risk of experiencing a critical event and maybe be used to determine if patients need to be admitted or can be managed at an outpatient basis.

**Funding:** Government Support - Non-U.S.

## TH-PO962

### Neutralising Antibodies Against SARS-CoV-2 and Variants of Concern in In-Centre Haemodialysis Patients in the United Kingdom

Edward Carr,<sup>1</sup> Rupert Beale.<sup>1,2</sup> NAOMI Consortium, Crick COVID Immunity Consortium, Legacy Study Consortium *'The Francis Crick Institute, London, United Kingdom; <sup>2</sup>Royal Free Hospital, London, United Kingdom.*

**Background:** Haemodialysis patients have significant morbidity and mortality from SARS-CoV-2 infection. In-centre haemodialysis (IC-HD) patients are at particular risk at times of high community transmission as they must attend healthcare settings for life-preserving treatment sessions. In the UK, adenoviral or mRNA vaccines were used for doses 1 and 2 in IC-HD. mRNA vaccines were used for subsequent doses. IC-HD patients are not reported by the phase 3 vaccine trials. Given the coalescence of uraemia, immunosuppressive primary renal diseases and treatments, together with prior experience using other vaccines (for example influenza), we anticipated that IC-HD patients would have an attenuated response to SARS-CoV-2 vaccination.

**Methods:** As a UK-wide consortium, we have used a high-throughput live virus microneutralisation assay to determine the ability of IC-HD patient sera to neutralise ancestral SARS-CoV-2 and variants of concern (VOCs). Ancestral binding Spike antibodies were also assessed by an ancestral S1 ELISA and by a flow cytometry method with full-length trimeric Spike.

**Results:** We will report IC-HD neutralisation titres after fourth doses and to the newest VOCs, BA.4 and BA.5. Neutralising responses to the first three doses in IC-HD patients are already published by the consortium (Carr *et al.* The Lancet 2021 and 2022). We will show heterogeneity in the cross-neutralising ability of IC-HD patient sera, and explore how population-level ancestral binding antibody correlations neutralisation titres might not generalise to the individual patient.

**Conclusions:** Three doses were required for most IC-HD patients to generate neutralising titres against Delta and Omicron BA.1. Further doses are likely required to maintain high serological protection in this vulnerable group of renal patients.

**Funding:** Private Foundation Support, Government Support - Non-U.S.

## TH-PO963

### COVID-19 Mortality in Kidney Transplant Recipients: Analysis of Risk Factors

Michael Turk, Laith Alhuneafat, Ali W. Rizvi, Naman Gupta, Katherine Barnett, Ramya Gutta, Shane Mealy, Tabeer Rana, Aisha Shah, Alisha Sharma, Omar Osman, Kalathil K. Sureshkumar. *Allegheny Health Network, Pittsburgh, PA.*

**Background:** Mortality rates for COVID-19 infection vary widely. Immunocompromised patients in general have worse outcomes. We aimed to evaluate kidney transplant recipients (KTRs) who were admitted for COVID-19 infection and investigate patient specific factors or comorbidities that may have influenced mortality rates.

**Methods:** In this retrospective study, we identified KTRs who developed COVID-19 infection between March 2020 and January 2022 within our integrated health network. Through chart review, patient characteristics were collected and stratified by 90-day mortality.

**Results:** Out of 114 KTRs hospitalized with COVID-19 infection, 24 (21.0%) died during admission, and another 7 died within 90 days of admission bringing total 90-day mortality to 31/114 (27.2%). Among the 114 hospitalized patients, 53 (46.5%) had received at least one prior COVID-19 vaccine dose including 35 who received two doses and 9 who received  $\geq 3$  doses. KTRs who survived following COVID-19 hospitalizations were significantly younger and were more likely to be vaccinated (Table).

**Conclusions:** Approximately 1 out of 4 KTRs admitted for COVID-19 infection died within 90-days. Older age was a mortality risk factor and vaccination conferred protection against mortality in these immunocompromised patients. Our study highlights the importance of vaccination in these patients. Relatively small sample size likely limited identification of other potential risk factors for mortality in our analysis.

#### Patient characteristics

## FR-PO001

**Effect of the Seraph® 100 Biomimetic Pathogen Adsorbing Device on Inflammatory Biomarkers in 42 COVID-19 Patients**

Jan T. Kielstein,<sup>1</sup> Borchina Dan-Nicolae,<sup>1</sup> Julius Schmidt,<sup>2</sup> <sup>1</sup>Academic Teaching Hospital Braunschweig, Braunschweig, Germany; <sup>2</sup>Medizinische Hochschule Hannover, Hannover, Germany.

**Background:** Lack of pharmacological treatment options in severely ill hospitalized COVID-19 patients prompted explorations of extracorporeal treatments. The Seraph® 100 Microbind® Affinity filter, remove viruses, including SARS-CoV-2 from the blood. Data from an international registry, from a multicenter evaluation in the US, as well as from several case reports suggest that Seraph® 100 can not only be safely used but it may have an impact on patient centered outcome parameters. As it is unknown whether the effect of the Seraph® 100 in COVID-19 patients is solely based on the removal of the virus or, as suggest by a recent observation, by additionally modulating inflammation, we set out to perform a biomarker study.

**Methods:** We performed this prospective multicenter observational trial at three tertiary care hospitals in patients being treated with Seraph® 100 for severe COVID-19 between June 2020 and April 2021. Biomarkers were obtained before the treatment as well as 2-4 hours after the treatment, as well as 4 days after the Seraph® 100 treatment. Routine clinical chemistry parameters were performed in the respective clinical chemistry labs using certified methods. For the assessment of the inflammatory markers a Bio-Plex Pro Human Cytokine Screening Panel, 48-Plex #12007283 (Bio-Rad) was used.

**Results:** From June 1<sup>st</sup> 2020 to April 1<sup>st</sup> 2021, 42 patients with COVID-19 treated with the Seraph® 100 in our hospitals could be included in the study. Hemoperfusion treatment was initiated in median 3 days after hospital admission. At beginning of the treatment 41/42 (98%) of patients were in the ICU; 8/42 (19%) needed mechanical ventilation, 3/42 (7%) were on additional ECMO support; 27/42 (64%) needed pressors. Seraph® 100 treatment significantly reduced d-dimer comparing pre-treatment data with data obtained 2-4 hours after treatment. Four days after treatment hemoglobin, LDH, D-dimer, troponin and ferritin were significant reduced. From the interleukin assay IL-1b, IL-8, IL-10, IL-13, IL-15, Eotaxin, G-CSF and IP-10 were significantly reduced 2-4 hours after treatment, but not 4 days later. The median hospital stay was 20 days. After 3 months 20/42 (48%) of patients had died.

**Conclusions:** In conclusion, our data show that Seraph® 100 leads to a significant reduction of biomarkers that are either predictive of adverse outcome or the severity COVID-19.

## FR-PO002

**Hemoperfusion With Seraph-100 Is Not Associated With Improved Survival in Severe COVID-19 Patients**

Maria Martinez, Paula Ardura, Mercedes Artola, Arturo Lorenzo, Arinson Vasquez, Amanda Francisco, Maria Isabel Acosta-Ochoa, Maria Bustamante, Pablo Gonzalez, Elena Bustamante, Armando Coca. *Hospital Clinico Universitario de Valladolid, Valladolid, Spain.*

**Background:** Seraph-100 Blood Filter (ExThera Medical) is a hemoperfusion device designed to treat bloodstream infections. Its membrane binds pathogens, reducing bacterial and viral blood titers. The device received an authorization for emergency use in critically-ill COVID-19 patients by the FDA. We summarize the efficacy and safety profile of the device in a sample of COVID-19 ICU patients.

**Methods:** 25 consecutive COVID-19 patients admitted in the ICU between Nov 2021 and Feb 2022 were retrospectively reviewed. 11 patients received a single treatment with Seraph-100 plus standard care. Subjects in the control group received standard care only.

**Results:** We found no differences between groups regarding age, sex or comorbidities. Treatment with Seraph was well tolerated and was associated with no modifications of leukocyte count or CRP levels. No differences regarding in-hospital mortality (LR=0.37;P=0.54) or length of ICU stay were observed. Patients treated with Seraph suffered Gram-positive associated pneumonia less frequently.

**Conclusions:** Seraph hemoperfusion was not associated with better results in our sample. This may be due to small sample size and high heterogeneity present in parameters such as disease severity, other complications, length of ICU stay or hemoperfusion dosage. To improve results it is necessary to better define the most appropriate timing and dosage for each case.

	Treated with Seraph	Control Group	P value

## FR-PO003

**Persistently Elevated Urinary Levels of Serpin A3 Appear to Predict Kidney Recovery and Survival in Critically Ill COVID-19 Patients Who Required KRT**

Noemi Del Toro-Cisneros, Miguel A. Martinez-Rojas, Isaac González Soria, Juan Antonio Ortega-Trejo, Norma Bobadilla, Olyinka Vega. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

**Background:** Numerous studies have suggested a possible role for acute kidney injury (AKI) biomarkers in predicting renal recovery after kidney replacement therapy (KRT) with poor performance. In this study, we investigated urinary SerpinA3 (USerA3) as a biomarker to predict renal recovery (RR) after AKI in critically ill COVID-19 patients with invasive mechanical ventilation (IMV).

**Methods:** Prospective cohort study of patients with critical COVID-19 in ICU with IMV and who required KRT, admitted to our Institute in Mexico City (Mar 2020 - Feb 2022). Patients with CKD stages 4 or 5 and kidney transplant were excluded. SerpinA3, KIM-1, NGAL and HSP-72 were measured in urine on day 0 (start of KRT) and days 1, 3, 7 and 14. We performed log10 transformation only for urinary USerA3 and, subsequently performed repeated sample ANOVA for each one of the biomarkers.

**Results:** Sixty patients were included. 52% died before discharge, 38% had complete RR after 90 days and 10% partial RR. Characteristics at baseline for KRT are shown in Table 1. No differences or trends were found in KIM-1 (p=0.380), NGAL (p=0.956), or HSP-72 (p=0.899). In Figure 1 appears USerA3 behavior along the study, showing a clear tendency to be different among the groups. We can observe that the patients who died presented lower amount of USerA3 compared to those who survived. On the other hand, patients with partial RR exhibited USerA3 excretion with a tendency to be lower than those with complete RR, especially in measurements 4 and 5 (day 7 and day 14, respectively).

**Conclusions:** In this study, we observed that USerA3 seems to be a predictor of RR and survival, which probably reflects a greater renal functional reserve.

Table 1. Clinical characteristics of the patients included in this study.

Characteristic	Dead (n=31)	Complete recovery (CR) (n=23)	Partial recovery (PR) (n=6)	p-value
Age (mean $\pm$ SD), years	56 $\pm$ 12	52 $\pm$ 13	47 $\pm$ 10	0.187

Figure 1. Marginal means of urinary Serpin A3

## FR-PO004

## Validation of a Modified Renal Angina Index (RAI) in Critically Ill Patients With COVID-19

Noemi Del Toro-Cisneros, Nathan Berman, Adela U. Pérez, John Hernandez Flores, Adrián Esteban Caballero-Islas, Ricardo Correa-Rotter, Olynka Vega. Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.

**Background:** The renal angina index (RAI) is a tool validated in multiple studies in pediatric and adult populations, to predict the development of severe AKI. The aim of this study was to evaluate the efficacy of the RAI in predicting severe AKI in critically ill patients with COVID-19 and to validate a modified model.

**Methods:** Prospective cohort analysis of all COVID-19 patients with invasive mechanical ventilation (IMV), admitted to the intensive care unit (ICU) of our Institute in Mexico City from 03/2020 to 01/2022. AKI was defined according to KDIGO guidelines. Patients with CKD stages 4 or 5 or AKI on admission were excluded. RAI was calculated using the method of Matsuura *et al* (Figure 1). Outcome was defined as the development of severe AKI (stage 2 or 3) at 24 and 72 hours after ICU admission. Since all patients had 5 points corresponding to IMV, we performed a logistic regression analysis to look other factors associated with the severe AKI and with them development a modified RAI (mRAI) and compared the efficacy of both scores.

**Results:** Of the 452 patients, 30% developed severe AKI. Fig 1 shows the performance of the RAI to predict the development of severe AKI, with an AUC of 0.67 at 24 h and AUC of 0.73 at 72 h. In a multivariate analysis, adjusted for age and sex, we obtained BMI  $\geq 30$  kg/m<sup>2</sup>, SOFA  $\geq 6$ , and Charlson Index as risk factors for development of the outcome (Table 1). In the new proposed score (mRAI), the conditions were summed and multiplied by the Cr delta (Figure 1).

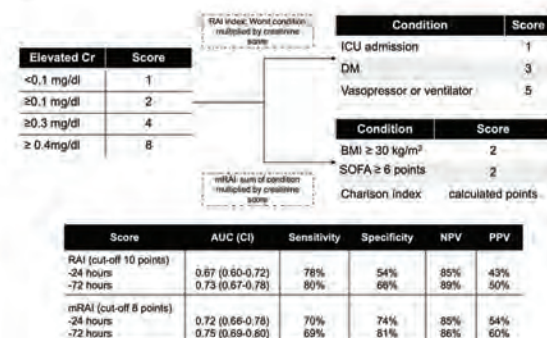

**Conclusions:** The original RAI in patients with critical COVID-19 with IMV is a limited tool. The modified score (mRAI) adds predictive performance and improves risk stratification in critically ill patients with IMV.

Table 1. Logistic regression analysis for severe AKI development.

	OR crude			OR Adjusted

## FR-PO005

## Prophylaxis for Vulnerable Patients at Risk of COVID-19 Infection (PROTECT-V): A Platform Trial Experience

Rona M. Smith,<sup>1,2</sup> Wendi Qian,<sup>2</sup> Davinder P. Dosanjh,<sup>3</sup> Francis Dowling,<sup>2</sup> Katrina L. Gatley,<sup>2</sup> Zehra Yilmaz,<sup>2</sup> Vivekanand Jha,<sup>4</sup> Toby J. Humphrey.<sup>2</sup>  
<sup>1</sup>University of Cambridge, Cambridge, United Kingdom; <sup>2</sup>Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; <sup>3</sup>Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; <sup>4</sup>The George Institute for Global Health, New Delhi, India.

**Background:** Despite the introduction of vaccination, there remains a need for pre-exposure prophylactic agents against SARS CoV-2. Several patient groups are more vulnerable to COVID-19 infection by virtue of underlying health conditions, treatments received or suboptimal responses to vaccination.

**Methods:** PROTECT-V is a platform trial testing pre-exposure prophylactic interventions against SARS CoV-2 infection in vulnerable patient populations (organ transplant recipients; individuals with oncological/haematological diagnoses, immune deficiency, or autoimmune diseases requiring immunosuppression or on dialysis). Multiple agents can be evaluated across multiple vulnerable populations sharing placebo groups, with the option of adding additional treatments at later time points as these become available. The primary endpoint is symptomatic COVID-19 infection, and each agent will be independently evaluated in real time when the required number of events occur.

**Results:** The trial commenced with the first intervention, intranasal niclosamide (UNI911) and matched placebo (1:1 ratio) in February 2021. As of 14<sup>th</sup> May, 1175 patients from 36 UK sites and 6 Indian sites had been enrolled. A second inhaled intervention, ciclesonide with matched placebo, will be added to the platform in the UK imminently. In parallel to the repurposed drug arms, a monoclonal antibody arm, sotrovimab, will enrol vaccine non-responders in a 1:1 ratio, active: placebo in the UK.

**Conclusions:** The PROTECT-V trial platform brings greater efficiency, running multiple sub-trials within one master protocol. It is an exemplar trial demonstrating the success of collaboration in the COVID-19 pandemic. The platform is jointly funded from charitable (LifeArc, Kidney Research UK, Addenbrooke's Charitable Trust), government (NIHR), and industry (Union Therapeutics (Hellerup, Denmark) for the niclosamide arm; Vir/GSK for the sotrovimab arm) sources and focuses on patient populations often excluded from clinical trials due to complex disease, but remain vulnerable to infection despite the success of vaccination. The trial is sponsored by Cambridge University Hospitals NHS Foundation Trust and University of Cambridge in the UK, and The George Institute for Global Health in India. Clinicaltrials.gov: NCT04870333; EudraCT: 2020-004144-28.

**Funding:** Commercial Support - Vir/GSK; Union Therapeutics, Private Foundation Support

## FR-PO006

## TNFR-1, TNFR-2, and KIM-1 Plasma Concentrations After COVID-19 and Association With Kidney Function

Lili Chan,<sup>1</sup> Nanditha Anandakrishnan,<sup>1</sup> Aparna Saha,<sup>1</sup> Stefanie Defronzo,<sup>1</sup> Gohar Mosoyan,<sup>1</sup> Kristin Meliambro,<sup>1</sup> Juan Wisnivesky,<sup>1</sup> Girish N. Nadkarni,<sup>1</sup> Sharon Stapleton,<sup>2</sup> Fergus Fleming,<sup>2</sup> Steven G. Coca,<sup>1,2</sup> Evren U. Azeloglu,<sup>1</sup> <sup>1</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>2</sup>Renalytix, New York, NY.

**Background:** Biomarkers TNFR1, TNFR2, and KIM1 are associated with progression of kidney disease. These biomarkers have not been evaluated in patients who have recovered from COVID-19.

**Methods:** Patients who had COVID-19 and recovered were followed longitudinally at an outpatient clinic with labs and surveys as part of the Mount Sinai Post-COVID clinic. Blood was sent for creatinine at baseline and 6 month follow up visit. We measured plasma TNFR1, TNFR2, and KIM-1 from the first post-COVID visit via Renalytix' proprietary multiplex assay. eGFR was calculated using the 2021 CKD-EPI formula.

**Results:** 450 COVID survivors had serum creatinine values measured at baseline (222±89 days post-COVID) and 6 month (419±97 days post-COVID) follow up. The average age of patients was 50±14 years, 62% were female, 60% were white, and 17% were Black. 23% were hospitalized, 4% required ICU admission, and 2% of patients reported AKI. eGFR at the baseline visit was 94±21 and at 6-months was 96±22 ml/min/1.73m<sup>2</sup>. At the baseline visit, KIM-1, TNFR-1, and TNFR-2 levels were highest in patients who were hospitalized and had AKI (Figure 1a) and concentrations of all three were associated with lower eGFR 6 months later (Figure 1b).

**Conclusions:** Severity of illness during COVID is associated with higher levels of plasma TNFR1, TNFR2, and KIM1 several months after recovery. The degree of biomarker elevation post-COVID was associated with lower kidney function more than 1 year post-COVID.

**Funding:** Commercial Support - Renalytix

Figure 1A: Violin Plot of KIM-1, TNFR-1, and TNFR-2 stratified by hospitalization and AKI.

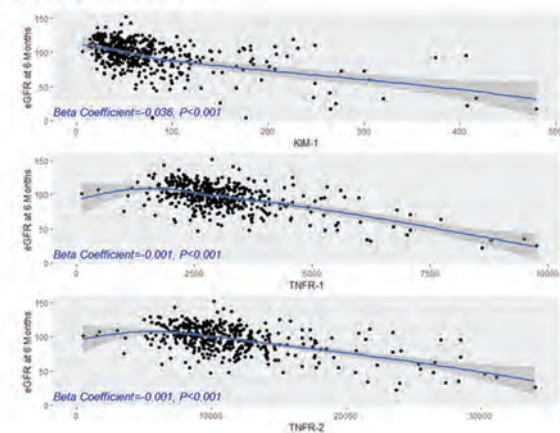

Figure 1B: Scatter plot with regression line of KIM-1, TNFR-1, and TNFR-2 and eGFR at 6 months.

## FR-PO007

## SARS-CoV-2 S Protein Is a Competitive Inhibitor of Furin Mediated ENaC Activation

German R. Magaña,<sup>1,2</sup> Kevin Garcia Avila,<sup>3,2</sup> Hector Carbajal-Contreras,<sup>1,2</sup> Consuelo Plata,<sup>2</sup> Erika Moreno,<sup>1</sup> Norma H. Vázquez,<sup>1</sup> Gerardo Gamba,<sup>1,2</sup> Maria Castañeda-Bueno,<sup>1,2</sup> Unidad de Fisiología Molecular <sup>1</sup>Universidad Nacional Autónoma de México, Ciudad de México, México; <sup>2</sup>Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubiran, Ciudad de México, México; <sup>3</sup>Instituto Tecnológico y de Estudios Superiores de Monterrey, Ciudad de México, México.

**Background:** Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is the causative agent of COVID-19 (Coronavirus disease 19). SARS-CoV-2 causes a multisystemic infection, which frequently presents with pulmonary oedema, endothelial damage and electrolytic abnormalities. An essential physiopathological feature of SARS-CoV-2 involves cleavage of its S protein by furin or furin-like enzymes. It has been shown by sequence-based evidence that the S protein polybasic aminoacid sequence is identical to the consensus sequence for furin cleavage present in the human alpha subunit of the epithelial sodium channel (ENaC). Furin and furin-like enzymes are also involved in the posttranslational regulation of ENaC in many tissues, including the lung, endothelium, and the kidney, where cleavage is associated with increased activity of the channel. ENaC is involved in the regulation of fluid clearance, Na<sup>+</sup>, K<sup>+</sup> and acid-base homeostasis, and endothelial function. Thus, we hypothesized that the S protein competes with ENaC for furin-mediated cleavage and activation.

**Methods:** We injected synthetic mRNA encoding WT S protein and mutant S protein lacking the furin consensus sequence (Δ-Spike) into *X. laevis* oocytes with αβγ-ENaC subunits. We then performed whole-cell voltage-clamp experiments and protein analysis by western blot.

**Results:** We observed an interdependent competitive effect on the cleavage of both the S protein and ENaC when co-expressed, which was partially prevented with the injection of Δ-Spike. We also found a decrease in the amiloride-sensitive sodium current in oocytes injected with the WT S protein but not with Δ-Spike. This suggests diminished function of ENaC in the presence of WT S protein that depends on its furin cleavage site.

**Conclusions:** These findings show evidence of a competitive interaction between the S protein and ENaC for furin-like enzymes. This suggests that SARS-CoV-2 infection may impair ENaC activity in human epithelia, which gives a plausible explanation to pulmonary oedema, endothelial damage, and electrolyte disturbances in patients with COVID-19.

## Use of Non-Approved and Approved Treatments for COVID-19 by CKD Status in Medicare

Nicholas S. Roetker,<sup>1</sup> Wendy L. St. Peter,<sup>3,1</sup> Madison Hoover,<sup>1</sup> James B. Wetmore,<sup>1,2</sup> Kirsten L. Johansen,<sup>1,2</sup> <sup>1</sup>Hennepin Healthcare Research Institute, Minneapolis, MN; <sup>2</sup>Hennepin Healthcare, Minneapolis, MN; <sup>3</sup>University of Minnesota Twin Cities, Minneapolis, MN.

**Background:** Hydroxychloroquine, chloroquine, and ivermectin gained popularity for treatment of COVID-19 in 2020. Remdesivir was approved for treating hospitalized COVID-19 in late 2020. We studied the uptake of these drugs early in the pandemic in a 5% sample of Medicare fee-for-service beneficiaries with and without CKD.

**Methods:** We examined the percentage of beneficiaries receiving ≥1 Part D covered prescription for hydroxychloroquine or chloroquine and ivermectin in each month of 2020. Among first COVID-19 hospitalizations from November 2020-June 2021, we examined the percentage receiving remdesivir using ICD-10-PCS. Analyses included those aged ≥66 years without ESRD; CKD was defined by ≥1 inpatient or ≥2 outpatient diagnoses.

**Results:** Use of hydroxychloroquine and chloroquine increased in March 2020 and then subsided in the ensuing months, remaining slightly elevated through 2020 (Figure A). Receipt of these drugs was higher in patients with CKD than in those without. Ivermectin use was uncommon in both groups before spiking in December 2020 (Figure B). Among COVID-19 inpatients, 55% without CKD and 44% with CKD received remdesivir, which was used more often in men than in women, less often in Blacks than in Whites or Hispanics, and less often in those with the low-income subsidy than in those without.

**Conclusions:** In 2020, Medicare beneficiaries with and without CKD showed similar spiking patterns in use of the approval-revoked or non-approved drugs hydroxychloroquine/chloroquine (in March) and ivermectin (in December). Through June 2021, remdesivir was used less in patients with CKD than in those without for hospitalized COVID-19, likely because the FDA recommends not using remdesivir if eGFR is <30 mL/min. Lower income and Black patients were less likely to receive remdesivir than others.

**Funding:** NIDDK Support

### A. Percentage of Medicare beneficiaries receiving Part D covered hydroxychloroquine or chloroquine, by month, 2020

### B. Percentage receiving Part D covered ivermectin among Medicare beneficiaries, by month, 2020

### FR-PO009

#### SARS-CoV-2 Saliva Testing to Determine Viral Shedding Duration in Hemodialysis Patients

Ohnmar Thwin,<sup>1</sup> Xiaoling Wang,<sup>1</sup> Zijun Dong,<sup>1</sup> Lela Tisdale,<sup>1</sup> Zahin S. Haq,<sup>1</sup> Sarah Ren,<sup>1</sup> Lemuel Rivera Fuentes,<sup>1</sup> Nadja Grobe,<sup>1</sup> Peter Kotanko.<sup>1,2</sup> <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Hemodialysis (HD) patients are vulnerable to COVID-19. Early detection of COVID-19 in dialysis clinics informs isolation and infection control policies. Saliva testing is an alternative to nasopharyngeal swab to detect SARS-CoV-2. The understanding of viral shedding in HD patients is limited. We explore viral shedding duration in HD patients and determine its correlation with immunosuppression.

**Methods:** Eligible patients diagnosed with COVID-19, confirmed by nasal swab RT-PCR within 2 weeks of COVID-19 diagnosis, were recruited. They were given Salivette Saliva Collection kits and instructed to chew a cotton swab for 60 seconds.

**Results:** 30 COVID-19 positive patients participated (Table 1). Each patient provided up to 7 saliva samples. 65 samples were collected for an average of 11±8 days (range 0-36) after diagnosis. 26 samples showed at least one COVID-19 target gene (N, ORF1ab) with cycle threshold <38 cycles. 12 patients had at least 1 positive sample, and 23 patients had at least 1 negative sample. Of the 23 patients who had at least one negative sample, median days to first negative sample is 9 days (range 0-36). For the 7 patients who only had positive samples, median days to last positive sample is 9 days (range 0-36). There is no observed difference between vaccinated (n=24) and vaccinated patients (n=6). 6 out of 30 patients took immunosuppressants such as Tacrolimus, Hydroxychloroquine, and Mycophenolate sodium. Median days to turn negative (or use last positive date if negative results never achieved) was 15 days for immunocompromised group and 8 days for non-immunocompromised group (Fig.1)

**Conclusions:** Immunocompromised HD patients shed COVID-19 virus for a significantly longer period. While our study did not explore the shedding of viable SARS-CoV-2, a longer isolation should be considered in immunosuppressed HD patients. Studies on shedding of viable SARS-CoV-2 are warranted in immunocompromised HD patients to inform policies regarding isolation and contact tracing protocols, and vaccination strategies.

Table 1. Demographic characteristics of COVID-19 patients

	Total	HD patients	Immunocompromised patients
	(n=103)	(n=24)	(n=6)
Age			
Mean (SD)	60 (8.14)	63 (11.2)	69.5 (18.7)
Gender			
Female	33 (38.7%)	9 (37.5%)	2 (33.3%)
Male	70 (61.3%)	15 (62.5%)	4 (66.7%)
Comorbidities			
Hypertension	9 (20.0%)	4 (25.0%)	0 (0%)
Heart disease	24 (50.0%)	18 (75.0%)	6 (100%)
Medication status			
Yes	5 (16.7%)	5 (20.8%)	0 (0%)
No	25 (83.3%)	19 (79.2%)	6 (100%)
Race			
White	23 (77.4%)	17 (70.8%)	5 (83.3%)
Non-White	8 (22.6%)	7 (29.2%)	1 (16.7%)

Fig 1. Median times between immunocompromised and non-immunocompromised HD patients (n=6) had a median time of 15 days. Non-immunocompromised HD patients had a median time of 8 days (n=24).

### FR-PO010

#### Treatment of AKI With Continuous Renal Replacement Therapy and CytoSorb in Critically Ill Hospitalised Patients With COVID-19

Robert Ekar,<sup>1,2</sup> Eva Jakopin,<sup>1</sup> Masa Knehtl,<sup>1</sup> Nina Vodošek Hojs,<sup>1</sup> Nejc Piko,<sup>1</sup> Sebastjan Bevc,<sup>1,2</sup> Radovan Hojs.<sup>1,2</sup> <sup>1</sup>Univerzitetni Klinični Center Maribor, Maribor, Slovenia; <sup>2</sup>Univerza v Mariboru, Maribor, Slovenia.

**Background:** AKI is common in critically ill patients with COVID-19. The aim of this study was to evaluate the 30- and 60-day survival of patients with COVID-19 and AKI, treated in the ICU. We analysed two groups of patients: patients in the first group were treated with CRRT only, and patients in the second group were treated with CRRT plus hemoadsorption with Cytosorb cartridge.

**Methods:** This is a retrospective study of patients admitted with COVID-19 between March, 2020 and April, 2022 in all COVID ICUs of our hospital. Inflammatory and biochemical biomarkers at admission, length of ICU stay, and mortality at day 30 and day 60 after ICU admission were analysed.

**Results:** One hundred two patients (mean age 68.1±8.1 years, 74.5% male) had AKI requiring CRRT, and 44 (43.1%) out of these patients were treated concomitantly with CRRT and Cytosorb. Of the prior concomitant diseases, 39 (38.2%) patients had diabetes, 75 (73.5%) had hypertension, 22 (21.6%) had heart failure, and 26 (25.5%) had chronic kidney disease. Patients treated with CRRT and Cytosorb were younger (64.7 vs. 70.6 years; p<0.001), had lower serum creatinine levels (294 vs. 405 μmol/L; p<0.001), urea levels (29 vs. 48 mmol/L; p<0.001), higher levels of IL-6 (1754 vs. 385 pg/mL; p<0.001) and lactate dehydrogenase (8.8 vs. 7.1; p=0.038). We found no statistically significant difference between the two groups for serum lactate, ferritin, D-dimer, C-reactive protein, and procalcitonin. Onset of treatment was earlier in patients treated with CRRT and Cytosorb than in patients treated with CRRT alone (11.4 vs. 18.2 days; p=0.005). Mean length of stay in ICU was 27.4±20.2 days, with no differences between the two groups. Mortality 30 and 60 days after ICU admission was in all patients 58.8% and 76.5%. In patients treated with CRRT alone, mortality at 30 and 60 days was 65.5% and 84.5%, and in patients treated with CRRT and Cytosorb, 50% and 65.9%. The number of patients who died 60 days after ICU admission was statistically significantly higher in the group of patients treated with CRRT alone (χ<sup>2</sup>, p=0.029). The most common causes of death were sepsis and multiple organ failure (55.1%), acute respiratory failure (24.4%), and cardiac arrest (19.2%).

**Conclusions:** CRRT and CytoSorb cartridge treatment results in improved 60-day survival in COVID-19 ICU patients with AKI.

### FR-PO011

#### Antiviral Effects of Voclosporin on SARS-CoV-2 in Immunocompromised Kidney Patients

Eline J. Arends, Soufian Meziyerh, Dirk Jan Moes, Sylvia Kamerling, Sandra W. Van der kooij, Natacha S. Ogando, Eric J. Snijder, Martijn J. Van Hemert, Leo G. Visser, Mariet Feltkamp, Ton J. Rabelink, Cees van Kooten, Aiko P. De Vries, Yoe Kie Onno Teng, on behalf of all the VOCOVID investigators *Leids Universitair Medisch Centrum, Leiden, Netherlands.*

**Background:** Immunocompromised patients, including Kidney Transplant Recipients (KTRs) and lupus nephritis (LN) patients, are at increased risk for prolonged SARS-CoV-2 infection and developing COVID-19-related complications. Recently, we reported that voclosporin, a novel calcineurin inhibitor (CNI), demonstrated in vitro a more potent inhibitory effect on SARS-CoV-2 replication than other CNIs (tacrolimus and ciclosporin). Additionally the AURORA-2 study, where 216 LN patients were treated with voclosporin or placebo on top of standard of care, SARS-CoV-2 infection was detected in 12/100 placebo-treated patients (12%) compared to 7/116 voclosporin treated patients (6%) and more patients died due to COVID-19 in the placebo arm versus voclosporin arm (3% vs 0%). In this proof-of-concept study we assessed whether voclosporin demonstrated an added antiviral benefit in SARS-CoV-2 positive immunocompromised patients.

**Methods:** We performed a prospective, randomised, open-label, single-center, exploratory, proof of concept study in 20 KTRs with mild to moderate symptoms from a COVID-19 infection comparing time to viral clearance of SARS-CoV-2 between patients on standard immunosuppressive therapy with tacrolimus versus voclosporin (the VOCOVID study).

**Results:** In the VOCOVID study no difference in time to viral clearance or time to clinical recovery was found between both treatment arms. Pharmacokinetic analysis demonstrated that adequate trough levels of voclosporin were reached from day 4-8 after randomization. Looking at specific timepoint in a post-hoc analysis, indeed a significantly better viral clearance of SARS-CoV-2 was observed in voclosporin treated patients at day 4-8. No safety concerns were raised.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** The present study provides evidence that voclosporin has a favorable benefit-risk profile for immunocompromised kidney disease patients who contract a SARS-CoV-2 infection while requiring the continuation of their immunosuppressants.

## FR-PO012

### Assessing Fluid Management and Its Association With AKI in COVID-19 Patients

Salman Bhutta, Rezwan F. Munshi, Joshua Fogel, Narois Nehru, James R. Pellegrini, Eric H. Lam, Sandra Gomez Paz, Sofia Rubinstein. Nassau University Medical Center, East Meadow, NY.

**Background:** Managing fluid balance in COVID-19 patients can be challenging, particularly if they develop acute kidney injury (AKI). We study the relationship between fluid net input and output (FNIO) in patients with confirmed COVID-19 infection with development of AKI, time to development of AKI, in-hospital length of stay (LOS), and in-hospital mortality.

**Methods:** This is a retrospective study of patients (n=403) with confirmed COVID-19. Data for FNIO was from day 1 through day 10 or until development of AKI were recorded, whichever occurred first. Available FNIO data was calculated as a mean due to information not available for all days. Covariates included demographics, comorbidities, treatment, and management variables.

**Results:** Mean age was 58.1 (SD=16.5) years. There were 39.5% female and 53.1% Hispanic. Mean FNIO average was 612.2 (SD=747.4) mL. For the outcome variables, AKI occurred in 22.8%, in-hospital mortality occurred in 26.3%, mean days to AKI were 7.7 (SD=6.3), and mean LOS was 11.4 (SD=13.2) days. In the multivariate logistic regression analyses, increased FNIO mean was significantly associated with slightly increased odds for mortality (OR=1.001, 95% CI: 1.00, 1.001, p=0.03) but was not significantly associated with AKI (p=0.82). In the multivariate linear regression analyses, increased FNIO mean was significantly associated with lesser days to AKI (B=-6.92\*10<sup>-5</sup>, SE=<0.001, p=0.002) while FNIO mean was not significantly associated with LOS (p=0.75).

**Conclusions:** Increased fluid balance was associated with AKI development and increased mortality. Physicians should exercise caution with administering fluid in patients with COVID-19 to prevent such adverse outcomes.

## FR-PO013

### Renal Injury and Inflammatory Response in New Onset IgA Nephropathy After Infection With SARS-CoV-2 or COVID-19 Vaccination

Naser Hussein, Eva Vonbrunn, Kerstin U. Amann, Christoph Daniel. Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany.

**Background:** After infection with SARS-CoV-2 or vaccination against COVID-19, some patients develop kidney diseases, including minimal change nephrotic syndrome and IgA Nephropathy (IgAN). Here we characterized renal injury and inflammatory response in biopsies from patients with new onset IgAN diagnosed promptly after COVID-19 disease or vaccination.

**Methods:** Eleven kidney biopsies from patients who developed IgAN after SARS-CoV-2 infection and 6 from patients with new onset IgAN after vaccination against COVID-19 were diagnosed at Dep. of Nephropathology, FAU Erlangen-Nuremberg. Biopsies from patients with IgAN who had no prior COVID-19 disease (n=10) and zero-time biopsies from transplants (ZB; n=6) served as controls. Serum creatinine was assessed and kidney injury by analysis of podocyte loss, detection of Pax-8 positive parietal epithelial cells on the glomerular tuft and IF/TA. Macrophages and granulocytes were detected by triple staining of CD68, CD163 and myeloperoxidase.

**Results:** Significant podocyte loss, as assessed by nephrin staining, was observed in all three IgAN groups compared to ZB, as well as Pax8-positive parietal epithelial cells on glomerular tuft. The serum creatinine, as a marker of kidney function, was on average 1.8-3.5-fold higher in the IgAN groups compared to ZB, but did not reach significance level due to small sample numbers. IF/TA was below 20% in most investigated biopsies. No significant differences in renal function or injury were observed between different IgAN groups. While CD68+CD163+MPO+, CD68+CD163-MPO+ and CD68+CD163-MPO- (M2c-like macrophages) inflammatory cells were significantly increased in both COVID-19 IgAN groups, significant increase of CD68-CD163+MPO- cells compared to ZB control was restricted to IgAN w/o COVID-19 group (11.7±8.1 vs 0.8±0.9 cells / mm<sup>2</sup>). CD68+CD163-MPO- M1-like macrophages and CD68-CD163-MPO+ neutrophils tended to be higher in all IgAN groups but failed to reach the level of significance.

**Conclusions:** Changes in kidney function and renal damage was comparable in all three investigated IgAN groups independent on experience of COVID-19 or vaccination. Renal macrophage and neutrophil invasion tended to be higher in COVID-19 IgAN groups. However, no significant differences in inflammatory were observed in direct comparisons of IgAN groups.

**Funding:** Other NIH Support - German research foundation (DFG)

## FR-PO014

### CKD Results in Differential Expression of SCARF Genes That Potentially Facilitate SARS-CoV-2 Cell Entry and/or Replication

Sol M. Carriazo,<sup>1,2</sup> Marta Ribagorda,<sup>2</sup> Aranzazu Pintor Chocano,<sup>2</sup> Alberto Ortiz,<sup>1,2</sup> Maria Dolores Sanchez-Nino,<sup>2</sup> <sup>1</sup>Hospital Universitario Fundacion Jimenez Diaz, Madrid, Spain; <sup>2</sup>Instituto de Investigacion Sanitaria de la Fundacion Jimenez Diaz, Madrid, Spain.

**Background:** Chronic Kidney disease (CKD) is the risk factor that most increases the risk of lethal COVID-19. However, the underlying molecular mechanisms are unclear. CKD patients have an increased risk of multiple infections due to CKD-associated non-specific immunodeficiency. Whether specific defects are related to the defense against SARS-CoV-2 is unknown. SARS-CoV-2 and coronavirus-associated receptors and factors (SCARFs) regulate coronavirus cell entry and/or replication. We hypothesized that CKD may alter the expression of SCARF genes.

**Methods:** A literature search identified 32 SCARF genes of which 21 were directly related to SARS-CoV-2 or SARS-CoV infection and assessed their expression in target tissues of COVID-19 (kidneys, lungs, aorta and heart) in experimental CKD in mice fed adenine and compared them with controls.

**Results:** Out of 21 SCARF genes, 19 (90%) were differentially expressed in at least one organ in CKD. 15 genes had a differential expression that would be expected to favor SARS-CoV-2 infection and/or severity in at least one organ. Of these, 13 were differentially expressed in the kidney. Only 2 genes reported to protect from SARS-CoV-2, Ifitm3 encoding interferon induced transmembrane protein 3 (IFITM3) and Ly6e encoding lymphocyte antigen 6 family member 6 (LY6E), were downregulated in at least two non-kidney target organs (lung and heart), potentially predisposing to more severe lung/cardiovascular involvement in COVID-19 (Fig). The largest change was observed for Ifitm3.

**Conclusions:** CKD is associated with the differential expression of multiple SCARF genes in target organs of COVID-19. The decreased expression of Ifitm3 and Ly6e in heart and/or lung may contribute to increase the severity of COVID-19 in CKD. These data may allow the development of interventions that decrease the risk of severe COVID-19 in CKD patients.

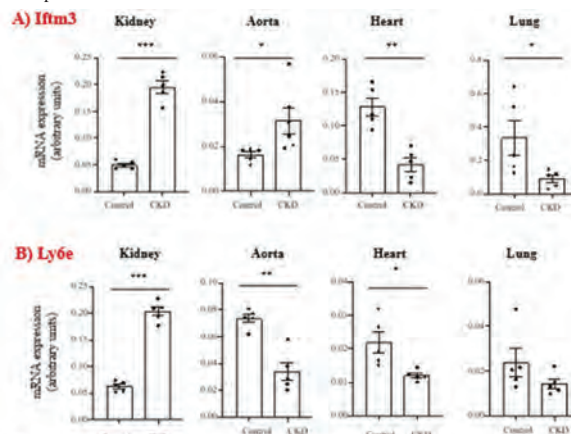

Figure 1. Differential gene expression of Ifitm3 and Ly6e in the kidney and in target organs of COVID-19 in experimental CKD.

## FR-PO015

### Neutralization of the Omicron Variant of SARS-CoV-2 Is Effective by a Human and a Mouse Soluble ACE2 Protein

Luise Hassler,<sup>1</sup> Vlad I. Nicolaescu,<sup>2</sup> Jan Wysocki,<sup>1</sup> Glenn Randall,<sup>2</sup> Daniel Batlle.<sup>1</sup> <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>The University of Chicago, Chicago, IL.

**Background:** We have previously reported that ACE2 618-DDC-ABD, a soluble ACE2 protein with extended duration of action and increased binding affinity for SARS-CoV-2, provides lung and kidney protection in a lethal mouse model of SARS-CoV-2 infection. Moreover, we showed that this protein also neutralizes the gamma and delta variant SARS-CoV-2 infection in Vero E6 cells. As omicron is most prevalent SARS-CoV-2 variant we tested whether ACE2 618-DDC-ABD can also neutralize this variant and hypothesized that it is more sensitive to mouse ACE2 as well as human ACE2.

**Methods:** The omicron BA.1 SARS-CoV-2 strain was incubated with various concentrations of ACE2 618-DDC-ABD (0-180ug/ml) for 1 hour at 37°C. Human ACE2 1-740 and mouse ACE2 1-740 were used as controls at the same concentrations. These mixtures were then used to infect Vero E6 cells. Cells were allowed to grow for 3-4 days until a noticeable cytopathic effect was observed in control wells (0ug/ml soluble ACE2 proteins). Cell numbers were assessed by staining cells with crystal violet and reading absorbance of each well at 595 nm. Values were then normalized to the 0ug/ml control and expressed as a percentage of the mock (no virus) control wells.

**Results:** ACE2 618-DDC-ABD (red) neutralized the omicron BA.1 variant at all concentrations tested and to a similar extent as native human soluble ACE2 1-740 (blue) used as control. Native mouse ACE2 1-740 (black) also neutralized infection completely at high concentrations while lower concentrations were less effective as compared to low concentrations of ACE2 618-DDC-ABD or human ACE2 1-740.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

miRNAs was followed by inhibition of ACE2 mRNA and protein levels and the effect was blocked by specific anti-miRNA oligonucleotides. The above results differed between the CF and non-CF cells.

**Conclusions:** miRNAs may be important effectors of TGF- $\beta$  modulating SARS-CoV-2 pathogenicity and replication in the CF airway. Ongoing studies focus on elucidating the mechanisms of SARS-CoV-2 invasion of kidney cells.

## FR-PO020

### Lack of Evidence for Kidney Invasion by SARS-CoV-2 in a Lethal Mouse Model

Mariya Syed,<sup>1</sup> Cosimo L. Cianfarini,<sup>1</sup> Luise Hassler,<sup>1</sup> Minghao Ye,<sup>1</sup> Jan Wysocki,<sup>1</sup> Yashpal S. Kanwar,<sup>1</sup> Dominique Missiakos,<sup>2</sup> Glenn Randall,<sup>2</sup> Daniel Battle.<sup>1</sup> <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>University of Chicago Department of Microbiology, Chicago, IL.

**Background:** There is an ongoing controversy as to whether SARS CoV-2 can infect the kidney parenchyma directly. To date, the presence of SARS CoV-2 in the kidney has been described mainly post-mortem in autopsy studies of patients who died of or with COVID-19, but this has not been examined in an experimental model where the timing of SARS-CoV-2 infection can be defined. We used transgenic mice expressing human ACE2 (k18hACE2) susceptible to lethal SARS-CoV-2 infection to study this issue directly on kidney tissue taken at defined time points and using lung tissue as positive control.

**Methods:** Transgenic k18hACE2 mice were inoculated with 3x10<sup>4</sup> PFU SARS-CoV-2 in a BSL-3 facility. Kidneys and lungs were removed from the animals sacrificed on days 5 to 7 and used for histology (PAS-staining), immunofluorescence (IF) of the S1 spike protein of SARS-CoV-2 and measurement of viral load by plaque assay. Kidney samples were additionally evaluated by IF using kidney injury markers NGAL and KIM-1.

**Results:** Kidney tissue stained using an anti-S1-spike antibody showed negative results in all samples (n=15). By plaque assay, viral titers were also not detectable in any of the kidneys. By contrast, lungs from infected mice showed strong staining for the S1 spike protein in 13 of 14 cases and this was associated with positive viral titers in all lung samples. Despite severe lung disease, only mild and variable kidney damage was observed by histopathology. Positive staining for NGAL in the proximal tubules was consistently seen, while KIM-1 staining was rarely positive.

**Conclusions:** In a transgenic mouse model with lethal SARS-CoV-2 infection and severe lung but mild kidney disease there is no evidence of S1 spike protein in the kidney, which is consistent with lack of detection of replicating virus by plaque assay.

**Funding:** Other NIH Support - 1R21 AI166940-01 (Grant Number), Private Foundation Support

## FR-PO021

### COVID-19-Associated AKI in Hospitalized Patients: Incidence, Risk Factors, and Outcomes in a Tertiary Care Center in Thailand

Suphanan Phisalwut, Narongrit Siriwananant, Pitchamon Inkong, Narittaya Varothai, Paramat Thimachai, Pamila Tasanavipap, Amnart Chairprasert, Naowanit Nata, Theerasak Tangwonglert, Wisit Kaewput, Oupphatham Supasindh, Bancha Satirapoj. *Phramongkutklao College of Medicine, Bangkok, Thailand.*

**Background:** Acute kidney injury (AKI) is a common complication of COVID-19 and related with severity and outcomes. However, relatively little is known about risk factors of AKI and outcomes among Thai hospitalized patients with COVID-19. The study described the incidence of different stages of AKI, risk factors and renal outcomes in hospitalized COVID-19-associated AKI patients.

**Methods:** The observational study involved a review of data from health records of COVID-19 pneumonia patients aged  $\geq 18$  years in the tertiary care center from June 1 to September 30, 2021. We describe the frequency of AKI, dialysis requirement, and adjusted hazard ratios (adjusted HR) with AKI.

**Results:** A total of 966 hospitalized COVID-19 pneumonia patients, AKI occurred in 170 (17.5%) and AKI stage 1, 2 and 3 was 45.2% (N=77), 25.2% (N=43) and 29.4% (n=50). 23 patients (13% of AKI) required dialysis. The independent risk factors for AKI were pre-existing CKD (aHR 1.74, 95%CI 1.03-2.93), cardiovascular disease (aHR 2.42, 95%CI 1.38-4.24), serum ferritin (aHR 1.001, 95%CI 1.001-1.002), history of diuretic use (aHR 2.68, 95%CI 1.08-6.64), respiratory support (aHR 3.33, 95%CI 1.65-6.73), and presence of septic shock (aHR 3.23, 95%CI 1.59-6.56). 44.7% had non renal recovery. In-hospital mortality in AKI patients was 54.1%. An adjustment for demographics, and laboratory values, the aOR for death was 2 (95%CI, 1.01-4.05)

**Conclusions:** AKI is common among patients hospitalized with COVID-19 and is associated with non-renal recovery and death. The predisposing factors are pre-existing CKD, cardiovascular disease, history of diuretic use and more severe COVID-19 presentation.

## FR-PO022

### Role of the Complement System and Vascular Endothelium in COVID-19 Pathogenesis

Niyousha Rostam Shirazi,<sup>1</sup> Christoph Licht.<sup>2</sup> <sup>1</sup>University of Toronto, Toronto, ON, Canada; <sup>2</sup>The Hospital for Sick Children, Toronto, ON, Canada.

**Background:** Coronavirus Disease 2019 (COVID-19) caused by SARS-CoV-2 infection has become a global pandemic, presenting with varying degrees of severity from respiratory distress to multi-organ damage. Kidneys are of several organs affected in COVID-19, with acute kidney injury (AKI) being a common consequence, occurring in more than 30% of patients with severe COVID-19. While the underlying mechanisms of COVID-19 pathogenesis remain poorly understood, there is evidence linking complement system overactivation and endothelial injury to organ damage that increases the risk of mortality in COVID-19. Evidence from previous coronavirus epidemics also suggest direct involvement of inflammation, complement dysregulation, and endothelial cell dysfunction. Thus, we hypothesize that vascular endothelial injury resulting from complement overactivation contributes to COVID-19-associated organ injury.

**Methods:** Clinical information and sera from SARS-CoV-2+ patients with mild (n=7) and severe COVID-19 (n=7) diseases were obtained from the Canadian COVID-19 Prospective Cohort Study (CANCOV). Complement activation on ECs was evaluated via immunofluorescence assays, measuring the deposition of complement products C3b and C5b-9 on Human Umbilical Vein Endothelial Cells exposed to control or patient sera. In addition, a permeability assay using a transwell model was used to measure the integrity of the endothelial monolayer exposed to patient sera.

**Results:** Complement was found to be overactivated on ECs treated with SARS-CoV-2+ patient sera compared to those treated with normal human serum as evidenced by significantly increased C3b and C5b-9 deposition. While ECs treated with sera from patients with mild COVID-19 seemed to have higher C3b deposition, ECs treated with sera from patients with severe COVID-19 disease were associated with higher C5b-9 deposition. In addition, increased permeability of the monolayer incubated with SARS-CoV-2+ patient sera was seen over time regardless of disease severity. However, ECs treated with severe COVID-19 patient sera had significantly increased vascular leakiness as evidenced by increased permeability of the treated monolayer.

**Conclusions:** Thus, we conclude that complement is overactivated in SARS-CoV-2+ patients and use of anti-complement therapies may be an effective strategy in treating COVID-19 associated vascular injury, hyperinflammation, and organ damage.

## FR-PO023

### Role of Urinary IL-6 (uIL-6) and Mechanical Ventilation (MV) Parameters in the Development of AKI in Severely Ill Patients With SARS-CoV-2

David Escamilla-Illescas,<sup>1</sup> Gustavo A. Casas-Aparicio.<sup>2</sup> <sup>1</sup>Medica Sur, Ciudad de Mexico, Mexico; <sup>2</sup>Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico.

**Background:** MV Parameters and biomarkers have been associated with the development of AKI in patients with ARDS due to SARS-COV-2. The objective was to analyze these factors in patients who required early MV (<6 hours from hospital admission).

**Methods:** Single center, prospectively study, conducted at the National Institute of Respiratory Diseases (INER) in Mexico City. We included patients with Pneumonia caused by SARS-COV-2 confirmed by rPCR who require early MV in September 2021. We recorded MV parameters and took a urine sample for measurement of IL-6 by ELISA immediately after the start of MV. Clinical and laboratories data was gathered from medical file. Patients were followed up during hospitalization to analyze outcomes. We define AKI according to KDIGO criteria using only serum creatinine. We used chi-squared and Mann Whitney-U test as appropriate, to compare variables between patients who developed AKI and those who did not. We calculated the area under the curve (AUC) for IL-6 and established a sensibility and specificity balanced cut-off point. We performed a multivariate logistic regression.

**Results:** We included 45 patients with a median age of 57 years-old, 66.7% were men. Plateau Pressure (PP), Peak Inspiratory Pressure (PIP), Driving Pressure (DP) and Static Compliance (SC) as well as uIL-6 were higher in the group with AKI. The AUC for uIL-6 was 0.819 (95% CI: 0.687-0.951;  $p < 0.001$ ), the cutoff with the best accuracy was 1.5 pg/mL. The results of univariate and multivariate logistic regression are shown in table 1.

**Conclusions:** Higher levels of uIL-6 and PP in patients who require early MV were associated to development of AKI during hospitalization. Pulmonary inflammation and stiffness may play a role in the development of AKI.

**Funding:** Government Support - Non-U.S.

Univariate and multivariate analysis for AKI

Variables	Unadjusted OR (95% CI)	p	Adjusted OR (95% CI)	p
Age	1.02 (0.99-1.06)	0.16	1.03 (0.97-1.09)	0.25
Male	1.31 (0.43-5.31)	0.52	5.68 (0.57-56.10)	0.13
u-IL-6 $\geq 1.5$ pg/mL	7.27 (1.69-31.25)	0.01	9.33 (1.04-83.46)	0.04
Plateau Pressure	1.23 (1.04-1.45)	0.01	3.04 (1.004-9.2)	0.04
Driving Pressure	1.21 (1.03-1.43)	0.02	0.92 (0.55-1.53)	0.75
Static Compliance	0.93 (0.87-1.00)	0.049	0.95 (0.76-1.19)	0.95
Peak Inspiratory Pressure	1.16 (1.02-1.33)	0.01	0.50 (0.22-1.11)	0.09

## Angiotensin-Converting Enzyme 2 and Urine Amino Acid Excretion Increase in COVID-19 Patients With AKI

Ander Vergara,<sup>1</sup> Kaiming Wang,<sup>1</sup> Daniele Colombo,<sup>4</sup> Mahmoud Gheblawi,<sup>1</sup> Jaslyn C. Rasmuson,<sup>1</sup> Rupasri Mandal,<sup>1</sup> Franca Del Nonno,<sup>4</sup> Brian Chiu,<sup>1</sup> James W. Scholey,<sup>3</sup> Maria Jose Soler,<sup>2</sup> David S. Wishart,<sup>1</sup> Gavin Oudit.<sup>1</sup>  
<sup>1</sup>University of Alberta, Edmonton, AB, Canada; <sup>2</sup>Hospital Universitari Vall d'Hebron, Barcelona, Spain; <sup>3</sup>University Health Network, Toronto, ON, Canada; <sup>4</sup>INMI Lazzaro Spallanzani IRCCS, Roma, Italy.

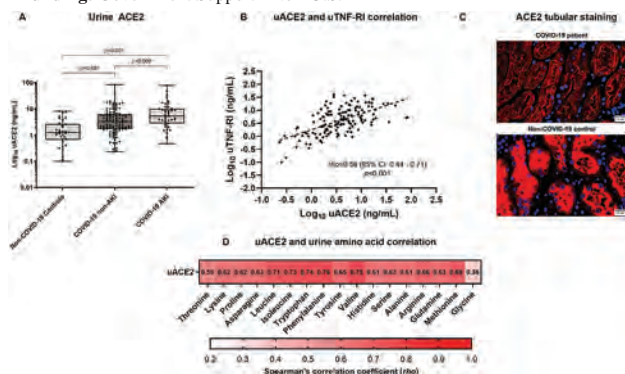

**Background:** Angiotensin-converting enzyme 2 (ACE2), the receptor for SARS-CoV-2, is highly expressed in the kidneys. ACE2 also possess a unique function to facilitate amino acid absorption. A persistent elevation in plasma ACE2 during COVID-19 is related to increased mortality. The present study sought to explore the relationship between urine ACE2 (uACE2) and renal outcomes in COVID-19 patients.

**Methods:** In 104 COVID-19 patients without acute kidney injury (AKI), 43 patients with COVID-19-mediated AKI, and 36 non-COVID-19 controls, uACE2, urine tumor necrosis factor receptors I and II (uTNF-RI and uTNF-RII), neutrophil gelatinase-associated lipocalin (uNGAL), and urine albumin-creatinine ratio were measured. We also assessed ACE2 staining in autopsy kidney samples and generated a propensity-score matched subgroup to perform a targeted urine metabolomic study to describe the characteristic urine signature of COVID-19.

**Results:** uACE2 was increased in patients with COVID-19, and further increased in those that developed AKI (Figure 1). After adjusting uACE2 levels for age, sex and previous comorbidities, increased uACE2 was independently associated with over 3-fold higher risk (OR 3.05, 95% CI: 1.23-7.58,  $p=0.017$ ) of developing AKI. Increased uACE2 corresponded to a tubular loss of ACE2 in kidney sections and strongly correlated with uTNF-RI and uTNF-RII, suggesting that ADAM17 could be responsible for ACE2 shedding. Urine quantitative metabolome analysis revealed an increased excretion of essential amino acids in COVID-19 patients, including leucine, isoleucine, tryptophan and phenylalanine. Additionally, a strong correlation was observed between urine amino acids and uACE2 (Figure 1).

**Conclusions:** Elevated uACE2 is related to AKI in patients with COVID-19. The loss of tubular ACE2 during SARS-CoV-2 infection demonstrates a potential link between aminoaciduria and proximal tubular injury.

**Funding:** Government Support - Non-U.S.

## FR-PO025

## RECOVID: Renal Outcomes and Mortality in Patients With COVID-19 Infection at UCLA

Peter Fahim, Charley Q. Jang, Tristan Grogan, Arseniy Vasilyev, Mohammad Kamgar, Niloofar Nobakht. *University of California Los Angeles, Los Angeles, CA.*

**Background:** Acute kidney injury (AKI) is a common complication in patients with COVID-19 infection with rates as high as 32% to 46% and has been associated with poor outcomes. Our study investigates the frequency, risk factors, need for kidney replacement therapy (KRT), and mortality among patients with COVID-19 infection and AKI in both vaccinated and unvaccinated populations.

**Methods:** This retrospective, observational study is a review of 2 years of data from early pandemic in March 2020 till March 2022. Data of patients aged  $\geq 18$  years with laboratory-confirmed COVID-19 admitted to UCLA Ronald Reagan Medical Center and UCLA Santa Monica Medical Center were analyzed.

**Results:** Among the 3527 hospitalized patients with COVID-19, AKI occurred in 972 (27.6%) patients. Of the 972 patients with AKI, 411 (42.3%) did not receive the COVID-19 vaccine, 94 (9.6%) were partially vaccinated (1 dose), and 465 (48.1%) were fully vaccinated patients (2 doses). Among AKI patients, in-hospital mortality was 46.2% in unvaccinated patients versus 12.4% in fully vaccinated (OR 6.1, 95% CI, 4.3 to 8.5) and 18% of unvaccinated patients remained on dialysis at discharge versus 12.2% among fully vaccinated (OR 1.6, 95% CI, 1.1 to 2.3).

**Conclusions:** Fully vaccinated patients with COVID-19 infection and AKI had less in-hospital mortality and were less dialysis-dependent at the time of discharge.

Table 1: Demographics, race/ethnicity, and comorbidities

		Not vaccinated [N(%)=411(42.28%)]	Two doses [N(%)=467(48.05%)]
Demographics	Age at diagnosis (Mean (SD))	66.98 (19.65)	67.39 (17.26)
	Female	152 (36.98%)	180 (38.54%)
	BMI (Mean (SD))	28.29 (7.11)	27.98 (7.37)
	Smoking - current or former	122 (29.87%)	175 (39.68%)
Race/Ethnicity	White	182 (44.28%)	254 (54.39%)
	Black or African American	56 (13.63%)	46 (9.85%)
	Hispanic or Latino	136 (33.09%)	153 (32.76%)
	Asian	30 (7.3%)	29 (6.21%)
	American Indian or Alaska Native	1 (0.24%)	
	Native Hawaiian or Other Pacific Islander	3 (0.73%)	1 (0.21%)
Comorbidities	CHF	126 (30.66%)	133 (28.48%)
	MI	75 (18.25%)	88 (18.84%)
	PVD	101 (24.57%)	147 (31.48%)
	CVD	90 (21.9%)	129 (27.62%)
	Dementia or chronic cognitive deficit	69 (16.79%)	51 (10.92%)
	COPD	115 (27.98%)	190 (40.69%)
	Rheumatologic disorder	27 (6.57%)	42 (8.99%)
	PUD	22 (5.35%)	28 (6%)
	Liver disease	54 (13.14%)	118 (25.27%)
	Diabetes with end-organ damage	83 (20.19%)	128 (27.41%)
	Diabetes without end-organ damage	149 (36.25%)	198 (42.4%)
	Paraplegia or hemiplegia	25 (6.08%)	24 (5.14%)
	CKD	131 (31.87%)	194 (41.54%)
	Active cancer	81 (19.71%)	130 (27.84%)
	HIV	2 (0.49%)	4 (0.86%)

## FR-PO026

## Impact of Metabolic Acidosis on All-Cause Mortality in Patients With COVID-19

Yaerim Kim,<sup>1</sup> Soie Kwon,<sup>2</sup> Jeonghwan Lee,<sup>3</sup> Jin hyuk Paek,<sup>1</sup> Woo Yeong Park,<sup>1</sup> Kyubok Jin,<sup>1</sup> Seungyeup Han,<sup>1</sup> Dong Ki Kim,<sup>2</sup> Jung Pyo Lee.<sup>3</sup> <sup>1</sup>Keimyung University School of Medicine, Daegu, Republic of Korea; <sup>2</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>3</sup>Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.

**Background:** Low total CO<sub>2</sub> (tCO<sub>2</sub>) levels are significantly associated with all-cause mortality. Lots of factors are related to the poor prognosis of COVID-19, it was a lack of data to evaluate the impact of tCO<sub>2</sub>. We evaluated the impact of metabolic acidosis on all-cause mortality in patients with COVID-19.

**Methods:** We retrospectively reviewed the data from two independent hospitals that care for admitted patients with COVID-19 between February 2020 and September 2021. We excluded subjects with underlying end-stage kidney disease, no data of tCO<sub>2</sub> value, and age under 18 years old. The primary outcome was in-hospital mortality. We evaluate the impact of tCO<sub>2</sub> as a continuous variable on mortality using the Cox-proportional hazard model. In addition, we tried to find the relative value of tCO<sub>2</sub> to increase the risk of mortality using a generalized additive model. We also evaluated the impact of such a value of tCO<sub>2</sub> and 22mEq/L of tCO<sub>2</sub> on mortality.

**Results:** A total of 4,423 patients were included, and the mean age was 54.7±18.3 years old. Mean tCO<sub>2</sub> was 26.2±3.6 mEq/L, and there were 792 (17.9%) with tCO<sub>2</sub> <22 mEq/L. Increased in 1 mEq/L of tCO<sub>2</sub> significantly decreased risk for all-cause mortality after adjustment with age, sex, history of hypertension, diabetes, and laboratory results such as serum white blood count, hemoglobin, platelet, calcium, phosphate, albumin, and eGFR (adjusted HR 0.95, 95% CI 0.91, 0.99). We found that the level of 24 mEq/L of tCO<sub>2</sub> as a cut-off value to increase risk of mortality. In the Cox-proportional hazard model, the risk of all-cause mortality was significantly increased by around 1.6 times in subjects with lower tCO<sub>2</sub> irrespective of the cut-off value of 22 or 24 mEq/L.

**Conclusions:** Decreased tCO<sub>2</sub> significantly increased the risk of all-cause mortality in patients with COVID-19. Monitoring of tCO<sub>2</sub> could be a good indicator to predict prognosis, and it needs to be considered to encourage in patients with a specific condition.

## FR-PO027

### Outcomes Among Hospitalized Patients With COVID-19 and AKI: Role of SARS-CoV-2 Vaccine

Jose L. Torres Cuevas, Froylan D. Martinez-Sanchez, Hector R. Gonzalez Sanchez, Santiago Saenz-Ancira, Yatzil Reyna Juárez, Alejandra Diaz-Jarquín, Carlos A. Romero-Reyes, Luis A. Ibarra Santoyo, Joana B. Juarez, Mauricio A. Salinas-Ramirez, Erika K. Tenorio-Aguirre. *Hospital General Dr Manuel Gea Gonzalez, Ciudad de Mexico, Mexico.*

**Background:** COVID-19 and Acute kidney injury (AKI) are associated with increased mortality and worse kidney outcomes. Although vaccines against SARS-CoV-2 have decreased the rate COVID-19 morbimortality, the role of immune protection against SARS-CoV-2 in the setting of AKI has not been fully yielded

**Methods:** Retrospective case-control study that included clinical and biochemical data of 412 (78 vaccinated and 334 non-vaccinated) patients with severe COVID-19. Cox regression analyses were used to evaluate the effect of the vaccine in mortality and AKI outcomes

**Results:** The mean age of the patients was 55±15 years, 64% were women, the mean body mass index was 28±5 kg/m<sup>2</sup>, and median in-hospital stay was 10(6-16) days. The rate of mortality and AKI 3 was 29% vs 10% and 27% vs 13%, for unvaccinated and vaccinated patients, respectively. Cox proportional hazard ratios for survival and prevention of AKI are shown in table 1

**Conclusions:** The SARS-CoV-2 vaccine was independently associated with lower mortality and AKI progression in patients with severe COVID-19

Table 1. Cox proportional hazard model of SARS-CoV-2 vaccination and the risk for mortality, development of Acute Kidney Injury (AKI), and AKI stage 3

SARS-CoV-2 Vaccine	Mortality		AKI 1-3*		AKI 3*	
	HR (95%CI)	p value	HR (95%CI)	p value	HR (95%CI)	p value
Unadjusted	0.382 (0.185-0.785)	0.009	0.629 (0.441-0.897)	0.010	0.528 (0.274-1.017)	0.056
Model 1	0.348 (0.168-0.719)	0.004	0.597 (0.418-0.853)	0.005	0.498 (0.256-0.967)	0.040
Model 2	0.440 (0.211-0.919)	0.029	0.585 (0.407-0.842)	0.004	0.464 (0.234-0.919)	0.028
Model 3	0.444 (0.213-0.927)	0.031	0.534 (0.368-0.776)	0.001	0.493 (0.246-0.985)	0.045

Model 1 was adjusted by age, sex, and Body Mass Index; model 2 included model 1 plus type 2 diabetes, blood pressure >140/90 mmHg, chronic kidney disease, renal replacement therapy, and AKI 3; and model 3 included model 2 plus serum levels of D-dimer, lactic dehydrogenase, C-reactive protein, and ferritin.

\* In model 2 variable AKI 3 was not included in the Cox regression analysis.

## FR-PO028

### Assessment of Magnesium Disturbances and Clinical Characteristics in Patients With COVID-19 In São Paulo, Brazil

Claudia M. Helou, Marcia Fernanda Arantes de Oliveira, Igor Smolentzov, Camila E. Rodrigues, Lucia Andrade. GRUPO IRA do HC-FMUSP Universidade de São Paulo Laboratório de Pesquisa Básica em Doenças Renais, São Paulo, Brazil.

**Background:** Infection with severe acute respiratory syndrome coronavirus 2 has resulted in a global pandemic. The objective of this study was to investigate the prevalence, causes, and clinical implications of magnesium disturbances, including their possible association with treatment outcomes, among patients with COVID-19.

**Methods:** This cohort study was conducted at the Hospital das Clínicas, a tertiary care academic medical center in the city of São Paulo, Brazil. We included only patients diagnosed with COVID-19, and all clinical data were extracted from medical records.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

The patients were classified as having hypomagnesemia (HypoMg, plasma Mg ≤ 1.58 mg/dL) or hypermagnesemia (HyperMg, plasma Mg ≥ 2.55 mg/dL), and the groups were compared in terms of clinical features and outcomes. We analyzed data collected at admission, ≤ 72 h after admission, or both.

**Results:** We analyzed 3,777 patients. Data regarding magnesium levels were available for 3,162 of those patients, and 344 (10.9%) were found to have HyperMg (240 men and 104 women). The mean age of the HyperMg group patients was 62.2 ± 0.8 years (range, 15-98 years). Of the HyperMg group patients, 54% died during hospitalization, 86% required mechanical ventilation, 13.4% developed AKI, 4% required dialysis, and 4.3% presented cardiac arrhythmia. Comorbidities included COPD (in 6%), diabetes (in 36.6%), hypertension (in 61.5%), and cardiovascular disease (in 17%). Seven patients presented moderately high levels of Mg (> 4.0 mg/dL), and all of those patients died. Of the 344 HyperMg group patients, 97 (28%) had hypernatremia and 27 (8%) had hyponatremia. HypoMg was found in 166 (5.2%) of the patients (84 men and 82 women). The mean age of the HypoMg group patients was 59.0 ± 1.4 years (range, 18-99 years), and 23% died during hospitalization. Of the 166 HypoMg group patients, 11 (6.6%) had hypernatremia and 11 (6.6%) had hyponatremia.

**Conclusions:** Magnesium disturbances, especially HyperMg, appear to be common in COVID 19, increasing the risk of death. Further studies are needed in order to determine the cause of the high rate of hypermagnesemia in patients with COVID-19.

**Funding:** Government Support - Non-U.S.

## FR-PO029

### Risk Factors for AKI in Patients With COVID-19 in Two University Hospital of Colombia

Kateir Contreras,<sup>1,2</sup> Oscar R. Barbosa Silva,<sup>3</sup> Ana C. Munoz,<sup>3</sup> Juan S. Suarez,<sup>2</sup> Camilo A. Gonzalez,<sup>1,3</sup> Patricia Rodriguez,<sup>3,1</sup> Martha C. Valderrama Rios,<sup>2</sup> Paola Garcia,<sup>3,1</sup> Diana C. Vargas angel,<sup>1,3</sup> Jorge A. Cortes.<sup>2</sup> COVAKI /Hospital Universitario San Ignacio, Bogotá, Colombia; <sup>2</sup>Universidad Nacional de Colombia, Bogotá, Colombia; <sup>3</sup>Pontificia Universidad Javeriana, Bogotá, Colombia.

**Background:** Patients with COVID-19 have a high incidence of acute kidney injury (AKI), which is associated with mortality. The objective of our study is to know the factors associated with AKI, to manage the level of care and health resources according to risk.

**Methods:** We design an observational retrospective cohort study in 2 hospitals in Bogotá, Colombia. Adults hospitalized for > 48 hours between March 2020 and March 2021, with confirmed SARS-CoV-2 infection. The main outcome was incidence of AKI during the first 28 days from admission. A descriptive analysis of the sociodemographic and clinical characteristics of the study population was performed. Univariate and bivariate analysis and multivariate logistic regression model was conducted for the outcome AKI.

**Results:** We included 1584 patients, 60.4% male, 46.8% older than 65 years. The incidence of AKI was 46.5%, stage 1 in 60.7%, Stage 2 in 15.7%, and stage 3 in 23.6%. Renal replacement therapy was performed in 11.1% of patients with AKI. Table 1 summarizes cohort characteristics and the bivariate analysis. In the multivariate analysis, sex, age, hypertension, CKD, treatment with oral antidiabetics, diuretics, statins, qSOFA, platelet count, CRP, D-dimer, treatment with vancomycin, piperacillin tazobactam, requirement of vasopressor support were related with AKI. The interactions antihypertensive /diuretics, PAFI /Requirement of invasive mechanical ventilation, Hypertension /antihypertensives, were associated with AKI (P value <0.5). Hospital crude mortality for AKI was 45.5% versus 11.7% without AKI (p<0.0001)

**Conclusions:** AKI is frequent in patients hospitalized with COVID 19, conventional risk factors are the rule, we denote other known markers of severity for COVID-19 in association with AKI. These results allowed us to manage the hospital resource

Characteristic	Total (n=1584)	Non-AKI (n=846)	AKI (n=738)	p-value

## FR-PO030

### Clinical Characteristics and Outcomes of Critically Ill COVID-19 Patients That Required Continuous Renal Replacement Therapy With and Without Adjuvant Blood Purification

Victor M. Ortiz-Soriano,<sup>1</sup> Stuart M. Carter,<sup>1</sup> Lucas J. Liu,<sup>1</sup> Jin Chen,<sup>1</sup> Javier A. Neyra.<sup>2</sup> <sup>1</sup>University of Kentucky, Lexington, KY; <sup>2</sup>University of Birmingham at Alabama, Birmingham, AL.

**Background:** oXiris use received EUA by the FDA as a blood purification adjuvant for COVID-19 critical illness. We evaluated clinical characteristics and outcomes of patients with COVID-19 critical illness that received CRRT with vs. without oXiris.

**Methods:** Single-center, retrospective cohort study of adult ICU patients with COVID-19 critical illness requiring CRRT (3/2020 to 4/2021). oXiris exposure was defined as a minimum use of 48 h within the first 72 h of CRRT initiation and use of at least 50% of time if the patient died within the first 72 h of CRRT. Data were analyzed with and without propensity-score (PS) matching and with PS-regression.

**Results:** 114 critically ill COVID adults admitted to the ICU required CRRT during the study period. Of these, 11 patients used oXiris without meeting the definition of exposure and were excluded. Of the 103 remaining patients, 31 used oXiris and 72 did not. Mean (SD) age of the cohort was 60 (12) years, 66% were male, and 81% white. There were no differences in demographics between both groups. Similarly, there was no difference in baseline kidney function or prevalence of ESRD. Patients that received oXiris had more frequently sepsis (90% vs. 63%,  $p=0.004$ ) and more frequently received IL-6 inhibitors but CRRT indications were similar in both groups, being the most common one fluid overload in about two-third of patients. Critical illness parameters including SOFA scores (median of 11 in both groups) and extracorporeal organ support (ECMO or mechanical ventilation) were also similar in both groups. Inpatient mortality was not different between both groups (74% in the oXiris group vs. 65% in the non-oXiris group,  $p=0.37$ ). Further, 28-day ventilator, CRRT and ICU free-days were comparable in both groups. Similarly, kidney recovery rates were not different based on oXiris exposure. These results were consistent in all adjusted analyses. There were no circuit or filter related complications attributed to oXiris.

**Conclusions:** The use of oXiris as adjuvant treatment of blood purification during CRRT appears feasible and safe. We did not observe differences in mortality, kidney recovery, or resource utilization among patients exposed vs. non-exposed to oXiris. The clinical impact of oXiris needs to be further evaluated in interventional studies.

## FR-PO031

### Kidney Outcomes in Critically Ill Patients With and Without COVID-19

Frances Tian, Leila R. Zelnick, Mark M. Wurfel, Pavan K. Bhatraju, Bryan R. Kestenbaum. University of Washington, Seattle, WA.

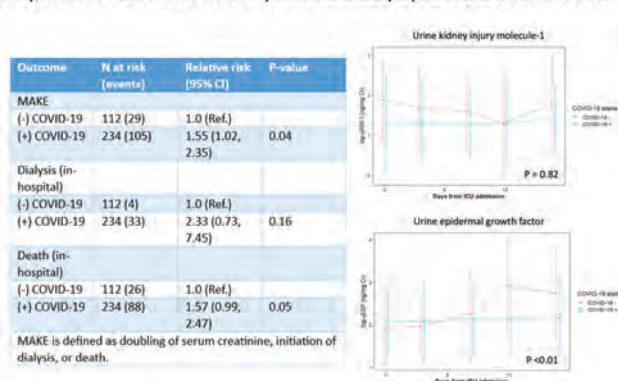

**Background:** Case series have described high rates of AKI in critically ill persons with covid-19. However, no study has directly compared kidney outcomes in similarly ill persons with and without covid-19 that are contemporaneously enrolled.

**Methods:** We assessed 346 participants from a study of covid-19 in critical illness enrolled from University of Washington from April 2020 to May 2021. Patients in the ICU were recruited if symptoms of lower respiratory tract infection prompted covid testing. 2/3 of the cohort were covid positive; the remaining 1/3 had another cause of respiratory illness and served as controls. We defined major adverse kidney events (MAKE) as doubling of serum creatinine, dialysis, or death during hospitalization. Among 186 patients with available urine samples, we also assessed kidney injury molecule-1 (KIM-1), epidermal growth factor (EGF), and Cr. We used inverse probability of treatment weighting with propensity scores to increase similarity between the comparison groups.

**Results:** Mean age was 55 years; 64% were male, and mean admission serum Cr was  $1.3 \pm 1.0$  mg/dL. Baseline characteristics, including APACHE III and SOFA scores, were similar between groups after propensity weighting. Among Covid-19 patients the incidence of MAKE was 45% and in non-covid-19 patients was 26%. Covid-19 positivity was associated with a 55% greater incidence of MAKE and each component of MAKE was numerically higher in the covid-19 positive group (figure). The covid positive group had lower urine EGF levels (indexed to urine Cr) over time. Urine KIM-1 levels were similar.

**Conclusions:** The incidences of clinical kidney outcomes are numerically higher in critically ill patients with covid-19 compared with similarly ill control patients without covid-19. Urinary concentrations of EGF are lower in covid positive patients.

### Comparison of clinical outcomes and kidney markers in critically ill persons with and without covid-19

## FR-PO032

### Validation of UCSD-Mayo Risk Score for Predicting Hospital-Acquired AKI in COVID-19 Patients

Rolando Claude-Del Granado,<sup>1,2</sup> Nicholas Y. Barbosa,<sup>1,2</sup> Marina Wainstein,<sup>3</sup> Sally Shrapnel,<sup>4</sup> ISARIC Clinical Characterization Group <sup>1</sup>Hospital Obrero No 2 - CNS, Cochabamba, Bolivia, Plurinational State of; <sup>2</sup>Universidad Mayor de San Simon, Cochabamba, Bolivia, Plurinational State of; <sup>3</sup>The University of Queensland Medicine Program, Brisbane, QLD, Australia; <sup>4</sup>The University of Queensland Mathematics Discipline, Brisbane, QLD, Australia.

**Background:** Acute kidney injury (AKI) in patients hospitalized with coronavirus disease 2019 (COVID-19) is common and often associated with poor prognosis. Early prediction of AKI that may allow early and effective interventions is essential to improve clinical outcomes. In this study we aimed to validate the UCSD-Mayo risk score for AKI in a non-ICU population of patients hospitalized with COVID-19 in a Bolivian referral center.

**Methods:** One hundred and thirty-nine patients hospitalized with COVID-19 from Hospital Obrero No 2 – CNS in Cochabamba, Bolivia were enrolled in this study. Data for predictor variables was extracted from patient's medical records and the International Severe Acute Respiratory and Emerging Infection Consortium (ISARIC - WHO) case report forms at hospital admission. The UCSD-Mayo risk score was calculated using the original equation (Nephrol Dial Transplant. 2017; 32(5): 814–822). Patient information was recorded from the time of diagnosis and renal function was followed up daily up to 7 days. AKI was defined using KDIGO serum creatinine criteria.

**Results:** A total of 77 patients (55.4%) developed AKI, 75.3% were male with a mean age of 67 years (SD 15). The patients who developed AKI had significantly higher UCSD-Mayo score ( $\geq 5$  points) than those without AKI (36.4% [n=28] vs. 17.7% [n=11]; 0.015). Positive and negative predictive values for the optimal cutoff value of  $\geq 5$  points in the cohort were 72% and 51% respectively with an odds ratio of 2.65 (95% CI 1.19–5.89;  $p=0.015$ ). The UCSD-Mayo risk score performance was regular in predicting AKI with a ROC-AUC of 0.632 (95% CI 0.540 - 0.725;  $p=0.07$ ). As expected, mortality was higher in patients who developed AKI compared to those that did not (57%, [n=44] vs. 40.3% [n=25]; 0.049). None of the patients who developed AKI required KRT.

**Conclusions:** We validated the performance of UCSD-Mayo risk score in predicting hospital-acquired AKI in COVID-19 patients, which showed regular performance. More studies will be needed in order to validate this score in COVID-19 patients. This type of risk assessment tools could help clinicians stratify patients for primary prevention, surveillance and early therapeutic interventions to improve the care and outcomes of COVID-19 patients.

## FR-PO033

### Osmotic Demyelinating Syndrome and COVID-19

William A. Vasquez Espinosa,<sup>1</sup> Aditi A. Joshi,<sup>1</sup> Megha Puri,<sup>1</sup> Christian C. Toquica Gahona,<sup>1</sup> Carla F. Vasquez Espinosa,<sup>2</sup> Shaunak A. Dwivedi.<sup>1</sup> <sup>1</sup>Saint Peter's University Hospital, New Brunswick, NJ; <sup>2</sup>Universidad UTE, Quito, Ecuador.

**Introduction:** Osmotic demyelination syndrome (ODS) is a dreaded complication of rapid sodium correction in high-risk hyponatremic patients. Predisposing factors include chronic alcoholism, malnourishment, severe hyponatremia. SARS-CoV2 infection may also be a risk factor as it is linked with multiple patterns of brain injury, renal damage and hyponatremia.

**Case Description:** Patient is a 48-year-old female with history of alcohol use disorder who presented with malaise, vomiting, diarrhea for 3 days. On admission, the patient was stuporous and confused. She was clinically hypovolemic. Initial labs demonstrated severe hyponatremia (102 mmol/L), hypokalemia (2.2 mmol/L), HCO<sub>3</sub> of 35mmol/L, lactic acid of 4 mmol/L, no EtOH, preserved GFR. SARS-CoV2 PCR was positive. She was not hypoxic, her chest X-ray was clear. The patient was resuscitated with 1L of isotonic saline, potassium correction was attempted. Her bloodwork 4 hours later showed Na of 113 mmol/L and K of 2.4 mmol/L. At this point patient had prominent diuresis, UNa was 13mmol/L, Uosm 175mOsm/kg and U spec gravity 1.006. Immediately DDAVP and D5W were started. She had a poor response to this therapy and her sodium continued raising

even at maximal doses. At 24h her sodium was 118 mmol/L and at 48h it was 125mmol/L with stabilization at this level. She had clinical improvement and was more responsive on day 3. On the following days, sodium gradually drifted toward 132 mmol/L. On day 5 she developing worsening mental status. She was found poorly responsive with fixed gaze, aphasia, minimally removing extremities from pain, able to blink when asked. Brain MRI revealed signal abnormalities in the central pons, bilateral thalami, caudate, basal ganglia, subinsular regions consistent with ODS. Intensive treatment was restarted with D5W and DDAVP. Na of 124mmol/L was achieved at 24h. Over the course of the following days, she had partial recovery. She was discharged to rehab, able to smile, move her head and partially move her extremities.

**Discussion:** SARS-Cov2 causes hyponatremia through several mechanisms. Poor oral intake, gastrointestinal losses, kidney injury and SIADH have been described. All of them may occur at the same time and cause hypovolemic/euvolemic states with high ADH. Volume replacement rapidly shuts off the ADH drive predisposing patients to get sodium overcorrection.

#### FR-PO034

##### COVID-19 Vaccination as a Trigger for Atypical Hemolytic Uremic Syndrome

Romy N. Bouwmeester,<sup>1</sup> Arjan D. Van Zuilen,<sup>2</sup> Jack F. Wetzels,<sup>1</sup> Nicole Van De Kar,<sup>1</sup> <sup>1</sup>Radboudumc, Nijmegen, Netherlands; <sup>2</sup>University Medical Center Utrecht, Utrecht, Netherlands.

**Introduction:** After introduction of COVID-19 vaccination, rare but severe thrombocytopenia-associated complications have been reported. Although several patients developed aHUS after COVID-19 infection, to date it is unknown if COVID-19 vaccination could trigger aHUS in pediatric and adult patients with a pathogenic complement variant.

**Case Description:** Here we present three adult and one pediatric aHUS patient (all with pathogenic C3 variants) who developed a total of 5 episodes of onset cq relapse of atypical hemolytic uremic syndrome (aHUS) at a median of 7 days (range 2-26) after mRNA based (Pfizer/BioNTech's, BNT162b2) and adenoviral (AstraZeneca, ChAdOx1 nCoV-19) COVID-19 vaccination. Other aHUS triggering or explanatory events were absent in all patients. During eculizumab treatment, kidney function recovered in all but one adult. Eculizumab was discontinued after stabilization of kidney function and a median treatment duration of 12 weeks (2.5-15).

**Discussion:** We identified COVID-19 vaccination, independent of the vaccine type, as a potential trigger for aHUS onset and relapse in pediatric and adult patients. We hypothesize that the synergistic effect of a local complement-amplifying condition and a pre-existing (pathogenic) complement genetic variant might cause conversion of a "normal" pro-inflammatory state into an unrestrained overactivation of the alternative pathway. We advise clear patient instruction and routinely monitoring of serum creatinine, proteinuria, mechanical hemolytic anemia (MAHA) parameters, and blood pressure approximately 3-7 days after COVID-19 vaccination in patients with a previous episode of aHUS, and/or a proven (likely) pathogenic variant in complement protein(s), and who are not treated with complement inhibitory therapy (eculizumab/ravulizumab). In addition, aHUS should be included in the differential diagnosis of patients with vaccine-induced thrombocytopenia, especially if co-occurring with MAHA and acute kidney injury.

#### FR-PO035

##### A Rare Case of IgG4-Related Kidney Disease With a Rapid Growing Renal Tumor After COVID-19 Vaccination

Rei Nakazato, Akiko Mii, Akira Shimizu. *Nihon Ika Daigaku, Bunkyo-ku, Japan.*

**Introduction:** IgG4-related diseases (IgG4-RD) are characterized by organomegaly, high IgG4 level and marked infiltration of IgG4(+) cells in the affected organs, with renal involvement in approximately 25% of cases. The coexistence of AAV with IgG4-RD has been reported in some case, while ANCA-associated vasculitis (AAV) is often associated with autoimmune diseases. There have also been some reports of new renal lesions caused by the COVID19 vaccine, such as minimal change disease, IgA nephropathy, and vasculitis, but there are still no reports of new-onset IgG4-RD.

**Case Description:** A 61-year-old man developed fever, malaise, thirst and polydipsia the day after a second vaccination of COVID19 (mRNA-12733, Moderna). Blood test showed kidney dysfunction, high IgG4 level, and MPO-ANCA positivity. Brain MRI showed enlargement of pituitary gland. Salivary gland scintigraphy showed secretory impairment in the submandibular and parotid glands. CT scan revealed a rapid growing left renal tumor and CT-guided needle biopsy was performed. Renal specimens showed diffuse infiltrates of CD138(+) plasma cells in the interstitium. More than 40% of IgG(+) cells were IgG4-positive, accompanied by interstitial fibrosis with a "striform" pattern. Focal necrotic and granulomatous lesions were detected with tubular atrophy and tubulitis. Bowman's capsules were disrupted by massive interstitial inflammation in some glomeruli, but no obvious proliferative lesions. Finally, he was diagnosed as IgG4-RD and steroid therapy was started. Desmopressin was administered for central enuresis. The systemic symptoms were improved gradually and the renal tumor was reduced.

**Discussion:** In this case, it is suggested that immunological changes caused by the vaccine or allergic reaction to the vaccine may trigger the onset of the disease. Elevated MPO-ANCA titer and tubulointerstitial nephritis with necrotic and granulomatous lesions may have been associated with AAV. However, the patient had renal tumor with characteristic pathological findings of IgG4-RD, accompanied by hypophysitis and sialadenitis. We concluded that the main condition in our case is IgG4-RD. IgG4-related kidney disease after COVID-19 vaccination is extremely rare. Careful monitoring after the COVID19 vaccine is important with immunological abnormalities.

#### FR-PO036

##### Successful Outcome of AKI in a Patient With Leptospirosis and COVID-19 Infection

Irma Tchokhonelidze, Tamar Tevdoradze. Tbilisi State Medical University Clinic Tbilisi State medical University, Tbilisi, Georgia.

**Introduction:** Severe leptospirosis manifests as pulmonary edema leading to ARDS. Superimposed Covid-19 increases the risk ARDS and AKI. Cytokine storm is the main incriminating factor in both. High-dose steroids have been used to facilitate the effects of covid-19 and leptospirosis.

**Case Description:** A 31-year-old male farmer was admitted to ER on Nov 10, 2020. According to PMH, the diseases presented on Nov 3 with chills, fever, abdominal pain, diarrhea. On admission he had decreased urine output, edema, fever, abdominal pain, diarrhea. Laboratory tests were significant for uremia, abnormal liver enzymes, thrombocytopenia, leukocytosis, elevated LDH. Leptospirosis serology test was positive. Doxycycline 200mg added. Hemodialysis was started. Oxygen saturation fell to 74% on room air. Nasopharyngeal swab tested positive for COVID-19. Methylprednisolone 500mg i/v for three consecutive days, followed by 32mg. Chest CT showed bilateral ground-glass opacities Fig.1. From Nov 23 his clinical condition improved: urine output increased, oxygen saturation became 98% on room air, bowel movements one time per day. He was discharged. In December serum creatinine dropped to basic levels (89 µmol/L). CT scan of the lungs showed almost complete resolution of the opacities Fig.2.

**Discussion:** Our case demonstrates successful resolution of the severe ARDS, AKI, with complete restoration of the kidney function under steroid therapy. Further trials are needed to elaborate recommendations on steroid therapy during co-existing covid-19 and leptospirosis.

#### FR-PO037

##### A Case of Idiopathic Immune-Complex Mediated Glomerulonephritis Following Moderna COVID-19 Vaccination

Shota Obata,<sup>1</sup> Kunihiko Ishioka,<sup>1</sup> Sumi Hidaka,<sup>1</sup> Mitsuru Yanai,<sup>2</sup> Shuzo Kobayashi.<sup>1</sup> <sup>1</sup>Shonan Kamakura Sogo Byoin, Kamakura, Japan; <sup>2</sup>Sapporo Tokushukai Byoin, Sapporo, Japan.

**Introduction:** mRNA vaccines for COVID-19 have been used worldwide, and a small number of cases have been reported in which mRNA vaccines may have triggered glomerulonephritis such as IgA nephritis, ANCA-associated vasculitis, or MCNS. This is the first case of immuno-complex mediated glomerulonephritis (ICGN) following mRNA vaccination, and we investigated the case including abnormalities in complement regulation.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Case Description:** A 71-year-old female with hypertension was referred to our nephrology department with proteinuria and microscopic hematuria. She had had microscopic hematuria and had been examined by urologists, but no apparent abnormality was found. She had received the Moderna COVID-19 vaccine a week before noticing leg swelling. At admission, her vital signs were normal except for her blood pressure of 165/116. She has pitting edema in her lower legs. Lab data revealed serum creatinine of 0.94mg/dL, urinary protein of 1.5g/day, and urine blood of 1+. There was no evidence of hypocomplementemia or various autoantibodies. On day 2, she underwent a renal biopsy showing enlarged mesangial matrix and hyperplasia of mesangial cells with endocapillary proliferation in all glomeruli. GBM duplication and subendothelial and subepithelial electron dense deposits were observed with prominent intracellular proliferation. IF showed peripheral and mesangial deposits of IgG, C3, and C1q, with IgG predominance, suggesting ICGN secondary to infection-related glomerulonephritis. However, the investigation did not detect any etiology of ICGN. She received methyl prednisone of 1000 mg IV for 3 days followed by prednisone of 40 mg daily. She responded to the treatment and was discharged with no hematuria and decreased proteinuria of 0.62 g/day.

**Discussion:** We have experienced idiopathic ICGN following the Moderna COVID-19 vaccine. Cases with MPGN pattern injury are classified as hematologic, infection-related, collagen disease, or complement dysregulation, and idiopathic cases are considered to be rare. Since this case has mild hematuria prior to vaccination, we hypothesize that the vaccine exacerbates her glomerulonephritis or may affect complement regulation. Therefore we examine the patient's complement regulation genes and also the literature on the possibility of vaccines affecting complement dysregulation.

#### FR-PO038

#### **IgA Vasculitis After COVID-19 Vaccination: A Rare but Significant Complication**

Michael W. George, Kristen Tomaszewski, Sylvester Dorobisz, John R. Sedor. Cleveland Clinic, Cleveland, OH.

**Introduction:** A 24 year old male presented with rash, gastrointestinal bleeding and nephrotic syndrome one week after first COVID vaccination. Renal biopsy revealed crescentic IgA nephritis. He was treated steroids and responded clinically but continues to have proteinuria.

**Case Description:** A 24 year old male with history of cerebral palsy presented with a vasculitic rash, hematochezia and edema. He had no prior history of renal or autoimmune disease. Symptoms developed one week after first dose of Moderna mRNA-1273 vaccine. Serum albumin was 1.6 g/dL and urine protein-creatinine ratio 8.5. Endoscopy showed esophagitis and small bowel ulcerations. Renal biopsy showed focally crescentic and necrotizing proliferative glomerulitis with IgA dominant deposits consistent with IgA vasculitis with renal involvement. He received pulse dose solumedrol followed by prednisone taper. Cyclophosphamide was initiated but then stopped due to cytopenias. After several weeks GI bleeding resolved spontaneously and proteinuria improved but remained in the nephrotic range. The course was further complicated by positive COVID testing prior to discharge- he was asymptomatic and received sotrovimab. On follow-up three months later the patient's edema resolved and serum albumin normalized. He continues to have subnephrotic range proteinuria with 2.3 grams/24 hours and active urinary sediment with dysmorphic red cells. He remains on steroid taper with plan for repeat renal biopsy to inform decisions regarding further immune suppression. He has not been rechallenged with COVID vaccine.

**Discussion:** Rare associations between COVID vaccination and both de-novo and relapsing glomerular lesions, including minimal change disease, IgA nephropathy, ANCA and anti GBM glomerulonephritis, have been reported. COVID infection itself has been associated with an FSGS type lesion termed COVID-associated nephropathy (COVAN). As highlighted by this case, unvaccinated or partially vaccinated patients are at increased risk for COVID infection. Thus even in those with known glomerular disease, vaccination should still be recommended. Studies are needed to determine if patients with off-target glomerulopathies can be safely rechallenged with COVID vaccine, whether the course of COVID vaccine-associated disease glomerular lesions mimic the primary glomerular disease and how to optimally manage these patients.

#### FR-PO039

#### **De Novo ANCA (-) Pauci-Immune Crescentic Glomerulonephritis After Injection of COVID-19 mRNA Vaccine**

Heejin Cho, Hyo jin Boo, Jin Ho Hwang. Chung Ang University Hospital, Seoul, Republic of Korea.

**Introduction:** To prevent the spread of the COVID-19 pandemic, vaccinations have been authorized for emergency use and implemented worldwide. As with the others, COVID-19 vaccines are known to cause mild and transient side effects such as fever, myalgia, and fatigue, but severe and consistent adverse events have rarely been reported. We present a case of de novo glomerulonephritis after injection of COVID-19 mRNA vaccine, BNT162b2 (BioNTech, Pfizer, NY, USA).

**Case Description:** A 48-year-old man with no past medical history was referred for suddenly and persistently worsening renal insufficiency for only a month and a half after the second dose injection of the vaccine. He presented with arthralgia and skin rash a week after the vaccination. Abdominal pain and diarrhea started two weeks later, and he was admitted to the hospital for enteritis treatment. Upon colonoscopy, multiple ulceration and petechiae suggestive of vasculitis were observed in the terminal ileum. While taking prednisolone for a few weeks the gastrointestinal symptoms improved, but the renal function continues to deteriorate. A kidney biopsy was performed for the rapid decline in renal function accompanying nephrotic-range proteinuria (urine protein to creatinine ratio 3389mg/gCr), and anti-neutrophil cytoplasmic autoantibody (ANCA)-negative

pauci-immune crescentic glomerulonephritis was diagnosed. He started treatment with high-dose steroid pulse therapy and oral cyclophosphamide, and then gradually took steroid tapering, showing improvement in proteinuria and renal function over several weeks.

**Discussion:** To date, several cases of glomerulonephritis suspected to be related to the COVID-19 vaccine have been reported. This is the first case report of ANCA-negative pauci-immune crescentic glomerulonephritis with extrarenal involvement after COVID-19 mRNA vaccine injection. It is difficult to find definite evidence to suspect or prove the causal relationship, except when there is a temporal association after vaccination or when the disease manifestations are unusual compared to well-known pathologic findings. Further in-depth studies are needed for de novo glomerulonephritis that occurs after vaccination and COVID-19 infection.

#### FR-PO040

#### **Mixed Nephrotic/Nephritic Syndrome in a Pediatric Patient With SARS-CoV-2 Infection**

Eva M. Glenn Lecea,<sup>1</sup> Marleni R. Torres Nunez,<sup>1</sup> Ana L. Paredes.<sup>2</sup> <sup>1</sup>Nicklaus Children's Hospital, Miami, FL; <sup>2</sup>Kidz Medical, Miami, FL.

**Introduction:** Glomerular diseases in children generally present as a variety of findings that include hematuria, proteinuria, edema, and hypertension. Glomerular diseases can be isolated to the kidney or present as a component of a systemic disorder. Emerging reports show that SARS-CoV-2 infection precedes the appearance of various autoimmune diseases.

**Case Description:** Twelve-year-old Hispanic female with history of migraines, obesity, hypercholesterolemia, and NAFLD, who presented with anasarca, fever, and fatigue. On exam, she had hypertension (138/89 mmHg) and anasarca with ascites. Labwork was remarkable for K+ 5.6 mmol/L, Cr 1.07 mg/dL, albumin 2.1 gm/dL, AST 48 IU/L, cholesterol 265 mg/dL, triglycerides 178 mg/dL, CRP 2.6 mg/dL and ESR 80 mm/hr. UA with >500 proteinuria, moderate blood, 100 RBCs, 49 WBCs, and negative leukocyte esterase and nitrites. A rapid strep test and Hepatitis Panel were negative. ANA <1:10, C3 complement level low at 36 mg/dL, C4 normal. Abdominal US showed hepatomegaly, echogenic bilateral kidneys, and a small pleural effusion. SARS-CoV2 antigen test was positive. She was managed with antihypertensives, albumin infusions, and furosemide. She was readmitted 2 weeks later from the Nephrology clinic since her creatinine was 1.5 mg/dL and she persisted with generalized edema. Repeat SARS-CoV2 PCR was negative. At this time, she presented ANA titer in ≥1:1280, strongly positive SSA, SSB, and SM antibodies, low C3 (43.0 mg/dL) and low C4 (7.4 mg/dL). Renal biopsy specimens showed more than 50 percent of glomeruli affected with mesangial and extracapillary hypercellularity, segmental cellular crescents, interstitial fibrosis, and marked deposition of immunoglobulins and complement, consistent with lupus nephritis Grade IV.

**Discussion:** Systemic Lupus Erythematosus (SLE) is an autoimmune condition that has been described in correlation with SARS-CoV-2 infection in adult patients. Our patient fulfills SLICC criteria for SLE and a temporal relationship exists between SARS-CoV-2 infection and the development of SLE antibodies. SARS-CoV2 has also been reported to directly cause nephritis, although with more tubular than glomerular involvement. A renal biopsy is required for accurate diagnosis.

#### FR-PO041

#### **A Rare Case of Granulomatous Interstitial Nephritis in a Patient With COVID-19-Associated Collapsing Glomerulopathy**

Manal Alotaibi, Carla L. Ellis, Shikha Wadhvani, Yonatan A. Peleg. Northwestern University Feinberg School of Medicine, Chicago, IL.

**Introduction:** AKI in patients with COVID-19 is common. Among glomerular pathologies in COVID 19, COVID 19 Associated Collapsing Glomerulopathy (COVAN) remains the most common pattern of injury. AIN is a less common finding in patients with COVID-19. Reports of a subtype of AIN, granulomatous interstitial nephritis (GIN), among COVID-19 patients, are rare and have not been reported in association with COVAN. Here, we report a case of COVAN associated with severe GIN

**Case Description:** A 52YOM who presented with fever and fatigue. The physical exam was remarkable. The patient tested positive for COVID-19 and was found to have oliguric AKI with a creatinine of 9.6 mg/dl and nephrotic range proteinuria. Therefore iHD was initiated. Serologies and infection studies were negative. Fungal serologies were negative. A kidney biopsy revealed up to 32 glomeruli, four of which were globally sclerotic. Up to four glomeruli had features of glomerular collapse. The interstitium showed severe, diffuse edematous change with inflammatory infiltrates and focal interstitial granulomas. EM showed extensive foot process effacement and multiple TRI. Additional stains were negative. After the biopsy results returned, the patient was started on high-dose steroid. He experienced side effects with the high dose and therefore was transitioned to an every other day regimen. Losartan was added and prednisone taper was started. He was doing very well clinically at the last visit with resolving AKI and proteinuria

**Discussion:** We have presented a rare case of GIN in a patient with COVAN. With negative infectious and autoimmune evaluation, it is possible the GIN was secondary to drug exposure and/or potentiated by the inflammatory milieu of COVID-19 infection. Even several years into the pandemic, we continue to find new kidney pathology among COVID-19. Kidney biopsy was absolutely necessary in this case and informed a dedicated treatment plan that allowed a remarkable recovery of kidney function

## FR-PO042

### COVID-19 Mimicking Classic Hemolytic Syndrome in a Toddler

Apoorva Jagadish, Patricia Pichilingue Reto, Radhakrishna Baliga. *LSU Health Shreveport, Shreveport, LA.*

**Introduction:** Coronavirus disease 2019 (COVID-19) is a heterogenous, predominantly pulmonary disease, caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Thrombotic microangiopathy (TMA), a triad of hemolytic anemia, thrombocytopenia and end organ damage, is present in severe COVID-19 and Hemolytic uremic syndrome (HUS). Classic HUS is commonly caused by Shiga toxin (ST) producing *Escherichia coli* 0157:H7 (ST-HUS). We report a toddler with features of classic HUS with positive PCR testing for SARS-CoV-2.

**Case Description:** A 2-year healthy girl presented with diarrhea of 7 days that turned bloody 2 days prior to admission. Previously, several family members with respiratory symptoms tested positive for COVID-19. On admission, she appeared jaundiced with generalized swelling, BP was 137/85 mm Hg (>99%). By day 2, her diarrhea subsided, she was oliguric, fatigued and listless. She was treated symptomatically and BP was controlled with labetalol. Pertinent laboratory data: Hemoglobin 5.1 g/dL, reticulocyte 8.4%, platelets 51 K/uL lactate dehydrogenase 833 U/L and haptoglobin < 8 mg/dL. Serum creatinine (SCr) was 0.71 mg/dL with eGFR of 67 mL/min/1.73m<sup>2</sup> and Urine showed +3 protein and blood. Random sample (RS) urine protein to Cr ratio was 5.1 (<0.2). Stool culture was negative for *E. coli* 0157:H7 and other enteropathogens. Shiga toxin 1 and 2 were negative by enzyme immune assay. Nasal swab was positive for SARS-CoV-2 by PCR. Genetic renal panel v8 for aHUS was negative. Complement, Coombs and ANA negative. ADAMTS13 level >100%. By day 5, symptoms subsided and kidney function improved significantly with SCr at 0.55 mg/dL (eGFR 81mL/min/1.73m<sup>2</sup>). She was discharged on Lisinopril. Four months later, BP was 107/73 mm Hg and SCr 0.32 mg/dL (eGFR 127mL/min/1.73m<sup>2</sup>). Urine had trace protein with RS urine protein to Cr ratio of 0.32.

**Discussion:** Both COVID-19 and HUS cause severe endothelial dysfunction resulting in release of inflammatory cytokines, complement dysregulation, and development of TMA. COVID-19 has been reported as a potential trigger of aHUS in patients with kidney involvement wherein genetic testing revealed complement defect. Our patient had features of classic HUS, was negative for ST-HUS and ST, but positive for SARS-CoV-2. COVID-19 may be considered in children with bloody diarrhea followed by hemolytic anemia, thrombocytopenia and acute kidney injury.

## FR-PO043

### Twelve-Year-Old Girl With Steroid Resistant Nephrotic Syndrome With Collapsing Focal Segmental Glomerulosclerosis After COVID-19 Vaccination

Chika Masuda,<sup>1</sup> Tomoko Horinouchi,<sup>1</sup> Hideaki Kitakado,<sup>1</sup> Yuta Ichikawa,<sup>1</sup> Yu Tanaka,<sup>1</sup> Atsushi Kondo,<sup>1</sup> Nana Sakakibara,<sup>1</sup> Norishige Yoshikawa,<sup>2</sup> Kandai Nozu,<sup>1</sup> <sup>1</sup>Kobe Daigaku Daigakuin Igakuken Kenkyu Igakubu, Kobe, Japan; <sup>2</sup>Shakai Iryo Hojin Aijinkai Takatsuki Byoin, Takatsuki, Japan.

**Introduction:** With the increase of COVID-19 vaccinations, the development of nephrotic syndrome (NS) after vaccination is one of the new concerns. Most NS cases after vaccination are accompanied by minimal change, while others include focal segmental glomerulosclerosis (FSGS). Although an association between COVID-19 infection and collapsing FSGS has been reported especially in patients with *APOL1* risk variants, no cases of childhood collapsing FSGS cases after COVID-19 vaccination have been reported up to now.

**Case Description:** Twelve-year-old Japanese girl had been administered BNT162b2 (Pfizer/BioNTech) vaccine. Soon after that, edema had gradually appeared and 15 days after the injection, she was referred to our hospital because of severe edema. She did not have any past nor family history. Blood examination showed severe hypoalbuminemia (sAlb 1.4 g/dL) without kidney dysfunction (eGFR 118.0 mL/min/1.73m<sup>2</sup>) or hypocomplementemia. Urinalysis showed severe proteinuria (urine protein/Cr 12.8 g/gCr) with hematuria, indicating nephrotic syndrome. Prior to treatment, collapsing FSGS was confirmed by kidney biopsy. Prednisolone (PSL) 60 mg/day was started according to the clinical guidelines for pediatric nephrotic syndrome. She had not achieved the complete remission 28 days after administration of PSL, and cyclosporine and lisinopril treatment was started. In addition, we administered two cycles of methyl prednisolone pulse therapy. Finally, she achieved the complete remission after 2.5 months treatment. Comprehensive genetic testing revealed no variant in genes causing steroid resistant NS or asymptomatic proteinuria.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Discussion:** The new onset of NS after vaccination, including COVID-19 vaccination, has been reported. The actual mechanism has not been clarified yet, but some immunological impact is reported to be associated the onset after the vaccination. Interestingly, this patient showed collapsing FSGS which is common as a secondary FSGS, especially in patients with the *APOL1* risk variants suffered viral infection. Collapsing FSGS accompanied by COVID-19 infection had been reported to be associated with interferon activation or VEGF activation. Patients with collapsing FSGS after COVID-19 vaccination may have a common etiology.

## FR-PO044

### Atypical Hemolytic Uremic Syndrome due to Factor H Antibodies Following COVID-19

Salman B. Mahmood, Nattawat Klomjit. *University of Minnesota Twin Cities, Minneapolis, MN.*

**Introduction:** Atypical hemolytic uremic syndrome (aHUS) is a form of thrombotic microangiopathy (TMA) characterized by dysregulated complement activation. Antibodies to factor H (anti-FH), a regulator of the alternative complement pathway, are a recognized cause of aHUS particularly in children. We present the case of an elderly patient who developed aHUS following COVID-19.

**Case Description:** A 74-year-old male presented with weakness, petechial rash involving extremities and diarrhea for 2 weeks. Prior history included hepatitis C infection status-post treatment 2 years ago with associated cirrhosis. Three weeks ago, the patient had been diagnosed with COVID-19. His symptoms of sore throat, cough and fever had by now resolved. Initial investigations showed leukocytosis and AKI with an active urinary sediment and nephrotic range proteinuria (Fig 1). Hemoglobin and platelets were normal and a blood smear was negative for hemolysis. Imaging revealed small bowel enteritis suggestive of an infectious or vasculitic process. Infectious workup returned negative. Autoimmune serologies revealed a borderline positive ANA, low C3 and low-normal C4. Renal biopsy revealed diffuse endothelial injury with swollen endothelial cells, focal mesangiolysis and glomerular basement membrane duplication. Hence, pulse dose steroids were started and complement function panel sent. Soon after steroid initiation, the patient's renal function, leukocytosis and rash improved. Ultimately, complement testing returned positive for anti-FH. At follow-up, renal function had returned to baseline with continued steroid taper.

**Discussion:** COVID-19 is associated with TMA likely due to endothelial toxicity or complement pathway dysregulation. Our patient had no prior history of renal or hematologic disease. Given the chronology of events, it is likely that COVID-19 triggered formation of anti-FH, in turn leading to development of aHUS in our patient.

Lab Test	Diagnosis	At Admission	Steroids started					At 2-month follow-up
			Hospital Day 1	Hospital Day 7	Hospital Day 10	At Discharge

Further investigations:

Serologies: anti-MPO, anti-PR3, anti-GBM, ds-DNA, anti-Scl 70, anti-RNP, cryoglobulin, ASO, Shiga toxin, hepatitis B surface antigen and antibody, hepatitis B core IgM, hepatitis C RNA, HIV antigen/antibody combo all negative

Serum protein electrophoresis: No monoclonal band

Urine protein electrophoresis: No monoclonal band

Kappa/Lambda (Ratio): 15.4/4.0 (3.8) at presentation; 3.0/1.3 (2.3) at follow-up

Bone Marrow Biopsy: Low level patchy kappa restricted plasma cell neoplasm involving 3-4% cellularity, 46, XY. Flow cytometry with polyclonal B cells. Does not meet diagnostic criteria for multiple or smoldering myeloma.

Fig 1. Lab trend during admission and at follow-up.

## FR-PO045

### IgA Vasculitis With Cryoglobulin-Like Deposits in Kidney Following COVID-19 Infection

Rajib K. Gupta,<sup>1</sup> Austine Y. Mengno,<sup>2</sup> <sup>1</sup>LSU Health Shreveport, Shreveport, LA; <sup>2</sup>Reading Hospital, West Reading, PA.

**Introduction:** Infection-related IgA glomerulonephritis with large paramesangial immune deposits appearing like intraluminal cryo deposits have occasionally been described in literature temporally associated with *Staphylococcus* infection. COVID-19 associated glomerular disease is classically known to manifest as collapsing glomerulopathy, although other types have been reported.

**Case Description:** We present a case of a 76-year old Hispanic female with a history of type 2 diabetes, hypertension and a 2-month old history of COVID-19 pneumonia who recently presented with acute kidney injury, dark urine, shortness of breath and leg edema. 2 weeks prior, she had presented with a history of purpuric rash. Urinalysis had shown hematuria and proteinuria, and a skin biopsy showed IgA vasculitis. Blood culture for *Staphylococcus* was negative. A kidney biopsy now showed IgA glomerulonephritis with focal crescents along with intraluminal pseudothrombi (cryo-plugs) positive for IgA on immunofluorescence. Electron microscopy showed intraluminal occlusive electron-dense

deposits. Serum cryoglobulin was negative. The patient was treated with steroids and oral cyclophosphamide, and she responded significantly to treatment.

**Discussion:** Our case shows a unique glomerular manifestation of COVID-19 infection in the form of IgA vasculitis with intraluminal cryo-like features, not previously described in literature.

#### FR-PO046

##### An Atypical Case of DNAJB9 Negative Fibrillary Glomerulonephritis Associated With COVID-19 Infection

Pir Shehzad,<sup>1,2</sup> Sabiha M. Khan,<sup>1,2</sup> Spencer Hodgins,<sup>1,2</sup> Jonathan Freeman,<sup>1,2</sup> Gregory L. Braden.<sup>1,2</sup> <sup>1</sup>Baystate Medical Center, Springfield, MA; <sup>2</sup>University of Massachusetts Chan Medical School, Worcester, MA.

**Introduction:** FGN is a rare immune-complex mediated GN characterized by the demonstration of Congo-red negative, randomly organized nonbranching fibrils with a diameter of 15 nm - 25 nm on electron microscopy and more recently the presence of DNAJB9 protein in almost all patients. FGN has been associated with HCV infection, autoimmune disease, malignancy, and monoclonal gammopathies. We report a unique case of DNAJB9 negative FGN associated with COVID-19 Infection.

**Case Description:** 74 yo M with Afib, HTN, HFrEF, and DM presented with fatigue and dizziness. Labs revealed an elevated serum creatinine of 1.0 mg/dL above the baseline of 0.7 mg/dL. The patient was positive for COVID-19 infection without overt symptoms. The patient had been vaccinated against SARS-CoV-2. The patient developed oliguric AKI with a rapid rise in serum creatinine over 4 days. Urinalysis revealed pyuria, hematuria, and 4+ albuminuria with 14 gm of proteinuria on quantification (TP/Cr). He had hypocomplementemia, normal immunofixation, negative ANA, dsDNA, RF, ANCA, anti-GBM antibody, viral hepatitis antibodies, and cryoglobulin. MRA ruled out renal vein thrombosis. The patient was started on 1g methylprednisolone for three days. His creatinine peaked at 9.9 mg/dL and was started on hemodialysis. A kidney biopsy was done. Light microscopy showed DPGN with IF demonstrating a full house pattern most consistent with Class IV Lupus Nephritis. The Congo-red stain was negative. Electron microscopy was delayed. He was started on Euro-lupus protocol with IV Cytoxan, 500 mg IV every 2 weeks for 6 weeks, and Prednisone. The patient was discharged on maintenance Euro-lupus protocol and had an excellent response to therapy with normalization of serum creatinine to his baseline of 0.7 mg/dL and a decrease in proteinuria (TP/Cr of 0.47). The electron microscopy results later showed non-branching randomly arranged fibrils with thickness ranging from 15 nm - 30 nm characteristic of FGN. Testing for DNAJB9 was negative.

**Discussion:** DNAJB9 has been identified in all but a few cases of FGN. There is currently no known association between COVID-19 infection and FGN. Our case is unique since it's DNAJB9 negative and potentially establishes a new association between FGN and COVID-19 infection which can cause AKI reversible upon IV Cytoxan therapy usually reserved for crescentic FGN.

#### FR-PO047

##### ANCA-Associated Vasculitis Following Johnson & Johnson COVID-19 Vaccine in Nepal

Kamal Ranabhat,<sup>1</sup> Sangam Shah,<sup>2</sup> <sup>1</sup>Government of Nepal Ministry of Health and Population, Kathmandu, Nepal; <sup>2</sup>Tribhuvan University Institute of Medicine, Maharajgunj, Nepal.

**Introduction:** Antineutrophil cytoplasmic autoantibodies (ANCA) associated vasculitis (AAV) after influenza vaccination has been previously reported, there are a very few case reports of AAV following COVID-19 vaccination.

**Case Description:** A 52-year-old hypertensive female presented with complaints of fever, joint pain, and weakness of all limbs. She developed symptoms 12 days after getting vaccinated with Johnson and Johnson (J & J) COVID-19 vaccine in late July 2021. The fever occurred for 10 days, intermittent type, and associated with chills and rigor. The joint pain was for 3 days which was acute in onset involving small joints of hands and feet. Concurrently she also developed weakness of all four limbs with relatively more weakness in lower limb than upper limbs. She consumed alcohol occasionally. Urinalysis revealed 12 red blood cells per high-power field (HPF), 4 white blood cells/HPF, and 0.631 gm/day protein with albumin (2+). Serologic evaluation was notable for increased C-reactive protein, decreased C3 complement level, normal C4 level, positivity for p-ANCA and c-ANCA (3+). Renal ultrasound showed tiny non-obstructive calculus in both kidneys. Following this she was started on antibiotics, NSAIDs, and methylprednisolone. She was planned for kidney biopsy and was started on cyclophosphamide. Blood transfusion was done. Renal biopsy revealed necrotizing and crescentic glomerulonephritis with insignificant glomerular immune complex deposit suggesting ANCA associated glomerulonephritis in the view of history of ANCA positivity (Figure 1). She was discharged after 10 days of hospitalization.

**Discussion:** AAV following adenovirus vector vaccine has not been reported previously. There have been reports of AAV after administration of influenza vaccine. So, J&J vaccines was thought to be a potential trigger for development of AAV. The temporal causal association between autoimmune manifestations like AAV and COVID-19 vaccines can be explained by hypothesized mechanisms like molecular mimicry, defective neutrophilic apoptosis, polyclonal activation, and systemic proinflammatory cytokine response.

Figure 1(left & right): Immune complex deposit

#### FR-PO048

##### Tip Variant of Focal Segmental Glomerulosclerosis Post COVID-19 Vaccination

Kanza Haq,<sup>1</sup> Claire F. Schretlen,<sup>1</sup> Carmen E. Cervantes,<sup>1</sup> Mohamad A. Hanounh.<sup>1,2</sup> <sup>1</sup>Johns Hopkins University School of Medicine, Baltimore, MD; <sup>2</sup>Nephrology Center of Maryland, Baltimore, MD.

**Introduction:** Rapid and mass SARS-CoV-2 vaccination has been a pivotal strategy to curb the COVID-19 pandemic. The use of developed mRNA vaccines has provided effective protection against COVID-19 infection. However, few cases of immune-mediated reactions, such as de novo/relapsing glomerulonephritis (GN) have been reported.

**Case Description:** A 45-year-old man with no PMH presented with progressive worsening lower extremity edema 1 week after receiving the Janssen vaccine (Ad26. COV2). He was not taking any prescribed or over the counter medications. His physical exam showed BP of 160/90 mmHg and +2 lower extremity edema. Laboratory studies revealed the following: BUN 97 mg/dL, serum creatinine 6.7 mg/dL (baseline 0.8 mg/dL), serum albumin 1.8 g/dL and 24-hour urine protein of 6.5 g. Serological workup was negative. A kidney biopsy showed focal areas of segmental glomerulosclerosis (FSGS), associated with endocapillary foam cells and epithelial cell capping, predominantly involving the takeoff point of the proximal tubule (fig 1). The areas of segmental sclerosis herniated into the proximal tubule. Immunofluorescence was negative and electron microscopy revealed diffuse epithelial foot process effacement (fig 2). The patient was diagnosed with tip variant of FSGS and started on oral prednisone 80 mg daily. He required initiation of dialysis and has no evidence of renal recovery to date.

**Discussion:** New cases and relapses of GN's can present shortly after mRNA COVID-19 vaccination. IgA nephropathy, FSGS and minimal change disease have been reported. The tip variant of FSGS usually presents as a primary podocytopathy and has the best prognosis among the various forms of FSGS due to its high response to steroid therapy and low risk of progression.

#### FR-PO049

##### A Case of Collapsing Focal Segmental Glomerulosclerosis in Post-mRNA COVID-19 Vaccination

Shabtab Khan, Sheryl C. Caberto. *Emory University School of Medicine, Atlanta, GA.*

**Introduction:** The association of collapsing Focal Segmental Glomerulosclerosis (FSGS) and mRNA COVID-19 vaccine has been reported. The APOL1 genotype is present in about 75% of African descendants with FSGS. This increases the rates of FSGS as well as HIV-associated nephropathy. We present a case of African-American male with Human Immunodeficiency Virus (HIV) who developed collapsing FSGS after mRNA covid vaccination.

**Case Description:** A 24-year-old male with history of well-controlled HIV on Biktary was referred to nephrology for acute kidney injury (AKI) with nephrotic-range proteinuria. Outpatient workup for nephrotic syndrome was unrevealing. Two months prior to AKI, patient received Moderna mRNA COVID-19 vaccine. Renal function worsened with creatinine of 1.6 mg/dL from 1.3 mg/dL with 6 grams of proteinuria. Renal biopsy was done which revealed collapsing FSGS with 10% interstitial fibrosis and tubular atrophy. This was unlikely due to HIV. Treatment was started with Methylprednisolone, Mycophenolate and Lisinopril. A booster COVID-19 vaccine was not recommended.

**Discussion:** Proteinuric renal disease is common in patients with history of HIV, but for a patient with well-controlled HIV, other causes of glomerular diseases must be ruled out. We present this case to consider mRNA COVID-19 vaccine as a potential cause of nephrotic syndrome. Glomerular diseases have been reported in temporal association with Moderna and Pfizer BioNTech vaccines. In a case series of 29 biopsy proven glomerular disease that were documented within 1 month of a covid vaccination, 27 out of 29 cases were new onset glomerular diseases. The most common glomerular disease was IgA nephropathy. This is a case of collapsing glomerulopathy in relationship with COVID-19 vaccine. Collapsing FSGS has been commonly reported as a cause of AKI in COVID-19, but in our case, we have a patient with collapsing FSGS in the setting of COVID-19 mRNA vaccination. It is unclear of what mechanism attributed to FSGS, but it is possible to consider an inflammatory response against the spike protein as a 'second hit' phenomenon to susceptible individuals, such as African Americans with APOL-1 risk alleles or HIV. This is a potential adverse effect that must be considered after mRNA covid vaccination.

#### FR-PO050

##### The Mosaic of Autoimmunity

Aditi A. Joshi, William A. Vasquez Espinosa, Nida Arabi. *Saint Peter's University Hospital, New Brunswick, NJ.*

**Introduction:** Lupus nephritis (LN) is one of the most common manifestations affecting 45% of patients with systemic lupus erythematosus (SLE). Here we present a case of rapid progression of LN in the setting of recent COVID-19 infection, suggesting a possible synergistic cascade of cytokines contributing to rapid disease flare up.

**Case Description:** 52-year-old hispanic lady with past medical history of hypertension and newly diagnosed SLE presented to the clinic with chief complaint of generalized anasarca, fatigue and low back ache. She was found to have a hemoglobin of 8.8 along with severe leukopenia. Urinalysis was positive for large amount of blood, protein with a protein: creatinine ratio of 9 gm. ANA titer was positive along with low levels of C3 complement and normal levels of C4 complement. Creatinine of 2.3 which was 4 times higher than her baseline. Labs from 2 months ago showed creatinine of 0.57. Of note, the patient was diagnosed with COVID-19 a month ago. She had a renal biopsy and was diagnosed with stage IV LN and was started on dialysis.

**Discussion:** LN usually has an indolent course with people developing ESRD within 5 years of diagnosis of lupus. This case strikes out as a rapid progression of LN with progression to ESRD within less than 3 months of diagnosis of SLE. COVID-19 a few months before she was diagnosed with Lupus is a possible source of a cytokine storm. Suggested mechanisms of induction of autoimmunity include both molecular mimicry as well as bystander activation whereby the infection may lead to activation of antigen presenting cells that may in turn activate pre-primed auto-reactive T-cells, thus leading to pro-inflammatory mediators, which in turn may lead to tissue damage. Strategies to prevent rapid progression to ESRD in these patients needs to be studied and better understood. Perhaps patients with autoimmune conditions like SLE need more robust management of diseases like COVID-19 which is known to alter and activate the immunological cascade. As per recent literature exaggerated extrafollicular B cell response characteristic of active SLE also characterizes the B cell response to COVID-19. Understanding and targeting the B cell pathway could potentially help dampen a severe response and disease progression. Overlap including racial preponderance of disease severity also needs to be studied further.

#### FR-PO051

##### Paxlovid Use in COVID-19 Infection: An Ounce of Prevention Is Worth a Pound of Cure

Randa Abd algayoum, Mario A. Leone, Khaled Nashar, Reem Daloul, Kalathil K. Sureshkumar. *Allegheny Health Network, Pittsburgh, PA.*

**Introduction:** Paxlovid (nirmatrelvir+ ritonavir) is a promising new combination drug that can significantly reduce hospitalization and all-cause mortality in Covid-19 infection. Ritonavir is a potent inhibitor of cytochrome-P450 system CYP3A enzymes and concomitant use with calcineurin inhibitors (CNI) such as tacrolimus can dangerously increase CNI blood levels. We present a heart transplant recipient on tacrolimus who developed acute kidney injury (AKI) and refractory life-threatening hyperkalemia following Paxlovid use and successful treatment using P450 induction with phenytoin along with dialysis support.

**Case Description:** A 43-year-old male with CKD stage III and previous heart transplant on tacrolimus was admitted with dyspnea, malaise, and oliguria. Few days earlier, he developed Covid-19 infection and received 5-day course of Paxlovid prescribed from elsewhere. On presentation, patient was hypervolemic, with the following serum values: K+ 7.1 mEq/L (peaking to 8.3 despite medical therapy), HCO3- 17 mEq/L and creatinine 4.67 mg/dL (baseline 3.0). Patient required emergent hemodialysis. Tacrolimus trough level came back as >60 ng/mL. Patient was started on IV phenytoin 100 mg every 12 hours. Tacrolimus levels remained extremely high over next few days with subsequent improvement (fig.). Patient required 4 dialysis sessions. Subsequently urine output improved, and serum creatinine returned to baseline.

**Discussion:** Paxlovid use will likely increase with Covid-19 surge. This drug has important safety risks in organ transplant recipients and kidney disease as highlighted by our case, where supratherapeutic tacrolimus levels due to P450 inhibition resulted in AKI and hyperkalemia. Empiric dose reduction or withholding CNI agents when initiating Paxlovid with close CNI level monitoring is recommended. Risk mitigation strategies are also important such as interruptive alerts in electronic health records, educational outreach, and alerting pharmacies about Paxlovid-CNI interactions.

Serial K+ and Tac levels

## FR-PO052

**Proceed With Caution: Drug Interaction Complicates Use of Nirmatrelvir/Ritonavir in Kidney Transplant Recipients With COVID-19**  
 Shikha Shailly, Clifford D. Miles, Scott G. Westphal, Kathleen Borghoff, Audai Ma'ayah. *University of Nebraska Medical Center, Omaha, NE.*

**Introduction:** Kidney transplant recipients are at increased risk of severe COVID-19 infection due to poor response to vaccination and immunosuppression. Antiviral therapies are thus important to mitigate risk of severe disease. Nirmatrelvir/ritonavir, an oral antiviral, has increasingly been used in higher risk patients with COVID-19. Unique to transplant patients is the risk of calcineurin inhibitor (CNI) drug interaction and potential for severe drug toxicity.

**Case Description:** A 57-year-old male received a kidney transplant 8 months ago. Immunosuppression includes tacrolimus, mycophenolate, and prednisone, and he was fully vaccinated and boosted against SARS-CoV-2. He presented with headache, fevers, and body aches and COVID antigen test was positive. His primary care provider prescribed nirmatrelvir/ritonavir, and immunosuppression was continued. Two days later he developed nausea, vomiting, diarrhea, and fatigue prompting emergency evaluation. It was unclear if symptoms were drug-related or due to COVID-19 infection. Given the high risk of severe COVID-19, nirmatrelvir/ritonavir was continued, and tacrolimus was held. Two days later, tacrolimus level was checked and resulted at 75.6 ng/mL, complicated by acute kidney injury. He was admitted, treated with intravenous fluids and phenytoin to enhance CNI metabolism. Symptoms and graft function improved, and tacrolimus level decreased but remained high 2 days later (54 ng/mL). Tacrolimus remained on hold at discharge and was restarted when level normalized.

**Discussion:** Nirmatrelvir inhibits M<sup>pro</sup>, a protease enzyme required for SARS-CoV-2 replication. As a potent inhibitor of CYP3A, nirmatrelvir/ritonavir may interact with drugs metabolized through this pathway, including CNIs. This patient's tacrolimus level was severely elevated even after 2 days of drug cessation leading to toxicity and hospitalization. Use of nirmatrelvir/ritonavir with CNIs requires extreme caution. The antiviral benefit may be opposed by risks incurred through drug interaction. If used, we recommend holding or reducing the CNI dose and close monitoring of levels. Providers and patients should be educated about this interaction, and alternative treatments may be preferable.

## FR-PO053

**Importance of Renal Biopsy in the Current COVID-19 Era: Acute Phosphate Nephropathy in a Patient With COVID-19 and New Systemic Lupus Diagnosis**

Mathura Babu. *Ascension St John Hospital, Detroit, MI.*

**Introduction:** Lupus nephritis is a common manifestation of systemic lupus erythematosus. About 40-60% of patients with systemic lupus erythematosus will have renal involvement. We present a case of a young lady with SARS-CoV-2 pneumonia who additionally presented with alopecia, arthritis and acute renal injury. Initially, the consulting team presumed the diagnosis to be due to lupus nephritis. The patient was treated with IV methylprednisolone and oral prednisone. The renal biopsy revealed widespread calcium phosphate crystals within the tubular lumens, suggestive of acute phosphate nephropathy. Electron microscopy showed diffuse foot process effacement consistent with minimal change disease.

**Case Description:** A 20-year-old lady with no past medical history presented with right-sided chest pain, myalgias, fever, and vomiting for 5-6 days. She had proteinuria and serum creatinine of 5 mg/dL. She was SARS-CoV-2 positive. She also had frontal alopecia and photosensitivity over the past five months, along with swelling/tenderness in her wrists and MCPs over the past year. The patient's mother had a diagnosis of lupus which was well controlled on Hydroxychloroquine. Further lab work revealed lymphopenia, positive for smith, coombs, cryoglobulins, RF, RNP, and SSA. Other pertinent work-up was negative. The patient was started on induction therapy for possible lupus nephritis of 1 g IV solumedrol daily for three days. The patient progressively became anuric, and creatinine peaked to 8 mg/dL. Dialysis was initiated. Her urine output improved after the third dialysis session, and dialysis was stopped. Her creatinine improved to 2.4 mg/dL. After the biopsy confirmed phosphate nephropathy, a focused history failed to reveal a cause. She denied sodium phosphate bowel preparations, consuming star fruit or ethylene glycol exposure.

**Discussion:** This case shows the importance of biopsy even in a well-known condition such as lupus nephritis. The etiology of renal failure in SARS-CoV-2 is primarily acute tubular necrosis, with collapsing focal segmental glomerulosclerosis also reported. Calcium phosphate deposition is not a reported complication of COVID-19 or lupus nephritis. The tubuloreticular inclusions can be found with lupus nephritis and viral infection. The etiology of phosphate-induced nephropathy remains unclear.

## FR-PO054

**AKI in COVID-19 Infection: Role of Hypercatabolic Status**

Qasim Muhammad,<sup>1</sup> Ping Li,<sup>2</sup> <sup>1</sup>The George Washington University, Washington, DC; <sup>2</sup>Veterans Health Administration, Washington, DC.

**Introduction:** Acute Kidney Injury (AKI) is a very common complication of patients with SARS-CoV-2 virus (COVID-19) infection. COVID-19 infected patients have longer hospital length of stays and higher mortality rate. There are multiple postulated mechanisms for AKI in the setting of COVID-19. Some researchers reported that the COVID-19 virus directly binds to the ACE-2 receptors in proximal tubules and leads to tubular dysfunction. In rare cases, a hypercatabolic state can be seen that carries a significantly higher mortality rate with ensuing hyperuricemia and hyperphosphatemia.

**Case Description:** We describe a patient presenting with severe AKI with hypercatabolic state in the setting of COVID-19 infection. 40 year old male with a history of hypertension and CHF (EF 35%) presented with fatigue, diarrhea, nausea and vomiting for 10 days after COVID-19 infection. He was found to have severe AKI with blood urea nitrogen of 254 and creatinine of 21 mg/dL which was associated with hyperkalemia, gap acidosis, severe hyperuricemia (23 mg/dL) and hyperphosphatemia (17 mg/dL). Despite aggressive volume resuscitation in the ICU, the patient remained oliguric with no improvement in kidney function for two days. He was subsequently initiated on hemodialysis. After getting 2 sessions of dialysis without ultrafiltration, renal recovery was noted eventually normalizing within 10 days. Extensive work up indicated the patient had no tumor lysis syndrome and rhabdomyolysis on this admission.

**Discussion:** There are multifactorial mechanisms for AKI in patients with COVID-19 infection including direct viral invasion of the kidney proximal tubules. Our case demonstrated that a hypercatabolic state may contribute to AKI in these patients. The proposed mechanisms involve elevated serum uric acid levels causing small renal arterial constriction, glomerular auto-dysregulation and tubular crystallization due to supersaturation causing to kidney tubular injury. Thus, clearance of uric acid and phosphorus with dialysis may promote more rapid kidney function recovery.

## FR-PO055

**A Case of Membranous Nephropathy Post SARS-CoV-2 Vaccination**

Luis G. Osorio,<sup>1</sup> Esteban Rodriguez,<sup>1</sup> Smita Padala,<sup>1,2</sup> <sup>1</sup>HCA Florida Citrus Hospital, Inverness, FL; <sup>2</sup>VSP Nephrology Associates, Lecanto, FL.

**Introduction:** Emergency use authorization and mass vaccination programs worldwide have lowered the burden of the COVID-19 pandemic. Vaccine complications not previously seen in clinical studies continue to manifest. We present a case of membranous nephropathy (MN) following the SARS-CoV-2 vaccination with successful treatment.

**Case Description:** Our patient is a 58-year-old woman with past medical history of hypothyroidism seen at a nephrology clinic for evaluation of new onset symptoms of dyspnea, severe bilateral pedal edema, and proximal muscle weakness for 4 months. The patient had 3+ proteinuria and microscopic hematuria on urinalysis obtained by primary care provider. She also had a rapid decline in serum albumin to 2.2 g/dL and new onset hypercholesterolemia at 415 mg/dL. Before initial presentation, she had normal labs and no symptoms. Upon presentation to our nephrology clinic, the patient had proteinuria of 2,360 mg/day on a 24-hour urine collection, random urine protein-to-creatinine ratio (UPCR) of 5,459 mg/g and random urine albumin-to-creatinine ratio (UACR) of 3,539 mg/g. She had no risk factors for chronic kidney disease. The only recent change in the health management of the patient was the administration of two doses of the SARS-CoV-2 vaccine several weeks prior to presenting with her initial symptoms 4 months ago. The phospholipase A2 receptor (PLA<sub>2</sub>R) antibody was elevated at 287 IU/mL. Serological tests for other sources of proteinuria were negative. Renal biopsy performed was consistent with primary MN. The patient was started on rituximab infusion given 2 weeks apart based on Mentor Trial. Additional treatment included apixaban, sulfamethoxazole/trimethoprim DS, losartan, and L-carnitine. After two doses of rituximab, she had resolution of dyspnea, pedal edema and muscle weakness. Repeat labs revealed UPCR to 1000 mg/g, UACR to 629 mg/g, improvement of PLA<sub>2</sub>R to 8 IU/mL. Our patient achieved immunological remission and partial clinical remission.

**Discussion:** This case illustrates a potential association of the SARS-CoV-2 vaccination and autoimmune mimicry leading to MN. We hope that this will help clinicians become aware of a potential complication not widely recognized and an effective management strategy. We hope further investigations of this possible association are performed as more cases are discovered.

## FR-PO056

### Can COVID-19 Vaccination Be the Culprit for New-Onset Crescentic Glomerulonephritis? The Correlation vs. Causation Conundrum

Akbar A. Khan,<sup>1</sup> Grant Kirby,<sup>2</sup> <sup>1</sup>Hospital Municipio de San Juan, San Juan, Puerto Rico; <sup>2</sup>Johns Hopkins University, Baltimore, MD.

**Introduction:** While the development, delivery, and implementation of the mRNA vaccines have been spectacular, consideration for potential rare side effects on organ systems was not clear. Although emergency use authorization trials of these vaccines in the USA did not demonstrate major safety concerns, unique side effects after mass-scale vaccination are now being reported more frequently. Here, we describe a case of new-onset crescentic & sclerosing GN with linear basement membrane staining for IgG, kappa, and lambda by immunofluorescence in a 30-yo healthy female three days after receiving her Tozinameran (Pfizer-BioNTech) booster vaccine.

**Case Description:** 30 y/o Caucasian female with no PMH presented with a CC of gross hematuria 3 days after receiving her booster of Tozinameran. Retrospectively reported symptoms of pedal edema, generalized athralgia, tinnitus, and paresthesia of lower limbs. UA revealed dysmorphic RBCs and proteinuria. CT urethrogram, & cystoscopy revealed left hydronephrosis, no nephrolithiasis or urothelial lesions. Kidney biopsy revealed crescentic & sclerosing GN, with linear GBM staining for IgG, Kappa, & Lambda on IF. Several glomeruli showed segmental scars & fibrous crescents in addition to focal cellular crescents of varying ages raising the possibility of concurrent ANCA vasculitis. Her GBM antibody was 25. Additional workup of ANCA, PLA2R, PR3, ana, c3/c4 levels, dsDNA, and hepatitis studies returned negative. On admission, BP was 175/103, and HR 104. Labs were notable for hemoglobin 13.3, WBC 16.6k, & BUN/creatinine 16/1.5. The PE was unremarkable. She received pulse IV steroid therapy, cyclophosphamide, Lupron, and daily plasma exchange (PLEX) for 5 days until her GBM antibody cleared. She responded well to treatment. Her renal function improved, and she was discharged without requiring dialysis.

**Discussion:** Our case demonstrates a possible correlation & causation scenario after receiving a Tozinameran booster shot activating anti-GBM disease with concurrent ANCA-negative vasculitis demonstrated by kidney biopsy. Although the mechanism of *de novo* anti-GBM disease & ANCA-negative vasculitis post-SARS-CoV-2 vaccine remains to be explained, pharmacovigilance is vital in our efforts to ascertain answers.

## FR-PO057

### Ravulizumab for COVID-19 Kidney Injury

Aliza Anwar Memon,<sup>1</sup> Hasban Ahmed,<sup>2</sup> Andrew M. Siedlecki,<sup>2</sup> <sup>1</sup>Saint Louis University, Saint Louis, MO; <sup>2</sup>Brigham and Women's Hospital, Boston, MA.

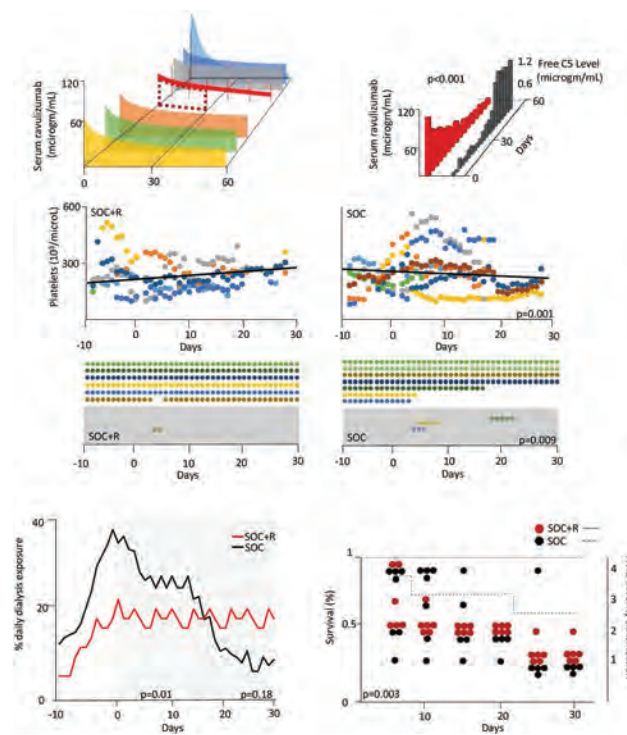

**Background:** The evidence suggests that the primary events in AKI occur on the luminal surface of the endothelial cells in the microvasculature of kidney. These findings can be explained by the activation of the complement resulting in endothelial injury. Ravulizumab inhibits the cleavage of C5 into C5a and C5b thus preventing endothelial dysfunction. In this study, we report the use of ravulizumab to treat AKI in the setting of COVID-19 infection with focus on a primary follow-up period of 30 days.

**Methods:** Patients were randomized in a placebo-controlled fashion. One group received placebo and standard care (SOC) while the second group received SOC and ravulizumab. Outcomes were rigorously assessed for 30 days after enrollment.

**Results:** 13 (11.4% of screened) patients identified to have COVID-19 infection were enrolled in the study. Six patients were randomized to receive ravulizumab in addition to standard of care (SOC+R) and seven patients were randomized to SOC. Three patients randomized to the SOC group died after enrollment. Mean number of hospital free days after enrollment was 290±47 (SOC+R) vs 164±144 (SOC) respectively. Free C5 levels increased over 30 days following ravulizumab infusion and corresponded with decreasing ravulizumab blood levels over the same time interval ( $p=0.001$ ). During this same time period there was a decreased number of anuric days observed in the SOC+R compared to SOC ( $p=0.009$ ). There was a reduced frequency of dialysis events in the SOC+R for ten days after enrollment ( $p=0.001$ ).

**Conclusions:** Due to the recurrent impact of COVID-19 infection throughout the world, targeted therapies for concomitant kidney injury merit future investigations to reduce incidence of AKI and potentially reduce future prevalence of CKD.

**Funding:** Commercial Support - Alexion Pharmaceuticals Inc

## FR-PO058

### Incidence of COVID-19-Associated AKI: Effect of Time

Claudine T. Jurkovitz, Richard Caplan, Kevin Ndura, Michael T. Vest. *Christiana Care Health Services Inc, Wilmington, DE.*

**Background:** Acute Kidney Injury (AKI) is a known complication of COVID-19. Recent reports have suggested a decrease in AKI incidence with time. The objective of this study was to evaluate the incidence of AKI over time and determine whether changes in patients' characteristics could explain this decrease.

**Methods:** Data were selected from the Cerner Real-World Data™, a cloud-based platform of de-identified electronic health records data from >100 health systems. Our study population was defined as hospitalized adults with COVID-19 in 2020-2021. We excluded patients with known end-stage kidney disease and those whose first interaction with the health system was the COVID-related hospitalization. AKI was defined as an increase in serum creatinine by  $\geq 0.3$  mg/dl within 48 hours or  $\geq 1.5$  times the baseline. We used logistic regression to estimate the association between time categorized in quarters and occurrence of AKI after adjusting for demographic variables and comorbidities identified from the Elixhauser ICD10-based algorithm. To determine whether the effect of demographic and comorbidities on the likelihood of AKI varied with time, we also ran separate logistic regression models for each quarter.

**Results:** Our analytical dataset included 152,296 patients. Of those 49% were female, 12% black, 71% white, 29% Hispanic, mean age was 61±19, 32% had diabetes, 55% hypertension, 14% Kidney Disease, 20% coronary artery disease, 14% congestive heart failure, 24% COPD, 10% liver disease and 21% developed AKI while hospitalized. The incidence of AKI decreased from 28% in 2020 quarter one (2020Q1) to 19% in 2021Q4 (test of trend  $p<0.001$ ). The odds of developing AKI for 2020Q2 to 2021Q4 compared to 2020Q1 were Odds Ratio=0.80, 95% CI 0.72-0.89, 0.73 (0.66-0.81), 0.72 (0.66-0.80), 0.72 (0.65-0.80), 0.58 (0.53-0.65), 0.67 (0.60-0.74), 0.61 (0.52-0.71) respectively. After adjusting for covariates, the effect of time although attenuated (highest 2020Q2 OR=0.79 (0.71-0.88), lowest 2021Q4 OR=0.67 (0.58-0.79) remained significant. Time did not modify the effect of the demographic variables and comorbidities on developing AKI.

**Conclusions:** The decrease in AKI incidence with time is independent of the effect of demographic risk factors and comorbidities. This decrease is likely related to improvement in patients volume management, treatment with steroids, anticoagulation and early treatment of the virus.

## FR-PO059

### Renal Outcomes in Hospitalized Patients Receiving Hemodialysis After Infection With Acute COVID-19

Abhishrey Raj, Alpana Raizada. *University College of Medical Sciences, Delhi, India.*

**Background:** Kidney injury in acute COVID-19 infection has been associated with decreased survival and prolonged duration of hospitalization irrespective of patient population or severity of illness. Outcomes among hospitalized patients with COVID-19

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

and kidney injury in terms of recovery of renal function are insufficiently assessed. A good understanding of the same is vital to plan post-discharge renal care, and to estimate the potential burden that COVID-19 confers on the nephrology community.

**Methods:** In a cohort study, we included patients who received hemodialysis (HD) during hospital stay after infection with COVID-19 at our center following kidney injury during the second wave of the pandemic in New Delhi between June and December, 2021. Participants were excluded if they received dialysis following previously existing chronic renal failure. Participants were followed-up telephonically for a period of six months to assess renal function and need for HD. Recovery of renal function was considered early if serum creatinine improved by 33% of peak value during hospital stay, or late if a 33% reduction in follow-up evaluation was noted over the discharge serum creatinine.

**Results:** A total of 62 patients (34 (54.8%) men and 28 (45.2%) women) with a mean age of 51.2 years (+16.3), and mean urea of 181 mg/dl (+95.7) and mean creatinine of 6.9 mg/dl (+3.5) at presentation were included in the cohort. Of these, 31 (50%) had presented with mild, 11 (17.7%) with moderate and 20 (32.3%) with severe disease. Ten (16.1%) succumbed to illness during hospital stay and another 12 (19.3%) patients died during the follow up period. 34 (54.8%) patients were discharged from hospital on HD, and 18 (29%) were not advised HD at discharge. While 30 (75%) of the survivors had indicated early renal recovery at discharge, none had recovered renal function at the end of follow up period. A median decline of 48% and 44% at follow up was noted from the peak and presentation values of creatinine recorded during hospital stay.

**Conclusions:** Patients undergoing hemodialysis after hospitalization with acute COVID-19 infection had poor short-term outcome and survivors continued to have renal impairment after six months. It is important to recognize recovery rates and patterns to offer early comprehensive renal care.

## FR-PO060

### Follow-Up Care of Critically Ill Patients With AKI

Rachel Jeong,<sup>1,2</sup> Alix Clarke,<sup>1</sup> Matthew T. James,<sup>1</sup> Robert R. Quinn,<sup>1</sup> Pietro Ravani,<sup>1</sup> Sean M. Bagshaw,<sup>3</sup> Henry T. Stelfox,<sup>2</sup> Neesh I. Pannu,<sup>4</sup> Ngan Lam.<sup>1</sup> <sup>1</sup>Cumming School of Medicine, Division of Nephrology, University of Calgary, Calgary, AB, Canada; <sup>2</sup>Department of Critical Care Medicine, University of Calgary, Calgary, AB, Canada; <sup>3</sup>Department of Critical Care Medicine, University of Alberta, Edmonton, AB, Canada; <sup>4</sup>Department of Medicine, Division of Nephrology, University of Alberta, Edmonton, AB, Canada.

**Background:** Acute kidney injury (AKI) occurs in more than half of critically ill patients in the intensive care unit and is associated with adverse outcomes. The 2012 Kidney Disease Improving Global Outcomes guideline recommends follow-up at 3 months post-discharge for assessment of kidney health. It remains unclear whether these recommendations are followed. Our objective was to determine processes of follow-up care for critically ill patients with AKI.

**Methods:** We conducted a retrospective cohort study in Alberta, Canada, using linked healthcare databases within the Alberta Kidney Disease Network. We included critically ill adult patients with evidence of AKI (defined as  $\geq 50\%$  or  $\geq 26.5$   $\mu\text{mol/L}$  serum creatinine increase from baseline) from 2005-2018. The primary outcome was an outpatient nephrology follow-up visit within 3 months of discharge. Secondary outcomes were an outpatient serum creatinine or urine protein measurement, and a follow-up visit by a family physician within 3 months of discharge.

**Results:** There were 29,732 critically ill adult patients with AKI. The median age was 68 years, 39% were female, and the median estimated glomerular filtration rate was 72 mL/min/1.73 m<sup>2</sup>. The cumulative incidence of receiving nephrology follow-up within 3 months before dying or requiring maintenance kidney replacement therapy was 5%. At 3 months, 64% and 28% of patients had an outpatient creatinine and urine protein measurement, respectively, and 89% received follow-up by a family physician. Factors associated with nephrology follow-up were younger age, urban residence, lower baseline estimated glomerular filtration rate, higher baseline albuminuria, previous nephrology visit, shorter hospitalization stay, higher severity of AKI, receipt of acute dialysis, inpatient nephrology consultation, kidney biopsy, and worse kidney function at the time of discharge.

**Conclusions:** Many critically ill patients with AKI do not receive the recommended follow-up care. Our findings illustrate a significant gap in the transition of care for critically ill patients with AKI. Further research is needed to determine if follow-up care is associated with improved patient outcomes.

## FR-PO061

### Race-Agnostic Computable Phenotype for Kidney Health Assessment in Adult Hospitalized Patients

Tezcan Ozrazgat-Baslanti, Yuanfang Ren, Esra Adiyek, Tyler J. Loftus, Mark S. Segal, Azra Bihorac. University of Florida, Gainesville, FL.

**Background:** Acute kidney injury (AKI) and chronic kidney disease (CKD) are clinically used categorizations of kidney health. Standard race adjustments for estimating glomerular filtration rate (GFR) and reference creatinine can yield a lower AKI and CKD prevalence among African Americans (AA) to ones from non-adjusted estimates.

**Methods:** We developed race-agnostic computable phenotypes that assess kidney health among 139,152 subjects admitted to the University of Florida Health between 1/2012-8/2019. We removed the race modifier from the formula used by the race-adjusted algorithm to calculate the estimated GFR and creatinine (*race-agnostic algorithm 1*). In the second race-agnostic algorithm (*race-agnostic algorithm 2*), these calculations

rely on 2021 CKD-EPI refit without race formula as endorsed by the National Kidney Foundation. We validated computable phenotypes developed for preadmission CKD and AKI presence on 300 selected cases using clinical adjudication.

**Results:** Race-agnostic algorithms identified CKD and AKI in 23% and 15% of encounters, respectively. Among 86,379 AA admissions, 26,908 (31%) and 26,003 (30%) had CKD based on race-agnostic algorithm 1 and 2, respectively. Race adjustment reclassified 2,113 (8%) to no CKD and 7,901 (29%) to a less severe CKD stage compared to race-agnostic algorithm 1, while it reclassified 1,208 (5%) to no CKD and 4,606 (18%) to a less severe CKD stage compared to race-agnostic algorithm 2. Of 12,451 (15%) AKI encounters based on race-agnostic algorithm 1, the race adjustment reclassified 591 (4.7%) to no AKI and 305 (2.4%) to a less severe AKI stage. Of 12,251 (14%) AKI encounters based on race-agnostic algorithm 2, the race adjustment reclassified 382 (3.1%) to no AKI and 196 (1.6%) to a less severe AKI stage. Phenotyping algorithm based on refit without race formula performed well in identifying patients with CKD and AKI with a sensitivity of 100% (95% CI 97%-100%), 99% (95% CI 97%-100%), and a specificity of 88% (95% CI 82%-93%) and 98% (95% CI 93%-100%), respectively.

**Conclusions:** Race-agnostic algorithms identified substantial proportions of additional patients with CKD and AKI compared to race-adjusted algorithms in AA patients. The phenotyping algorithm is promising in identifying patients with kidney disease, assessing quality of care, and improving clinical decision-making.

### Use of a Policy Tree Algorithm to Identify Maximal Treatment Effect of Crystalloid Therapy in a Cohort of Critically Ill Patients With Sepsis

Wonsuk Oh,<sup>1</sup> Hannah Kittrell,<sup>2</sup> Girish N. Nadkarni.<sup>3</sup> <sup>1</sup>Icahn School of Medicine at Mount Sinai Department of Genetics and Genomic Sciences, New York, NY; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>3</sup>Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY.

**Background:** Sepsis-associated acute kidney injury (SA-AKI) is a significant health problem in intensive care units. As SA-AKI can progress, it is important to individualize therapy early based on patient characteristics to prevent progression. We aimed to use a machine learning causal inference method to identify groups of patients that have more than the average population treatment effect, specifically in relation to intravenous crystalloids.

**Methods:** We identified critically ill adult patients with sepsis admitted to a tertiary academic medical center. The baseline of this study is 1 hour after sepsis onset. We excluded patients (i) who were discharged within 48 hours of onset, (ii) with a history of kidney failure, (iii) without vital signs measurement during the admission, (iv) with AKI stage 1-3 present before the baseline, and (v) without serum creatinine or urine output measurements after the baseline. The study outcome was the difference between baseline serum creatinine and peak serum creatinine during the follow-up periods. We applied a policy tree algorithm, a state-of-the-art machine learning method, to learn rule-based policy (treatment strategies) through a doubly robust estimator with a form of decision trees. We gradually increased the tree's depth (accounting for more variable interactions) and evaluated average treatment effects of crystalloids on limiting the increased peak serum creatinine levels in identified patients.

**Results:** We applied the policy tree algorithm on 19,179 patients. 13,204 (68.7%) patients developed AKI stage 1 or higher. As we gradually increased the policy tree, the tree identified 832, 1188, 1999, 2425, and 3384 patients who showed maximal average treatment effects (ATE) of decreasing peak serum creatinine level, and ATE showed 0.246 (95% CI: 0.008, 0.484), 0.404 (0.191, 0.617), 0.436 (0.275, 0.597), 0.526 (0.376, 0.676), and 0.553 (0.418, 0.648), respectively. Mean ATE for the entire population was -0.076 (-0.108, 0.044).

**Conclusions:** We used the policy tree algorithm to identify subgroups of patients with sepsis with differing benefits of crystalloid therapy on SA-AKI prevention. Our results suggest that policy learning-based patient discovery can be useful for achieving personalized therapy of sepsis to prevent SA-AKI.

**Funding:** NIDDK Support, Other NIH Support - NHGRI

## FR-PO063

### Personalized Recommendations for AKI Using a Kidney Action Team (KAT-AKI): Design, Rationale, and Early Data

Abinet M. Akilu, Kyle D. O'Connor, Francis P. Wilson. CTRA (Clinical and Translational Research Accelerator) Yale School of Medicine, New Haven, CT.

**Background:** AKI is common during hospitalization and is associated with high morbidity and mortality. Although studies have looked at the utility of electronic alerts in improving AKI outcomes, no prior study has evaluated real time, personalized AKI recommendations. Our study aims to assess the impact of individualized AKI-specific recommendations from a trained clinician and pharmacist delivered immediately after electronic detection of AKI in hospitalized patients.

**Methods:** KAT-AKI is a randomized-controlled trial conducted across 8 hospitals at two major hospital systems. A real-time electronic AKI alert system informs a dedicated team comprising a physician and pharmacist who independently review the chart in real-time, screen for eligibility, and provide AKI-specific recommendations, across the following domains: diagnostics, medications, volume, potassium and acid-base management. Recommendations are delivered to the primary team in the alert arm of the study and logged for future analysis in the usual care arm. The primary outcome is a composite of progression to higher AKI stage, dialysis and mortality 14days after randomization. A key secondary outcome will be percentage of recommendations implemented by the primary care team within 24hours from randomization.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Results:** As of May 16, 2022, there were 342 individuals enrolled out of 507 screened. Median(IQR) age was 72.2(60.0,81.5) yrs. 48.8% were female, 12.3% Hispanic and 19.6% were Black. Nearly half(49%) were on a general medical floor at the time of alert and 14.4% were admitted to an ICU. Virtually all participants (99.1%) were recommended to have at least one diagnostic intervention. 180(52.6%) individuals had recommendations to discontinue a medication or to dose-adjust a medication. Of the 90 with medication discontinuation recommendations, 23.3% were on NSAIDs. The median(IQR) time from AKI alert to recommendation was 0.52(0.18,0.90) hr.

**Conclusions:** Conducting a randomized clinical trial using an electronic AKI alert coupled with a team of clinicians is feasible and generates valuable data about early AKI management.

**Funding:** Other U.S. Government Support

### Outcomes Following Community-Acquired AKI: A National Study of US Veterans

Virginia Wang,<sup>1,2</sup> Lindsay Zepel,<sup>1</sup> Matthew L. Maciejewski,<sup>2,1</sup> Erin B. Chang,<sup>1</sup> M. Alan Brookhart,<sup>1</sup> C. Barrett Bowling,<sup>2,1</sup> Clarissa J. Diamantidis,<sup>1</sup> <sup>1</sup>Duke University School of Medicine, Durham, NC; <sup>2</sup>Durham VA Medical Center, Durham, NC.

**Background:** Community-acquired acute kidney injury (CA-AKI) develops outside of the hospital and is the most common form of AKI. Due to limited availability of outpatient lab and integrated health data, CA-AKI outcomes are poorly studied. This study leveraged national data to examine associations between incident CA-AKI and subsequent hospitalization and mortality.

**Methods:** We constructed a retrospective cohort of active primary care patients in the Veterans Health Administration (VA) in 2013-2017, excluding Veterans with no recorded outpatient serum creatinine (SCr) and those with a history of severe kidney disease ( $\geq$  Stage 5 or kidney transplant). CA-AKI was defined as  $\geq 1.5$ -fold relative increase in outpatient SCr or inpatient SCr ( $\leq 24$  hours from admission), from a reference value defined as the preceding outpatient SCr  $\leq 12$  months prior. We compared outcomes in Medicare and VA databases from a pooled cohort of patients with CA-AKI and a 5% random sample without observed CA-AKI. Cox models estimated associations between CA-AKI and 2-year all-cause hospitalization and mortality, adjusting for patient characteristics.

**Results:** With an annual cumulative CA-AKI incidence of approximately 2% in 2013-2017, the analytic cohort consisted of all 220,777 Veterans with CA-AKI and 492,539 controls with no CA-AKI. Those with CA-AKI had a higher hazard of 2-year all-cause hospitalization (hazard ratio [HR]=1.89, 95% confidence interval [CI] 1.87, 1.90) and mortality (HR=2.72, 95% CI 2.67, 2.77) compared to those without CA-AKI. These risks increased with greater CA-AKI severity (hospitalization: Stage 1 HR=1.80, 95% CI 1.78, 1.81; Stage 2 HR=2.23, 95% CI 2.19, 2.27; Stage 3 HR=2.68, 95% CI 2.60, 2.76; mortality: Stage 1 HR=2.50, 95% CI 2.45, 2.54; Stage 2 HR=3.45, 95% CI 3.35, 3.55; Stage 3 HR=4.57, 95% CI 4.38, 4.76). Compared with no CA-AKI, CA-AKI within 24 hours of hospital admission was associated with greater hazard of mortality (HR=3.81, 95% CI 3.72, 3.90) than among those with CA-AKI in the outpatient setting (HR=2.42, 95% CI 2.37, 2.46).

**Conclusions:** In a national cohort of Veterans, CA-AKI was associated with an approximately two-fold increased risk of hospitalization and mortality. Strategies to improve identification and follow-up management is critical to mitigate adverse outcomes of CA-AKI.

**Funding:** NIDDK Support, Veterans Affairs Support

#### FR-PO065

### AKI and ESRD Progression in Older Adult Veterans With Advanced CKD

Danira Medunjanin,<sup>1</sup> Bethany Wolf,<sup>1</sup> Roberto Pisoni,<sup>1,2</sup> David J. Taber,<sup>1,2</sup> John L. Pearce,<sup>1</sup> Kelly J. Hunt,<sup>1,2</sup> <sup>1</sup>Medical University of South Carolina, Charleston, SC; <sup>2</sup>VA Medical Center Ralph H Johnson, Charleston, SC.

**Background:** Those  $\geq 65$  years represent the largest growing age category in the US. Advanced age is a major risk factor for the development of CKD, which has high heterogeneity in disease progression. Hospitalization rates for AKI are increasing, especially amongst older adults who are at particular risk given their high comorbidity burden and susceptibility to nephrotoxins. Previous AKI epidemiologic analyses have focused on hospitalized populations which may bias results towards sicker populations, particularly when results are extrapolated to ambulatory CKD populations.

**Methods:** This was a national longitudinal cohort study which performed competing risk regression analysis on 24,133 older Veterans ( $\geq 65$  years), with incident CKD stage 4 from 2011-2013 to determine the association between AKI and progression to ESRD while evaluating age as an effect modifier. The following covariates based on a priori selection were adjusted for: AKI severity and history, age, sex, race-ethnicity, service-connected disability, Elixhauser comorbidity burden, NSAIDs, ACE inhibitors, diuretics, rural residence, and driving distance to nearest primary care. Veterans were followed until December 31, 2016, or death. AKI was defined according to the modified KDIGO AKIN definition. Due to the time constraint in defining AKI ( $\leq 7$  days), we were limited to inpatient labs. Most studies of hospitalized patients with AKI assign a baseline SCr at the time of admission which may not reflect stable levels of kidney function. Because the VA is the largest integrated health care system in the US, we can access outpatient SCr labs prior to hospitalization to determine an appropriate baseline kidney function. ESRD was defined by entry into the USRDS registry. Death was considered the competing risk.

**Results:** Adjusted modeling demonstrated AKI was independently associated with a 1.9-fold increased risk [HR: 1.91 95% CI: 1.64-2.23] of ESRD progression. Age was not an effect modifier of this relationship (p-value=0.08). Though non-significant, AKI was associated with a 6% increase [HR: 1.06 (95% CI: 0.96-1.16)] in death.

**Conclusions:** Regardless of AKI status, death was far more frequent than ESRD in this population (51.1% vs. 14.5%). Despite this, our national cohort study showed that AKI was a substantial and independent risk factor for the development of ESRD in older Veterans with advanced CKD.

**Funding:** Veterans Affairs Support

#### FR-PO066

### The Burden of AKI in a Cohort of 5217 CKD Patients

Ulla T. Schultheiss,<sup>1,5</sup> Fruzsina K. Kotsis,<sup>1,5</sup> Charlotte Behning,<sup>4</sup> Jennifer Nadal,<sup>4</sup> Anna Kottgen,<sup>1</sup> Kai-Uwe Eckardt,<sup>2,3</sup> Markus P. Schneider,<sup>3</sup> <sup>1</sup>Institute of Genetic Epidemiology, Faculty of Medicine and Medical Center, University of Freiburg, Freiburg, Germany; <sup>2</sup>Department of Nephrology and Medical Intensive Care, Charité – Universitätsmedizin Berlin, Berlin, Germany; <sup>3</sup>Department of Nephrology and Hypertension, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen-Nürnberg, Germany; <sup>4</sup>Institute of Medical Biometry, Informatics and Epidemiology, University Hospital Bonn, Bonn, Germany; <sup>5</sup>Department of Medicine IV - Nephrology and Primary Care, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany.

**Background:** Chronic Kidney Disease (CKD) is associated with an increased risk for acute kidney injury (AKI), which is a risk factor for mortality. While in-patient AKI has been studied extensively, characteristics of out-patient AKI have been less studied. We therefore characterized in- and out-patient AKI in a large German CKD (GCKD) patient cohort.

**Methods:** Over 6.5 years of follow-up, in-patient-AKI events were adjudicated from hospital discharge letters and categorized based on the GCKD study adjudication catalogue: i) increase of creatinine  $>0.3$  mg/dl, ii) doubling to triplication of creatinine, iii) creatinine value  $>4$  mg/dl plus an acute increase of  $>0.5$  mg/dl, iv) initiation of temporary renal replacement therapy. Out-patient-AKI events were calculated based on an algorithm by Hapca et al. 2020, using time windows prior- and post-AKI, applying similar criteria to categorize AKI as for in-patient-AKI.

**Results:** In 5217 CKD patients, 1411 in-patient-AKI events in 636 participants (median 1, IQR: 1-6) vs. 1114 out-patient-AKI events in 624 participants (median 1, IQR: 1-10) occurred. Recurrent events were recorded more frequently for out-patient-AKI compared to in-patient-AKI. Baseline characteristics for participants without any AKI event compared to participants experiencing at least one event in either in-patient-AKI or out-patient-AKI were a mean  $\pm$  standard deviation (m  $\pm$  sd) age for participants without an AKI event of 59.3  $\pm$  12.2 years, of 62.2  $\pm$  10.7 for in-patient-AKI, and of 58.8  $\pm$  12.6 for out-patient-AKI. Men were more likely to experience an AKI event than women for both in- and out-patient-AKI. Mean baseline eGFR values were lowest for participants without AKI (29.5  $\pm$  5.8 ml/min/1.73m<sup>2</sup>), but similar for both in-patient and out-patient-AKI (~31.1  $\pm$  6.3 ml/min/1.73m<sup>2</sup>). Median UACR values were  $>300$  mg/g for those with an out-patient-AKI event compared to 52.7 mg/g for those with an in-patient-AKI event. Prevalent cardiovascular disease was similar between in-patient-AKI and out-patient-AKI groups (e.g. 30% coronary heart disease), but ~8-15% higher than for participants without AKI.

**Conclusions:** Our study emphasizes the high burden of both in- and out-patient-AKI in CKD patients. Our analysis could further demonstrate that UACR values were higher for out-AKI-patients, which may help to better target preventative measures.

#### FR-PO067

### Platelet Factor 4 Antibodies and Severe AKI

Charlotte Thomas,<sup>1</sup> Rafia W. Ali,<sup>1</sup> Isabel Park,<sup>1</sup> Helena Kim,<sup>1</sup> Samuel Short,<sup>2,1</sup> Hanny Al-Samkari,<sup>3</sup> David E. Leaf,<sup>1</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>University of Vermont College of Medicine, Burlington, VT; <sup>3</sup>Massachusetts General Hospital, Boston, MA.

**Background:** Production of platelet factor 4 (PF4) antibodies is the seminal event in the development of heparin-induced thrombocytopenia, a common and often devastating complication in hospitalized patients. PF4 antibodies can cause macrovascular arterial and venous thrombosis, however, only limited data are available on their association

with microvascular thrombosis. Since the kidney is a highly vascularized organ, and renal microvascular thrombosis has been observed in multiple kidney diseases, we hypothesized that the appearance of PF4 antibodies in the circulation is independently associated with a higher risk of development of severe acute kidney injury (AKI) among hospitalized patients.

**Methods:** We performed a retrospective cohort study of all adult inpatients who had a PF4 test during an admission to two large academic hospitals in Boston, MA, between 2015 and 2021. Data were extracted using ICD-9/10 diagnosis and procedure codes. The primary exposure was a positive PF4 antibody immunoassay test. The primary outcome was severe AKI, defined as  $\geq 200\%$  increase in serum creatinine compared to the hospital admission value or receipt of kidney replacement therapy within 7 days following the PF4 test. We used multivariable logistic regression to adjust for potential confounders.

**Results:** The cohort consisted of 4224 patients who had a PF4 test, of whom 469 (11.1%) tested positive. Among those with a positive PF4 test, 50 (10.7%) developed severe AKI compared to 235 (6.3%) with a negative test ( $P<0.001$ ). In a multivariable model adjusted for age, sex, race, baseline eGFR, comorbidities, and severity of illness, patients with a positive PF4 test had 51% higher odds of developing severe AKI (95% CI, 1.08–2.13) compared to patients with a negative test (**Figure**). Patients with a positive PF4 test also had higher risk of developing AKI (any stage), the composite of AKI or death, and arterial and venous thrombosis, with similar magnitudes of association seen with thrombosis as with AKI (**Figure**).

**Conclusions:** PF4 positivity is independently associated with a higher risk of severe AKI in hospitalized patients.

**Figure. PF4 Antibodies and Renal and Extrarenal Outcomes.**

\*Adjusted for age, sex, race, baseline eGFR, hypertension, hyperlipidemia, chronic liver disease, active malignancy, WBC count, hemoglobin, invasive mechanical ventilation, sepsis, and shock. Abbreviations: CVA, Cerebrovascular Accident; DVT, Deep Vein Thrombosis; PE, Pulmonary Embolism.

## FR-PO068

### Electronic Alert Outpatient Protocol Improves the Quality of Care for the Risk of Postcontrast AKI Following Computed Tomography

Seokwoo Park, Eun-Jeong Kwon, Ho Jun Chin, Ki Young Na, Sejoong Kim. *Seoul National University Bundang Hospital Department of Internal Medicine, Seongnam, Gyeonggi-do, Republic of Korea.*

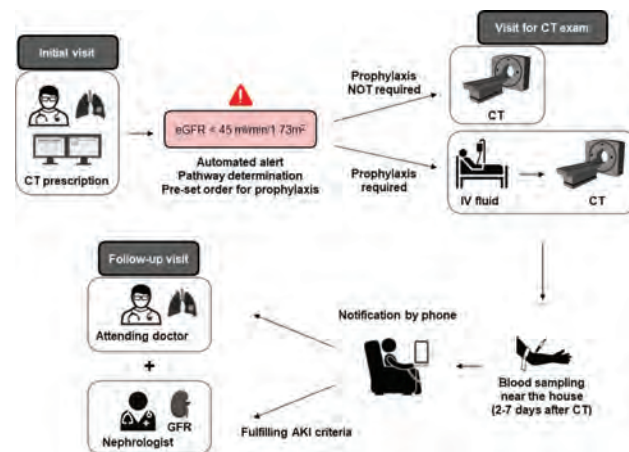

**Background:** Prevention and diagnosis of postcontrast acute kidney injury (PCKI) after contrast-enhanced computed tomography (CECT) requires intravenous fluid administration and follow-up measurements of serum creatinine in high-risk patients, which is often burdensome in outpatient department. Here, we investigated whether an electronic alert system can promote quality improvement regarding prevention and timely diagnosis of PCKI, and long-term outcomes.

**Methods:** In March 2018, we launched an automated alert system incorporated with hospital information system in a tertiary hospital in South Korea. The system identifies patients with baseline renal dysfunction, provides with protocolized prescription of fluid regimen, and recommends follow-up serum creatinine measurement. Severe PCKI was defined as increase in serum creatinine from baseline of more than 50%. Participants were categorized according to the time period when CECT was prescribed, before and after the launch of the system. Propensity for the surveillance of PCKI with serum creatinine measurement, severity of PCKI, and admission within 6 months were compared using logistic regression. Risks of mortality and renal replacement therapy were analyzed with Cox regression.

**Results:** Historical and alert group included 289 and 309 participants, respectively. After the introduction of alert system, participants were more likely to be followed for the surveillance of PCKI (66.7% versus 29.4%;  $OR_{adj}$ , 5.37;  $P<0.001$ ). Within those followed-up, severe PCKI was less common in alert group (5.3% versus 10.6%;  $OR_{adj}$ , 0.31;  $P=0.051$ ), albeit not statistically significant. The two groups did not differ in terms of admission ( $P_{adj}=0.597$ ), mortality ( $P_{adj}=0.589$ ), and renal replacement therapy ( $P_{adj}=0.434$ ).

**Conclusions:** An automated alert system can assist in appropriate prevention and reduce underdiagnosis of PCKI, concomitantly limiting clinical burdens of care providers. Whether the system may improve long-term outcomes is yet uncertain.

### Risk Prediction for AKI in Patients Hospitalized With COVID-19: Withstanding Variants Over Time

Meredith C. McAdams, Pin Xu, Michael M. Li, Mauricio Ostrosky-Frid, Duwayne L. Willett, Christoph U. Lehmann, Susan Hedayati. *The University of Texas Southwestern Medical Center, Dallas, TX.*

**Background:** Acute kidney injury (AKI) is common in patients hospitalized with COVID-19, predictive models for AKI are lacking. We aimed to develop the best predictive model for AKI and assess performance over time.

**Methods:** Patients with positive SARS CoV-2 PCR hospitalized between 3/1/2020 to 1/14/2022 at 19 Texas hospitals were included. Those with AKI present on admission were excluded. Comorbidities, demographics, baseline laboratory data, and inflammatory biomarkers were obtained from the EHR and used to build nested models for AKI in an inception cohort. Models were validated in four out-of-time cohorts. Model discrimination and calibration measures were compared to assess performance.

**Results:** Of 13,468 patients, 5,676 were in the Inception Cohort and 7,792 in subsequent validation cohorts grouped based on predominance of COVID variants, with cohorts 1 and 3 containing a mix of variants, cohort 2 corresponding to Delta predominance, and cohort 4 to Omicron. Prevalence of AKI was 13.7% in inception and 12.6%, 12.4%, 13.3%, and 14.4% in the validation cohorts. Proportion of AKI stages 2 or 3 vs. 1 was lower in the Omicron-dominant cohort 4 compared to the inception cohort (28/139 vs. 257/776,  $P=0.008$ ), but was no different for cohorts 1-3. The final model containing demographics, comorbidities and baseline WBC, hemoglobin, hsCRP, ferritin, and D-dimer, had an AUC=0.781 (95% CI, 0.763, 0.799). Compared to the inception cohort, discrimination by AUC (validation 1: 0.785 [0.760, 0.810],  $P=0.14$ , validation 2: 0.754 [0.716, 0.795],  $P=0.14$ , validation 3: 0.778 [0.751, 0.806],  $P=0.14$ , and validation 4: 0.743 [0.695, 0.789],  $P=0.14$ ) and calibration by ECI (validation 1: 0.116 [0.041, 0.281],  $P=1.0$ , validation 2: 0.081 [0.045, 0.295],  $P=0.64$ , validation 3: 0.055 [0.030, 0.162],  $P=1.0$ , and validation 4: 0.120 [0.043, 0.472],  $P=0.50$ ) showed stable performance over time.

**Conclusions:** Using demographics, comorbidities, admission laboratory values, and inflammatory biomarkers, we developed and externally validated a model to accurately predict AKI in hospitalized patients with COVID-19. A lower proportion of patients hospitalized during the Omicron-dominant period of the pandemic experienced severe AKI, but our predictive model withstood changes in practice patterns and virus variants.

**Funding:** NIDDK Support

## FR-PO070

### Use of TIMP-2 and IGFBP-7 for Prediction of AKI After Cardiac Surgery

David Delijani,<sup>1,2</sup> Pey-Jen Yu,<sup>3,1</sup> Jamie S. Hirsch,<sup>4,1</sup> Steven Fishbane,<sup>4,1</sup> Purva D. Sharma,<sup>4,1</sup> Tyllis Chang,<sup>1</sup> Alan Hartman,<sup>3,1</sup> Hugh Cassiere,<sup>3,1</sup> Kenar D. Jhaveri,<sup>4,1</sup> *Northwell Health, New Hyde Park, NY; <sup>2</sup>Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; <sup>3</sup>Dept of Cardiothoracic Surgery, Manhasset, NY; <sup>4</sup>Division of Kidney Diseases and HTN, Great Neck, NY.*

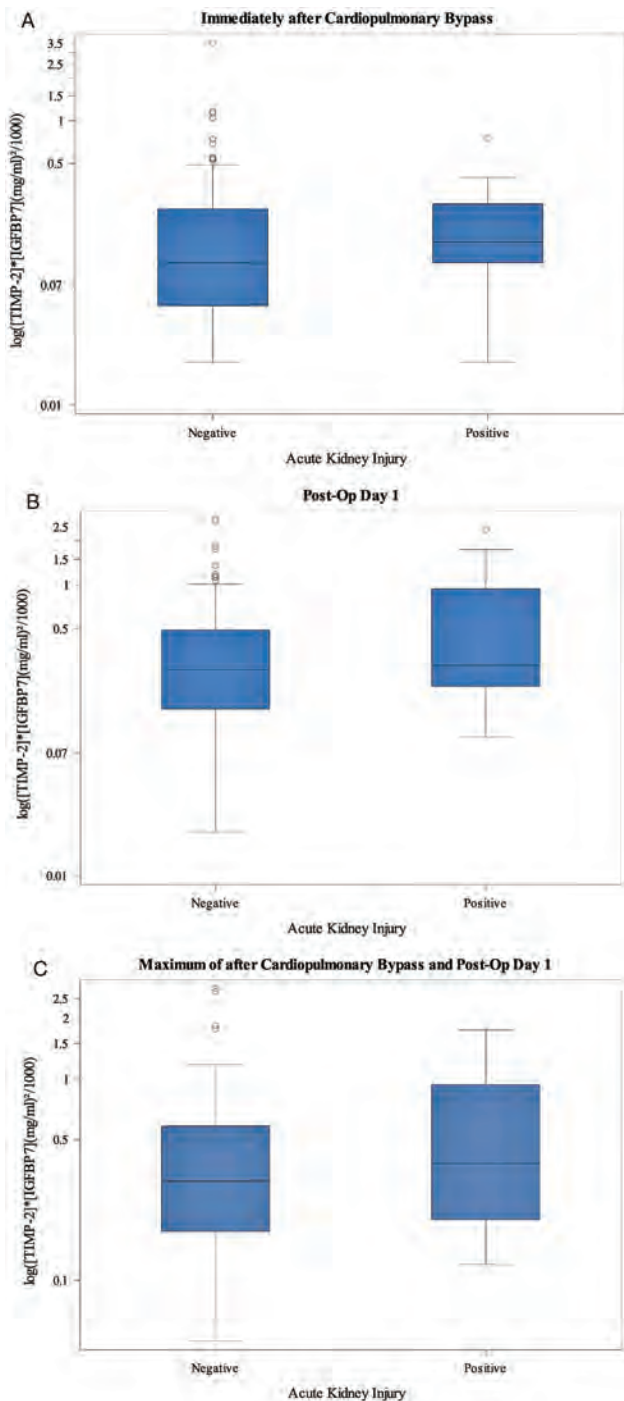

**Background:** Cell cycle arrest urinary biomarkers, tissue inhibitor of metalloproteinases-2 (TIMP-2) and insulin-like growth factor-binding protein 7 (IGFBP-7) have been used for early detection of acute kidney injury (AKI) in critically ill patients. The purpose of this study was to validate the use of these urinary biomarkers in patients undergoing open heart surgery.

**Methods:** In a single center prospective observational study, urine samples were collected in 108 consecutive patients who underwent open heart surgery. Immediately after separation from cardiopulmonary bypass and on postoperative day one, and were sent for the biomarker [TIMP2]\*[IGFBP7]. Acute kidney injury was defined based on KDIGO criteria and levels of [TIMP2]\*[IGFBP7] were analyzed for the ability to predict AKI.

**Results:** Of the 108 patients, 19 (17.6%) patients developed postoperative AKI within 48 hours of surgery. At the threshold of  $>0.3$  (ng/mL) $^2$  /1000, post-cardiopulmonary bypass [TIMP-2]\*[IGFBP-7] had a sensitivity of 13% and specificity of 82% for predicting postoperative AKI. Postoperative day 1 [TIMP-2]\*[IGFBP-7] had a sensitivity of 47% and a specificity of 59% for predicting postoperative AKI. There were no differences in [TIMP-2]\*[IGFBP-7] values at either time points between patients that developed postoperative AKI as compared to those that did not. (Figure). Limitations include a single center study and small sample size.

**Conclusions:** Urinary [TIMP-2]\*[IGFBP-7] was not predictive of the risk of AKI after cardiac surgery in this study population. More studies are needed to confirm these markers for AKI after cardiac surgery.

Box and whisker plots comparing median and interquartile range of urinary [TIMP-2]\*[IGFBP-7] levels between patients with and without AKI at different time points. A: Immediately after separation from cardiopulmonary bypass. B: Postoperative day one. C: Maximum value of separation from cardiopulmonary bypass and Postoperative day one.

## FR-PO071

### CCL14 Predicts Response to Diuretics in Patients With Moderate to Severe AKI

Sevag Demirjian,<sup>1</sup> Lakhmir S. Chawla,<sup>2</sup> Eric Hoste,<sup>3</sup> Patrick Kampf,<sup>4</sup> Jay L. Koyner,<sup>5</sup> Paul McPherson,<sup>4</sup> John A. Kellum.<sup>6</sup> <sup>1</sup>Cleveland Clinic, Cleveland, OH; <sup>2</sup>Veterans Affairs, San Diego, CA; <sup>3</sup>Universiteit Gent, Gent, Belgium; <sup>4</sup>Astute Medical Inc, San Diego, CA; <sup>5</sup>University of Chicago, Chicago, IL; <sup>6</sup>University of Pittsburgh, Pittsburgh, PA.

**Background:** Non-recovery in patients with moderate to severe acute kidney injury (AKI) is associated with morbidity and mortality. Elevated CCL14 levels predict persistent AKI and might facilitate better patient management. We examined whether there is an interaction between CCL14 and diuretic use on urine output in order to guide subsequent volume management.

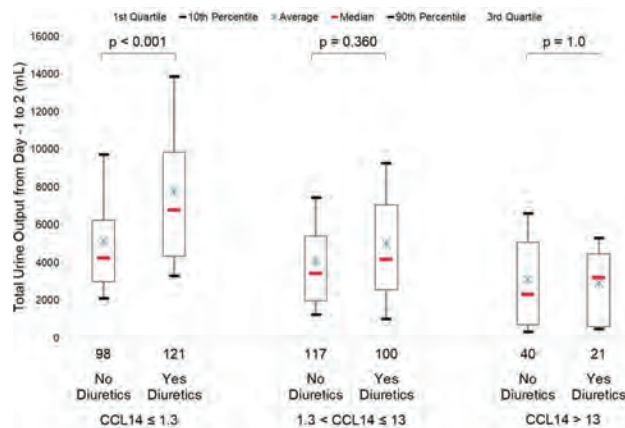

**Methods:** We analyzed data on 497 patients enrolled in 2 prior studies where urine output was documented the day prior, and two days following CCL14 measurement. Diuretic use was defined as any diuretic exposure from one day prior to one day following the CCL14 measurement. Urine output was compared across previously reported three categories of CCL14 ( $\leq 1.3$ ,  $>1.3$ - $13$ ,  $>13$  ng/mL) and by diuretic status using Tukey's honestly significant difference test.

**Results:** In the overall cohort 242 (49%) patients received diuretics; 55%, 46% and 34% in patients with low, intermediate and high CCL14 levels, respectively. Urine output over 72 hours was greater with diuretics when CCL14 was low ( $\leq 1.3$  ng/mL) (difference in means (95%CI) = 2596 ml (1157 - 4034) ml,  $p < .001$ ), but not when CCL14 was elevated (Figure).

**Conclusions:** Response to diuretics was only observed in patients with low CCL14 ( $\leq 1.3$  ng/mL) corresponding to low risk for persistent AKI. Identifying patients with AKI who are unlikely to respond to diuretics may guide clinicians at the bedside to choose alternative means for volume management.

**Funding:** Commercial Support - Astute medical

	No diuretic use(n=255)	Diuretics Use (n=242)	p value
Male	150 (59%)	154 (64%)	0.311

## FR-PO072

**Serum Response Factor, a Novel Early Diagnostic Biomarker of AKI**

Long Zhao, Yan Xu. *The Affiliated Hospital of Qingdao University, Qingdao, China.*

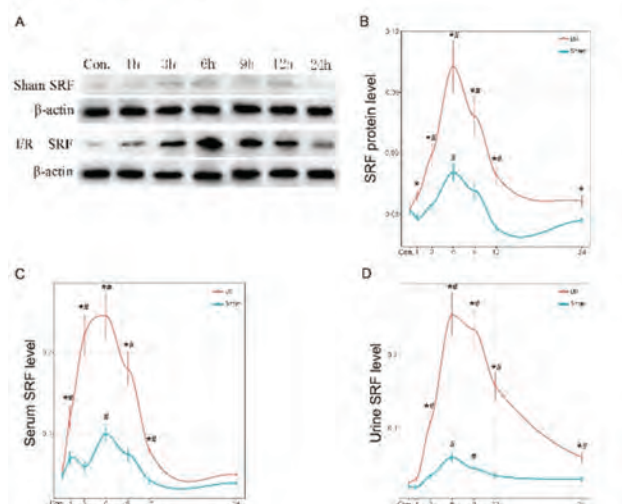

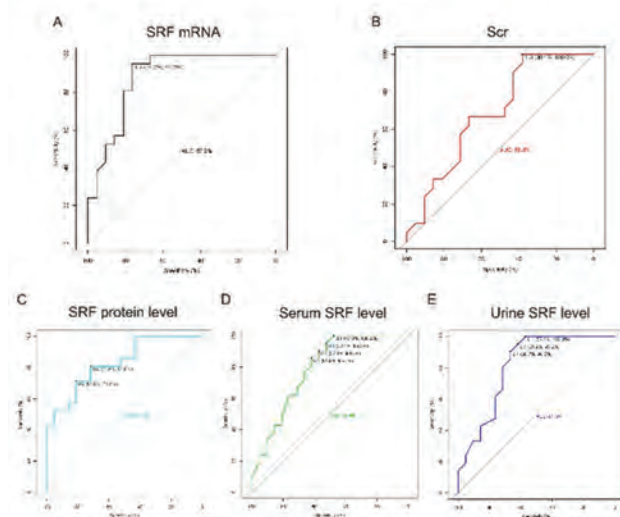

**Background:** Studies have shown that serum response factor (SRF) is increased in chronic kidney injury, such as diabetic nephropathy, hyperuricemic nephropathy and renal cell carcinoma. The objective is to explore the early diagnostic value of SRF in acute kidney injury (AKI).

**Methods:** AKI-related microarray data were analyzed, and the expression and location of SRF were investigated in the early phase of AKI.

**Results:** Bioinformatics results demonstrated that SRF was dramatically elevated 2-4 h after ischemia/reperfusion (I/R) in mouse renal tissue (Figure 1). In I/R rats, SRF was mostly expressed and located in renal tubular epithelial cells (TECs) (Figure 2). SRF started to increase at 1 h, peaked at 3-9 h and started to decrease at 12 h after I/R (Figure 3-4). The areas under the ROC curve of renal SRF mRNA, renal SRF protein, urinary SRF, serum SRF and serum creatinine (Scr) were 87.9%, 83.0%, 81.3%, 78.8%, 68.8%, respectively (Figure 5).

**Conclusions:** SRF is remarkably upregulated in early (before 24 h) AKI and can replace Scr as a potential new early diagnostic biomarker of AKI.

**Funding:** Government Support - Non-U.S.

**Figure 1****Figure 2****Figure 3****Figure 4****Figure 5**

## FR-PO073

**Ouabain as an Early Marker of AKI**

Lorenzo Cocchini,<sup>1</sup> Marta De Filippo,<sup>1</sup> Matteo Marcello,<sup>1</sup> Davide Raimondo,<sup>1</sup> Chiara Lanzani,<sup>2,1</sup> Elisabetta Messaggio,<sup>2</sup> Lorena Citterio,<sup>2</sup> Laura Zagato,<sup>2</sup> Giuseppe Vezzoli,<sup>2,1</sup> Paolo Manunta,<sup>2,1</sup> Marco Simonini.<sup>2</sup> <sup>1</sup>Università Vita Salute San Raffaele, Milano, Italy; <sup>2</sup>IRCCS Ospedale San Raffaele, Milano, Italy.

**Background:** Acute kidney injury (AKI) is a common post-cardiac surgery complication and its influence on morbidity and mortality makes it necessary to identify new preoperative biomarkers and solid predictive models for AKI. This study was designed to create a new powerful score for postoperative AKI risk and to validate the use of endogenous ouabain (EO) as biomarker of individual susceptibility for AKI after cardiac surgery.

**Methods:** 1174 patients undergoing elective cardiac surgery were enrolled in the study and included in the analysis. The primary outcome was AKI development, according to KDIGO 2012 guidelines. Preoperative blood samples were collected to evaluate EO basal levels. Different preoperative clinical variables were analyzed, among which classic anthropometric variables, comorbidity and surgery-connected variables.

**Results:** AKI was developed in 21.6% of patients (9% developed severe AKI, stage  $\geq 2$ ), and it is significantly correlated to postoperative death and to preoperative EO levels in plasma (p-value < 0.001). Moreover the higher was EO level, the greatest was the incidence

of AKI: the patients in the first EO tertile developed AKI with a frequency of 14.1%, 18.0% in the second tertile, and 28.8% in the third one. A significant association was also found among EO and cardiac and kidney basal function (EF and eGFR,  $p$ -value = 0.005 and  $p$ -value = 0.003, respectively). Five independent risk factors turned out to be significantly correlated to AKI and severe AKI: age, FE, NYHA class, reoperation and complex surgical intervention ( $p$ -value < 0.001 for all of them). In the light of these results, a clinical predictive model for AKI, based on the preoperative clinical values significantly associated with AKI and on the preoperative EO, was developed. The inclusion of EO in the predictive model led to a significant improvement in the prediction capacity of the score (AUC per Severe AKI = 0.82, 95% CI 0.771–0.858,  $p$ -value < 0.001).

**Conclusions:** In conclusion, AKI is correlated to high postoperative mortality. EO preoperative level in plasma is strongly associated to cardiac and kidney basal function and a prediction score that includes it results in better patient stratification and more effective pre-operative counseling.

## FR-PO074

### Association of Serum Ferritin and Hepcidin With Renal Recovery in Community Acquired AKI

Jasmine Sethi, Vivek Kumar, Ashok K. Yadav. Post Graduate Institute of Medical Education and Research, Chandigarh, India.

**Background:** Acute kidney injury (AKI) is an expanding overall health concern. The present study was designed to study the association of serum iron, ferritin and hepcidin with renal recovery at 4 months in patients of community acquired AKI.

**Methods:** It is a prospective observational cohort study. All admitted patients aged between 13–70 years and diagnosed to have CA-AKI were eligible for screening. Patients with pre-existing CKD, suspected glomerulonephritis, chronic liver disease, transplant recipients, previous history of blood transfusion and suspected malignancy were excluded. The subjects had scheduled follow up visits at 1 and 4 months after discharge with renal function test and spot urinary PC ratio.

**Results:** Between October 2020 to July 2021, 100 patients of community acquired acute kidney injury were enrolled in the study after taking informed consent. Out of 100, 4 patients expired and 1 patient was lost to follow up. Out of 95 patients, 76 patients had complete renal recovery whereas 19 patients progressed to chronic kidney disease at the end of 3 months. The mean age of the study sample was 43.2 years with sex ratio of 2:1. Most common aetiology of CAAKI was found to be sepsis related which accounted for 42% cases followed by tropical illness and pancreatitis contributing almost equally 17% and 16% respectively. Other rare causes include snake/ wasp bite (5%), poisoning (3%), acute gastroenteritis (10%). Around half of the cohort had stage 3 acute kidney injury at admission. Higher baseline serum Ferritin and hepcidin showed a statistically significant association with renal recovery at 4 months. On multivariate analysis Diabetes, Ferritin and Hepcidin were significantly affecting renal recovery at 4 months.

**Conclusions:** Renal non recovery was seen in a significant proportion of patients ( $n=19$ , 20%) with community-acquired AKI. Elevated baseline serum ferritin and hepcidin were associated with a favourable renal outcome in CA-AKI. Ferritin and hepcidin can be used as prognostic markers in patients with AKI for predicting renal recovery.

## FR-PO075

### Platelet Count Is a Novel Independent Predictor of Major Adverse Kidney Events

Isabel Park,<sup>1</sup> Samuel Short,<sup>2</sup> Charlotte Thomas,<sup>1</sup> Helena Kim,<sup>1</sup> Rafia W. Ali,<sup>1</sup> David E. Leaf.<sup>1</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>University of Vermont College of Medicine, Burlington, VT.

**Background:** Thrombocytopenia is associated with increased mortality in patients with established acute kidney injury (AKI). We investigated whether lower platelet count is independently associated with incident AKI.

**Methods:** We performed a retrospective cohort study in two groups of patients: those admitted to the ICU ( $n=71,749$ ) and those who underwent cardiac surgery (CS;  $n=21,981$ ) at two academic medical centers in Boston, MA between 2005 and 2018. Patients with end-stage kidney disease and those who already had AKI at study entry were excluded. The primary exposure was platelet count, assessed on ICU admission and preoperatively in the ICU and CS cohorts, respectively. Platelet count was assessed categorically (<30, 30–49, 50–99, 100–149, 150–450, and >450  $\times 10^9/L$  in the ICU cohort, and <100, 100–149, 150–450, and >450  $\times 10^9/L$  in the CS cohort). In both cohorts, platelet counts of 150–450  $\times 10^9/L$  served as the reference group. The primary outcome was Major Adverse Kidney Events within 7 days (MAKE7) following ICU admission or CS, defined as doubling of creatinine, dialysis, or death. We used multivariable logistic regression to adjust for confounders.

**Results:** In both the ICU and CS cohorts, we observed a monotonic increase in risk of MAKE7 with platelet counts below the reference range of 150–450  $\times 10^9/L$ . In the ICU cohort, patients with a platelet count <30 vs. 150–450  $\times 10^9/L$  had a 3.58-fold (95% CI, 3.05–4.19) higher risk of MAKE7 in fully adjusted models (Figure 1A). In the CS cohort, patients with a platelet count <100 vs. 150–450  $\times 10^9/L$  had a 2.28-fold (95% CI, 1.62–3.22) higher risk of MAKE7 in fully adjusted models (Figure 1B).

**Conclusions:** Lower platelet count is strongly and independently associated with a higher risk of MAKE7 in patients admitted to the ICU and in those undergoing CS.

Model 1 is unadjusted. Model 2 adjusted for age, sex, race, baseline eGFR, diabetes, CHF, PAD, CAD, chronic lung disease, chronic liver disease, active malignancy, previous or current smoker, and solid organ transplantation. Model 3 is further adjusted for ICU type, hemoglobin, WBC count, INR, sepsis, shock, and mechanical ventilation.

Model 1 is unadjusted. Model 2 adjusted for age, sex, race, baseline eGFR, hemoglobin, hypertension, diabetes, CHF, and PAD. Model 3 is further adjusted for combined CABG/valve procedure, and surgery status (elective vs. non-elective).

## FR-PO076

### Serum Uromodulin as a Marker for AKI and Chronic Nephron Loss

Eva Vonbrunn, Nadja Ebert, Kerstin U. Amann, Christoph Daniel. Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany.

**Background:** Uromodulin (Umod) is expressed exclusively in the kidney in the thick ascending limb of the loop of Henle. It is secreted in the urine, where it is the most abundant glycoprotein. To a minor degree, Umod is also released basolaterally from cells into the serum. Actually, serum Umod-levels are an established, sensitive and robust marker for chronic kidney disease (CKD). Here, we investigate serum Umod-levels, renal Umod protein and mRNA expression in acute kidney injury (AKI) and in rat models of nephron loss.

**Methods:** Umod was first assessed in AKI using an ischemia-reperfusion (I/R) rat model. Blood and kidney samples were collected 10 min, 6h, 24h, 3d, 5d and 8w post reperfusion. To investigate the effect of nephron number on Umod levels, sera and tissue from healthy rats, uni- and 5/6-nephrectomized (Snx) rats were studied. Renal function (serum creatinine), histological changes (acute tubular injury), and renal damage markers (KIM-1) were evaluated in both models. Serum Umod levels were measured by ELISA and renal Umod mRNA expression by multiplex gene expression analysis. The amount and distribution of Umod protein in the kidney was examined by antibody-based detection methods.

**Results:** In AKI, serum creatinine increased markedly 24h after I/R. Serum Umod was also transiently increased, peaking between 6-24h and correlating with injury. Simultaneously, the amount of Umod-positive kidney cells decreased from  $12.4 \pm 7.7\%$  in healthy rats to  $1.8 \pm 1.7\%$  in kidneys 24h after I/R. In healthy kidneys Umod was detected mainly in the inner and outer strips, while it was substantially reduced and homogeneously distributed in the medulla, inner strip, and outer strip 24h after I/R. Moreover, mRNA expression of Umod decreased continuously after I/R and was lowest on day 1-5. In the models of nephron loss serum Umod correlated positively with nephron number showing highest levels in healthy rats ( $2192.2 \pm 323.8$  pg/ml), which were significantly reduced after uni-nephrectomy ( $1262.9 \pm 208.8$  pg/ml) and further reduced after Snx ( $939.8 \pm 193.5$  pg/ml).

**Conclusions:** Serum Umod appears to be a sensitive marker for AKI showing a transient increase in serum levels in parallel with loss of Umod-expressing cells. Umod serum level correlated positively with nephron number. Thus, serum Umod appears as promising marker to assess acute and chronic renal failure.

**Funding:** Other NIH Support - German research foundation (DFG)

## FR-PO077

### The Correlation Between Neutrophil-to-Lymphocyte Ratio and Contrast-Induced AKI and Establishment of New Predictive Models by Machine Learning

Yi Lu, Fangfang Zhou, Youjun Xu, Shuzhen Zhang, Qun Luo. Ningbo Huamei Hospital University of Chinese Academy of Sciences, Ningbo, China.

**Background:** This study intends to explore the correlation between NLR and CI-AKI, and to establish new predictive models of CI-AKI by machine learning.

**Methods:** The data of patients who underwent elective vascular intervention, coronary angiography and percutaneous coronary intervention in our hospital from January 2016 to December 2020 were retrospectively collected. The patients were divided into AKI group and non-AKI group. The analysis of linear trends was used to assess the correlation between the NLR levels and risk of AKI after the sample was divided into tertiles based on the distribution of controls. Logistic regression was used to analyze the correlation between NLR and CI-AKI, and machine learning methods were used to establish logistic regression (LR), random forest (RF), gradient boosting decision tree (GBDT), extreme gradient boosting (XGBoost) and naïve bayes (NB) models. The diagnostic value of the machine learning model was evaluated by receiver operating curve (ROC), and the proportion of feature variables was calculated.

**Results:** (1) 2230 patients were included in this study, and the incidence of CI-AKI was 5.38%. Compared with patients in non-AKI group, patients in AKI group had higher levels of NLR [ $3.38(2.60,5.35)$  vs  $2.79(1.98,4.18)$ ,  $P<0.001$ ], and further multivariate logistic regression analysis showed that NLR was an independent risk factor for CI-AKI (OR=1.054,  $P=0.048$ ). (2) After dividing patient into tertiles based on NLR, those with higher NLR had higher risk of postoperative AKI than those with lower NLR ( $2.69\%$  vs  $5.95\%$  vs  $7.51\%$ , trend  $P=0.046$ ). (3) Gradient Boosting Decision Tree(GBDT) model has the best predictive performance of CI-AKI (AUC=0.738), followed by RF, NB, XGBoost and LR models respectively (The AUC values are 0.727, 0.725, 0.719, 0.711). Four indicators included in the GBDT model, which were NLR, serum creatinine, fasting plasma glucose, and the use of  $\beta$ -blocker.

**Conclusions:** There is a significant correlation between NLR and CI-AKI, and the GBDT, RF, NB, XGBoost and LR models established after incorporating this indicator have good effects in predicting and diagnosing the occurrence of CI-AKI.

**Funding:** Government Support - Non-U.S.

## FR-PO078

### Effects of Low Hemoglobin Levels on the Development of Contrast-Induced AKI

Fangfang Zhou, Yi Lu, Youjun Xu, Shuzhen Zhang, Qun Luo. HwaMei Hospital, University Of Chinese Academy of Science, Ningbo, China.

**Background:** The aim of this study was to evaluate the relationship between low hemoglobin levels and the development of CI-AKI in patients undergoing angiographic intervention, coronary angiography (CAG) and/or percutaneous coronary intervention (PCI).

**Methods:** Patients aged  $\geq 18$  years who underwent elective angiographic intervention and CAG and/or PCI in the Department of Cardiology and Vascular Surgery of our hospital from January 2016 to December 2020. According to KDIGO criteria of AKI, patients were divided into: (1) AKI group: AKI occurred after CM was used; (2) Non-AKI group: no AKI occurred after CM was used. The baseline characteristics of patients, preoperative use of medicines, laboratory test indicators (eGFR was calculated using EPI formula) and other parameters of each patient were collected retrospectively. SPSS 22.0 software was used for statistical analysis.

**Results:** A total of 2230 patients were included in the study. The hemoglobin (g/L) in patients with CI-AKI was  $117.50(108.00,133.00)$ , significantly lower than that in patients without CI-AKI ( $130.00(118.00,142.00)$  ( $P<0.001$ )). The low hemoglobin group was assigned according to hemoglobin level (male,  $<120$  g/L; female,  $<110$  g/L;  $N=40$ ) and normal hemoglobin group (male  $120-160$ g/L; female,  $110-150$ g/L;  $N=80$ ). Multivariate logistic regression analysis showed that 4.30% of patients in the normal hemoglobin group developed CI-AKI, and 10.87% of patients in the low hemoglobin group developed CI-AKI, low hemoglobin (male,  $<120$  g/L; female,  $<110$  g/L) was an independent protective factor for CI-AKI (OR=1.667,  $=0.001$ ). The independent risk factors for CI-AKI in patients with low hemoglobin level were hyperlipidemia (OR=5.556,  $P=0.01$ ) and atrial fibrillation (OR=2.703,  $P=0.039$ ) and history of coronary artery disease (OR=2.833,

$P=0.006$ ), use of ACEI (OR=3.521,  $P=0.023$ ) and ARB (OR=2.732,  $P=0.011$ ), fasting glucose increased (OR=1.186,  $P=0.001$ ). For patients with normal hemoglobin level, independent risk factors for CI-AKI were increased systolic blood pressure (OR=1.015,  $P=0.008$ ) and positive urine protein (OR=2.114,  $P=0.019$ ), increased neutrophil/lymphocyte ratio (OR=1.079,  $P=0.017$ ), history of chronic kidney disease (OR=5.102,  $P<0.0001$ ), use of low molecular weight heparin (OR=2.222,  $P=0.002$ ) and spironolactone (OR=2.564,  $P=0.033$ ).

**Conclusions:** Low hemoglobin level is an independent risk factor for CI-AKI.

**Funding:** Government Support - Non-U.S.

### Epidemiology and Long-Term Outcomes of Severe AKI in Thailand: A Prospective Multicenter Study

Suri Tangchitthavornkul,<sup>1</sup> Nuttha Lumlertgul,<sup>1,14</sup> Sadudee Peerapornratana,<sup>1,14</sup> Veerapatr Nimkietkajorn,<sup>2</sup> Petchdee Oranrigsupak,<sup>4</sup> Wanjak Pongsitisak,<sup>5</sup> Kamonwan Tangvoraphonkchai,<sup>6</sup> Atchara Aksornrat,<sup>7</sup> Sompote Intarak,<sup>8</sup> Theerapon Sukmark,<sup>9</sup> Anan Chuasuwan,<sup>3</sup> Kamol Khositrangsikun,<sup>10</sup> Watanyu Parapiboon,<sup>11</sup> Pichaya Tantiyavarong,<sup>12</sup> Karjbundit Surasit,<sup>13</sup> Somchai Eiam-Ong,<sup>1</sup> Nattachai Srisawat.<sup>1,14</sup> <sup>1</sup>Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; <sup>2</sup>Buddhachinaraj Phitsanulok Hospital, Phitsanulok, Thailand; <sup>3</sup>Bhumibol Adulyadej Hospital, Bangkok, Thailand; <sup>4</sup>Nan Hospital, Nan, Thailand; <sup>5</sup>Division of Nephrology, Department of Internal Medicine, Faculty of Medicine Vajira Hospital, Navamindradhiraj University, Bangkok, Thailand; <sup>6</sup>Department of Medicine, Mahasarakham University Hospital, Mahasarakham, Thailand; <sup>7</sup>Sichon Hospital, Nakhon Si Thammarat, Thailand; <sup>8</sup>Mahasarakham Hospital, Maha Sarakham, Thailand; <sup>9</sup>Thungsong Hospital, Nakhon Si Thammarat, Thailand; <sup>10</sup>Maharat Nakhon Si Thammarat Hospital, Nakhon Si Thammarat, Thailand; <sup>11</sup>Maharat Nakhon Ratchasima Hospital, Nakhon Ratchasima, Thailand; <sup>12</sup>Thammasat University Hospital, Pathum Thani, Thailand; <sup>13</sup>Nakornping Hospital, Chiang Mai, Thailand; <sup>14</sup>Center of Excellence in Critical Care Nephrology, Chulalongkorn University, Bangkok, Thailand.

**Background:** Acute kidney injury (AKI) contains a high short-term morbidity and mortality. However, little is known regarding long-term outcomes, especially in the resource constrained settings. We aimed to evaluate 1-year major adverse kidney events (MAKE<sub>365</sub>) in patients with severe (stage 3) AKI by kidney recovery patterns at 28 days or hospital discharge.

**Methods:** We analyzed the data from InSEA RRT registry—a multicenter prospective cohort study conducted between January 2021 and January 2022. Critically ill patients with stage 3 AKI as defined by KDIGO were enrolled and classified by recovery status after 28 days or at hospital discharge as early, late, and nonrecovery. Primary outcome was MAKE<sub>365</sub> which is a composite of persistent kidney dysfunction, long-term dialysis, and all-cause mortality on day 365 after enrollment.

**Results:** A total of 1,534 patients from 14 hospitals across Thailand were enrolled. Among these, 755 (49%) patients died, 401 (51%) patients experienced early recovery, 188 (24%) late recovery, and 190 (24%) never reversed AKI. The incidence of MAKE<sub>365</sub> was 68.4 per 100 person-years of all patients. Nonrecovery were more likely to develop MAKE<sub>365</sub> than recovery (adjusted HR 4.24 ;95% CI, 3.20-5.61;  $P<0.001$ ). The incidence of new CKD and CKD progression were 82.8 and 42 per 100 person-years. Patients with older, cancer, mixed ICU, and no nephrologist follow-up were also at risk for MAKE<sub>365</sub>.

**Conclusions:** Nonrecovery AKI was independently associated with adverse long-term outcomes. Recognition and close follow-up of patients with non-recovered AKI is crucial. Novel intervention might improve long-term outcomes and need further study.

### AKI During Pregnancy: Baseline Characteristics and Long-Term Outcomes

Mistafa Hafid, Abdel-Rauof M. Akkari, Omar K. Salameh, Muhammad Abdulbasit, Nasrollah Ghahramani. Penn State College of Medicine, Hershey, PA.

**Background:** Pregnancy-related acute kidney injury (AKI) is a serious public health problem and is an important cause of maternal and fetal morbidity and mortality. The incidence of pregnancy-related AKI has increased due to increase in maternal age and higher detection rates. Using a large multicenter cohort, we analyzed the differences in demographic characteristics in pregnant women who developed AKI during pregnancy with those who did not develop AKI.

**Methods:** We performed a retrospective multi-center cohort study using TriNetX Research Network database, a federated medical records network, to identify 1,537,027 pregnant women from 46 healthcare organizations (HCOs) in the United States. From this group, we then identified women who has a confirmed diagnosis of AKI during their pregnancy. We calculated the odds ratio (OR) and 95% confidence interval (CI) of diagnosis of offstage Renal Disease (ESRD) and death in the first five years after pregnancy.

**Results:** 4,867 pregnant women (from 40 HCOs) had a confirmed diagnosis of AKI during pregnancy. Compared with the non-AKI group, women in the AKI group were older ( $37.9 \pm 17.5$  vs.  $31.4 \pm 8.9$ ;  $p<0.0001$ ) and more likely to: • be African American ( $p<0.001$ ) • have a Body Mass Index (BMI)  $> 30$  kg/m<sup>2</sup> ( $p<0.001$ ) • have a BMI  $< 20$  kg/m<sup>2</sup> ( $p<0.001$ ) • be nicotine dependent during pregnancy ( $p<0.001$ ) Within the first five years

after pregnancy, a total of 4798 women (434 with AKI) were diagnosed with ESRD and 5136 women (550 with AKI) died. After propensity matching, AKI was associated with higher odds of ESRD (OR: 33.6; CI:30.4 to 37.3), and mortality (OR: 41.7; CI: 38.0 to 45.8).

**Conclusions:** Among pregnant women, those who developed AKI during pregnancy were more likely to be older at time of pregnancy, African American, have a BMI above 30 kg/m<sup>2</sup> or below 20 kg/m<sup>2</sup>, and to be nicotine dependent during pregnancy. AKI during pregnancy was associated with higher likelihood of ESRD and death within five years after pregnancy.

## FR-PO081

### Recovery of AKI After Cardiac Surgery

Ankit Sakhuja,<sup>1</sup> Priyanka Priyanka,<sup>2</sup> John A. Kellum.<sup>2</sup> <sup>1</sup>West Virginia University, Morgantown, WV; <sup>2</sup>University of Pittsburgh, Pittsburgh, PA.

**Background:** Acute kidney injury (AKI) is a common complication after cardiac surgery. Development of this cardiac surgery associated AKI (CSA-AKI) is associated with increased mortality and healthcare costs. AKI lasting longer than 3 days (non-recovery) is associated with worse outcomes. There is, however, a lack of studies looking into epidemiology of recovery of CSA-AKI.

**Methods:** This was a retrospective observational study using data from High-Density Intensive Care -15 Database from University of Pittsburgh Medical Center. Data from 2008 – 2014 was included for this study. Patients undergoing cardiac surgery were identified using ICD-9-CM codes. AKI was identified using KDIGO criteria. Patients with continued AKI at discharge were identified as having acute kidney disease (AKD). Missing variables were imported using Multivariate Imputation by Chained Equation (MICE). We used Kruskal-Wallis and Chi-Square/Fisher Exact tests to compare continuous and categorical variables respectively. We used multivariable logistic regression models to identify risk factors for development of non-recovery of AKI and AKD after cardiac surgery.

**Results:** Among 6,440 patients, 5228 (81.9%) developed CSA-AKI. Of those who developed CSA-AKI, 98.2% developed it within 72 hours after cardiac surgery. We found that 84% of CSA-AKI was transient, resolving within 72 hours. AKI that persisted for more than 3 days (non-recovery) was about as likely to be seen with serum creatinine as with urine output, whereas transient AKI was more likely to be urine output based. Risk factors for non-recovery of AKI included thrombocytopenia, congestive heart failure, chronic obstructive pulmonary disease, CABG combined with valve surgery, black race and emergent admission. Development of AKD was seen in less than 10% patients. Risk factors for development of AKD included longer duration of surgery, congestive heart failure, use of intra-aortic balloon pump, black race and emergent admission.

**Conclusions:** AKI is very common after cardiac surgery but majority of it resolved within 3 days of onset. Transient AKI is more often associated with isolated oliguria, whereas non-recovery is about as likely to be seen with oliguria and as with azotemia.

## FR-PO082

### Temporal Evolution of AKI After Cardiac Surgery

Ankit Sakhuja,<sup>1</sup> Priyanka Priyanka,<sup>2</sup> John A. Kellum.<sup>2</sup> <sup>1</sup>West Virginia University, Morgantown, WV; <sup>2</sup>University of Pittsburgh, Pittsburgh, PA.

**Background:** Acute kidney injury (AKI) is a common complication after cardiac surgery and is associated with high mortality. There is a well-defined timing of injury to the kidneys in these patients, which provides a unique opportunity for trial of novel therapeutic agents. There is, however, very little information about the temporal evolution of AKI after cardiac surgery. Understanding of the temporal evolution is important to inform trials for novel therapeutic strategies for prevention and management of CSA-AKI.

**Methods:** This was a retrospective observational study using data from High-Density Intensive Care -15 Database from University of Pittsburgh Medical Center. Data from 2008 – 2014 was included for this study. Patients undergoing cardiac surgery were identified using ICD-9-CM codes. AKI was identified using KDIGO criteria. We used Kruskal-Wallis and Chi-Square/Fisher Exact tests to compare continuous and categorical variables respectively. We used multivariable logistic regression models to identify risk factors for development of stage II/III AKI at 72 hours based on serum creatinine and urine output based criteria.

**Results:** Among 6,440 patients, 5228 (81.9%) developed CSA-AKI. Of those who developed CSA-AKI, 91% developed it within 24 hours and 98% within 72 hours after cardiac surgery. Stage I AKI within first 72 hours after cardiac surgery was the most common initial manifestation of CSA-AKI (98.7%). Majority of AKI within first 72 hours after cardiac surgery was due to isolated decrease in urine output. Additionally, the maximum AKI stages as scored by urine output exceeded those scored by serum creatinine by approximately 50% over first 10 days after cardiac surgery. The risk factors for stage II/III AKI by 72 hours after cardiac surgery differed based on whether the severity was seen due to rise in serum creatinine or decrease in urine output. Patients who developed AKI within first 24 hours were more often obese, with chronic kidney disease and diabetes. They also consistently had higher major adverse kidney events at 30d, 90d, 180d and 1 yr after surgery.

**Conclusions:** AKI is very common after cardiac surgery and is characterized by both oliguria and azotemia with former being much more frequent. Majority of CSA-AKI is notable within 24 hours after cardiac surgery with stage I being the initial manifestation. AKI manifesting as azotemia has different risk factors than that manifesting as oliguria.

## FR-PO083

### Association of Acute eGFR Changes With Mortality and Heart Failure Hospitalizations Among Patients Admitted for Acute Heart Failure Requiring Hemodynamic Monitoring

Run Banlengchit,<sup>1</sup> Hocine Tighiouart,<sup>1,2</sup> Jake Gillberg,<sup>1</sup> Marcelle Tuttle,<sup>1</sup> Jeffrey M. Testani,<sup>3</sup> Tatsufumi Oka,<sup>1</sup> Michael S. Kiernan,<sup>1</sup> Mark J. Sarnak,<sup>1</sup> Wendy I. McCallum.<sup>1</sup> <sup>1</sup>Tufts Medical Center, Boston, MA; <sup>2</sup>Tufts Medical Center Institute for Clinical Research and Health Policy Studies, Boston, MA; <sup>3</sup>Yale School of Medicine, New Haven, CT.

**Background:** Acute changes in estimated glomerular filtration rate (eGFR) are frequently encountered among patients admitted for acute heart failure (AHF). However, there is wide variation in how acute eGFR change is described, and whether these acute changes are associated with clinical outcomes.

**Methods:** Records for patients admitted with a primary diagnosis of AHF requiring invasive hemodynamic monitoring were collected from 2015 to 2021 from a single quaternary academic center. Using the CKD-EPI 2021 formula, each in-hospital creatinine was used to estimate GFR, and slopes of eGFR were calculated for each individual using linear mixed modeling. Multivariable Cox regression models were used to evaluate the association between in-hospital eGFR slope with risk of mortality and a composite of mortality or HF hospitalization after discharge, treating eGFR slope both as a continuous variable and in quartile analysis. Covariates included age, sex, race, diabetes, hypertension, and baseline eGFR.

**Results:** Among 727 patients admitted for AHF with both baseline and discharge eGFR available, the mean (SD) age was 61 (14) years with mean baseline eGFR of 57 (27) ml/min/1.73m<sup>2</sup>. Overall, eGFR increased by median (IQR) 1.3 ml/min/1.73m<sup>2</sup> per week (-1.5, 4.6). Over a median 14 (maximum 35) months follow-up, in reference to the quartile with the fastest increase in eGFR (Quartile 1), the quartile with fastest decline in eGFR (Quartile 4) was associated with increased risk of mortality and composite of mortality and HF hospitalization (Table).

**Conclusions:** Among patients admitted for AHF requiring invasive hemodynamic monitoring, an acute in-hospital decrease in eGFR was associated with increased risk of mortality and heart failure hospitalization, independent of baseline eGFR.

**Funding:** Other NIH Support - NCATS

Table. Hazard ratios for mortality and composite outcome per each 5 ml/min/1.73m<sup>2</sup> faster increase in in-hospital eGFR per week and by quartiles of slope, with Quartile 1 having the fastest increase and Quartile 4 the fastest decrease

	Continuous (n=727)	Quartile 1 Increase in eGFR (n=198)	Quartile 2 (n=184)	Quartile 3 (n=178)	Quartile 4 Decrease in eGFR (n=167)
Median eGFR slope (IQR), ml/min/1.73m <sup>2</sup> per week	1.3 (-1.5, 4.6)	7.7 (5.7, 11.8)	2.6 (1.8, 3.4)	-0.2 (-0.9, 0.4)	-4.5 (-7.0, -3.1)
<b>Mortality</b>					
N of events	258	68	76	83	71
Unadjusted	0.92 (0.84, 1.01)	Ref	1.23 (0.89, 1.71)	1.48 (1.08, 2.04)	1.44 (1.03, 2.01)

Data presented as hazard ratios (95% CI). Model is adjusted for age, sex, race, diabetes, hypertension, and baseline eGFR. Abbreviations: eGFR, estimated glomerular filtration rate

## FR-PO084

### Externally Validated Postoperative Long-Term Adverse Event Prediction Model for Non-Cardiac Surgery: An Extension of Simple Postoperative AKI Risk (SPARK) Model

Sehoon Park,<sup>1</sup> Soie Kwon,<sup>1</sup> Ji Eun Kim,<sup>2</sup> Jin Ho Hwang,<sup>3</sup> Chung Hee Baek,<sup>4</sup> Jeonghwan Lee,<sup>5</sup> Yong Chul Kim,<sup>1</sup> Dong Ki Kim,<sup>1</sup> Kwon Wook Joo,<sup>1</sup> Yon Su Kim,<sup>1</sup> Hajeong Lee.<sup>1</sup> <sup>1</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>2</sup>Korea University Guro Hospital, Seoul, Republic of Korea; <sup>3</sup>Chung Ang University Hospital, Seoul, Republic of Korea; <sup>4</sup>Asan Medical Center, Songpa-gu, Seoul, Republic of Korea; <sup>5</sup>Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.

**Background:** We aimed to construct an externally validated postoperative long-term adverse event prediction model based on acute kidney (AKI) related variables. We extended our previous Simple Postoperative AKI Risk (SPARK) model to suggest a comprehensive prediction-system for postoperative adverse events related to kidney function.

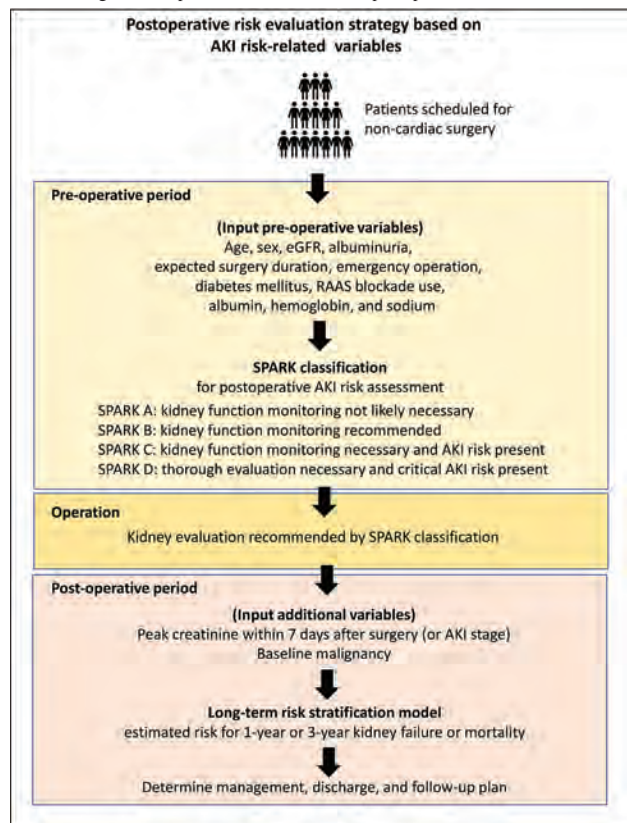

**Methods:** This model development study retrospectively included 4 observational cohorts. The model development cohort included 33,636 non-cardiac surgery patients from Seoul National University. Three external validation cohorts were constructed: including external non-cardiac surgery cases from other hospitals or duration (N=33,943, 56,012, and 15,220). Primary study outcome was composite adverse event of dialysis or mortality within 1 year. Multivariable Cox regression model including the variables consist of the SPARK index, baseline malignancy, and postoperative AKI stage was used for model construction.

**Results:** The prediction model for kidney failure or mortality within one year showed acceptable performance (c-index 0.752) in the development cohort. When the model was applied to the validation cohorts, the prediction performances were also acceptable (c-index 0.735, 0.755, and 0.843). The model has been constructed as a calculator with combination of the SPARK index for comprehensive usage for nephrologists for postoperative adverse event risk assessment based on kidney related variables.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** The prediction model for long-term adverse event after non-cardiac surgery provides a useful way to predict long-term risks based on kidney function related variables, along with the prediction for the risks of postoperative AKI.

#### FR-PO085

##### Effects of Cardiovascular Outcomes of Sacubitril-Valsartan in Patients With AKI

Hoon Young Choi,<sup>1,2</sup> Donghwan Oh,<sup>1,2</sup> Eunji Yang,<sup>1,2</sup> Jong Hyun Jhee,<sup>1,2</sup> Hyeoncheon Park,<sup>1,2</sup> <sup>1</sup>Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; <sup>2</sup>Gangnam Severance Hospital, Seoul, Republic of Korea.

**Background:** Sacubitril-valsartan reduced the risk of cardiovascular (CV) mortality among patients with heart failure with reduced ejection fraction (HFrEF). However, it is still unclear a long term protective effect on cardiac function in HFrEF patients with acute kidney injury (AKI). This study aimed to investigate the association between long term effects of CV protection and AKI treated by sacubitril-valsartan.

**Methods:** Data were retrieved from the Severance Open Big Data Portal. Patients under Sacubitril-valsartan or valsartan medication after diagnosis of heart failure between May 2015 and June 2021 (N = 782). A total of 295 patients with HFrEF treated by sacubitril-valsartan or valsartan were enrolled. The participants were divided into each group to study the effect of sacubitril-valsartan in patients taking valsartan as a control group. The ratio ( $\Delta$  Ejection Fraction(EF)/ $\Delta$  estimated glomerular filtration rate(eGFR)) was used to analyze the association between CV and renal outcomes during the study period.

**Results:** The total of 295 patients with HFrEF and the rate of patient with AKI accounted for 9.5% of the total. Baseline characteristics show that the mean age of the HFrEF patients with AKI was  $76.1 \pm 9.4$  years, and 65.5% were male. The mean level of eGFR were  $41.5 \pm 23.4$  in sacubitril-valsartan group and  $64.9 \pm 23.1$  mL/min/1.73m<sup>2</sup> in valsartan group. The mean level of EF (%) were  $28.0 \pm 6.4$  in sacubitril-valsartan group and  $37.5 \pm 12.6$  in valsartan group. When the association between renal outcome and cardiovascular outcome was analyzed by independent two sample t-test, the sacubitril-valsartan group improved cardiovascular outcomes compared to valsartan group (Difference value  $11.2 \pm 13.1\%$  in sacubitril-valsartan group and  $-0.6 \pm 11.1\%$  in valsartan group,  $P = 0.03$ ).

**Conclusions:** The present study demonstrated that HFrEF patients treated with sacubitril-valsartan had a significant improved cardiovascular outcome even if AKI.

#### FR-PO086

##### The Effects of Muscle Mass and Quality on Mortality of Patients With AKI Requiring Continuous Renal Replacement Therapy

Jiyun Jung,<sup>1</sup> Jangwook Lee,<sup>1</sup> Sung Joon Shin,<sup>1</sup> Hyosang Kim,<sup>2</sup> Jae Yoon Park.<sup>1</sup> <sup>1</sup>Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; <sup>2</sup>Asan Medical Center, Songpa-gu, Seoul, Republic of Korea.

**Background:** Sarcopenia which can lead to decline in physical ability has been known as risk factor on mortality and morbidity. However, little studies have found the effects of muscle mass on mortality of patients with Acute Kidney Injury (AKI) requiring Continuous Renal Replacement Therapy (CRRT).

**Methods:** We collected 2,221 AKI patients who received CRRT in 8 medical centers between 2006 and 2021. The skeletal muscle areas (SMA) with a threshold of  $-29$  to  $150$  Hounsfield units from CT images at the level of the 3rd lumbar vertebra was obtained through automated software at ASAN medical center. SMA was further categorized in normal attenuation muscle area (NAMA) and low attenuation muscle area (LAMA) to assess the density of muscle. We used Cox proportional hazard model to investigate the association between mortality within 1, 3, and 30 days and skeletal muscle index (SMA, NAMA, and LAMA). In addition, stratified analyses were conducted by sex, age, the acute physiology and chronic health evaluation (APACHE II) score, and the sequential organ failure assessment (SOFA) score to assess the susceptible subgroups.

**Results:** More than half of the patients (60%) were male and the mean age of patient was 66.01 years. The 30-day mortality rate was 52% (n=1,155). An IQR increase of SMA (38.2cm<sup>2</sup>) was associated with decreased mortality risk (Hazard ratio [HR]: 0.79, 95% confidence interval [CI]: 0.65–0.97). In subgroup analyses on muscle quality, we identified the 26% decreased risk of LAMA on mortality (HR: 0.74, 95% CI 0.63–0.87) while non-significant effects were found in NAMA (HR:1.05, 95% CI: 0.85–1.29). Stronger protective effects of muscle mass index on mortality were found in male, those who aged over 65 years, and high score group of APACHE II.

**Conclusions:** We found the protective effects of muscle mass on mortality of AKI patients requiring CRRT. In addition, even if the density was low, the effect of muscle mass itself was significant determinant factors on lowering mortality.

**Funding:** Government Support - Non-U.S.

#### FR-PO087

##### Circulating Endotoxin and Inflammatory Proteins Correlate With Kidney and Hospitalization Outcomes in Critically Ill Patients

Sian Piret, Fabliha Fairuz, Samaneh Gholami, Sobia N. Khan, Sandeep K. Mallipattu. *Stony Brook University, Stony Brook, NY.*

**Background:** Endotoxin, a component of gram negative bacterial cell walls, may be present in the circulation of critically ill patients with or without bacteremia, and is a potent trigger of AKI and inflammation. Our aim was to determine correlations between endotoxin levels, inflammatory proteins, and AKI and hospitalization outcomes in incident critically ill patients.

**Methods:** Patients were recruited from those aged 18 or over admitted to intensive care units (ICUs), who did not have end-stage renal failure requiring dialysis, or were on chronic immunosuppressive medication. Blood endotoxin levels were measured within 48 hours of ICU admission using the FDA-approved endotoxin activity assay (EAA). EAA results were categorized as either low/intermediate ( $<0.6$ ) or high ( $\geq 0.6$ ), or used as a continuous variable. Kidney parameters, vital signs, and dispositions were obtained from electronic medical records. AKI was defined as per KDIGO guidelines. Plasma proteomics was undertaken on 87 patients using the O-link Target 96 inflammation panel.

**Results:** A total of 106 patients were recruited between November 2020 and March 2022, with 4 patients testing positive for gram negative bacteria. EAA levels were  $<0.6$  in 54 patients (51%) and  $\geq 0.6$  in 52 patients (49%). There was a positive correlation between EAA and serum creatinine levels ( $p < 0.05$ ). Only 2/54 patients (3.7%) with EAA  $<0.6$  developed AKI stage III versus 9/52 patients (17.3%) with EAA  $\geq 0.6$  ( $p < 0.05$ ). Combined EAA plus SOFA score was significantly higher in patients with AKI versus no AKI ( $p < 0.0001$ ). Patients with EAA  $\geq 0.6$  has a significantly longer hospital stay than patients with EAA  $<0.6$  ( $p < 0.05$ ). Hierarchical clustering analysis using plasma proteomics data resulted in two clusters, with most of the patients without AKI represented in a separate cluster from those with AKI. Analysis of individual protein levels between the two clusters showed differences in levels of IL8, MCP-3, FGF23, IL-10, and CCL20. These proteins were also significantly higher when compared specifically in patients with AKI versus no AKI ( $p < 0.01$  –  $p < 0.0001$ ).

**Conclusions:** Endotoxin levels on admission to ICU correlated with kidney function and AKI, and patients with high EAA had longer hospital stay. Patients with AKI also had higher levels of specific circulating inflammatory proteins.

#### FR-PO088

##### Outcomes After AKI: Are We Communicating Effectively?

Ingi A. Elsayed. *University Hospitals of North Midlands NHS Trust, Stoke-on-Trent, United Kingdom.*

**Background:** Acute Kidney Injury (AKI) is widely recognised as both a prevalent and serious problem, associated with worsening of morbidity, an independent predictor of mortality & risk of development of CKD. NICE guidance (NG148) recommended improved communication between 2ry care & 1ry care, to enable appropriate follow up when needed.

**Methods:** We provide an institute wide (large teaching hospital, catchment area of 700,000) AKI service, comprised of consultant intensivist/nephrologist (lead) & two specialist nurses. We have implemented an e-Alert system, which integrates laboratory information system, using an NHS endorsed algorithm (based on biochemical criteria), with hospital admission systems to identify patients with AKI in real time. This generates a list that is forwarded daily to AKI team, where AKI specialist nurses review, all patients with AKI stages 2 & 3. We implemented an electronic communication system, using hospital discharge letters to document AKI, its stage and issue advice to 1ry care requesting interval repeat of kidney functions & referral to renal services where appropriate. We analysed the efficiency of this communication system, over one month (Oct 2019) and followed them up for three months afterwards.

**Results:** Over October 2019, we reviewed a total of 190 AKI patients, 136 of which were community-acquired AKI (71.5%). 106 of them were male (55.7%) and the median age of all patients was 74ys. 126 of patients presented with an AKI stage 2 (66.3%). Average baseline creatinine was 80.4 (SD 31) micromol/L and 92 of all patients were known to have CVD (48.4%); while 31 were to be known to have CKD3 or 4 prior to presentation (16.3%). Their LOS was 14.9 days on average. By the end of the study period, 56 patients died (29.5%); 36 of whom, died during their index admission. Electronic communication was issued for 100% of all survivors at time of discharge. Yet, 25 patients did not get repeat blood tests (13%) over 3 months after index presentation. Of those who had their bloods tested, 33 pateints' creatinine levels remained above baseline (17.3%) with only One patient referred to renal services by their 1ry care physician.

**Conclusions:** Improved communication to ensure better quality of care & prevent further episodes of AKI, is integral to care of AKI patients. Better systems to guarantee seamless care (including long term follow up) after AKI, are needed.

FR-PO089

**Building a Prediction Model for Postoperative AKI Using Machine Learning: The CMC-AKIX Model**  
Ji Won Min,<sup>1</sup> Hye Eun Yoon.<sup>2</sup> <sup>1</sup>Catholic University of Korea Bucheon Saint Mary's Hospital, Bucheon, Gyeonggi-do, Republic of Korea; <sup>2</sup>Catholic University of Korea Incheon Saint Mary's Hospital, Incheon, Incheon, Republic of Korea.

**Background:** Postoperative acute kidney injury (AKI) is associated with increased mortality and morbidity in patients undergoing surgeries performed under general anesthesia. There are several models that predict postoperative AKI risk, but most are single-center studies that need external validation.

**Methods:** In this retrospective cohort analysis, we included noncardiac surgeries performed between 2009 and 2019 at 7 university hospitals in South Korea. Postoperative AKI was defined as an increase of serum creatinine at least 1.5 times the baseline value or initiation of renal replacement therapy within 30 days of the postoperative period. We tested 6 machine learning prediction models: deep neural networks (DNN), logistic regression, decision tree, random forest, light gradient boosting machine (GBM), and naïve Bayes, and compared model performance using the area under the curve (AUC) of the receiver-operating characteristic.

**Results:** A total of 239,267 surgeries were included, and 7,935 postoperative AKI events (3.3%) occurred. The 6 different statistical analysis methods were run on various combinations of 40 independent preoperative predictors that we had selected (Table 1). Model 1 included all variables, Model 2 included variables that had been significantly associated with postoperative AKI in previous studies, and Model 3 included variables that were found significant in multivariate analysis. Among them, Model 1 run on DNN (AUC = 0.821) and light GBM (AUC = 0.823) and Model 3 run on DNN (AUC = 0.807) demonstrated the best prediction performance.

**Conclusions:** We have developed a high-performance risk prediction system for postoperative AKI that can be easily applied using preoperative patient characteristics and laboratory data.

**Continuous Prediction of Mortality During AKI Renal Replacement Therapy (RRT): A Deep Learning Approach**  
Lucas J. Liu,<sup>1</sup> Victor M. Ortiz-Soriano,<sup>2</sup> Jin Chen,<sup>1</sup> Javier A. Neyra.<sup>3</sup> <sup>1</sup>University of Kentucky, Lexington, KY; <sup>2</sup>University of Kentucky Medical Center, Lexington, KY; <sup>3</sup>University of Alabama at Birmingham, Birmingham, AL.

**Background:** AKI-RRT is associated with high risk of mortality. Continuous accurate prediction of mortality in these patients could assist with resource utilization and transition to palliative care when needed. Deep learning (DL) models have shown promise in risk-prediction using temporal EHR data. However, most existing methods fall short in clinical settings where the real-world EHR data are often asynchronous and irregular.

**Methods:** We developed a novel DL model based on Long Short Term Memory (LSTM) to continuously predict 24-hour mortality risk during AKI-RRT. Our model extends LSTM with two time-aware gates to handle irregular and asynchronous data, and a knowledge-aware gate that uses medical ontology to guide attention between multiple variables at each time step. We used data from 570 adult patients with AKI-RRT admitted to the ICU, excluding patients with ESRD, kidney transplant or those in whom RRT lasted <72h. We utilized 12 temporal features including vital signs and biochemical parameters and 6 static features including demographics, BMI and Charlson score. We assessed our model based on subpopulations according to static features and compared it with four existing models.

**Results:** Hospital mortality rate was 58.4%. Our model outperformed all others at almost all levels of subpopulations and all metrics for the continuous prediction of mortality during AKI-RRT (Table).

**Conclusions:** We developed a novel DL model with three additional gates for the continuous prediction of mortality during AKI-RRT. With the new gates, our model achieved better performance for the asynchronous and irregular EHR data. This model can be further enhanced and validated for augmenting bedside clinical decisions.

Table. Performance of mortality prediction for balanced datasets (positive (dead); negative (survived) = 1:1) on two subpopulations. Subpopulations were defined by hierarchical clustering at different levels of granularity where level 1 has the lowest and level 2 has the highest granularity based on demographics and comorbidity. The scores are shown as average and standard deviation.

FR-PO091

**Time-Trend of Postoperative AKI From a Multicenter Cohort Study**  
Jeongmin Cho,<sup>1</sup> Soie Kwon,<sup>1,2</sup> Sehoon Park,<sup>1</sup> Jeonghwan Lee,<sup>3</sup> Chung Hee Baek,<sup>4</sup> Ji Eun Kim,<sup>7</sup> Jin Ho Hwang,<sup>6</sup> Ji In Park,<sup>9</sup> Jiwon Ryu,<sup>8</sup> Jina Park,<sup>5</sup> Kook-Hwan Oh,<sup>1</sup> Kwon Wook Joo,<sup>1</sup> Hajeong Lee.<sup>1</sup> <sup>1</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>2</sup>Seoul National University College of Medicine, Seoul, Republic of Korea; <sup>3</sup>Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; <sup>4</sup>Asan Medical Center, Songpa-gu, Seoul, Republic of Korea; <sup>5</sup>Biomedical Research Institute, Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>6</sup>Chung Ang University Hospital, Seoul, Republic of Korea; <sup>7</sup>Korea University Guro Hospital, Seoul, Republic of Korea; <sup>8</sup>Seoul National University Bundang Hospital, Seongnam, Republic of Korea; <sup>9</sup>Kangwon National University Hospital, Chuncheon, Kangwon, Republic of Korea.

**Background:** After emphasis on prevention and early recognition of acute kidney injury (AKI) from the KDIGO 2012 AKI guideline, in-hospital AKI occurrence had reduced during the past two decades. However, understanding the time trend of post-operative AKI (PO-AKI) is lacking yet.

**Methods:** A retrospective cohort study was performed from 2005 to 2020. The patients who underwent non-cardiac major surgery more than 1 hour of operation time at 5 departments were enrolled. PO-AKI was defined as KDIGO AKI criteria within 7 days after surgery. Severe PO-AKI (S-PO-AKI) was defined as stage 2 or 3 AKI. The time period was divided into 3-year intervals and evaluated by join-point regression analysis and multivariate logistic regression.

**Results:** A total of 143,219 patients were included. During the study period, 8,604 (6.0%) PO-AKI and 1,197 (0.8%) S-PO-AKI occurred. The patients were older and more women. They had more comorbidities including diabetes mellitus (5.7%→13.7%), hypertension (12.8%→28.6%), coronary artery disease (1.8%→3.6%) as times go by. Preoperative NSAID usage was decreased whereas diuretics and RAAS blockades uses were increased with time. The PO-AKI incidence had decreased from 8.9% in 2014 to 4.6% in 2020. In join-point analysis, PO-AKI incidence decreased with annual percent change (APC) of -4.2 % per year (95% confidence interval [CI] -5.5 – -2.8%, *p*-value <0.001). Although, S-PO-AKI was not (APC -0.3%, 95% CI -2.1 – 1.5%, *p*-value = 0.732, Figure 1). The multivariate analysis showed that these trends were remained similarly even after adjustment with well-known risk factors (adjusted odds ratio [95% CI], 2005-2007, reference; 2008-2010, 0.77 [0.71-0.84]; 2011-2013, 0.69 [0.63-0.75]; 2014-2016, 0.55 [0.51-0.59]; and 2018-2020, 0.57 [0.53-0.62], *p*-value<0.001).

**Conclusions:** In this large-scale study, we found the PO-AKI had decreased recently, although the incidence of S-PO-AKI still had not changed.

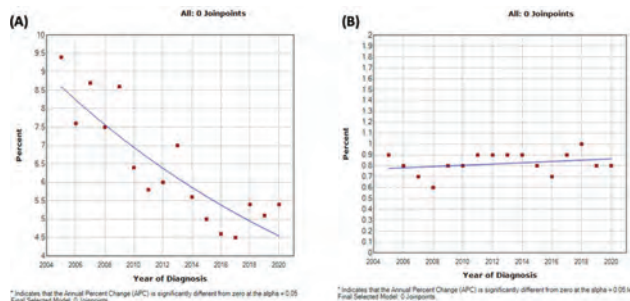

Figure 1. Joint-point regression analysis describing annual incidence trend of (A) PO-AKI and (B) S-PO-AKI.

## FR-PO092

### The Incidence and Risk Factor of Post-Operative Acute Kidney Disease After Non-Cardiac Surgery

Soie Kwon,<sup>1</sup> Sunah Yang,<sup>1</sup> Geumnae Nam,<sup>1</sup> Sehoon Park,<sup>1</sup> Jina Park,<sup>1</sup> Jiwon Ryu,<sup>7</sup> Jeonghwan Lee,<sup>2</sup> Chung Hee Baek,<sup>3</sup> Ji Eun Kim,<sup>4</sup> Ji In Park,<sup>6</sup> Jin Ho Hwang,<sup>5</sup> Dong Ki Kim,<sup>1</sup> Kook-Hwan Oh,<sup>1</sup> Kwon Wook Joo,<sup>1</sup> Yon Su Kim,<sup>1</sup> Hajeong Lee.<sup>1</sup> <sup>1</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>2</sup>Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; <sup>3</sup>Asan Medical Center, Songpa-gu, Seoul, Republic of Korea; <sup>4</sup>Korea University Guro Hospital, Seoul, Republic of Korea; <sup>5</sup>Chung Ang University Hospital, Seoul, Republic of Korea; <sup>6</sup>Kangwon National University Hospital, Chuncheon, Kangwon, Republic of Korea; <sup>7</sup>Seoul National University Bundang Hospital, Seongnam, Republic of Korea.

**Background:** The importance of acute kidney disease (AKD), the condition of which acute kidney disease (AKI) has not recovered, is being emphasized because it increases the risk of progression to chronic kidney disease (CKD). Although, there was a lack of large-scale cohort study on AKD after non-cardiac surgery.

**Methods:** We performed a retrospective cohort study from three tertiary referral center in South Korea. Among patients who underwent non-cardiac surgery over than 1 hour from 2014 to 2020, AKI was defined as whether the KDIGO AKI criteria were satisfied within 7 days after surgery. AKD was defined as a case of not recovering to less than 1.5 times from baseline creatinine within 7 days after peak creatinine after surgery in AKI group. The information of death event and initiation of renal replacement therapy were collected at 90 days after surgery. Logistic regression was used to investigate the risk factors that AKI progressed to AKD. In multivariate logistic regression, only variables with p-value less than 0.2 in univariate analysis were considered.

**Results:** A total of 178,565 patients were enrolled and 11,047 (6.2%) cases of AKI events were occurred. In whole population, 442(0.2%) patients newly started RRT and 2,157 patients dead (1.2%). 594 (8.2%) patients were progress to AKD and patients who progressed AKD had more risk of all-cause mortality and ESRD progression. (Figure 1) In multivariate logistic regression, surgery from urology (Odd ratio [OR] 2.13, 95% confidence interval [CI] 1.62-2.80,  $p < 0.001$  Table 1) and neurosurgery (OR 2.05, CI 1.16-4.62,  $p = 0.014$ ) department and leukocytosis (OR 1.04, CI 1.00-1.07,  $p = 0.024$ ) were associated with increased risk of progression to AKD. Patients who diagnose with malignancy before surgery (OR 0.62, CI 0.43-0.88,  $p = 0.008$ ) had lower risk of progression to AKD in the present study cohort.

**Conclusions:** Considering high mortality and poor renal outcome of AKD patients, physicians need pay attention to the occurrence of post-operative AKD after non-cardiac surgery.

**Funding:** Government Support - Non-U.S.

## FR-PO093

### Sepsis and Septic AKI Sequence: The Most Important Complication of Steroid Responsive Nephrotic Syndrome

Saptarshi Ghosh,<sup>1</sup> Debanjan D. Sinha,<sup>2</sup> Sanat K. Ghosh.<sup>2</sup> <sup>1</sup>Medical College and Hospital Kolkata, Kolkata, India; <sup>2</sup>Dr B C Roy Post Graduate Institute of Pediatric Sciences, Kolkata, India.

**Background:** Sepsis is a well recognized complication of nephrotic syndrome. Systemic inflammatory response syndrome (SIRS) insult in the nephrotic background initiates interplay between inflammation and oxidative stress, leading to septic acute

kidney injury (SAKI). Sepsis and SAKI sequence develop as a complication of nephrotic syndrome. Data on this subject is lacking. The present study is conducted to know the prevalence, clinical profile, morbidity and outcomes of this sequence in steroid responsive nephrotic syndrome.

**Methods:** This observational study is conducted at Dr B C Roy PGIPS, Kolkata, India. Consecutively hospitalised children with steroid responsive nephrotic syndrome below 12 years were included after exclusion of pre-existing chronic kidney disease. Sepsis & septic shock were identified by Sepsis-3 criteria and AKI was identified by KDIGO. AKI developing in the background of sepsis was defined as SAKI. Hospital stay, requirement of ICU care, inotropes, ventilator support and renal replacement therapy (RRT) were used as indicator of morbidity.

**Results:** Out of 235 subjects, 64 (27.23%) developed AKI. 59 (92.18%) of them were SAKI. Among the 59 subjects with SAKI, 40 (67.79%) had sepsis and 19 (32.20%) had septic shock. As per KDIGO, AKI staging of 59 patients with SAKI- 38 (64.4%), 12(20.33%) and 9 (15.25%) subjects developed stage 1, stage 2 and stage 3 AKI respectively. Severity of AKI was associated with sepsis 3 score ( $p$  value  $< 0.0000$ ). Clinical features included features of peritonitis, sepsis, or septic shock followed by prolongation of the oliguric phase, development of hypertension, azotemia, edema, azotemia subsided with diuresis. Hypertension persisted for a variable period. Duration of hospital stay, requirement of ICU care and mortality were higher in this group compared to non-AKI group ( $p$  value 0.0005360,  $< 0.0000001$  and 0.02215 respectively). Prevalence of sepsis-AKI sequence in steroid responsive nephrotic syndrome was quite high. Sepsis-3 score correlated with severity of AKI staging. SAKI was associated with increased length of hospital stay, increased frequency of inotropes & ICU requirement and increased mortality.

**Conclusions:** Sepsis--AKI sequence is the most important complication of steroid responsive nephrotic syndrome. Published data on septic AKI in nephrotic syndrome is very scanty.

## FR-PO094

### AKI in Patients With Leukemia Submitted to Allogeneic Hematopoietic Stem Cell Transplant: A Cohort Analysis

Claudia Costa, Natacha Rodrigues, Carolina Branco, Filipe Marques, Pedro D. Vasconcelos, Carlos M. Martins, Jose A. Lopes. Centro Hospitalar Universitario Lisboa Norte EPE, Lisboa, Portugal.

**Background:** Studies on acute kidney injury (AKI) in hematopoietic stem cell transplant (HSCT) consider several hematologic diagnoses in their cohorts and heterogeneous definitions for AKI. The purpose of this study was to evaluate the incidence, severity, and risk factors of AKI in patients with leukemia submitted to allogeneic HSCT considering serum creatinine (SCr) and UO.

**Methods:** We conducted a single-center retrospective cohort study including 164 patients with leukemia admitted for allogeneic HSCT between 2005 and 2015. KDIGO classification was used for AKI diagnosis considering daily values of SCr and 6-hour UO from admission day for HSCT until hospital discharge, and weekly evaluations within the first 100 days. We used survival analysis methods considering competing events to calculate AKI cumulative incidence, to establish AKI risk factors and to evaluate AKI impact on relapse, and Cox regression for AKI impact on 5-year mortality.

**Results:** The cumulative incidence of AKI was 58.5% at 30 days post-HSCT and 63.4% at 100 days post-HSCT. AKI diagnosis was firstly made by SCr criteria in 76.9%, by UO criteria in 15.4% and by both in 7.7%. The highest stage of AKI was 1 in 61.8%, 2 in 21.6% and 3 in 16.7%. Renal replacement therapy occurred in 12.5%. Independent variables associated with higher incidence of AKI included: hematopoietic cell transplant-specific comorbidity index (HCT-CI)  $> 2$  (Hazard Ratio (HR) 1.88, 95%CI 1.13-3.11,  $p = 0.015$ ), radiotherapy (RT) in the past (HR 2.07, 95%CI 2.07-1.06,  $p = 0.034$ ), serum lactate dehydrogenase (LDH) at hospital admission (HR 1.51, 95%CI 1.03-2.21,  $p = 0.035$ ), shock (HR 1.57, 95%CI 1.02-2.39,  $p = 0.039$ ), and sepsis (HR 3.36, 95%CI 1.22-9.24,  $p = 0.019$ ). AKI was an independent risk factor for 5-year mortality (HR 1.67, 95% CI 1.09-2.57,  $p = 0.020$ ).

**Conclusions:** AKI affects almost two thirds of leukemia patients submitted to allogeneic HSCT. Independent risk factors for AKI were HCT-CI  $> 2$ , previous RT, higher LDH levels at hospital admission, sepsis, and shock. AKI was independently associated with 5-year mortality. To our knowledge, this is the first study considering both SCr and UO criteria for AKI classification in leukemia patients after HSCT, which contributes to a more accurate determination of AKI incidence in these patients.

## FR-PO095

### The Risk of AKI in the Elderly With Advanced CKD

Nadir Goulamhousen, Josee Bouchard, Karyne Pelletier, Isabelle Chapdelaine, Stephan Troyanov. Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada.

**Background:** AKI in the elderly is associated with short- and long-term mortality, increased risk of ESKD, and functional decline. Estimating the incidence of AKI in advanced CKD is challenging, given that the 0.3 mg/dL threshold might not be of clinical significance. Using the KDIGO definitions, we assessed AKI frequency and recovery time in the elderly with advanced CKD as well as its predictors.

**Methods:** We included all patients  $\geq 70$  years of age and followed for  $\geq 3$  months at the Sacre-Coeur kidney protection clinic from 2012 to 2020. All AKI episodes, defined by an increase of 0.3 mg/dL over 48 hours or 1.5x increase over 7 days during the follow-up period were recorded. Given the elevated baseline creatinine, we also identified subpopulations of patients who also reached 0.5 and 1.0 mg/dL elevation in creatinine. We assessed differences between age groups. AKI recovery was defined as a return to within 0.3 mg/dL from baseline, within 2 or 7 days.

**Results:** We included 462 patients, of which 46 % were female, with an initial eGFR of  $20 \pm 8$  mL/min/1.73m<sup>2</sup>, and followed for a median of 21 [9-38] months. The rate of AKI was 36 events/100 patient-years, with 39 % experiencing at least one episode. AKI incidence was similar across age strata (Table), but recovery using the 1.5x criteria in those  $\geq 90$  years was lower (43 % vs. 79 %,  $p = 0.04$ ). CKD etiologies were not associated with the risk or recovery of AKI. Predisposing risk factors of AKI were a history of congestive heart failure (26 % vs. 13 %,  $p = 0.005$ ) and liver disease (44 % vs 15 %,  $p = 0.02$ ).

**Conclusions:** AKI frequency is elevated in the elderly with severe CKD, with an increased risk of non-recovery in the very old.

**Funding:** Private Foundation Support

FR-PO096

**Atorvastatin vs. Rosuvastatin for Contrast-Induced Nephropathy Prevention in Patients With Acute Coronary Syndrome Undergoing Percutaneous Coronary Intervention: A Meta-Analysis of Randomized Controlled Trials and Propensity-Score Matching**  
Naticha Leelaviwat,<sup>1</sup> Poemlarp Mekraksakit,<sup>1</sup> Gaspar Del Rio-Pertuz,<sup>1</sup> Juthipong Benjanuwattra,<sup>1</sup> Angkawipa Trongtorsak,<sup>2</sup> Samapon Duangkham,<sup>1</sup> Mahmoud Abdelnabi.<sup>1</sup> <sup>1</sup>Texas Tech University Health Sciences Center, Lubbock, TX; <sup>2</sup>AMITA Health, Chicago, IL.

**Background:** Statins have been reported to prevent contrast-induced nephropathy (CIN) via various mechanisms. However, the studies that compare the effect between atorvastatin and rosuvastatin following percutaneous coronary intervention (PCI) are still lacking. We conducted a systematic review and meta-analysis to compare atorvastatin and rosuvastatin for the prevention of CIN in patients with acute coronary syndrome (ACS) undergoing PCI.

**Methods:** Two investigators independently searched the databases of MEDLINE and EMBASE from inception to April 28, 2022. We included randomized clinical trials (RCTs) and propensity-score-matched (PSM) studies that compared atorvastatin and rosuvastatin and the effect on CIN in patients with ACS undergoing PCI. Data from each study were combined using the random-effects model and the generic inverse-variance method.

**Results:** Six studies (5 RCTs and 1 PSM study) involving 2,690 patients with ACS from October 2013 to August 2020 were included in our meta-analysis. There was no statistical difference between atorvastatin and rosuvastatin in preventing CIN (OR 1.2; 95% CI 0.89,1.61; I<sup>2</sup> = 0%). However, the use of high-dose atorvastatin was associated with a decreased risk of AKI following PCI in ACS patients compared to low-dose atorvastatin (OR 0.5; 95% CI 0.29, 0.87; I<sup>2</sup> = 0%).

**Conclusions:** Our meta-analysis indicated that the rate of CIN in patients with ACS undergoing PCI who received atorvastatin is not statistically different from those receiving rosuvastatin. Larger studies are needed to clarify this outcome.

FR-PO098

**Clinical Characteristics of AKI in Patients With Glyphosate Surfactant Herbicide Poisoning**  
In O Sun, A young Cho. Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea.

**Background:** In this study, we investigated the clinical characteristics of acute kidney injury (AKI) in patients with glyphosate surfactant herbicide (GSH) poisoning.

**Methods:** This study performed between 2008 and 2021 included 184 patients categorized into AKI and non-AKI groups. The incidence, clinical characteristics, and severity of AKI were compared between the AKI (n=82) and non-AKI (n=102) groups, based on the Risk, Injury, Failure, Loss of kidney function, and End-stage kidney disease classification.

**Results:** The incidence of AKI was 44.5%, of which 25.0%, 6.5%, and 13.0% patients were classified into the Risk, Injury, and Failure categories, respectively. Patients in the AKI group were older ( $63.3 \pm 16.2$  years vs.  $57.4 \pm 17.5$  years,  $P=0.020$ ) and had  $\geq 1$  comorbidities (52.4% vs. 32.7%,  $P=0.005$ ) than those in the non-AKI group. The length of hospitalization was longer ( $10.7 \pm 12.1$  days vs.  $6.5 \pm 8.1$  days,  $P=0.004$ ), and hypotensive episodes occurred more frequently in the AKI group (45.1% vs. 8.8%,  $P<0.001$ ). Electrocardiographic (ECG) abnormalities on admission were more frequently observed in the AKI than in the non-AKI group (80.5% vs. 47.1%,  $P<0.001$ ). Patients in the AKI group had poorer renal function ( $62.2 \pm 22.9$  mL/min/1.73 m<sup>2</sup> vs.  $88.9 \pm 26.1$  mL/min/1.73 m<sup>2</sup>,  $P<0.001$ ) on admission. The mortality rate was higher in the AKI than in the non-AKI group (18.3% vs. 1.0%,  $P<0.001$ ). Multiple logistic regression analysis showed that hypotension and ECG abnormalities upon admission were significant predictors of AKI in patients with GSH poisoning.

**Conclusions:** Blood pressure and ECG findings on admission may be useful predictors of AKI in patients with GSH intoxication.

FR-PO099

**Risk of AKI During Treatment With Lithium**  
Gisli Gislason,<sup>1</sup> Olafur S. Indridason,<sup>2</sup> Engilbert Sigurdsson,<sup>3,1</sup> Runolfur Palsson.<sup>2,1</sup> <sup>1</sup>Haskoli Islands, Reykjavik, Iceland; <sup>2</sup>Division of Nephrology, Landspítali–The National University Hospital of Iceland, Reykjavik, Iceland; <sup>3</sup>Mental Health Services, Landspítali–The National University Hospital of Iceland, Reykjavik, Iceland.

**Background:** Lithium intoxication is frequently associated with acute kidney injury (AKI), but the risk of AKI has otherwise not been well studied in persons using lithium. The aim of the study was to examine the risk of AKI in individuals on lithium treatment.

**Methods:** This was a retrospective cohort study of all persons treated with lithium in Iceland in 2003–2018. A control group comprised patients with affective disorders attending the outpatient clinic of the Mental Health Services at Landspítali–The National University Hospital in 2014–2016. Clinical and laboratory data were obtained from nationwide electronic medical records. Individuals with  $<2$  serum creatinine (SCr) values were excluded. Lithium exposure was defined as two or more measurable serum lithium levels or one or more filled lithium prescription. Individuals were censored at the time of last lithium exposure. AKI was defined using the SCr component of the KDIGO criteria. Risk assessment was performed using Cox proportional hazards with time-dependent variables.

**Results:** The lithium-treated group consisted of 2682 individuals, of whom 2017 (74.5%) were included in the study. Of those, 283 (14.0%) developed AKI. Of 1426 individuals in the control group, 1165 (81.8%) were included in the study and 48 (4.1%) of those developed AKI. Lithium use was an independent risk factor for AKI (hazard ratio [HR] 3.01, 95% confidence interval [CI], 2.25–4.23). When lithium users were analyzed separately, history of lithium toxicity (HR 2.87, 95% CI, 1.87–4.40) and higher mean lithium concentration (HR 1.15 per 0.1 mEq/L, 95% CI, 1.07–1.24) were significant risk factors for the development of AKI.

**Conclusions:** Lithium treatment is associated with a risk of AKI. History of lithium toxicity and higher blood lithium concentrations seem to contribute to AKI in lithium users. Lithium levels should be followed carefully in these patients and be maintained at lowest possible levels that meet their therapeutic needs at any given time.

**Funding:** Government Support - Non-U.S.

FR-PO100

**Statins and Contrast Induced-AKI: A Systematic Review and Meta-Analysis**  
Shriman Chittoor,<sup>1</sup> Kripa Kohli,<sup>1</sup> Sankar D. Navaneethan.<sup>2,3</sup> <sup>1</sup>Fort Bend Independent School District, Sugar Land, TX; <sup>2</sup>Baylor College of Medicine, Houston, TX; <sup>3</sup>Michael E DeBakey VA Medical Center, Houston, TX.

**Background:** Several treatment options are available to reduce the incidence of contrast-induced acute kidney injury (CI-AKI). Clinical trial evidence reported conflicting data on the incidence of CIN with statins. Hence, we conducted a systematic review and meta-analysis to evaluate the effects of statins as well as compare the effects of different doses of statins on the incidence of CI-AKI.

**Methods:** We searched MEDLINE and other databases (until March 2022) for randomized control trials (RCTs) that compared the effect of statin treatment on the incidence of CI-AKI or trials that compared high-dose vs. low-dose statin treatments on the occurrence of CI-AKI. Two authors independently assessed study quality and extracted data. Statistical analyses were performed using the random-effects model and results were expressed as a risk ratio (RR) for dichotomous outcomes with 95% confidence intervals (CI). Quality assessment was conducted using Cochrane quality assessment method.

**Results:** Seven RCTs (6635 patients) comparing statins to placebo and 2 trials (1204 patients) comparing low dose to high dose statins were included. There was a 59% reduction in the incidence of CIN with statins (7 trials, 6655 patients, Pooled RR- 0.59, 95% CI 0.44- 0.79) compared to placebo with no significant heterogeneity between the included studies [Figure]. However, there was no impact on the incidence of CI-AKI warranting dialysis with statins (Pooled RR- 0.28, 95% CI 0.05-1.70). High dose statins (vs. low dose statins) did not lower the incidence of CI-AKI (Pooled RR- 0.70, 95% CI 0.39-1.26) and CI-AKI warranting dialysis. Most included studies had mild-moderate risk of bias.

**Conclusions:** Statins use reduced the incidence of CI-AKI but without an impact on the incidence of AKI warranting dialysis. Large clinical trials examining the potential beneficial effects of high dose statins are warranted.

Incidence of CI-AKI with statins and placebo

## FR-PO101

### Patient Education to Improve AKI Outcomes and Awareness: A Scoping Review

**Michael Heung,**<sup>1</sup> Emily C. Capellari,<sup>1</sup> Ashita J. Tolwani,<sup>2</sup> Daniel P. Murphy,<sup>5</sup> Linda Awdishu,<sup>3</sup> Marlies Ostermann,<sup>7</sup> Jorge Cerda,<sup>4</sup> Patricia F. Kao,<sup>6</sup> AKI!Now Initiative <sup>1</sup>University of Michigan, Ann Arbor, MI; <sup>2</sup>The University of Alabama at Birmingham College of Arts and Sciences, Birmingham, AL; <sup>3</sup>University of California San Diego, La Jolla, CA; <sup>4</sup>Albany Medical College, Albany, NY; <sup>5</sup>University of Minnesota Academic Health Center, Minneapolis, MN; <sup>6</sup>Washington University in St Louis, St Louis, MO; <sup>7</sup>Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom.

**Background:** Survivors of acute kidney injury (AKI) have limited knowledge of AKI and many are unaware of their diagnosis. In order to optimize outcomes, increased AKI education and awareness are needed. The goal of the AKI!Now Initiative Education Subcommittee is to increase patient awareness and establish best practices in educating patients about AKI. As part of our needs assessment, we sought to characterize the current state of AKI patient education by reviewing the available literature on this topic.

**Methods:** Ovid Medline and CINAHL were searched to identify literature on patient-focused education and awareness around AKI. The search strategy included keywords and Medical Subject Headings related to AKI, education, information, specific educational materials (e.g., pamphlet, video, etc.), and purpose for information sharing (e.g., discharge and self-care). To increase sensitivity, adjacency searching was used in lieu of phrases for the patient education and information concepts. No limits were applied to the results. After screening for relevance based on inclusion criteria of 1) AKI population and 2) patient-focused education, the characteristics of included abstracts were summarized.

**Results:** Of the 419 abstracts identified with our search criteria, 371 were excluded (145 non-AKI focus, 213 without patient education, 13 other) leaving 48. Of these, 23/48 (48%) were published since 2019; 36/48 (75%) were in biomedical journals, compared to 5/48 (10%) in nursing and 5/48 (10%) in allied health journals. 23/48 (48%) abstracts were observational (including survey) studies, while 17/48 (35%) were review or editorial-type publications; no randomized trials were identified. Of the observational studies, 16/23 (70%) reported a patient education intervention, and 14/23 (61%) specified an outcome measure (6 clinical, 7 knowledge/awareness, 1 process). Of these 14 studies, 10 reported a statistically significant improvement in post-intervention outcomes.

**Conclusions:** In recent years there has been increasing interest in patient education around AKI, as reflected in the literature by more published research and calls for action. However, there remains a paucity of high-level evidence exploring effectiveness of various approaches to AKI education, especially regarding patient-centered clinical outcomes.

## FR-PO102

### Can Augmented Intelligence Assist in Delivering Continuous Renal Replacement Therapy? A Scoping Review

**Nada Hammouda,**<sup>1</sup> Javier A. Neyra,<sup>2</sup> <sup>1</sup>The University of Texas Southwestern Medical Center, Dallas, TX; <sup>2</sup>University of Alabama at Birmingham, Birmingham, AL.

**Background:** Despite advances in renal replacement therapy (RRT) technologies, the overall mortality rate for ICU patients on RRT is over 50%. Yet, CRRT delivery is not standardized, and there are no validated quality indicators to assess structure, processes and/or outcomes of programs. Digital health and artificial intelligence (AI) technologies have transformed most aspects of health service delivery, including patient diagnostics, risk classification, clinical decision support, and even workflow optimization such as patient scheduling. The current state of literature on the applications of AI in CRRT delivery remains unknown. We aimed to characterize the state of existing literature on the use of AI in CRRT delivery, and identify current gaps and future research priorities.

**Methods:** We searched PubMed, OVID Embase, Web of Science, Cochrane, Scopus and ProQuest, from inception onwards, for original papers published or translated in English. Study summaries were tabulated and analyzed for insight on the current state of research and potential future directions.

**Results:** 12 papers were selected, 6/6 (50%) in 2021, and 7/12 (60%) focused on machine learning to augment CRRT delivery. All innovations were in the design/validation phase of development. Primary research interests focused on early indicators of CRRT initiation, clinical prognostication, and identifying risk factors for mortality. Secondary research priorities included dynamic CRRT monitoring, predicting complications, and automated data pooling for point-of-care analysis. Identified literature gaps included implementation barriers, quality indicators, bias ascertainment, and quantifying social or machine-generated healthcare disparities.

**Conclusions:** Research on AI applications in CRRT delivery grows exponentially but the field remains premature. Future studies are needed on validation, structural implementation, quality assurance, bias and equity ascertainment. The next breakthrough in the field should be smart task delegation: its utility, hazards and overall benefit for patients, clinicians, and health systems.

## FR-PO103

### Unusual Consequences of Dietary Supplements in a Patient Presenting With AKI

**Sherif Badra,** Gajapathiraju Chamarithi, Ramon Ortiz Espinal, William L. Clapp, Rupam Ruchi. *University of Florida, Gainesville, FL.*

**Introduction:** Oxalate nephropathy is a rare disorder that can lead to acute kidney injury (AKI). Hereby, we report a case of secondary oxalate nephropathy with biopsy proven oxalate crystalline deposits.

**Case Description:** A 26-year-old male was referred for hospital admission after blood work showed worsening of creatinine (cr) from baseline 1.1 to 3.2 mg/dl. Past medical history was significant for polyglandular autoimmune syndrome and pancreatic insufficiency treated with pancreatic enzyme replacement therapy. The patient reported single episode of nephrolithiasis 7 years ago. Ultrasound showed no hydronephrosis or stones. Acute interstitial nephritis was suspected based on recent use of antibiotics for skin lesions consistent with sweet syndrome. Kidney biopsy was performed and showed tubulopathy with calcium oxalate deposits (Figure 1). Upon further evaluation in our stone clinic, patient reported taking daily Vitamin C and high oxalate supplements (turmeric). Genetic testing for primary hyperoxaluria was negative, and serum oxalate was normal. Patient was advised to maintain low oxalate diet and discontinue the supplements. Subsequent 24-hour urine showed an oxalate of 51 mg/d. Although there was partial recovery of renal function on follow up, with cr improving to 1.6 mg/dl, he developed chronic kidney disease (CKD) stage 3a secondary to oxalate nephropathy.

**Discussion:** Detailed history of high oxalate supplements is crucial for diagnosis of secondary hyperoxaluria. Renal biopsy can be useful in cases of oxalate nephropathy when etiology of AKI is unclear. Physicians should be aware about that condition that can lead to kidney failure. Our case shows the importance of kidney biopsy to diagnose oxalate nephropathy.

**Figure 1**  
**Top:** Birefringent tubular crystals (H&E, polarized)  
**Bottom:** Tubular calcium oxalate crystal (radiating or fan-like shape), (left, H&E) and (right, polarized)

## FR-PO104

**A Novel Case of Renal Mucormycosis Associated With Empagliflozin Use**  
Abdul Haseeb,<sup>1</sup> Muhammad Abu-Rmaleh,<sup>1</sup> Jeffrey G. Penfield,<sup>2</sup> Hao Liu,<sup>2</sup> Peter N. Van Buren,<sup>2</sup> Eleanor D. Lederer,<sup>2,1</sup> Swati Lederer.<sup>2,1</sup> *The University of Texas Southwestern Medical Center, Dallas, TX; <sup>2</sup>VA North Texas Health Care System, Dallas, TX.*

**Introduction:** Renal mucormycosis is a rare but often fatal disease. We describe the first case of renal mucormycosis associated with use of empagliflozin, a sodium glucose cotransporter-2 (SGLT2) inhibitor, in a diabetic patient.

**Case Description:** 63-year-old gentleman with uncontrolled diabetes, hypertension, and hepatitis C liver cirrhosis presented to the Emergency Department with left flank pain. He was on empagliflozin for diabetes mellitus. He was hemodynamically stable. Initial laboratory investigations revealed acute renal failure with a creatinine of 1.7 mg/dl (baseline 0.9 mg/dl). His HbA1c was 12.8%. Urine culture was negative. Imaging revealed left hydronephrosis with perinephric fat stranding. The presumptive diagnosis was a kidney stone but repeat imaging revealed emphysematous cystitis, left hydronephrosis with extensive pyelitis. Broad spectrum antibiotics were started, and a left percutaneous nephrostomy (PCN) tube was placed. A repeat urine culture from the left nephrostomy tube grew mold, of uncertain significance. The culture later speciated zygomycetes and posaconazole was initiated. Repeat imaging was concerning for liquefactive necrosis of the left kidney and an obliterated left ureter. New right-sided hydronephrosis developed, requiring right PCN tube. Liposomal amphotericin was started. He underwent left nephroureterectomy, partial cystectomy, with removal of both PCN tubes and placement of a right ureteral stent. Final microbiologic diagnosis was invasive mucormycosis. He was treated initially with both amphotericin and posaconazole, followed by posaconazole alone for a planned duration of 6-months.

**Discussion:** This is the first reported case of renal mucormycosis in the setting of SGLT2 inhibitor use. Patient's risk factors for infection were liver cirrhosis, uncontrolled diabetes, and SGLT2 inhibitor use. The successful outcome was due to the combination of aggressive antifungal therapy and surgery. SGLT2 inhibitors, commonly prescribed for their beneficial effects on cardiovascular and renal outcomes in diabetic patients, are well-tolerated but are associated with a risk of urinary tract infections (UTIs). Though UTIs are most frequently bacterial, rare and atypical organisms can occur, as was seen in this case. Providers should maintain a high index of suspicion when unexpected culture results are obtained.

## FR-PO105

**A Case of Rhabdomyolysis Leading to ESRD Secondary to Influenza A Infection in a 70-Year-Old Patient**

Nidal Alhosainat, Mohamed A. Mohamed Ahmed, Mahmood Mubasher, Wajid M. Choudhry. *Rochester Regional Health, Rochester, NY.*

**Introduction:** Rhabdomyolysis is a serious clinical syndrome characterized by muscle breakdown and release of damaging proteins. Influenza infection has been increasingly reported as a causative disease. We are reporting an unusual case of severe rhabdomyolysis with acute renal failure leading to ESRD due to influenza A infection

**Case Description:** A 70-year-old female with PMHx of hyperlipidemia and hypothyroidism, admitted with body aches along with flu-like symptoms for 4 days duration, no history of seizure or trauma, only on levothyroxine at home. Physical exam with stable vital signs, clear lungs. Labs were pertinent for WBC 31.0x10<sup>9</sup>, eosinophilia 20%, creatinine 1.4mg/dl (baseline 0.9) and AST/ALT 2590/530 mg/dl, hepatitis screen negative, urine analysis with +3 blood, 3 RBCs, +1 protein. CK 104,740 U/L, influenza A PCR positive, negative PCR for influenza B, COVID 19. Diagnosis of acute renal failure secondary to rhabdomyolysis secondary to influenza A was made, patient was started on oseltamivir and required renal replacement therapy, no recovery after 3 months and labeled ESRD

**Discussion:** Influenza A is a negative-sense RNA virus, transmitted by large droplets and small particle aerosols, complication of influenza includes but not limited to pneumonia, encephalitis, myocarditis and Myositis which can be secondary to Direct invasion of muscle tissue by the viral agent, Myotoxic cytokines release and Immunologic processes induced by the viral infection. Rhabdomyolysis is a syndrome characterized by muscle necrosis and the release of intracellular muscle constituents into the circulation. It might occur due to trauma, drugs, bacterial or viral infections or others, Creatine kinase levels are typically elevated. The risk of AKI is higher with CK levels of more than 15 to 20,000 units/L, caused mainly by Volume depletion resulting in renal ischemia, tubular obstruction due to heme pigment casts, and tubular injury from free chelatable iron. Treatment is mainly by large volume administration of isotonic fluids, renal replacement therapy may be needed for severe cases. **Conclusion:** Influenza can be a serious disease leading to serious complications, extra caution should be considered in patients who develop acute renal failure after influenza infection; rhabdomyolysis should be suspected, investigated, and treated appropriately

## FR-PO106

**Kratom Induced Acute Tubular Necrosis**

Victor A. Canela, Roberto L. Collazo-Maldonado. *Methodist Health System, Dallas, TX.*

**Introduction:** Kratom (*Mitragyna speciosa*) is part of the coffee plant family (Rubiceae). Its use has been linked to rural workers in Indonesia and Malaysia but recently has gained popularity in the Western world. The active compounds are indole alkaloids (mitragynine) which act as partial opioid agonists. Its effects are described as a

stimulant, analgesics and muscle relaxants. The potential drug to drug interactions, cross contamination and direct kidney injury makes it important for Nephrologists to recognize. This case highlights acute kidney injury in a young patient with daily use of Kratom.

**Case Description:** A 28 y/o Caucasian man with history of DM type 1 and Psoriasis presented with one week of nausea, vomit and decreased urine output. Medication list included an insulin pump, Enbrel and Valtrex. He reported increased use of daily Kratom pills in the last week for anxiety. On physical exam, his VS were normal but was found to be hypovolemic. BUN was 44 mg/dl, Cr 9.53 mg/dl. Electrolytes, LFT's CK were normal. Serologies were negative. U/A showed pyuria, 1+ eosinophils, no granular casts, no rbc's and no crystals. A 24-hr urine had 2 gm of proteinuria. Urine toxicology was negative. Renal U/S had normal kidneys with no hydronephrosis. His kidney function became worse despite adequate intravascular volume expansion; therefore, a kidney biopsy was done and was consistent with acute tubular necrosis. His Cr peaked at 13 mg/dl and kidney function gradually improved without the need of any kidney replacement therapy.

**Discussion:** Kratom consumption in the United States is unregulated and mostly available at herbal stores. The FDA has recommended to classify as Schedule I substance. We presented a case of oliguric AKI in a patient with Kratom consumption. Drug-to-drug interaction and cross contamination are the main safety concern of this substance. Rhabdomyolysis, acute hepatic and kidney injury have been reported. It is important for the practicing Nephrologist and general clinicians to be aware of such herbal supplements and their presentations. More studies are needed to establish the exact pathogenesis and relation to causality.

## FR-PO107

**Disseminated Lomentospora Infection Presenting as AKI**

Katrina Epperson,<sup>1,2</sup> Elliot Perens,<sup>1,2</sup> Christina Ruiz,<sup>1,2</sup> Katayoon Shayan,<sup>2,1</sup> Leidy Tovar Padua,<sup>1,2</sup> Caitlin E. Carter.<sup>1,2</sup> *University of California San Diego, La Jolla, CA; <sup>2</sup>Rady Children's Hospital San Diego, San Diego, CA.*

**Introduction:** Acute kidney injury (AKI) is a common complication of childhood leukemia and its treatment. One month after induction chemotherapy, the patient developed AKI without another obvious nephrotoxic insult, and a kidney biopsy showed angioinvasive fungus. He was found to have disseminated Lomentospora prolificans and succumbed to the infection. Invasive fungal infection commonly causes multiorgan dysfunction from infection, but AKI is an uncommon initial presentation.

**Case Description:** An 18yo male with trisomy 21 developed rapidly progressive AKI approximately after initiation of induction chemotherapy (vincristine, cytarabine, methotrexate, and PEG-asparaginase) for newly diagnosed leukemia. He developed non-oliguric AKI with a rise in serum creatinine from 0.75 to 3.7 mg/dL over 72 hours without hemodynamic instability, nephrotoxic medication exposure, or other evident cause of AKI. Evaluation for underlying causes of AKI, including urine microscopy and renal and renovascular ultrasound, were not diagnostic. Kidney biopsy demonstrated acute fungal tubulointerstitial disease. Brain MRI showed multiple lesions concerning for angioinvasive fungal disease. Plasma metagenomic next-generation sequencing identified Lomentospora prolificans. Due to the extensive multiorgan involvement, it was determined that infection was not curable and family opted to withdraw care. Postmortem blood, urine, skin tissue, and spinal fluid were positive for Lomentospora.

**Discussion:** Our patient suffered severe rapidly progressive AKI as the presenting finding of Lomentospora prolificans infection, a ubiquitous multi-drug resistant environmental filamentous fungi with very high mortality. His risk factors for Lomentospora disseminated disease included leukemia and chemotherapy-induced neutropenia. Treatment for localized Lomentospora includes excision of infected tissue and antifungal therapy, however disseminated disease is often fatal, as it was in this case.

PAS (a) and GMS (b) light micrographs demonstrating acute fungal infection of the kidney with numerous fungal organisms in multiple forms.

## FR-PO108

**Kidney Volume Is a Predictor of AKI Following Cardiovascular Surgery Independent of eGFR**

Takahisa Kasugai, Miho Murashima, Tatsuya Tomonari, Minamo Ono, Masashi Mizuno, Takayuki Hamano. *Nagoya City University Nagoya Shiritsu Daigaku, Nagoya, Japan.*

**Background:** Predictors of acute kidney injury (AKI) after cardiovascular (CV) surgery have been extensively studied. However, risk prediction has been suboptimal.

**Methods:** In this retrospective cohort study, we enrolled adults who underwent CV surgery from 2014 to 2021 at our facility and computed tomography (CT) scan within 6 months before surgery. We excluded those with multiple or large cysts, single kidney, creatinine > 4 mg/dL, or undergoing kidney replacement therapy. Exposure of interest

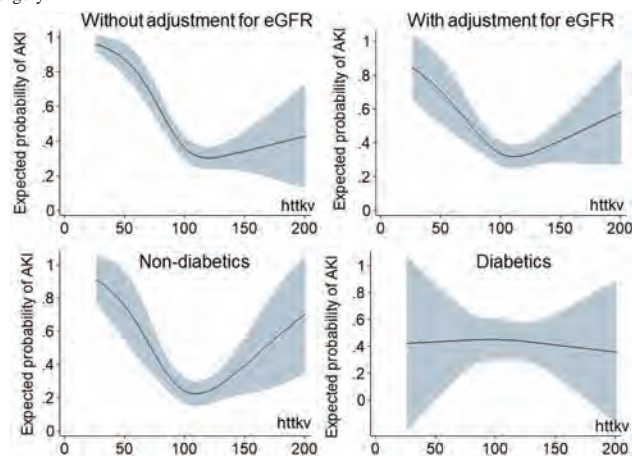

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

was height-adjusted total kidney volume (htTKV) measured by software using the three dimensional CT reconstruction. The outcome was postoperative AKI defined by the KDIGO creatinine criteria. We employed logistic regression models and the results were shown as cubic spline curves.

**Results:** Among 558 patients, 196 (35.1%) developed AKI. Those with smaller htTKV were older, less likely to be diabetic, and had lower eGFR. The association between htTKV and AKI was U-shaped after adjustment for confounders including eGFR. The odds ratio for AKI was 1.60 (1.47-1.75) and 1.06 (1.02-1.11) among those with htTKV $\leq$ 75 and  $>$ 125, respectively, compared with htTKV 75-125 mL/m<sup>2</sup>. The U-shaped relationship between htTKV and AKI was observed among non-diabetics but not among diabetics (p for interaction 0.05). There were no effect modifications by age, sex, eGFR, or the use of diuretics for the association between htTKV and AKI.

**Conclusions:** The Association between htTKV and AKI after CV surgery was U-shaped. Smaller htTKV might reflect more severe atherosclerotic changes independent of eGFR. A small increase in the incidence of AKI among those with large htTKV might be due to kidney congestion often observed in patients with pre-operative heart failure. htTKV could be a useful predictor for postoperative AKI among those undergoing CV surgery.

## FR-PO109

### Intravascular Hemolysis and AKI in Pediatric Patients Undergoing Extracorporeal Membrane Oxygenation (ECMO)

Amy Strong, Jarcy Zee, Rosanna Fulchiero, Diego Campos, Todd J. Kilbaugh, Benjamin L. Laskin, Michelle Denburg. *The Children's Hospital of Philadelphia, Philadelphia, PA.*

**Background:** AKI is common in ECMO patients. We sought to describe the impact of laboratory evidence of ECMO associated intravascular hemolysis on AKI.

**Methods:** This retrospective cohort study included patients treated with ECMO at a single center over ten years. The primary outcome was a composite of time to renal replacement therapy (RRT) or AKI (by creatinine based KDIGO criteria) after ECMO start. Serum creatinine closest to ECMO start time was considered the pre-ECMO baseline and used to determine abnormal kidney function at ECMO start. The patient's subsequent creatinine values were used to identify AKI on ECMO. Multivariable cause-specific cox proportional hazards models were used to assess the impact of markers of intravascular hemolysis on time to the composite outcome after controlling for confounders.

**Results:** 501 children were evaluated: median age 1.2 years, 56% male. Four models are presented in Table 1 each with a different marker of hemolysis (plasma free hemoglobin, LDH, minimum platelets and minimum hemoglobin). An elevated plasma free hemoglobin level, the most specific of these hemolysis markers, demonstrated a  $>$ 3-fold higher hazard for the composite outcome (p-value 0.001). Elevated LDH was associated with an adjusted hazard ratio of 2.4. Effect estimates were more pronounced in a sensitivity analysis of stage 2+ AKI/RRT: HR 6.5 (95% CI 3.3-12.8) for plasma free hemoglobin and 3.3 (95% CI 1.7-6.5) for LDH.

**Conclusions:** Laboratory findings consistent with intravascular hemolysis on ECMO were associated with a higher hazard of AKI or RRT in children undergoing ECMO.

**Funding:** NIDDK Support, Private Foundation Support

### Right Heart Failure and Reduced Kidney Function in Left Ventricular Assist Device Recipients

Carl P. Walther, Sankar D. Navaneethan. *Baylor College of Medicine, Houston, TX.*

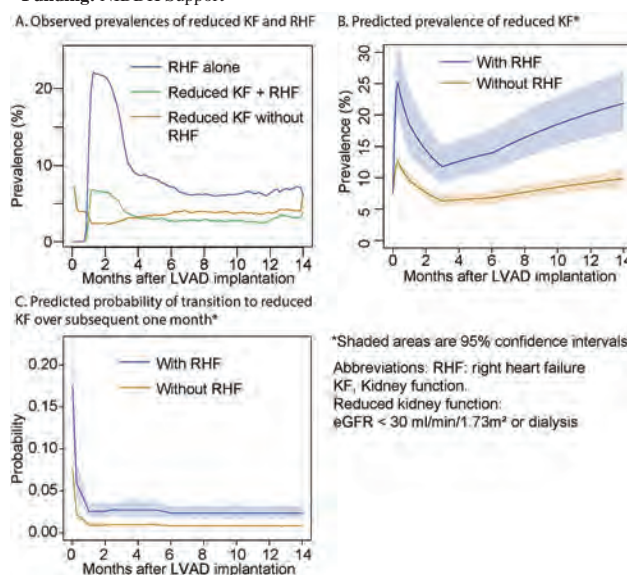

**Background:** Right heart failure (RHF) and kidney dysfunction are harmful complications of left ventricular assist devices (LVADs). RHF can cause kidney dysfunction through elevated renal venous pressure. We investigated the time-varying relationship of RHF with reduced kidney function in a national cohort of LVAD recipients.

**Methods:** We identified implantations of isolated continuous flow LVADs from 2016-17 in INTERMACS, a national registry. RHF was ascertained from the binary right heart failure variable in INTERMACS, an adjudicated variable based on persistent signs and symptoms of RHF. Multistate Markov models were used to analyze the relationship between time-varying RHF state and reduced kidney function (defined as eGFR  $<$ 30 mL/min/1.73m<sup>2</sup> or dialysis) over 14 months following LVAD implantation (censoring for heart transplant, LVAD removal, or death). Piecewise models were used, to account for varying baseline risk of reduced kidney function during follow-up, with cut points at 1 week and 1, 3, and 6 months.

**Results:** We identified 4,616 LVAD implantations. Median age was 59 years and 21% were female. There were 313 state changes to RHF and 752 state changes to reduced kidney function over 3,043 person-years. Risk for development of reduced kidney function, and prevalences of reduced kidney function and RHF, were highest early after LVAD implantation but remained substantial throughout follow-up (Figure). RHF was associated with higher risk of development of reduced kidney function: HR 2.93 (95% CI 2.18-3.94).

**Conclusions:** We found that RHF is associated with nearly 3 fold higher risk of development of reduced kidney function among LVAD recipients in a national cohort, with highest risk early after LVAD implantation. This demonstrates the importance of right heart function and renal venous pressure to kidney function in advanced heart failure and durable mechanical circulatory support.

## FR-PO111

**Kidney Donors With and Without Post-Donation AKI: Comparison of Baseline Characteristics and Long-Term Outcomes**

Abdel-Rauof M. Akkari, Mistafa Hafid, Muhammad Abdulbasit, Omar K. Salameh, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

**Background:** There is an increasing demand for kidney transplantation, especially from living donors. This has necessitated better understanding of medium-term and long-term risks of kidney donation. Using a large multicenter cohort, we analyzed the differences in demographic characteristics in donors who developed acute kidney injury (AKI) within the first year after donation with those who did not develop AKI.

**Methods:** We performed a retrospective multi-center cohort study using TriNetX Research Network database, a federated medical records network, to identify 42,955 donors  $\geq 18$  years from 59 healthcare organizations (HCOs) in the United States. From this group, we then identified donors who had a confirmed diagnosis of AKI within a year of donation. We calculated the odds ratio (OR) and 95% confidence interval (CI) of diagnosis of End Stage Renal Disease (ESRD) and death in the first five years after donation.

**Results:** 3,055 donors (from 39 HCOs) had a confirmed diagnosis of AKI within the first year after donation. Patients in the AKI group were older at time of donation ( $44.2 \pm 13.5$  years vs.  $40.8 \pm 12.9$  years;  $p < 0.0001$ ), and more likely to: • be male ( $p < 0.001$ ) • have a Body Mass Index (BMI)  $> 30 \text{ kg/m}^2$  ( $p < 0.001$ ) • have a diagnosis of hypertension at time of donation ( $p < 0.001$ ) • be on a diuretic agent at time of donation ( $p < 0.001$ ) • be nicotine dependent ( $p < 0.001$ ) Within the first five years after donation, a total of 5554 donors (1874 with history of AKI) were diagnosed with ESRD and 1266 donors (501 with AKI) died. After propensity matching, AKI was associated with higher odds of ESRD (OR: 15.2; CI: 14.1 to 16.5), and mortality (OR: 9.9; CI: 8.8 to 11.2).

**Conclusions:** Among kidney donors, those who developed AKI within the first year of donation were more likely to be older at time of donation, male, have a BMI  $> 30 \text{ kg/m}^2$ , carry a diagnosis of hypertension and be on a diuretic at time of donation, and to be nicotine dependent. AKI within first year of donation was associated with higher likelihood of ESRD and death within five years after donation.

## FR-PO112

**Long-Term Outcome of AKI: New-Onset Comorbidities and Survival**

Young Eun Choi,<sup>2</sup> Jihyun Yang,<sup>1,2</sup> Sungyeon Kim,<sup>2</sup> Suk Min Chung,<sup>2</sup> Ko Yoon Sook,<sup>2</sup> Lee Hee Young,<sup>2</sup> Yina Fang,<sup>2</sup> Tai yeon Koo,<sup>2</sup> Sewon Oh,<sup>2</sup> Myung-Gyu Kim,<sup>2</sup> Sang-Kyung Jo.<sup>2</sup> *Kangbuk Samsung Medical Center, Jongno-gu, Seoul, Republic of Korea; <sup>2</sup>Korea University Anam Hospital, Seoul, Republic of Korea.*

**Background:** Acute kidney injury (AKI) is known as a risk factor for short-term mortality and poor prognosis. In this study, we studied whether the AKI would be a risk factor for other comorbidities using the Korean national medical insurance database.

**Methods:** This study was performed using data from NHIS-NSC of Korea. The cohort was composed of 0.4% of the total eligible Korean population baseline population ( $n = 186,512$  AKI patients vs 45,000,000) between 2008 to 2013. We set that inclusion period as the index date. Patients who had been diagnosed with AKI using N17 code and dialysis requiring AKI (AKI-D) were defined as patients who were encoded with dialysis-related codes, the rest of the patients who had experienced AKI without a history of dialysis were defined as AKI-non-D. Patients with a previous history of AKI, end-stage kidney disease (ESKD), and dead before the index date were excluded.

**Results:** During a median follow-up of 1800 days, newly developed comorbidities including angina, myocardial infarction, cardiac failure, cerebral hemorrhage and cerebral infarction, percutaneous coronary artery intervention, coronary artery bypass graft, fractures, and dementia were observed in AKI-D survivors. Survivors of AKI regardless of AKI severity showed higher mortality compared to the normal population. Patients with AKI-D showed worse survival compared with AKI-non-D as well as ESKD. Most of the initial mortality drop was observed within 300 days. Female, elderly with coexisting comorbidities including hypertension, angina, cardiac failure, cerebral hemorrhage and infarction, malignancy, fracture history, and dementia were significant risk factors for mortality.

**Conclusions:** AKI episode has long-term adverse effects on comorbidities and poor survival which is worst with dialysis-requiring cases. Close monitoring for renal function with comorbidity management would be important to severe AKI survivors.

## FR-PO113

**Post Discharge Follow-Up Care in AKI Hospitalizations: A Health Systems Approach**

Prakash S. Gudsoorkar,<sup>1</sup> Jwalant R. Modi,<sup>1</sup> Karthikeyan Meganathan,<sup>1</sup> Charuhas V. Thakar.<sup>1,2</sup> *<sup>1</sup>University of Cincinnati, Cincinnati, OH; <sup>2</sup>Cincinnati VA Medical Center, Cincinnati, OH.*

**Background:** Acute kidney injury (AKI) survivors face increased risk of readmissions and fragmented post-discharge care. We operationalized and implemented a quality improvement program (QIP) to track metrics of readmissions and follow-up care after in AKI patients.

**Methods:** By automated informatics approach, from all renal consults except transplant we extracted AKI patients, reviewed by each calendar quarter (10/2015 to 09/2019). Outcome metrics were: i) 30- or 90-day readmission; ii) renal follow up in clinics or dialysis among eligible survivors.

**Results:** Of the 3,988 AKI patients (6,602 hospitalizations) 58.5% were male. Discharge disposition included 24% expired/hospice and 42% home (Fig 1). 2,591 (65%) were eligible for follow up care. The median time to readmission was 18 days (IQR=8-43); average 30- and 90-day readmission rate was 28% and 41% respectively (Fig 2). Of the eligible patients, renal follow up occurred in 38% (range 30-45%); of which clinic follow up was 33% (range 24-39%) and dialysis follow up was 5% (range 2-7%). The follow up trends were similar across quarters.

**Conclusions:** A prospective QIP of follow up care in AKI evaluates missed opportunities. This program can then help in implementation of post-discharge clinics and improve outcomes in AKI survivors.

## FR-PO114

**Identifying Key Challenges and Opportunities in the Care of AKI Survivors Not on Dialysis: AKINow Workgroup**

Emaad M. Abdel-Rahman,<sup>1</sup> Samuel A. Silver,<sup>2</sup> Erin F. Barreto,<sup>3</sup> Jorge Cerda,<sup>4</sup> Leslie S. Gewin,<sup>5</sup> Javier A. Neyra,<sup>6</sup> Jia Hwei Ng,<sup>7</sup> Anitha Vijayan.<sup>5</sup> *<sup>1</sup>UVA Health, Charlottesville, VA; <sup>2</sup>Queens University, Kingston, ON, Canada; <sup>3</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>4</sup>Albany Medical College, Albany, NY; <sup>5</sup>Washington University in St Louis, St Louis, MO; <sup>6</sup>University of Kentucky, Lexington, KY; <sup>7</sup>Northwell Health, Glen Cove, NY.*

**Background:** ASN recently established the AKINow initiative aiming to promote excellence in the prevention and treatment of AKI. One of the core policy, practice and research objectives of this workgroup is to identify gaps in the care of AKI survivors post hospitalization and develop quality evidence and benchmark existing strategies to care for these patients including insights from other stakeholders.

**Methods:** We held a focus group with key stakeholders that included nephrologists, primary care providers, advanced practice providers (APP), intensivists, pediatric providers, community providers, patients and allied health personnel. We sought perspectives on optimal plans for hospital discharge of AKI survivors, challenges and opportunities in their care, communication strategies across diverse stakeholders, patient and care partner education and activation, and preferred interventions.

**Results:** While 54% of the participants ( $n = 57$ ) identified integrated care delivery among providers to be the biggest barrier for care of AKI survivors, 23% thought that education and awareness among patients are the main challenge. 79% of the participants recommended RAAS blockers resumption should be after serum creatinine returns to baseline/ new baseline. They further suggested that currently 95% of the care of AKI

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

survivors is shouldered by nephrologists. This care is shared by Internists (51%), pharmacists (51%), RN (43%), APP (43%) and by other allied health personnel (8-22%). AKI patients' survivor testimonial about their experiences highlighted some of the gaps encountered in their care. Four breakout sessions (12-15/session) suggested specific recommendations to inform who is currently followed after AKI and by whom, different options for care delivery, and potential interventions/practices that may improve clinical and patient-centered outcomes

**Conclusions:** The stakeholder relationships formed, including those with patients, industry, and academia, will facilitate a collaborative research and practice agenda to advise the best and efficient practices after AKI. This represents an opportunity for the “recovery after AKI” workgroup of *AKINow* to provide leadership by raising awareness and promoting strategies focused on equitable and effective post-AKI care throughout the ASN and wider nephrology community

FR-PO115

Incidence, Risk Factors, and Outcomes of Neonatal AKI in Very Low Birth Weight Infants: A Retrospective Cohort Study in a Single Neonatal Intensive Care Unit in Japan

Erika Hidawa,<sup>1</sup> Naomi Hotta,<sup>2</sup> Hayato Sakurai,<sup>2</sup> Hiroko Kakei,<sup>2</sup> Masakazu Honda,<sup>2</sup> Tetsuya Kunikata,<sup>2</sup> Yuko Akioka,<sup>1</sup> <sup>1</sup>*Department of Pediatrics, Saitama Medical University, Iruma, Japan;* <sup>2</sup>*Department of Neonatology, Saitama Medial University, Iruma, Japan.*

**Background:** Premature neonates are at high risk of chronic kidney disease (CKD) due to low nephron number at birth. In very low birth weight (VLBW) infants, acte kidney injury (AKI) is common during admitted to the neonatal intensive care unit (NICU). AKI is a greater long-term risk of CKD. This study was aimed to determin the incidence, risk factors and outcomes of AKI in VLBW infants admitted to the NICU.

**Methods:** In this study, VLBW infants hospitalized between January 2014 and March 2020 in our NICU were enrolled. We examined the incidence of AKI, and analyzed the association with detailed maternal history, neonatal history, anthropometry, vitals and clinical signs of neonates. The diagnosis of AKI was defined by an increase in serum creatinine (SCr)>0.3 mg/dL or urine output <1 ml/kg per hour, the neonatal modification of Kidney Disease: Improving Global Outcomes criteria.

**Results:** In total, 234 VLBW infants were included. Incidence of AKI was 52.7% (n=125). Factors associated with a higher risk of AKI included: gestational age, birth weight, Apgar scores at 1, Apgar scores at 5, hyperbilirubineia, pulmonary surfactant, diuretics, vasopressors, blood transfusion, steroids for fetal maturation, length of stay as show in the table. In multiple regression analysis, compared with no-AKI, AKI were associated with higher risk of indomethacin for patent ductus arteriosus (odds ratio(OR), 145.97; 95%confidence interval (CI), 17.72-1202.20), small for gestational age (OR, 0.27; 95%CI, 0.092-0.81) and preeclampsia (OR, 0.040; 95%CI, 0.0017-0.98). SCr levels at discharge are not significantly different between neonates with AKI to no-AKI.

**Conclusions:** Early diagnosis and timely intervention in neonates who treated with indomethacin can prevent the progression of AKI and thus improve prognoses. We suggest that those neonates should be followed up for a long term to prevent CKD.

**Integration of Human Kidney Transcriptome and Plasma Proteome Identifies Novel Biomarkers of Proximal Tubule Maladaptation to Injury**  
Yumeng Wen,<sup>1</sup> Emily Su,<sup>1</sup> Leyuan Xu,<sup>2</sup> Steven Menez,<sup>1</sup> Dennis G. Moledina,<sup>2</sup> Paul M. Palevsky,<sup>3</sup> Lloyd G. Cantley,<sup>2</sup> Patrick Cahan,<sup>1</sup> Chirag R. Parikh.<sup>1</sup> <sup>1</sup>for the Kidney Precision Medicine Project (KPMP) and Translational Research in Biomarker Endpoints of Acute Kidney Injury (TRIBE-AKI) consortia <sup>1</sup>*Johns Hopkins Medicine, Baltimore, MD;* <sup>2</sup>*Yale School of Medicine, New Haven, CT;* <sup>3</sup>*University of Pittsburgh School of Medicine, Pittsburgh, PA.*

**Background:** There are no non-invasive approaches to identify maladaptive responses in proximal tubule (PT) after kidney injury.

**Methods:** We performed single nucleus RNA sequencing (snRNA-seq) analysis of kidney biopsy tissues from 6 participants with AKI and 7 healthy controls from the KPMP and HuBMAP consortia. We integrated differentially expressed genes in PT maladaptation with the plasma proteome (SomaScan) in cardiac surgery patients in

the TRIBE-AKI cohort. We evaluated the association between post-operative plasma proteins of maladaptive and healthy PT with KDIGO stage 2-3 AKI after surgery. We also performed reverse translational studies and confirmed these findings in a mouse model of maladaptive kidney repair following unilateral ischemia-reperfusion injury.

**Results:** SnRNA-seq analysis of kidney biopsy tissue in participants with AKI identified the subgroup of maladaptive PT cells characterized by advanced dedifferentiation and enrichment of pro-fibrotic pathways. Integrating 923 differentially expressed genes in PT maladaptation in participants from KPMP with the post-operative plasma proteome on 4040 protein aptamers in participants from TRIBE-AKI, we identified 4 proteins whose genes were specifically upregulated, and 5 proteins whose genes were specifically downregulated by PT maladaptation. The increases in COL23A1, TGFB2 and NLGN4X, and decreases in ENPP6 and PLG protein aptamers post-operatively were strongly associated with development of severe AKI during hospitalization. (Figure 1) The upregulation in *Col23a1* and *Tgfb2*, and the downregulation in *Enpp6* were associated with kidney atrophy in the mouse model of maladaptive kidney repair.

**Conclusions:** A multiomics approach of human kidney tissue interrogation discovered multiple novel protein markers to assess PT maladaptation and health with severe AKI.

**Funding:** NIDDK Support

Aptamer Odds Ratio (95% CI)	Model 1 (post-operative aptamer)	Model 2 (model 1 +age+ sex+ race+ comorbidities* + baseline eGFR)	Model 3 (model 2 + baseline ACR+ pre-operative aptamer)

Figure 1. Associations between post-operative plasma aptamers of PT maladaptation and PT health with KDIGO stage 2-3 AKI in 322 participants after cardiac surgery in the TRIBE-AKI consortium. Among 322 participants, 47 developed stage 2-3 AKI.

\*Comorbidities included hypertension, diabetes mellitus, congestive heart failure, and myocardial infarction. All aptamers were presented by gene names, the measurements were log2-transformed so that the odds ratio represents an increase in the odds of doubling aptamer levels. Abbreviation: ACR, urine albumin-creatinine ratio.

FR-PO117

Arginase 2 Is a Mediator of Cisplatin-Induced AKI Through Regulation of Macrophage Inflammatory Responses

Yushi Uchida,<sup>1,2</sup> Kumiko Torisu,<sup>2</sup> Seishi Aihara,<sup>2</sup> Hiroaki Ooboshi,<sup>1</sup> Toshiaki Nakano.<sup>2</sup> <sup>1</sup>*Department of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan;* <sup>2</sup>*Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

**Background:** Cisplatin is a classic and effective chemotherapeutic agent, but its application is limited by its nephrotoxicity. Cisplatin induces tubular damage followed by intensive infiltration of inflammatory cells such as macrophages. Arginine metabolism has emerged as a critical regulator of inflammatory responses in macrophages. Arginase 2 (ARG2) is an enzyme that degrades arginine, but its role in the inflammatory response of macrophages remains unclear. In this study, we investigated the inflammatory role of ARG2 in macrophages in cisplatin-induced acute kidney injury.

**Methods:** Male *Arg2*<sup>-/-</sup> and WT mice were treated with cisplatin (20 mg/kg) by intraperitoneal injection. After 3 days of treatment, mice were euthanized and the kidney and blood samples were collected for analysis. Bone marrow-derived macrophages (BMDMs) isolated from *Arg2*<sup>-/-</sup> and WT mice were stimulated with 100 ng/mL LPS for 24-hour to evaluate cytokine excretion (IL-6 and IL-1 $\beta$ ). Primary proximal tubular epithelial cells (PTECs) isolated from *Arg2*<sup>-/-</sup> and WT mice were cultured under 100  $\mu$ M cisplatin for 24-hour to evaluate tubular apoptosis induced by cisplatin.

**Results:** In vivo, ARG2 deficiency mitigated cisplatin-induced renal dysfunction (SCr: *Arg2*<sup>-/-</sup> 1.01 $\pm$ 0.11 mg/dL vs. WT 1.63 $\pm$ 0.20 mg/dL, p<0.05). Cisplatin-induced tubular injury was also significantly attenuated in *Arg2*<sup>-/-</sup> mice as compared to WT mice based on histological analysis. The protein levels of cleaved caspase-3 and the number of TUNEL-positive cells in the kidneys of cisplatin-treated *Arg2*<sup>-/-</sup> mice were lower than those in the kidneys of WT mice. In vitro, *Arg2*<sup>-/-</sup> BMDMs had decreased secretion of proinflammatory cytokines as compared to WT BMDMs (IL-6: *Arg2*<sup>-/-</sup> 1.96 $\pm$ 0.23 ng/mL vs. WT 4.02 $\pm$ 0.51 ng/dL; IL-1 $\beta$ : *Arg2*<sup>-/-</sup> 3.38 $\pm$ 0.44 ng/dL vs. WT 8.68 $\pm$ 1.41 ng/mL, p<0.05), while there was no significant difference in tubular apoptosis caused by cisplatin between *Arg2*<sup>-/-</sup> and WT primary PTECs.

**Conclusions:** The deficiency of ARG2 significantly alleviated cisplatin-induced acute kidney injury. Our results suggested that ARG2 is a key mediator of macrophage inflammatory response, but is not directly involved in tubular apoptosis by cisplatin. Inhibition of ARG2 may be beneficial for the treatment of cisplatin-induced acute kidney injury by attenuating the inflammatory response of macrophages.

## FR-PO118

**Mechanisms of Protection From Ischemic Injury With Renal Exosomes**

Katherine J. Kelly,<sup>1,2</sup> Jesus H. Dominguez,<sup>1</sup> <sup>1</sup>*Indiana University School of Medicine, Indianapolis, IN;* <sup>2</sup>*Richard L Roudebush VA Medical Center, Indianapolis, IN.*

**Background:** Ischemic renal injury results in tremendous acute and chronic morbidity and mortality and has no specific therapy. We have demonstrated marked improvement in postischemic kidney function and structure with exosomes (EV) from tubular cells given after renal failure was established. EV from skin epithelia or platelets were not effective, allowing the examination of the mechanisms of benefit with renal EV.

**Methods:** In a well established model of renal ischemia/reperfusion injury, EV or vehicle was given 24 hours after ischemia when renal failure was established. A model of anoxia/reoxygenation injury in primary renal tubular cells was used and apoptosis, inflammatory mediators, leukocyte adhesion and oxidative stress quantified in cells treated with vehicle or EV from different sources. Apoptotic cell death was quantified by TUNEL; leukocytes were fluorescently labeled to measure adhesion; expression of the inflammatory mediators C3, C5 and ICAM1 was evaluated by immunohistochemistry; generation of reactive oxygen species (ROS) was measured using dichlorodihydrofluorescein diacetate; and bax, superoxide dismutase and catalase expression analyzed by immunoblot.

**Results:** Renal EV, but not those derived from skin or platelets, significantly decreased anoxic renal cell death. A major effect of renal EV was anti-inflammatory (table). Leukocyte adhesion and expression of complement components C3 and C4 and intracellular adhesion molecule 1 were all significantly improved in the presence of renal EV as compared to either skin or platelet EV.

**Conclusions:** The benefits of renal exosomes in ischemic injury are multifaceted and include decreasing multiple pro-inflammatory mediators.

**Funding:** Other NIH Support - NIAID, Veterans Affairs Support

## FR-PO119

**Protein Lactylation Promotes AKI-CKD Transition by Activating NLRP3 Inflammasome**

Kehong Chen. *Army Medical Center of PLA, Chongqing, China.*

**Background:** Renal interstitial inflammation contributes to the progression of AKI-CKD transition. Recent studies have shown that protein lactylation caused by lactic acid accumulation can regulate chronic organ injury. So we investigated the role and mechanism of protein lactylation in AKI-CKD transition.

**Methods:** Severe renal ischemia-reperfusion(I/R) injury (severe AKI) was constructed by bilateral renal ischemia for 35min. The lactylation enhancer rotenone and the lactylation inhibitor sodium dichloroacetate (DCA) were used to verify the effect of protein lactylation. Lactylated proteomics was used to detect the changes of lactylated proteins in renal cortex at different time points, and the lactylated proteins related to renal function were screened for verification.

**Results:** The Scr of BUN levels did not return to normal value at 14 days after I/R injury. At day 28, renal interstitial fibrosis was observed with AKI-CKD transformation. The renal injury score was significantly increased at day 7 and renal interstitial fibrosis was enhanced at day 28 after treatment with protein lactylation enhancer. IL-1b and IL-18 were found to be the most significantly enhanced inflammatory cytokines in the blood of mice, and the NLRP3 inflammasome activation was significantly enhanced in renal tissues at 7 days. Meanwhile, lactylation inhibitor had a protective effect on AKI-CKD transition. Lactylated proteins in kidney were detected by Lactylated proteomics analysis at 0, 3 and 7 days after I/R, and the enrichment of differential lactylated proteins was analyzed. GO enrichment analysis was performed on lactylated differential proteins associated with renal function trends at 0-7 days. The results showed that the seven differential proteins with significant difference mainly existed in the tricarboxylic acid cycle. One of them is citrate synthase (CS), a key rate-limiting enzyme in the tricarboxylic acid cycle. Citrate synthase lactylation level increased significantly on day 3 after AKI, recovered slightly on day 7, but still failed to return to normal level on day 28.

**Conclusions:** Renal protein lactylation promotes activation of NLRP3 inflammasome, leading to AKI-CKD transition. Citrate synthase may be the key lactoacylated protein.

## FR-PO120

**Cholinergic Signaling Increases Macrophage-Macrophage Interactions and Protects Sepsis-Induced AKI**

Yasuna Nakamura,<sup>1</sup> Tsuyoshi Inoue,<sup>1</sup> Reiko Inagi,<sup>2</sup> Masaomi Nangaku.<sup>2</sup> <sup>1</sup>*Nagasaku Daigaku Igakubu Daigakuin Ishiyakugaku Sogo Kenkyuka, Nagasaki, Japan;* <sup>2</sup>*Tokyo Daigaku, Bunkyo-ku, Japan.*

**Background:** Nicotinic acetylcholine receptor agonists have been shown to activate the cholinergic anti-inflammatory pathway (CAP) and improve systemic inflammation and acute kidney injury. This inflammatory reflex is known as a nervous system-mediated

immune response. It is considered that the CAP activation is thought to be through  $\alpha 7$  nicotinic acetylcholine receptor ( $\alpha 7$ nAChR) expressed on macrophages, but no one has been demonstrated *it in vivo*.

**Methods:** To confirm the importance of  $\alpha 7$ nAChR in macrophages *in vivo*, macrophage-specific  $\alpha 7$ nAChR knockout (KO) mice (LysM-Cre; *Chrna7*<sup>fllox</sup> mice) were generated and tested whether GTS-21 ( $\alpha 7$ nAChR specific agonists) ameliorates lipopolysaccharide (LPS)-induced kidney injury. We also performed single-cell RNA sequencing (sc-RNA seq) of the spleen to identify the cells or genes that receive cholinergic signals in the spleen under LPS administration comprehensively.

**Results:** Administration of GTS-21 resulted in a decrease in systemic TNF- $\alpha$  production and kidney *Ngal* elevations by LPS in littermate wild-type (WT) mice, whereas the decreases were not observed in KO mice. This result suggested that the cholinergic signaling is mediated by  $\alpha 7$ nAChR on macrophages *in vivo*. In addition, sc-RNA seq identified that GTS-21 administration induces cell-cell interactions between macrophage-macrophages. *In vitro* transwell experiments using the macrophage cell line RAW 264 showed that GTS-21 increases macrophage-to-macrophage contacts. Furthermore, co-culture of macrophages suppressed TNF- $\alpha$  production induced by LPS as well as GTS-21 treatments. The anti-inflammatory and renal protective effects were canceled by splenectomy, suggesting that macrophage-macrophage cell interactions in the spleen are essential even *in vivo*.

**Conclusions:** Activation of cholinergic signaling via  $\alpha 7$ nAChR on macrophages increases macrophage-macrophage interactions in the spleen, resulting in anti-inflammatory and renoprotective effects in LPS-induced acute kidney injury.

**Renalase Protects Renal Injury by Maintaining Mitochondrial Dynamic Homeostasis**

Xiaoqia Guo,<sup>1</sup> Rongmin Chen,<sup>1</sup> Tian-Min Chen,<sup>1</sup> Gilbert W. Moeckel,<sup>1</sup> Robert L. Safirstein,<sup>1,2</sup> Elizabeth A. Jonas,<sup>1</sup> Gary V. Desir.<sup>1,2</sup> <sup>1</sup>*Yale School of Medicine, New Haven, CT;* <sup>2</sup>*Connecticut VAMC, West Haven, CT.*

**Background:** Renalase (RNLS) is a protein that participates in the salvage pathway for intracellular NADH. When secreted, it signals through the calcium ATPase ATP2b4 and activates kinases linked to survival. RNLS attenuates acute ischemic and cisplatin (CP)-induced kidney injury. We aim to elucidate the function of RNLS in renal mitochondrial homeostasis.

**Methods:** RNLS knockout (KO) and wild type (WT) mice were given CP at 15 mg/kg or vehicle control for 4 days and kidneys were collected and analyzed for structure with electron microscopy (EM), mitochondrial proteins with immunoblotting, and mitochondrial respiration assayed ex-vivo.

**Results:** CP induced severe renal damage in RNLS deficient animals as evidenced by plasma creatinine: KO  $1.178 \pm 0.285$  mg/dL, n=13 vs WT  $0.151 \pm 0.026$  mg/dL, n=14, p<0.005). EM analysis revealed that RNLS KO kidneys had 30% more mitochondria compared to control WT, while in CP treated animals, there was no difference in number of mitochondria between the strains. CP treatment induced 4-fold increase in autophagosomes in RNLS KO mice and only 2-fold increase in WT animals. Parkin protein, which plays a key role in mitophagy and mitochondrial motility and size, was not detected in WT control kidneys but was expressed in RNLS KO mouse kidneys. CP induced Parkin in WT and dramatically enhanced Parkin level in KO. AMPK $\alpha$  and AMPK $\beta$  were highly activated, and OPA-1 was reduced in RNLS KO AKI as compared to WT AKI kidneys. RNLS KO mouse kidneys exhibited reduced mitochondrial complex I and II activities as compared to WT (p<0.005 and p<0.05, respectively, n=5). Recombinant RNLS rescued the impaired mitochondrial activities of complexes I and II in RNLS KO kidneys (n=3, p<0.001).

**Conclusions:** Knockout of RNLS alters mitochondrial dynamics, and CP augmented mitophagy and autophagy during AKI as compared to WT-AKI. Recombinant RNLS attenuates mitochondrial dysfunction *in vitro*. These data suggest that renalase may be an effective therapeutic agent for mitochondrial relevant disorders, such as cisplatin-induced kidney injury and neurodegeneration.

## FR-PO122

**Apobec-1 Limits Cisplatin and Ischemia-Reperfusion-Induced AKI**

Xiaoqia Guo,<sup>1</sup> Leyuan Xu,<sup>1</sup> Heino Velazquez,<sup>1,3</sup> Tian-Min Chen,<sup>1</sup> Valerie Blanc,<sup>2</sup> Nicholas Davidson,<sup>2</sup> Gilbert W. Moeckel,<sup>1</sup> Robert L. Safirstein,<sup>1,3</sup> Gary V. Desir.<sup>1,3</sup> <sup>1</sup>*Yale School of Medicine, New Haven, CT;* <sup>2</sup>*Washington University in St Louis, St Louis, MO;* <sup>3</sup>*Connecticut VA Medical Center, West Haven, CT.*

**Background:** Cisplatin (CP) and Ischemia/reperfusion (I/R) Injury induces AKI whereby proximal tubules undergo regulated necrosis. Repair is almost complete after a single dose of CP. We now examine the role Apolipoprotein B MRNA Editing Enzyme Catalytic Subunit 1 (Apobec1) plays in the recovery from AKI.

**Methods:** Mice were given CP 15 mg/kg or subjected to 20 min IRI with contralateral nephrectomy and renal function, histology, mRNA, protein, lipids and single cell RNA sequencing were analyzed. Bone marrow-derived macrophages (BMDM) were isolated from WT and Apobec1 KO mice and treated with LPS and IL-4 that polarize BMDM to M1 and M2, respectively, followed by cytokine profiling.

**Results:** Apobec-1 KO caused more severe AKI, plasma creatinine (pCr) 2.07 mg/dL  $\pm 0.59$  (n=13) vs 0.23 mg/dL  $\pm 0.09$  (n=8) 3d, p < 0.01 and greater mortality than in WT. The kidneys of Apobec1 KO showed increased necrosis, neutrophil invasion,

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

KIM-1, NGAL, RIPK3, MLKL, TLR2, TLR4, and ASCL4 levels compared to WT kidneys ( $p < 0.01$ ). I/R injury was greater in Apobec1 KO as well ( $pCr\ 1.34 \pm 0.22$ ,  $n=6$  vs  $0.75 \pm 0.06$ ,  $n=5$ ,  $p < 0.05$  than WT). Apobec1 expression was restricted to invading macrophages in WT animals and single cell RNA sequencing revealed markedly increased inflammatory cytokine expression in these invading macrophages in the Apobec1 KO animals. BMDM from Apobec1 KO mice exhibited a maturation defect as they failed to polarize to M1 phenotype in response to LPS. The increase in macrophages seen in WT AKI kidneys was not observed in Apobec1 KO AKI kidney, suggesting a macrophage homing defect. The Apobec1 KO animals showed enrichment of cytokine-cytokine receptor, NF-kappa B, chemokine, and TNF signaling pathways.

**Conclusions:** We have identified Apobec1 as a crucial gene regulating the necrotic response to IR- and CP-induced nephrotoxicity. The absence of Apobec1 in macrophages prevented the transition of a cell death promoting phenotype to one supporting repair and regeneration. Apobec1 is a critical pro-survival response to renal injury and increasing Apobec-1 activity could be an effective strategy to reduce or prevent AKI.

### TGFβR1 Activation in Tubular Epithelial Cell Recruits Leukocytes That Deliver Lethal Hit in a Model of AKI

Emelie Lassen, Liping Yu, Ilse S. Daehn. *Icahn School of Medicine at Mount Sinai, New York, NY.*

**Background:** Activation of the TGFβ signaling pathway plays an important role in both acute kidney injury (AKI) and chronic kidney disease pathogenesis. We have previously shown that ligand-independent activation of TGFβR1 in proximal tubules (doxycycline inducible transgenic Pax8Tgfbf1) results in rapid epithelial cell injury and death, as well as immune cell infiltration. This study aims to determine the drivers and mechanism of epithelial cell injury in this novel model of TGFβR1 mediated AKI.

**Methods:** To determine the mechanisms involved in AKI observed in transgenic Pax8Tgfbf1 mice, we isolated and immortalized proximal tubular epithelial cells (mPTECs) from Pax8Tgfbf1 mice with hTERT and treated with doxycycline. Characterization was done by IF for proximal tubule markers (AQP1, APN) and by RT-PCR. Splenocytes were isolated by sieving spleens from single transgenic mice of the same background (FVB). Cell viability was assessed by MTT, cell death by Annexin V/PI (FACS) and by cleaved caspase 3 (IF). Chemokines and cytokines released by mPTECs were determined by Luminex.

**Results:** We confirmed activation of TGFβR1 and the canonical TGFβ pathway in doxycycline treated mPTECs. To our surprise, TGFβR1 activation in these cells caused mild cell damage that did not reflect the dramatic phenotype observed in the mouse. This suggested to us that additional mechanisms could be at play in driving the severe tubular injury phenotype. We examined the secretome of mPTECs +/- doxycycline to determine whether these cells could induce infiltration of proinflammatory cells that could potentiate injury. TGFβR1 activation induced the release of GM-CSF, LIF and MCP-1, suggesting recruitment and activation of infiltrate. Interestingly, an observed increase in VEGF by activated mPTECs could be involved in promoting vascular permeability. We next performed co-cultures with mixed allogenic leukocytes, and after 24hrs cell commitment to death was initiated by cleaved caspase 3, resulting in significant cell death of the mPTECs.

**Conclusions:** TGFβR1 in mPTECs promotes the recruitment of leukocytes by the secretion of key chemokines and facilitating vascular permeability. Activated leukocytes subsequently contribute to an injurious interplay triggering cell death pathways in mPTECs.

## FR-PO124

### Transcript Isoform Switching in Sepsis-Induced AKI

Amy Zollman,<sup>1</sup> Arvin Halim,<sup>1</sup> Jered Myslinski,<sup>1</sup> Pierre C. Dagher,<sup>1</sup> Takashi Hato,<sup>1,2</sup> <sup>1</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>2</sup>Richard L Roudebush VA Medical Center, Indianapolis, IN.

**Background:** In a subset of patients with sepsis-induced AKI, recovery of kidney function is observed. Understanding how such recovery unfolds will aid the development of targeted therapy. We have previously identified that translation shutdown is a hallmark of late phase sepsis. In a reversible model of endotoxemia, this late phase of sepsis is also a crucial transition period where tissue recovery begins. Notably, a set of genes are found to be highly resistant to translation shutdown. These resistant genes are enriched in pathways involved in RNA splicing. Thus, to examine the role of RNA splicing in tissue recovery, we performed long-read sequencing and analyzed temporal changes in RNA isoforms.

**Methods:** Reversible AKI was induced in mice by 5 mg/kg LPS iv. Kidneys were harvested at various time points. Full-length transcripts were prepared following the Nanopore protocol (SQK-DCS109) and sequenced on GridION.

**Results:** During the early course of endotoxemia, no significant changes were observed in the composition of RNA isoforms. In contrast, during late phases of endotoxemia (16–30 hrs), hundreds of genes exhibited distinct isoform switches. The emergence of isoform switches occurred during translation shutdown and the resultant alternative isoforms persisted throughout the recovery phase. Exon skipping and alternative exon ending were the 2 dominant modes of alternative splicing. Moreover, we found a number of very short isoforms consisting of a canonical first exon and a cryptic polyadenylated exon that originated from a first intron. Importantly, these short isoforms outnumbered their corresponding conventional protein coding isoforms. Because these

short isoforms lack sufficient lengths of open reading frame (<100 nt), they are predicted to fail in generating proteins. Thus, we surmise that the preponderance of short isoforms could serve as a novel endogenous gene downregulation mechanism. Indeed, we found that crucial stress-response genes including p53 exhibited this short isoform switch, thus effectively leading to downregulation of functional p53. Such isoform switch could permit cells to exit cell cycle arrest and promote tissue recovery in sepsis.

**Conclusions:** Transcript isoform switching is pervasive during the recovery phase of septic AKI. The genesis of the very short isoforms may have functional importance in controlling the expression of stress-response genes.

## FR-PO125

### Proteomics Reveals Defective Fatty Acid Oxidation During the Progression of AKI and Repair

Jia Chen. *Army Medical Center of PLA, Chongqing, China.*

**Background:** Acute kidney injury (AKI) is characterized by a rapid decrease in renal function with high mortality and risk of progression to chronic kidney disease (CKD). Ischemia and reperfusion injury (IRI) is a major cause of AKI. However, the cellular and molecular responses of the kidney to IRI are complex and not fully understood.

**Methods:** Herein, we conducted unbiased proteomics and bioinformatics analyses in a severe bilateral IRI mouse model on days 3, 7, and 21, and validated the results using IRI, unilateral ureteral obstruction (UUO), and biopsies from patients with AKI or CKD.

**Results:** The results indicated an obvious temporal expression profile of differentially expressed proteins and highlighted impaired lipid metabolism during the progression of AKI to CKD. Acyl-coenzyme A oxidase 1 (Acox1), the first rate-limiting enzyme of fatty acid beta-oxidation, was then selected, and its disturbed expression in the two murine models validated the proteomic findings. Accordingly, Acox1 expression was significantly downregulated in renal biopsies from patients with AKI or CKD, and its expression was negatively correlated with kidney injury score. Furthermore, in contrast to the decreased Acox1 expression, lipid droplet accumulation was remarkably increased in these renal tissues, suggesting dysregulation of fatty acid oxidation.

**Conclusions:** In conclusion, our results suggest that defective fatty acid oxidation might be a common pathological feature in the transition from AKI to CKD, and that Acox1 is a promising intervention target for kidney injury and repair.

## FR-PO126

### Regnase-3 in Kidney-Resident MØ Controls Severity of AKI and AKI-CKD Transition by Degrading Pre-mRNAs That Drive Their Polarization Towards a Pro-Inflammatory M1 Phenotype

Chenyu Li, Julian A. Marschner, Stefanie Steiger, Zhibo Zhao, Hans J. Anders. *Klinikum der Universität München Medizinische Klinik und Poliklinik IV - Standort Ziemssenstrasse, München, Germany.*

**Background:** Kidney resident macrophages (Mø) are involved in regulating AKI-CKD transition (PNAS 2021). The mRNA regulatory enzyme Regnase-3 is specifically expressed in Mø and involved in the interferon-γ signaling pathway (J Exp Med. 2019). Here we speculated that Regnase-3 would represent a kidney resident Mø-specific immune checkpoint that limits necroinflammation in AKI and AKI-CKD transition.

**Methods:** We generated transgenic mice with a conditional resident-Mø-specific Regnase-3 KO (Rank<sup>Cre/WT</sup>; Regnase3<sup>lox/lox</sup>; [Reg3cKO]) that bred at Mendelian ratios. 6-8 week-old mice were subjected to a unilateral ischemia-reperfusion injury (IRI) with or without nephrectomy (uNX). We measured GFR before and 1, 3, 7, 14, and 21 days after uIRI. In vitro, we stimulated Reg3cKO bone-marrow-derived Mø with H<sub>2</sub>O<sub>2</sub> and assessed cell metabolism, migration, and phagocytosis.

**Results:** After uIRI, the GFR significantly dropped in both WT and Reg3cKO mice at day 1. However, in Reg3cKO mice kidney function failed to fully recover compared with WT mice as indicated by the GFR at day 21 after uIRI. Serum creatinine as well as intrarenal Kim-1, Ngai, Timp2, and Tnfα mRNA levels were also higher in Reg3cKO mice together with more IFTA and interstitial F4/80+ cell infiltrates. Because uIRI is a model of persistent post-AKI ischemia, we turned to uIRI+uNX, an AKI model that restores reperfusion. Similarly, Reg3cKO mice showed delayed GFR recovery with only ~30% of baseline GFR at day 3 but ~50% for WT mice. In both Reg3cKO and WT mice the GFR fully recovered at day 14 after uIRI+uNX. However, the levels of Kim-1 and Ngai remained still higher in Reg3cKO mice with more IFTA and F4/80+ cell infiltrates. In vitro, after H<sub>2</sub>O<sub>2</sub> incubation, M0 and M1 but not M2 Reg3cKO Mø showed higher metabolic, migratory, and phagocytic capacity, as well as higher expression levels of CCR2/5, IL6, and TNFα T than WT, indicative of M1 Mø.

**Conclusions:** Regnase-3 might act as a negative regulator of resident Mø polarization towards an M1 phenotype, which contributes to the early injury phase of AKI and AKI-CKD transition. Mechanistically, Regnase-3 is likely to degrade certain pre-mRNAs to limit the expression of pro-inflammatory cytokines/chemokines and chemokine receptors during kidney necroinflammation.

## FR-PO127

**Autophagy Activates EGR1 via ERK to Induce FGF2 in Renal Tubular Cells for Fibroblast Activation and Fibrosis During Maladaptive Kidney Repair**

Man J. Livingston<sup>1,2</sup> Zheng Dong<sup>1,2</sup> <sup>1</sup>Augusta University Medical College of Georgia, Augusta, GA; <sup>2</sup>Charlie Norwood Department of Veterans Affairs Medical Center, Augusta, GA.

**Background:** Autophagy contributes to the regulation of maladaptive kidney repair including the development of tubulo-interstitial fibrosis. Our recent work reveals an autophagy-dependent tubular production and secretion of FGF2 into the interstitium where it acts as a key paracrine factor to activate fibroblasts for renal fibrosis. The mechanism by which autophagy induces FGF2 in renal tubular cells to promote maladaptive repair after AKI remains unclear.

**Methods:** Using various genetic and pharmacological approaches, this study examined the transcription factor early growth response protein 1 (EGR1) in post-ischemic mouse kidney tissues and in TGF- $\beta$ 1-treated proximal tubular cells.

**Results:** Following ischemic AKI, EGR1 was induced in the nuclei of chronically injured proximal tubules that were KIM-1-positive. Compared with wild-type mice, autophagy deficiency in iRT-*Atg7* KO (inducible, renal tubule-specific *Atg7* knockout) mice suppressed EGR1 expression in kidneys, indicating the induction of EGR1 was mediated by tubular cell autophagy. Consistently, TGF- $\beta$ 1 treatment induced EGR1 in cultured proximal tubular cells, which was also attenuated in *Atg7* KO tubular cells and by autophagy inhibitors. In TGF- $\beta$ 1-treated cells, EGR1 knockdown inhibited FGF2 mRNA and protein expressions. ChIP assay further detected an increased binding of EGR1 to *Fgf2* gene promoter region for transcriptional activation during TGF- $\beta$ 1 treatment. Interestingly, both FGF2 and EGR1 induction at mRNA levels were inhibited by FGF2 neutralizing antibody, suggesting a positive feedback between FGF2 and EGR1 that may contribute to EGR1-mediated FGF2 autoregulation. This feedback mechanism was further confirmed in *Fgf2* KO primary tubular cells and *Fgf2* KO mice. Upstream of EGR1, MAPKs (ERK, P38 and JNK) were activated in both post-ischemic kidneys and TGF- $\beta$ 1-treated tubular cells, whereas only ERK activation was attenuated by autophagy inhibition. Moreover, inhibition of ERK suppressed EGR1 induction in TGF- $\beta$ 1-treated tubular cells.

**Conclusions:** Together, these results suggest that autophagy activates ERK in tubular cells, which induces EGR1 for FGF2 transcription and autoregulation. FGF2 is then secreted into the interstitium for the activation of fibroblasts for fibrogenesis.

## FR-PO128

**PKM2 Exacerbates Cisplatin-Induced AKI Through Regulation of STAT3**

Lu Wen<sup>1,2</sup> Zheng Dong<sup>2,1</sup> <sup>1</sup>The Second Xiangya Hospital of Central South University, Changsha, China; <sup>2</sup>Augusta University, Augusta, GA.

**Background:** Pyruvate kinase M2 (PKM2) is an important rate-limiting enzyme catalyzing the last step of glycolysis. However, in addition to its vital role in energy metabolism in cytoplasm, PKM2 can translocate into the nucleus and interacts with signal transducer and activator of transcription 3 (STAT3) to regulate cell differentiation and inflammation. The role of nuclear PKM2 in renal pathophysiology is unknown.

**Methods:** To investigate the role of PKM2 in cisplatin-induced AKI, we generated kidney proximal tubule-specific PKM2 knock-out mice (PT-PKM2-KO) by crossing PKM2-floxed mice with PEPCK-CRE mice. PT-PKM2-KO or wild type mice of 8-10 weeks were intraperitoneally injected with 25 mg/kg of cisplatin to induce acute kidney injury (AKI). In vitro, we transfected PKM2-overexpressing plasmids into rat renal proximal tubular cells (RPTCs), followed by treatment with 20 $\mu$ M cisplatin for 24h. To determine the involvement of STAT3, we tested Stattic (inhibitor of STAT3) in PKM2 knock-out and wild type mice.

**Results:** Deficiency of proximal tubule PKM2 mitigated cisplatin-induced AKI in mice, suggesting an injurious role of PKM2. Consistently, overexpression of PKM2 aggravated cisplatin-induced apoptosis in RPTCs. Moreover, both STAT3 and phosphorylated STAT3 were increased in mice renal cortex cisplatin-induced AKI in mice. Notably, Stattic ameliorated cisplatin-induced AKI in wild type mice. but not in PKM2 knock-out mice.

**Conclusions:** These results indicate that PKM2/STAT3 signaling contributes to renal tubular injury in cisplatin-induced AKI, suggesting the PKM2/STAT3 pathway as a new therapeutic target in cisplatin nephrotoxicity.

**Funding:** NIDDK Support, Veterans Affairs Support

## FR-PO129

**Stanniocalcin-1 Ameliorates Ischemia-Reperfusion Kidney Injury via Selective Activation of AMPK- $\alpha$ 2**

Jenny S. Pan<sup>1,2</sup> Qingtian Li<sup>1</sup> David (Daud) Sheikh-Hamad<sup>1,2</sup> <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>Michael E DeBakey VA Medical Center, Houston, TX.

**Background:** Acute kidney injury (AKI) is common and is associated with increased morbidity, mortality, and development/progression of chronic kidney disease. Currently, therapeutic options remain limited. AMPK activation has been found to protect from AKI. However, there are concerns about off target effects as AMPK is ubiquitously expressed and exert a multitude of regulatory effects. We previously showed that STC1 protects

from ischemia-reperfusion (I/R) kidney injury through an AMPK-dependent pathway. In STC1 Tg kidneys, we observe preferential activation (phosphorylation) of the AMPK  $\alpha$ 2 isoform relative to the  $\alpha$ 1 isoform compared to WT kidneys. We hypothesize that kidney protection by STC1 is mediated through selective activation of the AMPK $\alpha$ 2 isoform.

**Methods:** In the current experiments, we sought to determine kidney phenotype after I/R kidney injury in mice with transgenic overexpression of STC1 and inducible, kidney tubular epithelium-specific knockdown of AMPK  $\alpha$ 1 (STC1 Tg; AMPK $\alpha$ 1f/f; Pax8rtTA; LC1-Cre; referred to as AMPK $\alpha$ 1KO) or AMPK  $\alpha$ 2 (STC1 Tg; AMPK $\alpha$ 2f/f; Pax8rtTA; LC1-Cre; referred to as AMPK $\alpha$ 2KO); all on C57B/6 background. 10-12 week old mice were subjected to bilateral kidney I/R (clamping of renal pedicles for 30 min with non-traumatic vascular clamps). Mice were euthanized after 72 hours; blood and timed urine were collected for calculation of creatinine clearance, and kidneys were harvested for analyses.

**Results:** Using antibodies that recognize both  $\alpha$ 1 and  $\alpha$ 2 isoforms of the catalytic subunits of AMPK, we observed preferential phosphorylation of the  $\alpha$ 2 isoform in STC1 Tg kidneys compared with WT kidneys. Kidney tubule-specific knockdown of AMPK  $\alpha$ 2 in STC1 transgenic mice (AMPK $\alpha$ 2KO) restored the susceptibility to I/R kidney injury (demonstrated by decreased creatinine clearance and urine output, and increased histologic injury and mitochondrial ROS). In contrast, kidney tubule-specific knockdown of AMPK  $\alpha$ 1 in STC1 transgenic mice (AMPK $\alpha$ 1KO) had no significant effect on STC1-mediated kidney protection (preserved creatinine clearance, kidney morphology and urine output; less ROS production).

**Conclusions:** The data suggest that STC1 ameliorates ischemia-reperfusion kidney injury via an AMPK- $\alpha$ 2-dependent pathway. Selective activation of the AMPK  $\alpha$ 2 isoform by STC1 may protect from AKI while minimizing off target effects of AMPK activation.

## FR-PO130

**Renal Injury Response in an Adult Pkd2 Mouse Model**

Sreelakshmi Cherakara, Zhang Li, Courtney J. Haycraft, Mandy J. Croyle, Bradley K. Yoder. *The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.*

**Background:** Autosomal Dominant Polycystic Kidney Disease (ADPKD) is caused by dysfunction of the primary cilium on the renal tubule epithelium due to either loss of proteins localized on the cilium or loss of cilia structure. Mutations in *Pkd1* or *Pkd2*, which encode PC1 and PC2, respectively, result in progressive cyst formation in mouse models of ADPKD. Previous studies have shown that renal injury accelerates cyst formation in these models suggesting the cilium/PKD1/PKD2 is involved in regulating injury and repair responses. Here we evaluate the role of *Pkd2* in regulating renal injury and repair processes and how dysregulation of this process may contribute to renal cyst formation.

**Methods:** The renal injury will be induced by a single IP injection of cisplatin (9.0 mg/kg body weight), a chemotherapeutic drug with nephrotoxic side effects in adult induced CAGG-CreERT2; *Pkd2* mutant mice. We analyzed the percentage of SOX9 (an indicator of injury) expressing cells at 3-, 7-, 14-, 21-, 28-, and 35-days post cisplatin injury using immunofluorescence (IF) and FACS.

**Results:** The number of cells expressing SOX9 peaked 7 days after cisplatin injection in both *Pkd2* mutants and wildtype controls then decreased through 28 days post injury. In wild type controls, a small number of SOX9+ cells remained at 28- and 35-days post injury. However, in *Pkd2* mutants, the number of cells expressing SOX9 at 28- and 35- days were more in injured epithelial cells than in the controls. In *Pkd2* mutant kidneys, many of the epithelial cells lining the forming cysts continue to express SOX9, and this number increases during cyst expansion.

**Conclusions:** These data show that following renal injury, *Pkd2* mutant and control kidneys have a similar increase in SOX9 expression in response to cisplatin-induced injury. However, in *Pkd2* mutant mice, the number of SOX9+ cells at 28-days post-cisplatin is higher when compared to controls and begins to increase through day 35. This suggests that the *Pkd2* mutant epithelium cannot complete the repair process after injury and *Pkd2* might be required for the completion of the repair process.

**Funding:** NIDDK Support

## FR-PO131

**The Human MicroRNA-mRNA Transcriptome in AKI**

Thomas De Luca, Ricardo Melo ferreira, Michael T. Eadon, Danielle Janosevic. *Indiana University School of Medicine, Indianapolis, IN.*

**Background:** MicroRNAs (miR) regulate gene expression by base-pairing to messenger RNA (RNA) and primarily repressing protein synthesis. Here, we describe miRNA and mRNA transcriptomic profiles in acute kidney injury (AKI). Further, we hypothesized that biobanked renal tissue biopsies (IB) with the pathologic diagnosis (path) of minimal change (MCD) or thin basement membrane (TBM) disease should demonstrate similar transcriptomic profiles to reference nephrectomies (Nx) and in comparisons with AKI.

**Methods:** AKI, IB, and nephrectomy (Nx) transcriptomic data (miR, RNA) were derived from stored human kidney tissues obtained in the routine clinical care of patients. AKI specimens carried path of acute interstitial or tubular necrosis (n= 39). IB specimens had path of MCD (n= 11) or TBM (n=1), IFTA <5%, no AKI. RNA was extracted from tissue (Qiagen miRNeasy), libraries prepared (RNA: Takara Total RNA-Seq, miR: Qiaseq) and sequenced. Differentially expressed genes (DEGs) and miRNAs (DEMs) were identified with DESeq2 using comparisons between: AKI/IB, AKI/Nx, IB/Nx. KEGG enrichment analysis was performed for DEGs and DEMs with FDR <0.05 using pathfindR for R, Mienturnet, and miRPathDbv2.0. MiRNA-mRNA interactions were identified using miRTarBase and miRDB.

**Results:** In AKI, increased miR-150-5p was associated with downregulation of IL1A, CTSS (related to MAPK signaling, metabolism). Similarly, increased miR-155-5p was associated with decreased HIF1a, known to exacerbate AKI. Next, we determined if IB can be used as a surrogate reference, and if each is distinct from AKI. In comparing the miRNA and mRNA transcriptomes of all samples, principal component analysis revealed 3 distinct clusters corresponding to IB, Nx and AKI. Comparing IB to Nx, enriched pathways included cell cycle, cancer pathways, and reactive oxygen species. AKI/Nx and AKI/IB comparisons enriched similarly in PI3K-Akt and related structural pathways (e.g. extracellular matrix, actin cytoskeleton, focal adhesion).

**Conclusions:** The miR and RNA targetome of AKI were similar when compared to both reference sets (IB and Nx). Our data suggest that miR regulate RNA in several important AKI-related pathways. Additionally, we propose the use of IB as tissue reference data for AKI.

**Funding:** Other NIH Support - This publication was made possible with support from Grant Number, UL1TR002529 (S. Moe and S. Wiehe, co-PIs) from the National Institutes of Health, National Center for Advancing Translational Sciences, Clinical and Translational Sciences Award., Private Foundation Support

## FR-PO132

**Effects of Delayed Treatment With Poly (ADP-Ribose) Polymerase Inhibitor After Ischemia-Reperfusion on Healing Phase of Renal Injury**  
Junseok Jeon,<sup>1</sup> Hojin Jeon,<sup>1</sup> Sung Bin Yoon,<sup>1</sup> Kyungho Lee,<sup>2</sup> Hye Ryoung Jang,<sup>1</sup> Jung eun Lee,<sup>1</sup> Yoon-Goo Kim,<sup>1</sup> Woosong Huh,<sup>1</sup> <sup>1</sup>*Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea;* <sup>2</sup>*Johns Hopkins University School of Medicine, Baltimore, MD.*

**Background:** Excessive activation of poly (ADP-Ribose) polymerase (PAPR) after DNA damage aggravates tissue injury, including postischemic kidney, through NAD<sup>+</sup> depletion. The beneficial effects of PARP inhibition on the early injury phase of renal ischemia-reperfusion injury (IRI) was demonstrated in several studies. However, the role of PARP inhibitions on the healing phase after renal IRI has not yet been determined. The effects of JPI-289, a novel PARP inhibitor, on the healing phase of ischemic AKI were investigated in murine renal IRI and hypoxic HK-2 cell models.

**Methods:** Male 9-week-old C57BL/6 mice were used for renal IRI surgery. Saline (control) or JPI-289 was injected into the peritoneum. JPI-289 100 mg/kg was administered twice at 24 and 48 hours after unilateral IRI (UIRI), and 50 or 100 mg/kg was administered once at 24 hours after UIRI or bilateral IRI (BIRI). HK-2 cells were treated with the JPI-289 after hypoxic insult.

**Results:** Renal function initially worsened and then recovered in the JPI-289 treated group compared to the control group after BIRI, but was comparable between groups after UIRI. Renal tubular necrosis and damage, inflammatory cell infiltration, and intrarenal expression of proinflammatory cytokines/chemokines were more prominent in the JPI-289 100 mg/kg twice treated group at 12 weeks after UIRI compared to the control group, although those were comparable between groups at 6 weeks after BIRI or UIRI. The extent of fibrosis was similar between the groups. JPI-289 treatment of 0.5 and 0.75 mg/mL at 3 or 6 hours after hypoxia facilitated the proliferation of hypoxic HK-2 cells, whereas further treatment after 24 hours suppressed proliferation even with lower dosages.

**Conclusions:** Our results suggest that late treatment of PARP inhibitors after renal IRI did not have a beneficial effect on the recovery of ischemic AKI, but rather could have a negative effect on healing.

**Single Cell Chromatin Accessibility Atlas During Murine Kidney Injury and Repair**

Yoshiharu Muto, Eryn E. Dixon, Haojia Wu, Nicolas Ledru, Parker C. Wilson, Yuhei Kiritani, Benjamin D. Humphreys. *Washington University in St Louis School of Medicine, St Louis, MO.*

**Background:** Recent single cell and single nucleus RNA-seq (snRNA-seq) studies revealed cell-specific molecular alterations in acute ischemic injury (AKI). We previously identified a failed-repair proximal tubular cell (FR-PTC) state with a persistent inflammatory signature after ischemic renal injury (IRI). However, the underlying epigenetic mechanisms driving the failed repair cell state is undefined.

**Methods:** We performed single nucleus ATAC-seq (snATAC-seq) on mouse kidneys after IRI: 4 hours, 12 hours, 2 days, 14 days, 6 weeks and sham (n = 3 for each) using the 10x Genomics platform. We integrated snATAC-seq data with the snRNA-seq data obtained from the same IRI mouse kidney samples, and a comprehensive bioinformatic analysis was performed on the dataset.

**Results:** We obtained 136,469 single-nucleus chromatin accessibility libraries with 193,731 peaks. We performed label transfer from snRNA-seq data to snATAC-seq using Seurat, and all major cell types (11 clusters) were identified. The proximal tubular cell (PT) cluster was further subclustered into 8 subtypes including FR-PTC, which showed specific promoter accessibilities on inflammatory molecules including Tnf, Ccl2 and Vcam1. Transcription factor motif enrichment analysis on accessible regions identified acute activation (4 hours after IRI) of NRF2 and AP1 in injured PT cells, although the most severely injured cells failed to activate NRF2, suggesting a potential therapeutic target. NF-κB transcription factors were activated specifically in FR-PTC to induce chronic inflammatory signatures. The most specifically accessible regions with NF-κB binding motifs in FR-PTC include potential distal enhancers for Ltbp2 and Edn1 that were up-regulated in FR-PTC. We constructed FR-PTC-specific cis-regulatory accessibility network to predict the cis interactions that shape these FR-PTC-specific gene expression signatures.

**Conclusions:** The first comprehensive snATAC-seq atlas of mouse IRI kidneys catalogued phase-specific and cell-specific activation of regulatory genomic regions and transcription factors that shape cell-specific responses to ischemic injury. Epigenetic mechanisms driving FR-PTC revealed in this study implicate potential novel therapeutic targets in AKI and its transition to chronic kidney disease.

## FR-PO134

**Mitochondrial-Driven Inflammation in Aged Kidneys Is Exacerbated by Nicotinamide Mononucleotide but Ameliorated by Elamipretide**

Tara A. Saleh,<sup>1</sup> Jeremy A. Whitson,<sup>2</sup> Peter S. Rabinovitch,<sup>1</sup> Mariya T. Sweetwyne,<sup>1</sup> <sup>1</sup>*University of Washington, Seattle, WA;* <sup>2</sup>*High Point University, High Point, NC.*

**Background:** Mitochondrial dysfunction is characterized by loss of structural integrity, decreased efficiency of the electron transport chain and is linked to cellular senescence and inflammation. With age, kidneys show progressive mitochondrial dysfunction, suggesting a therapeutic target to reduce aging kidney decline. Previously, systematic treatment of old mice with tetrapeptide, Elamipretide (ELAM), which interacts with the inner mitochondrial membrane to improve cristae structure and function, reduced mito-dysfunction and senescence in kidney and heart. We hypothesized that added intervention with Nicotinamide Mononucleotide (NMN), an NAD<sup>+</sup> precursor, which contributes to the efficiency of ATP generation, would enhance the mito-energetic capability, thus decreasing mito-dysfunction and senescence in aged kidneys.

**Methods:** Old male mice were treated for 8 weeks at 24 months-old (mo) with: ELAM (osmotic pump, 3mg/kg), NMN (drinking water, 300 mg/kg), or ELAM+NMN combined. Untreated control mice were 4 mo (young) and 26 mo (old). Treated kidneys were harvested at 26 mo and preserved as frozen and formalin fixed tissues. Liver was analyzed to clarify intervention responses as global vs. kidney-specific mechanisms.

**Results:** Contrary to our hypothesis, NMN was detrimental in aged kidney by increasing mRNA expression of inflammatory cytokine, IL1b, relative to aged control kidneys (23-fold vs. 9-fold normalized to young, p=0.0002). RNA in situ hybridization showed IL1b expression localized to the old NMN-treated proximal tubules. In NMN treated kidneys IL-1β downstream targets CCL2, an inflammatory chemokine, and proximal tubule injury marker, KIM-1, were significantly upregulated. This was reduced in mice treated with combined ELAM+NMN. Finally, kidney F4/80+ macrophages by immunohistochemistry were higher in NMN treated mice, relative to old control or combined treatment groups. IL1b-driven inflammation was not observed in livers of NMN treated mice, demonstrating kidney specificity.

**Conclusions:** This suggests that high doses of NMN supplementation exacerbates existing inflammation pathways in aged kidneys but that this is reduced by ELAM mitochondrial intervention. Further work seeks to track NMN metabolite levels in primary tubule cells to better understand NMN-induced injury and ELAM protection in aged kidneys.

**Background:** Integrin-linked kinase (ILK), a major scaffold protein between the extracellular matrix and intracellular signaling pathways, is involved in several pathophysiological processes during renal damage. There are few studies on the mitochondrial dysfunction that occurs after renal failure in the Folic Acid-induced nephropathy (FA). The aim of this work was to study the role of ILK in renal interstitial fibrosis associated with mitochondrial dysfunction that appears during acute kidney injury (AKI) to chronic kidney disease (CKD) transition induced by FA administration.

**Methods:** Males of the C57BL/6 WT strain and adult conditional ILK knock-down (cKD-ILK) were injected intraperitoneally with a single dose of FA (250 mg/Kg) dissolved in Sodium Bicarbonate (0.3 mmol/L), with sacrifice at 15 days. We determined the expression of ILK, extracellular matrix protein (Fibronectin: FN and Collagen type I: COL1A1), the profibrotic cytokine TGF-β1 and the mitochondrial electron transport

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

chain complexes (COXI: NADPH DH, COXII: Succinate DH, COXIII: Coenzyme Q, COXIV: Cytochrome C Oxidase and COXV: ATP Synthase) by Western Blot and COXIV activity by colorimetric assay kit in the mice renal cortex.

**Results:** ILK expression increases in the renal cortex of FA treated WT mice, which does not occur in the cKD-ILK FA group. Moreover, we observed an increase of fibrotic markers (FN, COL1A1) and TGF- $\beta$  in the WT FA group, which was significantly lower in FA cKD-ILK mice. Regarding the complexes of the mitochondria, we observed a notable protein decrease of these complexes in the WT FA group and the protein content of COXI and COXIV that was partly recovered after ILK deletion (as also occurs with COXIV activity). Positive correlations with ILK expression levels were obtained for all studied markers.

**Conclusions:** These data suggest that ILK plays a relevant role in the renal fibrosis development and mitochondrial dysfunction after FA-induced AKI-CKD transition, since its deletion prevents fibrosis and improves mitochondrial dysfunction. Further studies will be aimed to elucidate the underlying mechanism between ILK, mitochondrial dysfunction and fibrosis.

## FR-PO136

### Helix B Surface Peptide Protects Lipopolysaccharide-Induced AKI by Inhibiting Pyroptosis and Promoting Macrophage Polarization

Lili Huang,<sup>1</sup> Wenli Sai,<sup>1</sup> Fenfen Xiong,<sup>1</sup> Guijuan Feng,<sup>1</sup> Yuanwu Wu,<sup>2</sup> Hongsheng Zhao,<sup>1</sup> Bin Yang,<sup>1,3</sup> <sup>1</sup>Affiliated Hospital of Nantong University, Nantong, China; <sup>2</sup>Nantong University, Nantong, China; <sup>3</sup>University of Leicester, Leicester, United Kingdom.

**Background:** Sepsis is defined as life-threatening multiple organ dysfunction syndrome caused by a dysregulated host response to infection. Acute kidney injury (AKI) is one of the most common complications of sepsis. Helix B surface peptide (HBSP) is the derivative of erythropoietin (EPO) that retains the tissue protection of EPO, without erythropoiesis. Previous studies have shown that HBSP alleviated renal ischemia-reperfusion injury. In this study, we investigated the effect of HBSP on pyroptosis and underlying mechanisms in lipopolysaccharide (LPS)-induced AKI.

**Methods:** The mice were randomly divided into three groups: the control, LPS and LPS + HBSP group (n = 6-8). Serum creatinine (Scr) and blood urea nitrogen (BUN) were detected by the Fully Automatic Biochemical Analyzer, while tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interleukin (IL)-6, IL-18 and IL-1 $\beta$  were detected by quantitative real-time PCR (qPCR). Renal histological changes were evaluated by tubular interstitial damage (TID) score in H&E stained sections. Macrophage infiltration and polarization were analyzed by immunohistochemistry and flow cytometry measures. The expression of pyroptosis-related proteins was detected by Western Blot.

**Results:** Scr, BUN and TID score were increased by LPS compared with the control group, but was decreased by HBSP (P<0.01). The level of TNF- $\alpha$ , IL-6, IL-18 and IL-1 $\beta$  mRNA, as well as HMGB1 protein, was increased by LPS, but reduced again by HBSP (P<0.05). In addition, the pyroptosis in LPS-treated kidneys was obvious compared with the control group, but HBSP treatment reduced the expression of pyroptosis-related proteins including GSDMD-N and IL-1 $\beta$  and IL-18 (P<0.05). Macrophage infiltration and inflammation in the kidney were increased by LPS, but reduced by HBSP (P<0.05). Moreover, M1 macrophage activation was induced by LPS, while the transformation of M1 to M2 phenotype was promoted by HBSP (P<0.01).

**Conclusions:** The model of LPS-induced AKI was successfully established with increased inflammatory mediators and compromised renal function and histology. HBSP effectively protected LPS-induced AKI reflected by less inflammation and pyroptosis, and improved macrophage polarization, renal function and structure. These findings provide new insights to the therapeutic strategy of LPS-induced AKI.

## FR-PO137

### Validation of Inferred MicroRNA Activity From Kidney scRNAseq

Danielle Janosevic, Thomas De Luca, Guanglong Jiang. *Indiana University School of Medicine, Indianapolis, IN.*

**Background:** MicroRNA (miR) regulate renal injury and recovery processes in acute kidney injury (AKI). Single-cell RNAseq (scRNAseq) datasets are broadly available, in contrast to single-cell miRNAseq (scMiRseq). Thus, pipelines that computationally derive miRNA activity (miRa) from scRNAseq are appealing. These pipelines infer a miR's activity level through enrichment of miR binding motifs on mRNA and changes in the miR targetome, proposed as a surrogate for miR expression. We hypothesize that miRa derived from kidney scRNAseq will strongly correlate with expressed miR from bulk kidney sequencing.

**Methods:** Murine kidney scRNAseq were downloaded from NCBI's GEO: GSE151658. This data is a model of sepsis-AKI at 0, 1, 4, 16, and 27 hours after endotoxin (LPS) injection (i.v.). ScRNAseq data were normalized and miRa estimated using "miReact" R package. MiRa were averaged for all cells at each timepoint to generate the pseudobulk miRa dataset. To validate miRa, we performed a miRNAseq experiment with identical conditions to the above dataset (n=5 per timepoint) and sequenced miR from bulk kidney tissue. RNA was extracted from snap frozen kidneys (Qiagen miRNeasy), library prepared (Qiaseq) and sequenced (10-15 million read depth/sample). FASTQs aligned to mm10 transcriptome using STAR. Read counts were TMM normalized, log-transformed (counts-per-million) using EdgeR, generating the bulk miR expression

dataset. Pearson correlation was performed for each miR between pseudobulk miRa and bulk miR expression. Correlation scores with  $r > 0.7$  and p-value <0.05 were considered significantly correlated. Pathway analysis was performed with miRdb and Mienturnet.

**Results:** MiR activity analysis derived 1,588 miRa from the pseudobulk miRa data and 566 miRs identified in the bulk miR expression data, with 322 (of 566, 56%) miRs shared between pseudobulk miRa and bulk miR expression data. Of the shared miRs, 14 miRs were significantly correlated (of 322, 4%,  $p < 0.05$ ) with a bias towards -3p strands. Significantly correlated miRs (e.g., miR-1955-3p,  $r = 0.99$ , miR-323-3p,  $r = 0.98$ , miR-3069-3p,  $r = 0.97$ ) were related to inflammatory and immune response pathways.

**Conclusions:** In our murine kidney data, miRa was not well correlated with miR expression. The discordance of activity from expression warrants further exploration into the regulatory mechanisms of renal miR expression, which may improve computational predictions of miRa.

**Funding:** Other NIH Support - This publication was made possible with support from Grant Number, UL1TR002529 (S. Moe and S. Wiehe, co-PIs) from the National Institutes of Health, National Center for Advancing Translational Sciences, Clinical and Translational Sciences Award

### Dicarboxylic Acid Supplementation Protects Mice From AKI via Increased Renal Peroxisomal Activity

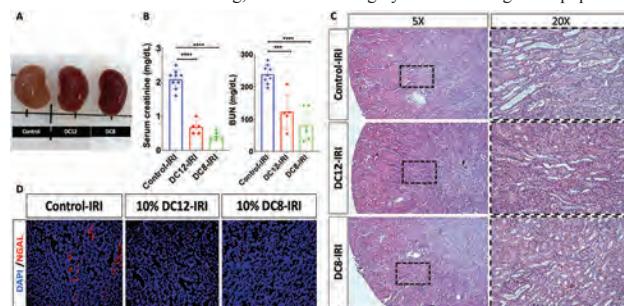

Anne C. Silva Barbosa,<sup>1,2</sup> Katherine Pfister,<sup>1,2</sup> Takuto Chiba,<sup>1,2</sup> Eric S. Goetzman,<sup>1,2</sup> Sunder Sims-Lucas,<sup>1,2</sup> <sup>1</sup>University of Pittsburgh, Pittsburgh, PA; <sup>2</sup>UPMC Children's Hospital of Pittsburgh Child Development Unit, Pittsburgh, PA.

**Background:** Lysine succinylation is a posttranslational modification associated with the control of acute kidney injury (AKI). Hypersuccinylation favors peroxisomal fatty acid oxidation (FAO) instead of mitochondrial. In addition, the medium-chain fatty acids dodecanedioic acid (DC<sub>12</sub>) and octanedioic acid (DC<sub>8</sub>), upon FAO, originate succinyl-CoA, a succinylation co-factor.

**Methods:** To test the roles of medium-chain fatty acids during AKI, mice were fed with a control, a 10% w/w DC<sub>12</sub>, or 10% w/w DC<sub>8</sub> diet, then, subjected to two models of AKI, unilateral renal ischemia-reperfusion (IRI), or an in-bolus cisplatin injection (20mg/kg). Supplementation was provided until sacrifice. Cisplatin animals were euthanized 3 days after injury, whereas IRI mice underwent contralateral nephrectomy on day 6 and were euthanized on day 7. Biochemical, histologic, genetic, and proteomic analyses were performed; the latter involving a lysine-succinylome-based mass spectrometry (LSMS).

**Results:** DC<sub>12</sub> prevented the rise of serum creatinine, blood urea nitrogen, and renal injury markers in mice during both models of AKI as well as improved morphology compared with controls. However, DC<sub>8</sub> was even more protective against AKI than DC<sub>12</sub>. Intriguingly, while DC<sub>8</sub> promotes succinylation in the kidneys only, DC<sub>12</sub> promotes it in both the liver and kidneys. Finally, LSMS evidenced that, regardless of surgical status, the kidneys of DC<sub>12</sub>- and DC<sub>8</sub>-fed mice showed, respectively, mild and extensive upregulation of a myriad of peroxisomal activity-related peptides, and a decline in mitochondrial FAO in comparison to control-fed mice.

**Conclusions:** DC<sub>8</sub> or DC<sub>12</sub> supplementation drives renal hypersuccinylation, promoting a shift from mitochondrial to peroxisomal fatty acid oxidation, and protecting against AKI. Dicarboxylic acid supplementation is convenient, inexpensive, easily administered, and efficient in preventing AKI. We believe this study could be translated in the future to the clinical setting, which would highly benefit the high-risk population.

## FR-PO139

### Higher Post-COVID-19 Urinary Mitochondrial DNA Level: Serves a Biomarker of Mitochondrial Distress and Inducer of Inflammatory Cytokines Secretion in Peripheral Blood Mononuclear Cells (PBMCs)

Narayan Prasad, Brijesh Yadav. *Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

**Background:** Severe acute respiratory corona virus-2(SARS-CoV-2) affected multiple organs including Kidney. SARS-CoV-2 open reading frame protein 3a induces necroptosis in infected cell leading release of mt-DNA, which binds to TLR9 and trigger innate immunity, which may lead to acute allograft injury.

**Methods:** Sixty-six live related renal allograft recipient previously hospitalized with SARS-CoV-2 infection were recruited after 2-3week of discharge. Patients were categorized either in non-AKI(n=47) or AKI(n=19) group, if hospitalization serum creatinine level was >30% of preCovid serum creatinine. A 50ml urine sample was collected for the mt-DNA gene NADH-ubiquinone oxidoreductase chain1(ND-1) and

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

nuclear 36B4 gene quantification by RT-PCR and urine N-GAL measurement by ELISA. A 10ml blood sample from 10 healthy volunteers was collected for PBMCs isolation. A  $1 \times 10^6$  PBMCs were stimulated for 24hrs. with 1 $\mu$ g/ml of urinary DNA or CpG oligodeoxynucleotide (5'-tcgtcgttttcggcgcgcgcg-3') in duplicate. Unstimulated PBMCs served as control. The gene expression of IL-10, IL-6, MYD88 was analyzed by the RT-PCR and IL-6, IL-10 level in supernatants by the ELISA.

**Results:** The precovid creatinine in non-AKI vs AKI patient was  $1.06 \pm 0.20$  vs  $0.97 \pm 0.27$ ,  $p = .14$ ; at hospitalization  $1.27 \pm 0.18$  vs  $1.84 \pm 0.37$ ,  $p < .001$ ; at discharge  $1.09 \pm 0.20$  vs  $1.11 \pm 0.32$  mg/dl,  $p = 0.73$ . The mean ND-1 gene Ct in non-AKI vs AKI was  $21.77 \pm 3.60$  vs  $19.44 \pm 2.58$  a.u.,  $p = .013$ . The normalized ND-1 Ct in non-AKI vs AKI was  $0.89 \pm 0.14$  vs  $0.79 \pm 0.11$  a.u.,  $P = 0.007$ . The median urinary N-GAL level in non-AKI vs AKI group was  $212.78$  (range,  $219.8$ - $383.06$ ) vs  $453.5$  (range,  $320.2$ - $725.02$ ;  $p = 0.015$ ) ng/ml. The area under curve of ND-1 Ct gene was  $0.73$ , normalized ND-1 Ct was  $0.71$ , uNGAL was  $0.66$  and normalized uNGAL was  $0.68$  for detecting the AKI. The IL-10 gene expression was downregulated in umt-DNA treated PBMCs compared to control ( $-3.5 \pm 0.40$  vs  $1.02 \pm 0.02$ ,  $p < 0.001$ ). IL-6 and Myd88 gene expression was upregulated. The culture supernatant IL-10 and IL-6 level in umt-DNA treatment PBMCs vs control was  $10.65 \pm 2.02$  vs  $30.3 \pm 5.47$ ,  $p = 0.001$ ; and  $200.2 \pm 33.67$  vs  $47.6 \pm 12.83$ ,  $p = 0.001$  respectively.

**Conclusions:** Quantification of umt-DNA can detect the post covid19 mitochondrial distress with higher sensitivity compare to uNGAL. umt-DNA induces robust inflammatory response in PBMCs may exacerbate the post-Covid19 allograft injury.

**Funding:** Government Support - Non-U.S.

## FR-PO140

### Aldehyde Dehydrogenase 2 Alleviates Mitochondrial Dysfunction by Regulating Aerobic Glycolysis via PI3K/AKT/mTOR Pathway in AKI

Jiaying Li, Xiaoxiao Shi, Limeng Chen. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

**Background:** The protective roles of mitochondrial enzyme acetaldehyde dehydrogenase 2 (ALDH2) in various diseases have been reported. In this study, we aimed to investigate the role of ALDH2 on AKI with aerobic glycolysis via the PI3K/AKT/mTOR pathway in different AKI models.

**Methods:** AKI models were established by cisplatin (cis) or maleic acid (MA) intraperitoneally (i.p.) in wild type (WT) and ALDH2 knockout (KO) mice and Alda-1 (ALDH2 agonist) was administrated for prevention experiments. We observed mitochondrial function, aerobic glycolysis, and the PI3K/AKT/mTOR pathway in vivo and in vitro with human renal proximal tubular epithelial (HK-2) cells stimulated by activation or knockdown ALDH2. Furthermore, the rescue experiment was done by LY294002 (inhibitor of PI3K) in HK-2 cells transfected with ALDH2 shRNA (shALDH2) plasmid.

**Results:** ALDH2 protein was reduced by 46% and 28% in cisplatin and MA induced AKI mice, accompanied by proximal tubular injury and mitochondrial dysfunction. ALDH2 agonist Alda-1 prevented the increase of serum creatinine (Scr) ( $38.54 \pm 4.92$  versus  $74.42 \pm 4.39$   $\mu$ mol/L,  $P < 0.0001$ ) in WT cis-AKI, while more severe ( $86.13 \pm 6.20$  versus  $62.29 \pm 3.19$   $\mu$ mol/L,  $P < 0.01$ ) in ALDH2 KO cis-AKI. In the MA-AKI mice, the renal function (Scr:  $20.09 \pm 3.65$  versus  $64.55 \pm 12.64$   $\mu$ mol/L,  $P < 0.001$ ) was recovered by Alda-1 pretreatment with reduced KIM-1 protein. In addition, decreased mitochondrial-related proteins (PGC-1 $\alpha$  and ATP5a1), mitochondrial DNA (mtDNA) and ATP content were observed in MA-AKI, but reversed by pretreatment with Alda-1. In HK-2 cells, knockdown of ALDH2 aggravated MA-induced mitochondrial dysfunction, indicated by decreased mitochondrial membrane potential and mitochondrial oxygen consumption rate (OCR) ( $54.80 \pm 7.34$  versus  $40.06 \pm 3.58$  pmol/min/ug.pro,  $P < 0.05$ ) with the activation of aerobic glycolysis and PI3K/AKT/mTOR pathway. Furthermore, LY294002 partially reversed the cell apoptosis percentage ( $15.50\% \pm 0.67$  versus  $19.50\% \pm 0.68$ ,  $P < 0.05$ ) of ALDH2 knockdown in MA-induced HK2 cells.

**Conclusions:** ALDH2 prevented tubular injury and apoptosis by rescuing mitochondrial dysfunction and aerobic glycolysis via the PI3K/AKT/mTOR pathway in cisplatin and MA-induced AKI.

## FR-PO141

### Primary Cilia Control Senescence Initiation in Stressed Renal Epithelial Cells

Jielu Hao, Xiaoyu Ma, Yingyi Zhang, Jinghua Hu. *Mayo Clinic Minnesota, Rochester, MN.*

**Background:** Cellular senescence is an irreversible proliferative arrest that reduces regenerative capacity of kidney after insults. Senescent cells may further exacerbate kidney injury by releasing pro-inflammatory senescent-associated-secretory phenotype (SASP). The molecular mechanism underlying stress-induced senescence remains poorly understood. Here, we discovered a direct cilium-nuclear axis in initiating senescence responses in renal tubular epithelial cells upon DNA damage.

**Methods:** Human renal cortical tubular epithelial cells (RTE) were exposed with 5 Gy by the X-ray irradiator to induce senescence. Senescent level was determined by measuring Senescent Associated (SA)-b-Gal staining, protein and RNA levels of SASP markers. Essential cilia gene *IFT88* was knocked down to disrupt ciliogenesis in RTE cells. Cas9 cell lines were generated to study knockout phenotypes. The expression and localization of key components were measured by western blotting, confocal imaging, and super-resolution Structure Illumination Microscopy. Immunoprecipitation assay and GST pull-down assay were performed to analyze protein-protein interaction.

**Results:** Using immunofluorescence, we observed that irradiation (IR) induces robust but transient ciliogenesis in RTE cells during senescence, which accompanied by downregulation of ciliary GTPases ARL13B and ARL3 and upregulation of transition

fiber protein FBF1. Upon DNA damage, FBF1 translocates from primary cilia to promyelocytic leukemia nuclear bodies (PML-NBs), a nuclear structure implicated in senescence regulation, to initiate senescence in stressed cells. Mechanistically, we discovered that the ARL13B-ARL3 GTPase cascade negatively regulates UBC9-mediated SUMOylation of FBF1 at the ciliary base in normal cells, whereas irreparable stresses suppress ARL expression and thus enhance FBF1 SUMOylation in stressed cells. SUMOylated FBF1 translocates from primary cilia to PML-NBs. FBF1 depletion abolishes stress-induced PML-NB upregulation and senescence initiation, whereas FBF1 overexpression causes opposite effects.

**Conclusions:** Our findings define a paradigm in which sensory cilia communicate directly with the nucleus to control senescence initiation in stressed renal tubular epithelial cells. These results further highlight the potential of targeting cilia in future senescence-related therapeutic strategies in kidney diseases.

## FR-PO142

### FDA-Approved Drug Lasmiditan Promotes Mitochondrial Biogenesis and Accelerates Recovery of Renal Function After Ischemia/Reperfusion Injury

Kevin A. Hurtado,<sup>1</sup> Jaroslav Janda,<sup>1</sup> Rick G. Schnellmann.<sup>1,2</sup> <sup>1</sup>The University of Arizona College of Pharmacy, Tucson, AZ; <sup>2</sup>Southern Arizona VA Health Care System, Tucson, AZ.

**Background:** Acute kidney injury (AKI) is an abrupt loss of renal function that can result from sepsis, ischemia and toxicant induced injury. AKI incidence has become more prevalent in the last few decades and is linked with the progression into chronic kidney disease (CKD). Mitochondrial dysfunction is associated with development of AKI and mitochondrial biogenesis (MB) has been shown to recover mitochondrial homeostasis and promote recovery from AKI. We studied the effect of lasmiditan, a 5-HT<sub>1F</sub> receptor agonist that was previously shown to induce MB *in-vitro* and *in-vivo*, in a mouse model of AKI.

**Methods:** Electron microscopy was utilized to examine mitochondrial number and morphology 48 h after two daily lasmiditan treatments (0.3 mg/kg). Mice underwent ischemia/reperfusion (I/R) to induce AKI. After 24 h, serum creatinine was measured and I/R treated mice were divided into two groups and dosed with lasmiditan. Mice were treated daily for 144 h or 288 h and serum creatinine measured. KIM-1 and mitochondrial markers were measured using immunoblot analysis. Histopathology analyses were performed to measure tissue damage and fibrosis.

**Results:** Lasmiditan treatment increased mitochondrial number in murine renal cortices. Serum creatinine levels were similar between the vehicle+I/R and lasmiditan+I/R groups at 24 h. At 144 h, serum creatinine was restored to sham levels in the lasmiditan+I/R group compared to vehicle+I/R group. KIM-1 protein decreased by half in the lasmiditan+I/R group compared with vehicle+I/R at 144 and 288 h. PGC-1 $\alpha$  was restored to sham levels at 144 h and increased at 288 h in the lasmiditan+I/R group. Collagen-I protein and interstitial fibrosis were decreased in the lasmiditan+I/R group at 288 h.

**Conclusions:** We demonstrate that the FDA approved drug lasmiditan stimulates MB and accelerates recovery of renal function after I/R and prevents interstitial fibrosis.

**Funding:** Veterans Affairs Support

## FR-PO143

### Dynamic ATP Changes and Mitochondrial Fragmentation in Podocyte During Ischemia Reperfusion Injury Determines Their Future Structure and Function

Masahiro Takahashi,<sup>1</sup> Shinya Yamamoto,<sup>1</sup> Shigenori Yamamoto,<sup>1,2</sup> Akihiro Okubo,<sup>1</sup> Masamichi Yamamoto,<sup>3</sup> Motoko Yanagita.<sup>1,2</sup> <sup>1</sup>Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; <sup>2</sup>Institute for the Advanced Study of Human Biology (WPI-ASHBi), Kyoto University, Kyoto, Japan; <sup>3</sup>National Cerebral and Cardiovascular Center Research Institute, Osaka, Japan.

**Background:** Previously, we demonstrated that ischemia reperfusion injury (IRI) results in dynamic and detrimental changes of ATP levels in proximal tubules, which are associated with kidney fibrosis in chronic phase. Although proteinuria after ischemia-related events in clinical settings, including kidney transplantation and AKI, has been documented, ATP dynamics in podocytes and the mechanisms underlying podocyte injury during IRI remains elusive.

**Methods:** GO-ATeam2 mice, which systemically express an ATP biosensor GO-ATeam2, were used for multiphoton microscopy-based intravital ATP imaging. TEM and FIB-SEM were used for microstructural analysis of podocytes. Correlations between ATP recovery in podocytes in acute phase of IRI and foot process effacement and mitochondrial fragmentation of podocytes in chronic phase were assessed. We also analyzed the efficacy of a mitochondrial fission inhibitor Mdivi-1 for structural integrity of podocytes after IRI *in vivo*, and after ATP-depletion stress *in vitro*.

**Results:** ATP levels of podocytes were decreased to the bottom level within 20 minutes during ischemia and recovered in 5 minutes after reperfusion. ATP recovery in podocytes after reperfusion became slower and insufficient after long ischemia. 3D analysis of podocyte mitochondria confirmed mitochondrial fragmentation as early as 30 minutes after reperfusion, when foot process effacement was not evident. Podocytes exhibited prominent foot process effacement and sustained mitochondrial fragmentation in chronic phase of IRI after long ischemia. There was a significant correlation between foot process width and mitochondrial roundness in chronic phase, both of which were inversely correlated with ATP recovery in acute phase. Finally, the administration of Mdivi-1 ameliorated cytoskeletal disarrangement of cultured podocytes after ATP-depletion stress, and foot process effacement in podocytes after IRI *in vivo*.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Conclusions:** ATP depletion and mitochondrial fragmentation in podocytes in acute phase of IRI could contribute to foot process effacement in chronic phase. Our results suggest ischemic stress could induce podocyte injury through ATP depletion and mitochondrial fragmentation, and the latter could be a therapeutic target.

### Ceramides as Mediators of Mitochondrial Dysfunction Driving Kidney Injury

Rebekah Nicholson, Ying Li, John A. Maschek, Deborah Stuart, Nirupama Ramkumar, Scott Summers. *University of Utah Health, Salt Lake City, UT.*

**Background:** Perturbations in proximal tubule mitochondrial function and lipid metabolism potentiate kidney injury and failed repair following ischemia reperfusion or obstruction. Sphingolipids such as ceramides are recognized as lipotoxic drivers of metabolic dysfunction. We investigate mechanisms of ceramides driving proximal tubule pathology and assess the efficacy of ceramide-lowering therapeutics to combat AKI.

**Methods:** We lowered whole-body ceramides via *Degs1* inducible global knockout (*Degs1<sup>l<sup>CKO</sup></sup>*) in male C57BL/6J mice prior to challenge with warm bilateral IRI (22 minute ischemia) or UUO and compared clinical and histopathological outcomes versus *Degs1<sup>fl/fl</sup>* littermate controls 24 hours after kidney reperfusion or 7 days after obstruction. In vitro, we examined effects of ceramide accrual on mitochondrial function in human immortalized proximal tubule epithelial cells treated with palmitate or C2-ceramide with an Agilent Seahorse Analyzer.

**Results:** *Degs1* global knockout decreased total cortex ceramide levels by 57%, preventing the 21% and 18% increase in ceramides in *Degs1<sup>fl/fl</sup>* surgery vs. sham groups following IRI or UUO, respectively. *Degs1<sup>l<sup>CKO</sup></sup>* animals had improved blood urea nitrogen [49.82±6.34(KO) vs. 81.02±2.13(fl/fl) mg/dL], plasma creatinine [0.32±0.11(KO) vs. 1.28±0.4(fl/fl) mg/dL], and cortex *Lcn2* expression [5.31±4.61(KO) vs. 36.36±21.50(fl/fl) relative to fl/fl sham] following IRI. Following UUO, *Degs1<sup>l<sup>CKO</sup></sup>* kidneys were less fibrotic with lower expression of fibrosis (*Col1a1*, *Col3a1*, *Fnl1*), inflammation (*Il6*), and injury (*Havcr1*) markers. Treatment of HK2 cells for 24 hours with 500mM palmitate, the primary substrate of ceramide biosynthesis, decreased basal and maximal mitochondrial respiration by 24% and 30%, respectively, vs. vehicle-treated controls. Co-treatment with 10mM myriocin, a ceramide synthesis inhibitor, prevented ceramide accumulation and rescued mitochondrial function. Treating cells with 15mM C2-ceramide, but not dihydroceramide lacking a double bond essential for lipid bioactivity, elicited similar impairments in mitochondrial oxygen consumption and acutely depleted mitochondrial ATP production.

**Conclusions:** Renal ceramides are implicated as drivers of kidney injury and mitochondrial dysfunction. Ceramide-lowering interventions may be effective strategies to prevent AKI.

### Spatially Resolved Distal Convoluted Tubule Transcriptome of AKI

Hyun Jun Jung, Sepideh Gharraie, Kyungho Lee, Emily K. Lo, Sanjeev Noel, Patrick Cahan, Hamid Rabb, Paul A. Welling. *Johns Hopkins University School of Medicine, Baltimore, MD.*

**Background:** Injury and failed repair transcriptome profiles of the renal proximal tubule and the loop of Henle have highlighted potential drivers of Acute Kidney Injury (AKI) and AKI to CKD. However, it is not clear if AKI affects gene expression profiles of other renal tubules, and whether injury is manifested focally by cell-cell communication or uniformly by autonomous mechanisms. Recent biomarker analyses raise the possibility that the distal convoluted tubule (DCT) might be especially sensitive to injury. This study aims to unravel gene expression responses of the DCT in AKI with spatial resolution at genome-wide depth.

**Methods:** Single-cell RNA sequencing (scRNA-Seq) data of human AKI patients (n=4) with healthy individuals (n=5) were obtained from the Kidney Precision Medicine Project (KPMP) and analyzed using Seurat (4.0). The 10x Genomics Visium Spatial Gene Expression platform was used to corroborate the human data in a mouse model of ischemia-reperfusion injury (IRI, ischemia for 30min followed by reperfusion for 24h), and to create an anatomical map of gene expression changes with CellRanger (6.0.1) and Seurat (4.0).

**Results:** Analyses of the KPMP scRNA-Seq data sets revealed that AKI is associated with remarkable alterations in the DCT transcriptome. This included increased expression of known kidney injury marker genes, Secreted Phosphoprotein 1 (Spp1), Lipocalin 2 (Lcn2) and Clusterin (Clu). A significant reduction of Epithelial growth factor (Egf) was also observed, paralleling changes in the loop of Henle. DCT-specific genes were altered, including decreased expression of Parvalbumin (Pvalb) and increased expression of Splat-like transcription factor 3 (Sall3). Spatial transcriptome profiling revealed IRI in mice has similar effects on gene expression as AKI in humans, affecting two distinct DCT cell-enriched clusters in the cortex, corresponding to early and late DCT. IRI affected the DCT transcriptome uniformly throughout the cortex.

**Conclusions:** In conclusion, the DCT transcriptome is especially sensitive to ischemic injury, exhibiting a unique injury-repair signature. The uniform change in gene expression across all DCT populations throughout the cortex suggests a cell-autonomous injury mechanism.

## FR-PO146

### scRNA-Seq Analysis of Polyploid Tubular Epithelial Cells Reveals a Specific Hypertrophy Program Triggered in Response to AKI

Letizia De Chiara, Elena Lazzeri, Paola Romagnani. *Universita degli Studi di Firenze, Firenze, Italy.*

**Background:** Acute Kidney Injury (AKI) is characterized by a rapid deterioration of kidney function. Recently, we showed that tubular epithelial cells (TC) respond to AKI by triggering polyploidization mediated hypertrophy, (i.e. increase their DNA content and dimension) which allows for a quick recovery of kidney function by providing increased functional output via cell hypertrophy. However, the processes that govern this response are currently unknown. Moreover, in the kidney polyploid TC mostly remain mononuclear, making their recognition challenging unless multiple targeted techniques are combined. Here, we explored the possibility to use single cell RNA-sequencing (scRNA-seq).

**Methods:** To identify polyploid TC, study their phenotype and dissect the mechanisms underlying polyploidization mediated hypertrophy, we applied scRNA-seq analysis *in vitro* and *in vivo* after ischemic injury combined with specific knocked-down experiments, cell sorting, pharmacological inhibition, chromatin-immunoprecipitation assay (ChIP) and *in vivo* transgenic models.

**Results:** Based on combined measurement of DNA content and cell cycle phase with the FUCCI reporter, we showed that primary proximal tubular cells (PTC) contain a fraction of polyploid TC. scRNA-seq of PTC revealed the presence of genes previously associated with different phases of polyploidization-mediated hypertrophy. A trajectory analysis suggested that PTC polyploidization starts with increased ribosome biogenesis, culminating in a YAP1 enriched signature. Sorting of polyploid PTC confirmed the YAP1 signature enrichment. scRNA-seq analysis on mouse kidneys at days 0, 2 and 30 after AKI confirmed our *in vitro* observations and suggested that polyploid TC have significantly increased transcriptome abundance, consistent with their increased DNA content. 2 days after AKI, TC specific YAP1 knock-out mice displayed less polyploid cells, smaller kidneys and TC compared to wild-type, in line with the concept that polyploid cells are hypertrophic. Finally, ChIP assays combined with targeted silencing confirmed YAP1 as the primary driver of TC polyploidization.

**Conclusions:** In conclusion: 1) scRNAseq can be successfully applied to study polyploidization if combined with the right tools and 2) scRNAseq revealed the presence of a specific hypertrophy program in polyploid TC driven by YAP1 activation.

## FR-PO147

### Strengths and Limitations of Integrating Single Cell and Spatial Transcriptomics to Study T Cells in Normal and AKI Kidneys

Sepideh Gharraie,<sup>1</sup> Kyungho Lee,<sup>1</sup> Kathleen Noller,<sup>1,2</sup> Emily K. Lo,<sup>1</sup> Hyun Jun Jung,<sup>1</sup> Johanna T. Kurzhagen,<sup>1</sup> Nirmish Singla,<sup>1</sup> Paul A. Welling,<sup>1</sup> Patrick Cahan,<sup>1</sup> Sanjeev Noel,<sup>1</sup> Hamid Rabb,<sup>1</sup> <sup>1</sup>*Johns Hopkins Medicine, Baltimore, MD;* <sup>2</sup>*Duke University School of Medicine, Durham, NC.*

**Background:** T cells are important in the pathogenesis of AKI but molecular mechanisms are poorly understood. We used single cell RNAseq as well as novel spatial transcriptomics to study T cells in normal and post AKI mouse kidneys. We also studied human kidneys and NIH KPMP data to assess clinical significance of our mouse data.

**Methods:** C57BL6 mice underwent bilateral ischemia reperfusion, then sacrificed at 24 hr. Kidney mononuclear cells from normal and ischemic mice isolated and sorted for CD4, CD8, and DN T cells. cDNA was synthesized and library preparation performed using 10X Chromium technology. scRNA-Seq was preprocessed on the Illumina NextSeq 500 platform. Sequencing reads were aligned to the mouse reference genome using the 10X Genomics Cell Ranger pipeline followed by downstream data analysis using Scanpy. Data was validated using qPCR. Spatial transcriptomics was performed using 10X Visium platform. "Normal" sections of human post-ischemic kidneys removed for tumor nephrectomies were evaluated. The NIH KPMP AKI data base was studied.

**Results:** scRNA-seq revealed a distinct gene profile for CD4, CD8 and DN T cells of mouse kidneys. We then identified genes that were significantly up or downregulated in each population after AKI. We selected highest expressing genes in each category, focusing on the DN T cells, and confirmed the expression of those genes including *Xcl1*, *Ly6c2*, and *Fcer1g* using qPCR. Spatial transcriptomics in normal and AKI mouse tissue showed a localized cluster of T cells in the outer medulla expressing similar genes. However, spatial transcriptomics with the current technology did not provide resolution needed to adequately study kidney T cells. Novel T cell gene signatures that we identified, were confirmed in Human kidney AKI tissue using qPCR as well as the NIH KPMP data set.

**Conclusions:** Single cell RNAseq is a useful discovery technique to study T cell gene expression in normal and AKI kidneys, and can be validated in human samples. However, spatial transcriptomics at the current technology has resolution limitations to study kidney T cells, but is useful for epithelial cell, macrophage, neutrophil, cytokine and chemokine studies.

**Microbiome Modulation After Severe AKI Accelerates Recovery and Decreases Fibrosis**

Sepideh Gharaie, Kyungho Lee, Jiaojiao Xu, Lois J. Arend, Jennifer L. Pluznick, Sanjeev Noel, Hamid Rabb. *Johns Hopkins Medicine, Baltimore, MD.*

**Background:** Most studies on modifying the microbiome to improve acute kidney injury (AKI) have focused on prevention. Effects on repair have not been well studied. We hypothesized that modifying gut microbiota with antibiotics (ABX) administered AFTER severe ischemic AKI in mice would accelerate kidney recovery and mitigate fibrosis.

**Methods:** C57BL6 mice underwent 50 min unilateral ischemia reperfusion injury (UIRI). Amoxicillin, metronidazole, combination of ABX (ampicillin, metronidazole, neomycin, vancomycin) or control were started after IR. Glomerular filtration rate (GFR) was measured in conscious mice via transcutaneous detection of FITC-sinistrin. Kidneys were evaluated for fibrosis with Masson's trichrome, mRNA expression of *Colla1*, *TGF $\beta$* , and  $\alpha$ SMA by qPCR, and immunophenotyped by flow cytometry. Stool 16s rRNA sequencing was performed. Germ free (GF) and CD4 KO mice with severe AKI were studied.

**Results:** Amoxicillin started post IRI increased GFR at 1, 2, 3 and 4 weeks compared to control (900 $\pm$ 26 vs 749 $\pm$ 31  $\mu$ L/min/100g,  $P<.01$ ; 922 $\pm$ 28.8 vs 707 $\pm$ 25,  $P<.01$ ; 922 $\pm$ 21 vs 811 $\pm$ 26,  $P=0.021$ ; and 931 $\pm$ 23 vs 758 $\pm$ 24,  $P<.01$ ). Amoxicillin decreased fibrosis percentage in both cortex and outer medulla compared to control (5.5 $\pm$ 1.2 vs 12.1 $\pm$ 2.3,  $P=.015$ ; 6.6 $\pm$ 0.7 vs 13.9 $\pm$ 1.2,  $P<.01$ ). Amoxicillin decreased *TGF $\beta$*  expression compared to control (0.6 $\pm$ 0.1 vs 1.1 $\pm$ 0.1,  $P=.013$ ). Amoxicillin decreased percentage of kidney CD4T cells (47.5 $\pm$ 1.8 vs 61.5 $\pm$ 2.4,  $P<.01$ ), while CD8 cells (39.4 $\pm$ 2.2 vs 26.2 $\pm$ 2.2,  $P<.01$ ) and PD1 expression on CD8 (21.1 $\pm$ 2.3 vs 7.73 $\pm$ 1.6,  $P<.01$ ) were increased. Amoxicillin did not accelerate kidney repair in GF mice, but was effective in CD4 KO mice. Amoxicillin increased stool *Alistipes*, *Anaerotruncus*, and *Lactobacillus* species and reduced *Holdemanella* and *Anaeroplasmia*. GFR level was increased in metronidazole ( $P=.02$ ) at 1 week and in ABX at 1 ( $P<.01$ ), 2 ( $P=.09$ ), and 4 ( $P=.011$ ) weeks. Fibrosis percentage in cortex and outer medulla was increased by metronidazole (22.3 $\pm$ 3.1 vs 17.4 $\pm$ 4.3 and 13.6 $\pm$ 1.6 vs 10.6 $\pm$ 1.2) and combination of ABX (28.7 $\pm$ 8.7 vs 17.4 $\pm$ 4.3 and 14.4 $\pm$ 1.6 vs 10.6 $\pm$ 1.2) versus control.

**Conclusions:** Modification of gut bacteria with amoxicillin administered after induction of ischemic AKI is a promising novel therapeutic approach to accelerate recovery of kidney function and mitigate AKI to CKD progression.

**Detection of Myeloid Cell Pleiotropy In Situ and the Unique Niches of Immune Cells in Ischemic Kidney Injury Using CODEX Imaging**

Angela R. Sabo,<sup>1</sup> Lauren A. Maghak,<sup>1</sup> Connor J. Gulbranson,<sup>1</sup> Shehnaz Khan,<sup>1</sup> Radmila Micanovic,<sup>1</sup> Kaice A. LaFavers,<sup>1</sup> Daria Barwinska,<sup>1</sup> James C. Williams,<sup>1</sup> Tarek M. El-Achkar,<sup>1,3</sup> Seth Winfree,<sup>2</sup> <sup>1</sup>*Indiana University School of Medicine, Indianapolis, IN*; <sup>2</sup>*University of Nebraska Medical Center, Omaha, NE*; <sup>3</sup>*Richard L Roudebush VA Medical Center, Indianapolis, IN.*

**Background:** Myeloid cells are involved in the pathogenesis of acute kidney injury (AKI), particularly at the early stage. Further, the renal protective protein Uromodulin (UMOD) plays a central role in modulating myeloid populations in the kidney. To understand the myeloid response during AKI *in situ* and how it is shaped by UMOD, we used CO-Detection by indEXing (CODEX) a cyclic imaging technique that allows for the imaging of more than 30 protein markers in one tissue. Such approach will preserve the spatial context and define the cellular niches that determine the pathogenesis of AKI.

**Methods:** Whole sections of murine renal tissue from wild-type and UMOD-knockout mice were harvested 6 hours after sham or 22-min ischemic injury and stained for nuclei and 33 different protein markers, targeting parenchymal, immune, and injury proteins. The collected images were processed and stitched using CODEX software and visualized in ImageJ/FIJI. Using nuclei, cells were segmented, associated markers quantitated, and cell types labeled using a semi-supervised tissue cytometry approach in the Volumetric Tissue Exploration and Analysis (VTEA) software.

**Results:** In sham and injured tissues, our marker panel labeled most cells in the kidney. VTEA cytometry and semi-supervised clustering allowed the identification and quantitation of all major epithelial, endothelial, stromal and immune cells and mapping of these various populations *in situ*. During AKI, phenotypic pleiotropy of infiltrating and resident myeloid cells was observed and spatially delineated. Using cell-centric neighborhood analysis, unique spatial niches of immune cells associated with specific epithelial and vascular cells were defined. The phenotypic pleiotropy and cells niches were altered by UMOD deficiency.

**Conclusions:** We establish a robust panel of protein markers to comprehensively capture the cellular diversity in murine kidneys and establish an analytical pipeline to uncover unique niches of immune/epithelial/vascular cells in injury. This approach will allow us to uncover the cell-cell interactions that underlie the pathogenesis of AKI and explain the protective role of Uromodulin during injury.

## FR-PO150

**Uromodulin Deficiency Shapes AKI Severity by Enhanced Oxidative Injury and Stress Response in Proximal Tubules With Early Activation of the Inflammasome**

Kaice A. LaFavers,<sup>1</sup> Radmila Micanovic,<sup>1</sup> Angela R. Sabo,<sup>1</sup> Shehnaz Khan,<sup>1</sup> Seth Winfree,<sup>2</sup> Tarek M. El-Achkar,<sup>1</sup> <sup>1</sup>*Indiana University Purdue University Indianapolis, Indianapolis, IN*; <sup>2</sup>*University of Nebraska System, Lincoln, NE.*

**Background:** Uromodulin (Tamm-Horsfall Protein, THP) is uniquely expressed in the kidney and its deficiency aggravates the severity of acute kidney injury (AKI). THP deficiency is a feature of chronic kidney disease (CKD) and is also induced by AKI early after injury. We have shown that loss of THP induces oxidative injury via TRPM2, a redox-regulating cationic channel. Therefore, we propose that THP deficiency observed in CKD and early AKI enhances injury severity by stimulating oxidative stress through TRPM2.

**Methods:** We used the ischemia reperfusion injury (IRI) model to induce AKI in THP<sup>+/+</sup> and THP<sup>-/-</sup> mice with a 22-minute clamp time and 6 or 24 hour recovery. Single cell RNA sequencing was used to delineate differentially expressed genes and pathways in proximal tubules. Large scale confocal imaging was done on whole kidney sections for spatial analysis. Pharmacological TRPM2 inhibition was achieved using 2-APB. Biochemical assays to measure kidney function, inflammation and gene expression were performed on tissue lysates or serum.

**Results:** Compared to THP<sup>+/+</sup>, THP<sup>-/-</sup> mice had significantly worse kidney injury at 24 hours (serum creatinine) and 6 hours post IRI (increased HAVCR1/KIM1 in S3 proximal tubules). Single cell sequencing of proximal tubules at 6 hours revealed that THP<sup>-/-</sup> mice had upregulated genes involved in oxidative stress, the integrated stress response (ISR) and regulated cell death pathways. THP<sup>-/-</sup> mice have increased expression of ATF3, a transcription factor activated by the ISR and IL-1 $\beta$ , a component of the inflammasome/pyroptosis pathway activated by oxidative injury. Inhibition of TRPM2 in THP<sup>-/-</sup> mice reduced renal oxidative injury 6 hours post IRI.

**Conclusions:** These results suggest that THP deficiency alters the early course of AKI towards severe injury by increasing the activation of TRPM2, thereby enhancing oxidative injury, stress response and activation of the inflammasome. These findings may have relevance to the increased risk of AKI in states of THP deficiency such as CKD. Increasing THP levels or targeting the pathways induced by its deficiency may have an important impact on improving the course and reducing the severity of AKI.

## FR-PO151

**Proteomic and Functional Analysis of Acute Galactic Cosmic Radiation Exposure in the Kidneys**

Stephen B. Walsh, Keith Siew. *University College London, London, United Kingdom.*

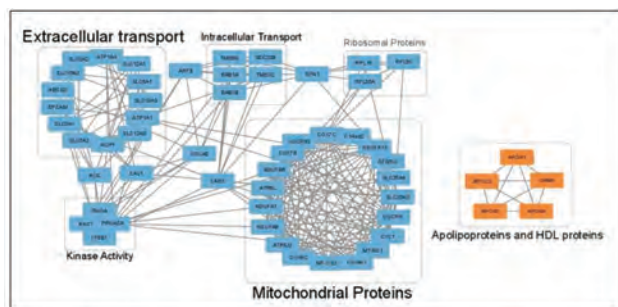

**Background:** There is concern regarding the effect of galactic cosmic radiation (GCR) exposure on cancer risk, cardiovascular and neurological health posed by longer missions planned as part of the Deep Space Transport/Mars Missions. However the kidney is the dose limiting organ in abdominal radiotherapy and total body irradiation. Chronic kidney dysfunction can occur with acute low linear energy transfer (LET; e.g.  $\gamma$ -radiation or X-rays) radiation doses as low as  $<0.5$ Gy. An astronaut on a Mars exploration mission has an estimated absorbed dose of 0.47Gy. We hypothesise that GCR may cause acute renal failure within the timeframe and GCR dose expected for an exploratory mission to Mars, which may require renal replacement therapy and would thus be mission critical.

**Methods:** To investigate this, snap-frozen kidneys from mice either exposed to an acute 0.5Gy dose of simulated GCR or sham control (n=10 per group) at Brookhaven National Laboratory, underwent quantitative TMT mass spectrometry proteomic analysis for markers of proximal tubule damage and pathways known to be involved in radiation nephropathy. Urine and plasma were also collected from these mice 24hrs after acute GCR exposure for biochemical and electrolyte analysis to look for early signs of renal tubular and glomerular filtration dysfunction.

**Results:** Network analysis of the proteome of whole homogenised kidney of GCR exposed animals showed a biologically significant ( $>10\%$ ) decrease in proteins associated with mitochondrial (e.g. CYC1, COX7C) or ribosomal function, intracellular transport and cell membrane transport (e.g. SLC12A1, SLC12A3) compared to sham exposed animals. There was a  $>10\%$  increase in apolipoproteins and HDL proteins (e.g. APOA4, APOA1) in GCR compared to sham exposed animals.

**Conclusions:** GCR exposed animals had proteomic and biomarker evidence of renal damage. This requires further investigation.

**Figure Legend:** Network analysis of proteome of homogenised renal tissue for animals exposed to GCR compared to animals exposed to sham. Blue nodes represent proteins with decreased expression (>10% decrease) after GCR, orange nodes represent proteins with increased expression (>10% increase) after GCR. Only highly connected (>10 1° degree neighbours) nodes are shown.

## FR-PO152

### Zero-Controlled Statistical Model for Single Nucleus ATAC-Seq Data Analysis and Demultiplexing

Zhen Miao, Junhyong Kim. *University of Pennsylvania, Philadelphia, PA.*

**Background:** Single nucleus ATAC sequencing (snATAC-seq) is a technique that detects open chromatin for each individual cell. While it is a key assay to augment single cell RNA-seq data, analysis methods for snATAC-seq are still in development. In particular, there is a lack of methods that explicitly incorporate probabilistic models.

**Methods:** Here, we developed a zero-controlled statistical model for snATAC-seq data that accounts for missing data and uneven sequencing coverage. Our model accounts for different sources of zero (biological vs non-biological zero); and the presence of excess zero in this highly sparse data. Our statistical model enables model-based differential feature identification, cell type classification/annotation, doublet detection, and batch effect correction.

**Results:** Our evaluations with both simulated data and real data show consistently better performance compared to existing methods that do not account for missing data. Applying our method to several snATAC-seq datasets from kidney samples showed high accuracy (over 0.9 ARI) for cell type label transfer tasks, while simultaneously detecting potential doublet cells. We applied our method to detect cell type-specific regulatory elements in each kidney cell types during injury repair process in the mouse system.

**Conclusions:** Here we present a statistical model for snATAC-seq analysis. Our evaluation suggests that accounting for missing rate disparity is important in snATAC-seq data analysis and we should adjust for different sources of zero present in the data to reduce false discovery.

## FR-PO153

### Embelin Attenuated Septic AKI by Inhibition of M1 Macrophage Polarization and NF- $\kappa$ B Signaling in Mice

Qiao Tang,<sup>1</sup> Yi Li.<sup>2</sup> *<sup>1</sup>North Sichuan Medical College, Nanchong, China; <sup>2</sup>Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China.*

**Background:** Acute kidney injury (AKI) is a clinical syndrome with high morbidity and mortality. As one of the most common reasons to AKI, there is currently no effective treatment for sepsis beyond supportive care. Embelin could demonstrate hepatoprotective effect against acute liver injury and regulate hepatic macrophage activity. However, the therapeutic effect and immunomodulatory role underlying Embelin action in septic AKI is unclear.

**Methods:** Current study aimed to elucidate the role and mechanism of Embelin in lipopolysaccharide (LPS)-induced septic AKI involving macrophage activation. In the study, Embelin was once intraperitoneal injection given to the mice after LPS injection. Then harvested the serum and kidney sample after 24 h. To explore the immunomodulatory role of Embelin in macrophages, we further isolated murine bone marrow-derived macrophages (BMDMs) and stimulated murine BMDMs with LPS followed by Embelin treatment.

**Results:** We observed that Embelin attenuated renal dysfunction and renal pathological damage following LPS injection. Embelin could inhibit translocation of phosphorylated NF- $\kappa$ B p65 in LPS-induced AKI *in vivo* and *in vitro*. Embelin also reduced the secretion of IL-1 $\beta$  and IL-6 whereas increased the secretion of IL-10 and Arg-1 both in BMDMs and murine serum after LPS induction.

**Conclusions:** It indicated that Embelin could suppress macrophage M1 activation and promote M2 polarization in LPS-induced AKI. Thus, Embelin could attenuate LPS-induced septic AKI by suppress of NF- $\kappa$ B p65 phosphorylation and regulated macrophage activation. This study suggested the potential therapeutic role of Embelin for septic AKI patients.

## FR-PO154

### Uromodulin and Injury Severity Alter Neutrophil Diversity and Signaling in AKI

Seth Winfree,<sup>1</sup> Kaice A. LaFavers,<sup>2</sup> Shehnaz Khan,<sup>2</sup> Radmila Micanovic,<sup>2</sup> Ricardo Melo ferreira,<sup>2</sup> Ying-Hua Cheng,<sup>2</sup> Michael T. Eadon,<sup>2</sup> Tarek M. El-Achkar.<sup>2</sup> *<sup>1</sup>University of Nebraska Medical Center, Omaha, NE; <sup>2</sup>Indiana University School of Medicine, Indianapolis, IN.*

**Background:** Neutrophils are central to the pathogenesis of acute kidney injury (AKI). Neutrophil subtypes have been described in infection, cancer, and sterile inflammation. Little is known about the role of neutrophil subtypes in AKI. The kidney is uniquely poised to affect neutrophil subtypes via Uromodulin (UMOD)-a protein made exclusively in the thick ascending limb and modulator of granulopoiesis. To explore a role for neutrophil subtypes and the impact of UMOD in AKI, we interrogated kidneys after ischemic injury in wild-type (WT) and UMOD knock-out (KO) mice with mesoscale confocal microscopy and single-cell and spatial transcriptomics.

**Methods:** Kidneys from WT or UMOD KO mice after Sham or 22- or 30-min ischemic injury were frozen in OCT for spatial transcriptomics, fixed for microscopy, or processed for single-cell RNASeq (whole kidney and CD45+ enriched cell suspensions). Sequencing results were processed with Cell Ranger and analyzed in Seurat (cell types), ReactomePA (pathways), Monocle (trajectories) and SPOTLight (deconvolution). Confocal microscopy was performed on whole kidney sections using the nuclear stain DAPI and markers of neutrophils, transcription factors and injury and cells were quantitated with tissue cytometry (Volumetric Tissue Exploration and Analysis).

**Results:** Neutrophil localization in the kidney in AKI was sensitive to injury severity and absence of UMOD. Transcriptionally, 7 distinct neutrophil subtypes were uncovered. Further, the proportions and pathway activation of these subtypes and neutrophil transcriptional trajectories were sensitive to the severity of ischemic injury. In severe injury there was an increase in putative immature neutrophils and CXCL3 expression in neutrophils. In injury of UMOD KO mice, neutrophils were retained in the cortex and CXCR2 ligands were uniquely upregulated in proximal tubule epithelia.

**Conclusions:** Our study uncovers an underappreciated diversity of neutrophil subtypes in AKI that is sensitive to injury severity and UMOD. We demonstrate unique subtypes of neutrophils in AKI correlated with changes in neutrophil localization and concomitant alterations in the CXCR2 signaling axis. Thus, our results suggest the neutrophil response in AKI is nuanced and modulated by injury severity and UMOD via the CXCR2 signaling axis.

**Funding:** Veterans Affairs Support

## FR-PO155

### AKI Post Allogeneic Bone Marrow Transplantation: Disease Understanding and Targeted Nanomedicines

Magdalini Panagiotakopoulou, Edgar A. Jaimes, Marcel M. Van den brink, Daniel A. Heller. *Memorial Sloan Kettering Cancer Center, New York, NY.*

**Background:** Allogeneic hematopoietic stem cell transplantation (allo-HCT) is a very effective treatment for a variety of hematologic malignancies, but also associated with serious complications, such as graft-versus-host-disease (GVHD), a severe immune condition that manifests in multiple organs including the kidneys. Kidney injury in the setting of allo-HCT has an incidence as high as 80% and leads to high patient morbidity and mortality, however, its progression and mechanisms remain poorly characterized. Moreover, no approved drugs for AKI of any etiology exist, as most experimental therapies have poor pharmacokinetic profiles and minimal efficacy in treating AKI in humans.

**Methods:** We used an MHC-disparate irradiation-conditioned murine model of GVHD to investigate the pathology, genetic and molecular signatures of GVHD-mediated AKI, via bulk RNA sequencing, immunohistochemistry and immunoassays. We have also used microfluidics to synthesize lipid nanoparticles that target overexpressed proteins in the GVHD kidneys.

**Results:** Our transcriptome analysis in kidney lysates of GVHD mice indicated significant immune and inflammatory pathway upregulation (including TNF-NF- $\kappa$ B and JAK-STAT pathways) which persisted for 14 days after transplantation. We also saw a significant increase in genes associated with renal damage and pro-fibrotic cascades. Our histological analysis demonstrated increased T-cell infiltration, apoptosis and renal damage and abnormal renal function was confirmed by elevated serum and urine biomarkers. By designing lipid nanoparticles that target overexpressed proteins in GVHD kidneys, we achieved enhanced localization of nanoparticles to the kidneys in the GVHD model.

**Conclusions:** We have investigated the histological and molecular features of AKI in an established murine model of GVHD to assess its pathophysiology and progression as well as to identify potential therapeutic targets. GVHD results in AKI characterized predominantly by T-cell infiltration, tubular gene dysregulation, renal function impairment and activation of inflammatory pathways. We have also shown that targeting specific overexpressed proteins specifically localizes nanoparticles to GVHD-AKI kidneys. We plan to use those nanoformulations to deliver small-molecule inhibitors of dysregulated pathways to the kidneys.

**Funding:** Other NIH Support - T32 Cancer Pharmacology Grant

## FR-PO156

**Immune Complex Tubulointerstitial Nephritis: An Unusual Presentation of Anti-LRP2 Nephropathy**

Fnu Fawad,<sup>1</sup> Taha Ayach,<sup>1</sup> A. Bernard Collins.<sup>2</sup> <sup>1</sup>University of Kentucky, Lexington, KY; <sup>2</sup>Massachusetts General Hospital, Boston, MA.

**Introduction:** Anti-LRP2 nephropathy/anti-brush border antibody (ABBA) disease is a recently described immune complex tubulointerstitial nephritis. It is characterized by renal failure with tubular injury, tubular basement membrane immune deposits and circulating antibodies to proximal tubular brush border. The antigen target for ABBA has recently been identified as LDL receptor-related protein 2 which is present in proximal tubular brush border. We present a case of immune complex TIN with biopsy features suggestive of anti-LRP2 nephropathy but no ABBA in the serum.

**Case Description:** A 76-year-old male with past medical history of myasthenia gravis was evaluated for unexplained worsening of renal function. His sCr had increased from 1.2 to 2.7 over 1.5 years. He had microscopic hematuria and minimal proteinuria. Serological workup showed positive ANA with a titer of 1:80 with speckled pattern, negative anti dsDNA, normal C3 and C4, negative ANCA, MPO and PR3 and normal IgG 4 level. Kidney biopsy was performed which showed chronic tubulointerstitial nephropathy with extensive IgG deposits and segmental membranous nephropathy. IF microscopy showed extensive TBM deposits of IgG, in addition to segmental membranous nephropathy. This combination of findings was felt to be suggestive of anti-LRP2 nephropathy. However, patient's serum when tested, was negative for ABBA. Patient was started on prednisone 60 mg daily which was tapered two months after initiation due to complicating nocardia infection. No further disease specific treatment was given for his ABBA disease, but on follow up his renal function has remained relatively stable with most recent sCr of 2.6.

**Discussion:** Although biopsy features in this case were suggestive of anti-LRP2 nephropathy, serum was negative for ABBA. It is noteworthy that testing for ABBA is not commercially available and was done in a research laboratory and sensitivity is not well established. Absence of serum ABBA in this case could also indicate the possible onset of spontaneous remission, which will also explain the relatively stable renal function more than one year after diagnosis. It is also possible that antibodies to antigens other than LDL receptor-related protein 2 may be playing a role in the pathophysiology of ABBA disease. Our case highlights the need for further investigation into the association of ABBA with anti-LRP2 nephropathy.

## FR-PO157

**Urinary Single-Cell Sequencing Captures Intrarenal Injury and Repair Processes in Human AKI**

Jan Klocke,<sup>1</sup> Seung J. Kim,<sup>2</sup> Christopher Skopnik,<sup>1</sup> Christian Hinze,<sup>1</sup> Leonie F. Wagner,<sup>1</sup> Luka Prskalo,<sup>1</sup> Emil Grothgar,<sup>1</sup> Nina Goerlich,<sup>1</sup> Kai M. Schmidt-Ott,<sup>1</sup> Kai-Uwe Eckardt,<sup>1</sup> Nikolaus Rajewsky,<sup>2</sup> Philipp Enghardt.<sup>1</sup> <sup>1</sup>Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>Max-Delbrück-Centrum für Molekulare Medizin in der Helmholtz-Gemeinschaft, Buch, Germany.

**Background:** Acute kidney injury (AKI) is a major health issue, the outcome of which depends primarily on damage and reparative processes of tubular epithelial cells (TEC). Mechanisms underlying AKI remain incompletely understood, specific therapies are lacking and monitoring the course of AKI in clinical routine is confined to measuring urine output and plasma levels of filtration markers.

**Methods:** Here we demonstrate feasibility and potential of a novel approach to assess the cellular and molecular dynamics of AKI by establishing a robust urine-to-single cell RNA sequencing (scRNAseq) pipeline for excreted kidney cells via flow cytometry sorting. We analyzed 42,608 single cell transcriptomes of 40 urine samples from 32 AKI patients and compared our data with reference material from human AKI post-mortem biopsies and published mouse data.

**Results:** We demonstrate that urine-excreted TEC are mostly derived from distal nephron segments and are more abundant in patients with severe kidney injury. Their transcriptomes mirror intrarenal pathology and reflect distinct injury and repair processes, including oxidative stress, inflammation, and tissue rearrangement. We also describe a potentially AKI-specific abundant urinary excretion of adaptive progenitor-like cells.

**Conclusions:** In conclusion, single cell transcriptomics of kidney cells excreted in urine provides non-invasive, unprecedented insight into cellular processes underlying AKI, thereby opening novel opportunities for target identification, AKI sub-categorization and monitoring of natural disease course and interventions.

## FR-PO158

**Decreasing Kidney Injury by Maintaining Na/K-Pump Functions Using Electric Energy**

Lei Wang, University of South Florida, Tampa, FL.

**Background:** Renal ischemia-reperfusion injury is an important contributor to the development of delayed graft function, which is associated with higher rejection rates and worse long-term outcomes of the allografts. One of the earliest impairments during ischemia is insufficient ATP supply-induced Na/K pump dysfunction, which results in subsequent cellular damage. Consequently, strategies that preserve ATP levels or Na/K pump function may limit the extent of renal injury during ischemia-reperfusion.

**Methods:** In this study, we developed a novel technique that applies an oscillating electrical field to first synchronize the Na/K pump molecules, and then modulate their pumping rates. We dubbed this technique as the synchronization modulation electric field (SMEF). We present this novel technique of using electric energy to substitute ATPs in fueling and activating the pumps, thereby efficiently maintaining cellular functions under ATP insufficient conditions. We tested the effectiveness of this technique in different models of ischemic renal injury in rodents and pigs, including an *in situ* renal ischemia-reperfusion injury model (predominantly warm ischemia) and the kidney transplantation rodent and swine models (predominantly cold ischemia).

**Results:** Our results show that application of the specially designed electric field effectively delayed ATP depletion during the ischemia and preserves Na/K pump activity, thereby alleviating kidney injury by about 45% (plasma creatinine of  $1.17 \pm 0.04$  and  $1.97 \pm 0.06$  mg/dL for electric field treated and untreated groups, respectively) and improving renal allograft function by over 50% compared with the controls.

**Conclusions:** This novel technique for preserving Na/K pump function may have therapeutic potential not only for ischemic kidney injury, but also for other diseases associated with dysfunction of Na/K pumps.

## FR-PO159

**Identification of Hub Biomarkers and Inflammation-Related Pathways Participating in the Progression of AKI**

Qiuju Chen, Xiao Zhang, Zhenjian Xu, Anping Xu, Sun Yat-Sen Memorial Hospital, Guangzhou, China.

**Background:** Acute kidney injury (AKI) is a common, potentially devastating condition associated with markedly increased morbidity and mortality. We aim to identify key biomarkers involved in the progression of AKI and search for potential therapeutic target.

**Methods:** Microarray datasets GSE87025 and GSE192532 were integrated and batch effect was removed through ComBat. Hub markers for AKI were mined based on differential expression analysis, weighted gene co-expression network analysis (WGCNA) and lasso regression, followed by GO and KEGG term analysis. The results were further validated in GSE81741 and GSE153625.

**Results:** A total of 474 differential genes were screened. Eight co-expression modules were obtained via WGCNA; of which, blue module had the highest correlation with AKI. A total of 270 intersecting genes were acquired by combining differential genes. Six hub markers (Serpina3n, Rrad, Lgals3, Il1rn, Slc34a2, Micall2) were subsequently obtained by lasso analysis as potential biomarkers for AKI. ROC curve analysis demonstrated a prime diagnostic value of the six hub markers. According to the functional enrichment analysis of the differential genes, hub markers were mainly elevated in inflammation-related pathways.

**Conclusions:** Six hub markers were identified which might be involved in the progression of AKI via inflammation-related signal pathways. Further studies are needed to validate our findings and explore effective strategies for AKI targeting these hub genes.

**Funding:** Government Support - Non-U.S.

**Redox Imbalance and Mitogen-Activated Protein Kinase (MAPK) Activation Mediates Pneumoperitoneum-Induced Kidney Injury**

Charbel Chalouhy,<sup>1,2</sup> Youakim Saliba,<sup>2</sup> Joelle Hajaj,<sup>2</sup> Maria Ajaimy,<sup>1</sup> Nassim Fares.<sup>2</sup> <sup>1</sup>Montefiore Medical Center, Bronx, NY; <sup>2</sup>Universite Saint-Joseph, Beirut, Lebanon.

**Background:** Given the widespread use of laparoscopic and robotic surgeries, the effects of pneumoperitoneum (PNP) - the cornerstone of abdominal minimally invasive surgery - on kidney function become of great interest. PNP during laparoscopy causes transient renal functional impairment via various detrimental factors, such as oxidative stress. We, therefore, investigated the oxidative signaling pathways inherent to PNP-induced kidney injury.

**Methods:** PNP was established at an intraperitoneal CO<sub>2</sub> pressure of 12 mmHg in Wistar rats (total = 45) randomly allocated into three groups: Sham (n=15), PNP1 (n=15), and PNP24 (n=15). PNP1 and PNP24 animals were sacrificed at one and 24 hours following PNP deflation, respectively. Renal histology, function, redox status, and signaling pathways were assessed.

**Results:** PNP induced kidney injury and dysfunction with altered KIM-1 profile. Both expression and activity of antioxidant (CAT, SOD1/2) and oxidant (NOS3) enzymes, lipid peroxidation, and renal RNA/DNA damage biomarkers revealed redox imbalance after PNP, with an excess H<sub>2</sub>O<sub>2</sub> production. Moreover, the antioxidant gene regulators FoxO3a and Nrf2 were activated (p<0.05). Nevertheless, PNP had no effect on the cellular apoptotic pathways Bcl2, Bid, Caspase 3 and 8. Finally, PNP stimulated the p38 and JNK mitogen-activated protein kinase (MAPK) pathways in the kidney (p<0.05).

**Conclusions:** Our results demonstrate for the first time that PNP induces acute kidney injury due to renal redox imbalance linked to MAPK activation. These insights may open the way for further investigation into the renal therapeutic impact of managing PNP-associated oxidative stress during minimally invasive surgery requiring pneumoperitoneum.

## FR-PO161

**Erythropoietin and Its Derived Peptide Helix B Surface Peptide in Ischemia-Reperfusion Induced AKI, Repair, or Fibrosis**

Cheng Han,<sup>1</sup> Yuanyuan Wu,<sup>2</sup> Fei Chen,<sup>1</sup> Wenli Sai,<sup>1</sup> Bin Yang.<sup>3,1</sup> <sup>1</sup>Affiliated Hospital of Nantong University, Nantong, China; <sup>2</sup>Nantong University, Nantong, China; <sup>3</sup>University of Leicester, Leicester, United Kingdom.

**Background:** Ischemia-reperfusion (IR)-induced acute kidney injury (AKI) often progresses to chronic kidney disease. Erythropoietin (EPO) and its derivative, helix B surface peptide (HBSP), significantly ameliorates AKI, but may lead to different outcomes at the late stage and their underlying mechanisms remain unclear. The effects and mechanisms of single and/or multiple administrations of high-dose EPO and HBSP are studies in IR induced-AKI, repair or fibrosis.

**Methods:** Mouse kidney epithelial TCMK-1 cells were stimulated by hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) for 24 h or recombinant transforming growth factor  $\beta$  (TGF- $\beta$ ) for 72 h, to mimic IR-related acute and chronic kidney injury respectively, with or without the treatment of 25-800 IU/mL EPO or 10-80 ng/mL HBSP. In addition, a mouse renal IR model was established by obstructed bilateral renal pedicles for 30 min and reperused for 2 weeks. Mice were treated with 5000 IU/kg EPO at the onset of surgery and/or every 3 days onwards, or 24 nmol/kg HBSP only once. The protein level of HMGB1 and  $\alpha$ -SMA, renal function and histology were assessed.

**Results:** H<sub>2</sub>O<sub>2</sub> stimulation significantly increased HMGB1 expression in TCMK-1 cells at 24 h, which was decreased by 100 IU/mL EPO, but not 200-800 IU/mL EPO; and dose-dependently decreased by 20-80 ng/mL HBSP. TGF- $\beta$  treatment greatly raised the level of  $\alpha$ -SMA in TCMK-1 cells at 72 h, which was decreased by 50 IU/mL EPO, but not 100-800 IU/mL EPO, and gradually reduced by 20-80 ng/mL HBSP. In the *in vivo* model, HBSP and a single dose of EPO both markedly improved kidney function and structure, reduced HMGB1 and  $\alpha$ -SMA protein, but increased E-cadherin protein. However, the multiple high-dose EPO did not show such impact. In addition, HBSP, but not EPO, greatly increased p-STAT5 protein in IR kidneys. Furthermore, the single dose of HBSP and multiple doses of EPO downregulated EPOR/ $\beta$ cR expression in IR kidneys, which was not altered by the single usage of EPO.

**Conclusions:** The low dosage of EPO and HBSP reduced inflammatory and fibrotic mediators in TCMK-1 cells, while single usage of EPO and HBSP attenuated renal injury with HBSP further reduced fibrosis. The different long-term roles of both in IR kidneys may attribute to the status of STAT5 pathway, but exact underlying mechanisms including EPOR/ $\beta$ cR involvement still need to be further explored.

## FR-PO162

**Inhibition of EPRS Reduces Tubulointerstitial Nephritis-Induced Fibrosis via Suppression of T Cell Proliferation and  $\gamma\delta$  T Cell Activation**

Seung Seok Han,<sup>1,2</sup> Donghwan Yun,<sup>1,2</sup> Dong Ki Kim,<sup>1,2</sup> Kook-Hwan Oh,<sup>1,2</sup> Kwon Wook Joo,<sup>1,2</sup> Yon Su Kim.<sup>1,2</sup> <sup>1</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>2</sup>Seoul National University College of Medicine, Seoul, Republic of Korea.

**Background:** Acute tubulointerstitial nephritis (ATIN), characterized by interstitial infiltration of immune cells, ultimately makes patients undergo dialysis because of irreversible fibrosis, but the agents modulating interstitial immune cells are lacking. The present study addressed whether glutamyl-prolyl-transfer RNA synthetase (EPRS), attaching glutamine and proline to transfer RNA, modulates the immune cell activity on ATIN and its pharmacological inhibition abrogates fibrotic transformation.

**Methods:** Wild-type (WT) and hetero-knockout (*Eprs*<sup>+/−</sup>) mice were treated with adenine-mixed diet to induce ATIN, and their immune and fibrotic profiles were compared. Small molecule inhibitor against EPRS was used in both *in vivo* and *in vitro* models to validate its therapeutic prospect. Human ATIN samples were used to translate the mouse results.

**Results:** The EPRS expression in certain immune cell subsets strongly increased after the ATIN induction, such as proliferating T cells and  $\gamma\delta$  T cells. The proliferation capacity of both CD4<sup>+</sup> and CD8<sup>+</sup> T cells and the interleukin-17 production of  $\gamma\delta$  T cells decreased in ATIN-induced *Eprs*<sup>+/−</sup> kidneys compared with in the counterpart WT kidneys. This different immunological milieu in *Eprs*<sup>+/−</sup> kidneys lowered fibrotic transformation compared to in WT kidneys at the chronic phase of ATIN (Figure 1). The use of inhibitor against EPRS protected the above immunopathological process on ATIN. The inhibitor also reduced proliferation of human blood-derived T cells and activity of  $\gamma\delta$  T cells similarly to the mouse results. The high expression of EPRS in human kidneys with biopsy-proven ATIN correlated with overzealous tubulointerstitial fibrosis.

**Conclusions:** The increased expression of EPRS in infiltrated proliferating T cells and  $\gamma\delta$  T cells is immunofibrotic driver of ATIN. Pharmacological inhibition of EPRS attenuates both inflammation and subsequent fibrosis on ATIN via suppression of T cell proliferation and  $\gamma\delta$  T cell activation, which will be a potential option for treatment of ATIN.

### Pirfenidone Confers Effective Prophylaxis of Renal Ischaemia Reperfusion Injury

Timothy Bowen,<sup>1</sup> Usman Khalid,<sup>2</sup> David A. Foxwell,<sup>1</sup> Robert Andrews,<sup>1</sup> Gilda Pino-Chavez,<sup>2</sup> Rafael E. Chavez,<sup>2</sup> Donald Fraser.<sup>1</sup> <sup>1</sup>Cardiff University School of Medicine, Cardiff, United Kingdom; <sup>2</sup>University Hospital of Wales, School, United Kingdom.

**Background:** Pre-clinical models show that direct or indirect ischemic preconditioning (IPC) confer protection from subsequent ischemic acute kidney injury (AKI). Nevertheless, IPC has not proved effective in clinical trials involving individuals at elevated risk of AKI. Using a drug repurposing approach, we have identified six compounds suitable for clinical testing to detect evidence of IPC-like benefit.

**Methods:** We used RNA sequencing to analyse the renal transcriptome following direct and indirect IPC in a rat bilateral IRI model. A common protective signature was identified, and Ingenuity Pathway Analysis (IPA) was performed to predict drug repurposing candidates that would confer similar changes in gene expression profiles. The effects of predicted candidates were then evaluated in vivo.

**Results:** Three repeated cycles of two minutes ischaemia followed by five minutes reperfusion conferred optimum benefit with either direct or indirect pulsatile IPC. Subsequent whole kidney transcriptomic profiling of sham, IRI, direct-IPC/IRI and indirect-IPC/IRI (n = 6 per group) mapped to 16,780 unique genes, of which 2,193 were differentially expressed between IRI and sham. IPA attributed these observations to an acute renal failure phenotype (p = 1.3 x 10<sup>-37</sup>) and renal proximal tubular toxicity (p = 5.1 x 10<sup>-15</sup>). Master regulators and pathways identified within inflammatory response, oxidative stress and cell cycle were diminished following both direct and indirect IPC. Based on comparison with transcriptomic information available for over 23,500 biological drugs and chemical compounds, IPA identified six repurposing candidates with potential for clinical testing for IRI prophylaxis: AG490, diphenyleniodonium, pirfenidone, pyrrolidine dithiocarbamate, SP600125 and U0126, which were then evaluated further in vivo. All exhibited functional benefits when administered as a single prophylactic dose pre-IRI, but pirfenidone produced the most effective prophylaxis.

**Conclusions:** We have identified a protective gene expression signature common to direct and indirect IPC that provides novel mechanistic insights into the pathology of IRI injury and IPC protection. Using this dataset, computational transcriptional analysis has identified candidate drugs for repurposing for use in IRI prophylaxis, of which pirfenidone performed best.

## FR-PO164

### IL-22 Promotes Kidney Injury Through Activation of DNA Damage Response

Kensei Taguchi,<sup>1,2</sup> Sho Sugahara,<sup>1</sup> Bertha C. Elias,<sup>1</sup> Craig R. Brooks.<sup>1</sup> <sup>1</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>2</sup>Kurume Daigaku, Kurume, Japan.

**Background:** Acute kidney injury (AKI) occurs in up to 20% of hospitalized patients. Increased production of proinflammatory cytokine both predicts mortality in patients with AKI and worsens outcomes. Interleukin-22 (IL-22) is a member of IL-10 family whose receptor, (IL-22RA1), is expressed exclusively on epithelial or endothelial cells. In the kidney, IL-22RA1 expression is limited to proximal tubule cells (PTCs). Recently, IL-22 has shown to regulate the DNA damage response (DDR). The DDR is known to act as a double-edged-sword in AKI. While DNA repair is necessary for recovery from AKI, overactivation of the DDR is a major contributing factor to cell death and worsens kidney injury.

**Methods:** 1; Nephrotoxic AKI was induced by repeated doses of aristolochic acid (AA) or single dose of cisplatin in 8 to 12-week-old male wild-type (WT) and IL-22 globally knockout mice. 2; To investigate kidney specific effect of IL-22, nephrotoxic AKI was induced in IL-22RA1 flox/flox; Six2-cre (IL-22RA1<sup>ΔPT</sup>) and IL-22RA1 flox/flox. 3; S31-201, an inhibitor of STAT3, was intraperitoneally injected into cisplatin-treated WT mice.

**Results:** IL-22 is upregulated ~500 fold in the urine of cisplatin treated mice with no increase in plasma levels. IL-22RA1 is predominantly expressed in S3 segment of PTCs in basal conditions and expands to S1-S2 segments in response to AKI. Deletion of IL-22 or its receptor nearly completely ameliorates kidney injury induced by cisplatin or AA. Analysis of the kidney tissue reveals reduced apoptosis and kidney injury markers. DDR activation, as measured by phosphorylation of p53 and Ataxia telangiectasia mutated (ATM), is reduced in both IL-22 knockouts and IL-22RA1<sup>ΔPT</sup>. Mechanistically, IL-22 induces activation of STAT3 to trigger the DDR and subsequent apoptosis, which was blocked by STAT3 inhibitor S31-201 in vitro and in vivo.

**Conclusions:** Our results demonstrate that in the absence of IL-22 or its receptor, the nephrotoxic effects of cisplatin or AA are ameliorated. The engagement of IL-22 to IL-22RA1 activates STAT3 to induce DDR signaling, p53 and ATM, resulting in increased apoptotic. Thus, targeting IL-22 can reduce the negative effects of STAT3, p53, and ATM activation in AKI, without interfering with their basal homeostatic functions, providing a safe alternative to targeting these pathways directly.

## FR-PO165

### Influenza A(H1N1)pdm09 Reaches the Kidney, Altering Immune Responses Without Causing Direct Tissue Injury

Holly Stowell-Connolly,<sup>1</sup> Abigail C. Lay,<sup>1</sup> Rachel Burt,<sup>1</sup> Elizabeth Oliver,<sup>2</sup> Anu Goenka,<sup>2</sup> Richard Coward.<sup>1</sup> Bristol Renal <sup>1</sup>University of Bristol Faculty of Health Sciences, Bristol, United Kingdom; <sup>2</sup>University of Bristol School of Cellular and Molecular Medicine, Bristol, United Kingdom.

**Background:** In 2009, a novel Influenza A(H1N1) virus caused the first pandemic of the twenty-first century. Patients commonly presented mild phenotypes, similar to seasonal influenza, however some developed complications requiring hospitalisation. Often critically ill patients exhibited major renal sequelae of acute kidney injury (AKI), leading to renal failure. Injury progression is poorly understood, with debates over development originating from direct viral infection of renal cells or pre-renal systemic inflammation.

**Methods:** Renal tissue and urine was taken from Babraham pigs (n=54) either daily (0-13 days) or weekly (0-3 weeks) following intranasal Influenza A(H1N1)pdm09 infection. IHC determined histological status of kidney tissue. Influenza A mRNA and nucleoprotein were detected by *in situ* hybridisation and IHC, respectively. Presence of H1N1 mRNA within urine was determined using qRT-PCR. Localised renal pro-/anti-inflammatory cytokine expression profiles were developed using qRT-PCR. CD4<sup>+</sup> and CD8α<sup>+</sup> T-cell infiltration and IgA deposition were detected by IF.

**Results:** Viral mRNA and protein was detected within kidney tissue at 1-6 days post-infection, similar to the timeline in respiratory tissue. Despite this, IHC revealed microscopic renal structure to be unchanged at all time points, with no evidence of necrosis/fibrosis. Consistent with this, pro-inflammatory cytokine mRNA decreased one-week post-infection (TNF-α, IFN-β, IFN-γ, and IL-4; p<0.05). Expression recovers after 7-14 days, often reaching levels greater than control (TNF-α, IFN-γ, IL-2, IL-4; p<0.05). Interstitial infiltration of CD4<sup>+</sup> and CD8α<sup>+</sup> cells, together with glomerular deposition of IgA, follows a similar trend (CD4 and IgA p<0.05). Urine samples were absent of H1N1 mRNA.

**Conclusions:** This work creates an infection timeline within the porcine renal system and highlights the ability of the influenza A(H1N1)pdm09 virus to reach the kidney without causing direct injury. Viral presence within renal tissue is cleared one-week post-infection, corresponding with a localised dampening of the immune system. This work demonstrates a direct role of Influenza A(H1N1)pdm09 in the kidney, and with current literature documenting AKI in COVID-19 patients, it is important to understand how respiratory viruses can contribute to AKI and mortality.

## FR-PO166

### Characterization of Regulatory B Cells and IL-10 in Response to Ischemic Reperfusion

Yunosuke Yokota, Kensei Taguchi, Sakuya Ito, Goh Kodama, Kei Fukami. Kurume Daigaku Igakubu Daigakuin Igaku Kenkyuka, Kurume, Japan.

**Background:** Acute kidney injury (AKI) occurs in up to 20% of hospitalized patients. Interleukin-10 (IL-10), an anti-inflammatory cytokine, modulates the progression of AKI via reducing pro-inflammatory cytokines including TNF-α and IL-6. Regulatory B cells (Breg) is considered a main source of IL-10. Breg is a subset with a CD1d<sup>hi</sup>CD5<sup>+</sup>CD19<sup>hi</sup> phenotype and comprises 1-3% of B cells in mouse spleen with smaller numbers in the blood, lymph nodes, intestine, and peritoneum under basal condition. However, the distribution of Breg in response to AKI remains unknown. Thus, we investigated Breg infiltration into ischemic reperfusion (IR) kidneys and examined the expression pattern of IL-10-producing cells.

**Methods:** Experiment 1; To study if Breg infiltrates into IR kidneys, IR was constructed by clamping left renal artery for 30 minutes in IL-10-IRES-GFP mice. The kidneys were isolated on day 1, 7, 14, 28, 42, and 70 after the surgery. Breg expression was examined by immunofluorescence staining. IL-10 expression was evaluated by real-time PCR. Experiment 2; A splenectomy was performed 7 days before ischemia IR surgery to investigate if splenectomy inhibits Breg infiltration.

**Results:** IL-10 was increased immediately after IR surgery and sustained until day7 in parallel with an increase in tubular injury. We identified that splenectomy did not attenuate renal dysfunction and fibrosis without any change in serum IL-10. Also, the increase in renal IL-10 mRNA was not altered by splenectomy. Large scan images demonstrated that number of interstitial GFP<sup>+</sup> cells in IR kidneys was increased from day7 when compared to sham kidneys and remained high until chronic phase. We also found that GFP signal in mesangial area of uninjured kidneys; however, the GFP expression disappeared after IR surgery. This finding indicates that mesangial cells in IR kidneys might produce IL-10 which is inhibited by IR injury.

**Conclusions:** We identified that IL-10 mRNA is upregulated in response to IR injury with an increase in number of interstitial GFP<sup>+</sup> cells. Mesangial cells might be capable of producing IL-10 which is inhibited by IR injury. Renal infiltration of IL-10-producing cells may be independent of spleen.

## FR-PO167

## NLRP3 Inflammasome Inhibition Decreases NETosis in AKI

David C. Tomaz, Asha Seth, Ricardo Parsons, Lorraine M. Irving, Lorraine Miller, Pernille B. Laerkegaard Hansen, Kevin Woollard. Biosciences Renal AstraZeneca PLC, Cambridge, United Kingdom.

**Background:** Kidney macrophages and neutrophils are inflammasome effector cells which can drive renal injury through expression of pro-inflammatory cytokines and formation of neutrophils extracellular traps (NETs). Acute kidney injury (AKI) is associated with NETs formation (NETosis), and a significant number of neutrophils infiltrate during the early injury stage, amplifying the inflammatory response. Different studies have shown an association between inflammasome activation and NETosis. Whether and how inflammasome inhibition affects NETosis-mediated injury and mechanisms of renal dysfunction remains to be fully explored.

**Methods:** We studied the role of NLRP3 inhibition and its effects on the kidney neutrophil infiltrate and kidney function in-vivo using an acute lipopolysaccharide (LPS) injury mouse model. In this model, mice were dosed with LPS (6mg/kg) or a saline solution intraperitoneally for 18 hours. Blood, urine and kidneys were collected and analysed. In vitro, we studied NETs using live cell imaging with SYTOX Green and histone staining. We further investigated mechanisms of NETs injury on renal proximal tubular endothelial cells (RPTCs) in-vitro using conditioning medium indirect co-cultures.

**Results:** In-vitro treatment with NLRP3 inhibitor (MCC950) dose-dependently reduced NET formation over 14 hours using LPS/ Nigericin and PMA inflammasome triggers. In vivo, MCC950 decreased plasma IL-1 $\beta$  and IL-18 and urinary IL-18 and protected against renal dysfunction induced by LPS, as evidenced by reduced plasma creatinine and blood urea nitrogen (BUN). Flow cytometry analysis showed a decreasing trend in myeloid infiltration and activation into the kidney. Interestingly, BUN and plasma creatinine correlated with the neutrophil infiltrate. More work is underway to characterise kidney NETs ex-vivo and PTEC injury in-vitro.

**Conclusions:** Our preliminary data suggests neutrophil infiltrate and NETs formation may accelerate tubular cell injury and death, promoting kidney dysfunction. In conclusion, we have demonstrated that NLRP3 inflammasome inhibition reduces kidney inflammation and inhibits NETosis-mediated kidney injury. The role of neutrophils as key effector cells and NLRP3 inflammasome pathway in kidney diseases warrants further investigation.

## FR-PO168

## pNaKtide Ameliorates Systemic Inflammatory Response in Murine Model of Sepsis by Antagonism of Na,K-ATPase Signaling

Duane G. Pereira, Sneha S. Pillai, Muhammad A. Chaudhry, Joseph I. Shapiro, Komal Sodhi. Marshall University Joan C Edwards School of Medicine, Huntington, WV.

**Background:** Inflammatory processes and oxidative stress play a central role in the development and progression of sepsis, which can lead to multiple organ dysfunction. Hence, the use of strategies to limit this systemic inflammatory response, can be interesting in the development of an effective sepsis therapy. In this context, our research group recently demonstrate that the NaK-ATPase signaling can exacerbate inflammation and oxidative stress process and that pNaKtide, an antagonist of NaK-ATPase, is able to improve pathophysiological abnormalities. The objective of this work is to demonstrate the involvement of NaK-ATPase signaling in increase inflammatory response and oxidative stress and to demonstrate the effect of pNaKtide administration in experimental model of sepsis, induced by cecal ligation and puncture (CLP), as a drug against septic shock.

**Methods:** Male C57BL/6 mice were used to induced experimental sepsis by CLP with or without, IP administration of pNaKtide (25mg/kg body wt) 24h before CLP surgery. Sham surgeries were performed and used as control for the CLP model. The severity of sepsis was assessed using the Murine Sepsis Score (MSS) at baseline, 4h, 8h and 24h after surgery for Sham and CLP. After 24h of Sham or CLP surgeries the mice were euthanized, blood was used for analysis of inflammatory markers and kidney was collected for biochemistry and morphological analysis.

**Results:** Systemic administration of pNaKtide was able to significantly improve the MSS after CLP surgery, as compared to CLP mice without pNaKtide injection. Histological analysis of kidney tissues by H&E staining showed a decrease in congestion, inflammatory infiltrate and hemorrhage in CLP mice with pNaKtide injection, as compared to CLP. As well, improved mRNA expression of inflammatory and macrophage infiltration markers, in kidney tissues of CLP mice. The pNaKtide administration also improved plasma levels of creatinine and urea, markers of kidney function.

**Conclusions:** Our study demonstrated that antagonism of Na,K-ATPase signaling by pNaKtide can attenuate the progression of CLP-induced sepsis by inhibiting the inflammatory process usually noted in this condition. Therefore, Na,K-ATPase signaling may serve as a viable clinical target for therapeutic intervention of sepsis and associated inflammatory mechanisms.

## Co-Registered Spatial Proteomics and Transcriptomics Identifies Scattered Proximal Tubule Cells

Michael T. Eadon,<sup>1</sup> Ricardo Melo ferreira,<sup>1</sup> Seth Winfree,<sup>5</sup> Blue Lake,<sup>4</sup> Ying-Hua Cheng,<sup>1</sup> Carrie L. Phillips,<sup>1</sup> Samir V. Parikh,<sup>2</sup> Daria Barwinska,<sup>1</sup> Michael J. Ferkowicz,<sup>1</sup> Angela R. Sabo,<sup>1</sup> Debora L. Gisch,<sup>1</sup> Timothy A. Sutton,<sup>1</sup> Ken Dunn,<sup>1</sup> Mahla Asghari,<sup>1</sup> Brad H. Rovin,<sup>2</sup> Katherine J. Kelly,<sup>1</sup> Sanjay Jain,<sup>3</sup> Pierre C. Dagher,<sup>1</sup> Tarek M. El-Achkar,<sup>1</sup> Kidney Precision Medicine Project <sup>1</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>2</sup>The Ohio State University College of Medicine, Columbus, OH; <sup>3</sup>Washington University in St Louis, St Louis, MO; <sup>4</sup>University of California San Diego, La Jolla, CA; <sup>5</sup>University of Nebraska System, Lincoln, NE.

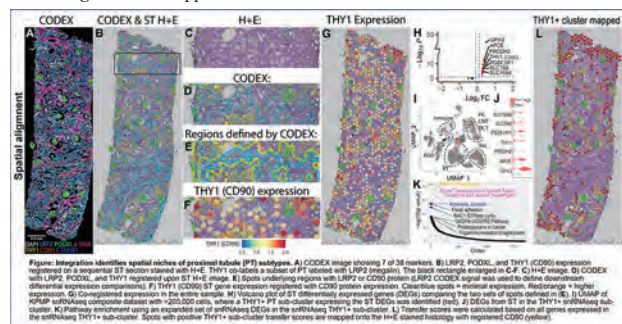

**Background:** THY1 (CD90) is a marker of mesenchymal stem cells. THY1 is expressed in the kidney and postulated to be upregulated in regenerative scattered tubular cells (STCs) of the proximal tubule (PT). The merged KPMP/HubMAP snRNAseq atlas does not contain a specific STC cluster. Using co-registered spatial transcriptomics (ST) and CO-Detection by indEXing (CODEX) immunofluorescence, we identified this STC sub-cluster within the snRNAseq atlas.

**Methods:** On consecutive sections of human kidney tissue (10  $\mu$ m thick, N=3), CODEX (44 antibodies including THY1 and megalin) and ST (>20,000 genes detected) were performed and co-registered to spatially align protein and gene expression. Protein expression of THY1 and megalin defined regions for downstream ST comparison. Using ST, THY1+ megalin+ regions were compared to THY1- megalin+ regions. Differentially expressed ST genes (DEGs) were used to define a novel subcluster in the snRNAseq atlas.

**Results:** A novel STC subcluster was defined within the snRNAseq atlas. DEGs of STCs included *THY1*, *SLC16A9*, and *PDZK1IP1*. STC enriched pathways included Rho GTPase cycle, RAC1, growth factor signal transduction, and cell adhesion related pathways, consistent with the expected functions of this regenerative cell. Using Seurat anchor methodology, the *THY1*+ sub-cluster, defined by snRNAseq, mapped back to regions of THY1 protein expression.

**Conclusions:** The integration of CODEX, ST, and snRNAseq datasets facilitated the identification of an important PT cell type which was under-represented in the KPMP snRNAseq atlas.

## FR-PO170

## Recombinant High-Density Lipoprotein Modulates Inflammatory Response and Renal Dysfunction in a Swine Model of Sepsis-Induced AKI

Alessandra Stasi, Rossana Franzin, Marco Fiorentino, Fabio Sallustio, Loreto Gesualdo. Università degli Studi di Bari Aldo Moro, Bari, Italy.

**Background:** Sepsis is a severe and dysregulated inflammatory disease that often precedes the development of acute kidney injury (AKI) with consequent worsening outcome. Although clinical data demonstrate that high-density lipoprotein (HDL) levels drop in septic patients with a poor prognosis, little is known about the molecular basis of HDL's role in systemic inflammation and renal function. Here we investigate whether the use of recombinant HDL, CER-001, is effective in reducing inflammation during sepsis and preventing AKI.

**Methods:** Sepsis was induced by intravenous infusion of a saline solution containing 300  $\mu$ g/kg of LPS in a porcine model. The animals were randomized into three groups: LPS (endotoxemic pigs, n=6), CER-001(20mg/kg) (LPS pigs treated with a single dose of CER-001 20mg/kg; n=6), and CER-001(40mg/kg) (LPS pigs treated with two doses of CER001 at time 0 and 3 hours later; n=6). Animals were sacrificed after 24h from the start of experimental procedure.

**Results:** We observed an increased survival rate in both CER-001 treated groups of pigs compared to the LPS group. Furthermore, LPS injection led to a time-dependent increase of IL-6 in endotoxemic animals with respect to basal condition (T0). CER-001 treatment was able to reverse LPS effects. In particular, the second infusion of CER-001 three hours after the first dose (T3) strongly reduced IL-6 serum levels back to basal level (LPS p<0.05). Similarly, we found high levels of TNF- $\alpha$ , MCP-1, sVCAM-1, s-ICAM-1 and ox-LDL in endotoxemic pigs that were significantly decreased in both CER-001 treatment arms. CER001 preserved liver and renal parenchyma, decreasing pathological scores of renal tubular and glomerular injury. Thus, CER-001 treatment preserved renal physiology, recovering urine output and decreasing creatine levels. Then, we evaluated the circulating LPS concentration in treated animals. We observed that LPS levels were

greatly reduced in treated animals and the effects are more evident after the second infusion of CER-001. Therefore, we also examined LPS levels in bile samples and we observed a dose-dependent increasing amount of endotoxin in the CER001 treated pigs.

**Conclusions:** The nephroprotective regimens with CER-001 may be a promising therapeutic approach for future sepsis induced-AKI treatment.

## FR-PO171

### GDF-15/GFRAL Axis, Survival, and Kidney Protection in Lipopolysaccharide and Folic Acid Nephropathy in Mice

Henriette Frikke-Schmidt, Rong Meng, George Ho, Krista P. Farrington, Alessandro Pocai, Shannon Mullican. Cardiovascular, Metabolism and Retina Therapeutic Area, Janssen Research & Development *Janssen Research and Development LLC, Spring House, PA.*

**Background:** GFRAL, the receptor for Growth/differentiation factor-15 (GDF-15), is expressed only in the hindbrain and while this axis regulates food intake, the role of GFRAL in described reno-protective effects of GDF-15 is not well understood. Overexpression of GDF-15 has been shown to protect against lipopolysaccharide (LPS) induced acute kidney injury and mortality in mice, but it is not confirmed if this is mediated through GFRAL. To explore this, we assessed survival and kidney injury in GDF-15 overexpressing (hNAG-1 mouse line generated by Prof. Thomas Eling) or GFRAL deleted (GFRAL<sup>-/-</sup>) mice challenged with LPS or folic acid (FA)

**Methods:** hNAG-1 mice and wild type (WT) controls were given 12 mg/kg of intraperitoneal (IP) LPS and monitored for survival. Acute kidney damage was induced in GFRAL<sup>-/-</sup> mice and WT controls by IP administration of LPS (200 ug for survival, 250 ug for kidney function) or FA (250 mg/kg) and monitored for survival, plasma creatinine (pCre), blood urea nitrogen (BUN) and proteinuria.

**Results:** **Survival:** 72 hours after LPS, 86% of hNAG-1 mice were alive compared to only 39% of WT (p=0.0071 Log-rank test). LPS treated GFRAL<sup>-/-</sup> mice did not show significantly different survival versus WT controls (47% vs 79%, no significant difference Log-rank test). 7 days after FA administration, only 33% of the GFRAL<sup>-/-</sup> mice survived compared to 78% of WT mice (p=0.0146 Log-rank test). **Kidney function:** 24 hours after LPS plasma pCre in the GFRAL<sup>-/-</sup> mice was increased versus WT controls (0.41±0.166 vs 0.27±0.080 mg/dl, p=0.0094 unpaired t-test) whereas BUN remained unchanged (129±12.8 vs 120±15.7 mg/dl). 7 days after FA only 33% of the GFRAL<sup>-/-</sup> mice survived compared to 78% in WT mice (p=0.0146 Log-rank test). On day 2 after FA (before any deaths occurred) GFRAL<sup>-/-</sup> mice had highly elevated proteinuria (2224±2508 vs 42.6±21.9 µg/mg urine albumin creatinine ratio, p=0.0046 unpaired t-test), whereas levels of plasma pCre (8.0±3.1 vs 5.8±4.7 mg/dl) and BUN did not change (42±24 vs 53±29mg/dl).

**Conclusions:** We confirm that GDF-15 overexpression improves survival in LPS challenged mice and show that lack of GFRAL augments LPS and FA induced kidney damage. Our data supports the involvement of GFRAL signaling in the observed reno-protective effect.

### T Cell Metabolic Programming and Protection by Glutamine Blockade in AKI

Kyungho Lee, Elizabeth A. Thompson, Sepideh Gharraie, Chirag H. Patel, Johanna T. Kurzhagen, Andrea M. Newman-Rivera, Phillip M. Pierorazio, Lois J. Arend, Sanjeev Noel, Barbara S. Slusher, Hamid Rabb. *Johns Hopkins University School of Medicine, Baltimore, MD.*

**Background:** T cells participate in AKI pathogenesis. T cells are regulated by metabolic programming, less understood in AKI. Among metabolic pathways, glutaminolysis is particularly important for effector T cell function. We aimed to study kidney T cell metabolism during AKI and effects of glutamine blockade.

**Methods:** C57B6 mice underwent 30 min ischemia-reperfusion surgery or cisplatin injection. Germ-free (GF) mice were also studied to evaluate the effect of gut microbiota on T cell metabolism. Kidney T cells were isolated and studied by a flow cytometry-based immune-metabolic assay with interrogating artificial intelligence metabolic programs. Mice were treated with the glutamine antagonist JHU083 and effects on AKI were evaluated. Kidney sections were scored for tubular injury. In vitro studies were performed on FACS-sorted kidney T cell culture exposed to hypoxia-reoxygenation.

**Results:** T cells from postischemic kidneys showed a distinct T cell subset with low levels of mTOR and oxidative phosphorylation-related enzymes. Kidney T cells from GF mice exhibited global downregulation of multiple metabolic enzymes compared to those from wild-type mice. Blocking glutamine utilization with JHU083 improved functional and structural renal outcomes in ischemic (serum Cr at 24h, vehicle vs JHU083, 1.6±0.2 vs 1.1±0.1 mg/dL, P=.026; cortical necrosis, 6.6±0.9 vs 4.2±0.5 %, P=.039) and cisplatin-induced AKI (serum Cr at 72h, 2.3±0.3 vs 1.2±0.2 mg/dL, P=.016; outer medullary necrosis, 57.1±3.7 vs 19.9±4.5%, P<.001). CD4 T cells from post-AKI kidneys in JHU083 treated group were skewed toward naïve phenotypes with lower proliferation in both ischemic (CD44, 67.5±1.7 vs 56.3±1.9%, P<.001; CD62L, 29.0±1.6 vs 42.8±2.2%, P<.001; Ki67 58.7±2.9 vs 50.6±2.1%, P=.035) and nephrotoxic AKI (CD44, 50.2±3.4 vs 40.9±2.4%, P=.037; CD62L, 37.5±3.2 vs 52.5±3.0%, P=.005; Ki67, 54.4±3.6 vs 43.8±2.7%, P=.031). In vitro hypoxia-reoxygenation upregulated glycolysis-related enzymes in kidney T cells, and JHU083 inhibited CD3/CD28 stimulated proliferation.

**Conclusions:** AKI and as well the microbiome influence kidney T cell metabolic programming. Glutamine blockade with JHU083 improved ischemic and cisplatin-induced AKI outcomes, and is a promising novel therapeutic agent for AKI.

**Funding:** NIDDK Support

## FR-PO173

### Role of Double-Negative T Cells in Repair After Experimental Severe AKI

Kyungho Lee, Sepideh Gharraie, Johanna T. Kurzhagen, Lois J. Arend, Sanjeev Noel, Hamid Rabb. *Johns Hopkins University School of Medicine, Baltimore, MD.*

**Background:** T cells mediate organ injury and repair. A proportion of kidney αβ T cells are unconventional double-negative (DN) T cells (CD4<sup>+</sup> CD8<sup>-</sup>), which have anti-inflammatory properties previously demonstrated to protect from early injury in AKI. However, their role in repair from AKI has not been studied. We aimed to elucidate the role of DN T cells in AKI repair.

**Methods:** C57B6 mice underwent unilateral ischemia-reperfusion injury (IRI) surgery with 40 min ischemia. DN T cells, isolated from *Fas<sup>l</sup>Δ<sup>Δ</sup>* mouse lymph nodes, were adoptively transferred AFTER IRI. Vehicle (neg. control) or Tregs (pos. control, Kidney Int 2009 PMID: 19625990) were also injected. GFR was measured by FITC-sinistrin-based method. Fibrosis was assessed with Masson trichrome staining. Profibrotic genes were measured with quantitative RT-PCR. T cells from postischemic kidneys were studied by flow cytometry.

**Results:** Percentages and the numbers of DN T cells markedly decreased in postischemic kidneys at 3 weeks from IRI compared to normal kidneys (18.7±1.1 vs 6.9±0.5% of αβ T cells, P<.001, 5.9±0.6×10<sup>4</sup> vs 0.9±0.3×10<sup>4</sup> cells/kidney, P<.001). DN T cell CD44 (95.0±0.4 vs 90.8±0.7%, P<.001) and CD69 (94.1±0.3 vs 85.8±1.1%, P<.001) were reduced, while DN T immune checkpoint TIGIT (0.6±0.2 vs 2.5±0.5%, P=.005) and NK1.1 (35.9±2.6 vs 52.4±3.5%, P=.004) were upregulated. Post-AKI transfer of DN T cells improved renal recovery, as did Treg transfer, with 3 week-GFR of 1176±27 µL/min/100g (vehicle, 1076±25, P=.001; Treg 1217±42, P=.399) and outer medullary fibrosis of 64.5±2.3% (vehicle, 82.0±1.9, P<.001; Treg 45.4±9.3%, P=.058). *Tgfb1* was lower in the DN T cell transfer group (1.0±0.1 fold) than vehicle group (vehicle, 1.3±0.1, P=.012; Treg, 0.8±0.1, P=.226). Postischemic kidneys from DN T cell transferred mice had less effector memory CD4 T cells (94.7±0.2%) compared to those from vehicle group (vehicle, 96.9±0.3, P<.001; Treg 93.7±0.3%, P=.021). DN T cell transfer enhanced tubular proliferation, with higher Ki67 expression of CD45<sup>+</sup> E-cadherin<sup>+</sup> cells (73.4±1.1; vehicle, 68.5±1.2, P=.011; Treg, 71.8±2.2%, P=.304).

**Conclusions:** Kidney DN T cells undergo quantitative and phenotypical changes long-term after severe ischemic kidney injury. Post-injury infusions of DN T cells, like T regs, can hasten repair and decrease fibrosis. A potential mechanism is by regulating kidney CD4 T cells.

## FR-PO174

### RNA-Binding Protein HuR Regulates the Progression of Septic AKI by Modulating CD147

Davey Li, Anna Tang, Nisha Sharma, Yufeng Huang. *University of Utah Health, Salt Lake City, UT.*

**Background:** Septic AKI is one of the most common complications in critically ill patients with a high risk of developing CKD and no cause-specific treatment. Hu antigen R (HuR), an RNA-binding protein governing mRNA stability and translation, has been identified as a key modulator in inflammation. We hypothesized that the enhanced HuR/pro-inflammatory actor circuit is a crucial mechanism for the transition of septic AKI to CKD and inhibition of HuR may reverse septic kidney injury.

**Methods:** Sustained administration of LPS (5mg/kg BW, i.p. every other day)-induced mice (n=5/each group) were treated without or with HuR inhibitor, KH-39 (50mg/kg BW) or niclosamide (NCS, 10mg/kg BW) i.p. daily for 7 days. Normal mice injected with saline served as controls.

**Results:** Repeated injection of LPS to mice developed chronic kidney damage, including increase plasma BUN levels and urinary albumin/creatinine ratio by 2.98 and 2.52-folds respectively. Histologically, LPS-injured kidneys showed accumulative inflammatory cells (including F4/80+ macrophages) infiltration and fibronectin (FN) & collagen (Col) deposition. Both a-SMA and FN as the markers of renal fibrosis were markedly increased by 6.1 and 9.73-folds respectively determined by Western blot. Notably, a significantly increased HuR expression was observed in diseased kidney, which was inhibited by HuR inhibitor, KH-39 or NCS. Immunofluorescent staining for HuR confirmed the Western blot measurement. In addition, CD147 expressed in tubular cells is involved in kidney disease mainly associated with increase inflammatory cell recruitment at site of injury. As expected, expression of CD147 was increased by 2.28-folds in LPS-injured kidney tubular cells determined by Western blot and IF staining. Interestingly, this increase was inhibited by KH-39 or NCS. Inhibition of HuR with KH-39 or NCS further largely reduced the elevated plasma BUN levels and albuminuria, and tubular injury, inflammation and tubulointerstitial fibrosis, compared to the untreated LPS-injured mice (P<0.05).

**Conclusions:** These results suggest that HuR is increased in LPS-injured kidneys and the progression of septic AKI to CKD induced by persistent inflammation is strongly reduced by HuR inhibition, at least, through downregulating CD147 expression. This study may provide a proof-of-concept for repurposing HuR inhibitor as a new therapy for septic kidney injury.

## FR-PO175

**Intu Deficiency in Renal Tubules Delays Kidney Repair yet Suppresses Renal Fibrosis After Kidney Injury**

Shixuan Wang,<sup>1,2</sup> Zheng Dong,<sup>1,2</sup> <sup>1</sup>Augusta University, Augusta, GA; <sup>2</sup>Charlie Norwood Department of Veterans Affairs Medical Center, Augusta, GA.

**Background:** Intu is an effector protein of the planar cell polarity network that is essential for embryonic development and maintenance of normal organ functions. It was recently demonstrated that Intu plays a protective role in renal ischemia/reperfusion injury via interacting partner Stat1. However, the role of Intu in kidney repair and fibrosis remains unknown.

**Methods:** We have established an inducible Intu knockout mouse model that was exposed to doxycycline to ablate Intu specifically from kidney tubules (iRT-Intu-KO). iRT-Intu-KO mice and wild-type littermates were subjected to unilateral renal ischemia/reperfusion or ureteral obstruction injury. Kidney repair/recovery was evaluated by histological, biochemical, immunohistochemical and immunofluorescence approaches. In vitro, we examined Intu-knockdown proximal tubular cells.

**Results:** We found that ablation of Intu in renal tubules delayed kidney recovery and ameliorated renal fibrosis after renal ischemia/reperfusion injury. These mice also had less renal fibrosis during unilateral ureteral obstruction. We further found that senescence was suppressed while cell proliferation was increased in Intu knockout kidneys following renal ischemia/reperfusion injury. In cultured renal tubular cells, knockdown of Intu inhibited cell migration, accompanied by the abnormality of centrosome orientation.

**Conclusions:** Knockout of Intu suppressed kidney recovery and weakened fibrosis, associated with centrosome orientation abnormality and senescence inhibition. These findings suggest that planar cell polarity may contribute to tubular repair after kidney injury, shedding light on new strategies for improving kidney repair and recovery.

**Funding:** NIDDK Support, Veterans Affairs Support

## FR-PO176

**Use of Daratumumab in a Patient With Proliferative Glomerulonephritis With Monoclonal Immunoglobulin Deposition**

Akshith Doddi,<sup>1</sup> Dalia Y. Ibrahim,<sup>2</sup> Khaled Shawwa,<sup>1</sup> <sup>1</sup>West Virginia University, Morgantown, WV; <sup>2</sup>The Ohio State University, Columbus, OH.

**Introduction:** Monoclonal gammopathy of renal significance is a pathogenic entity associated with end stage kidney disease. Proliferative glomerulonephritis with monoclonal immunoglobulin deposition (PGNMID) results from deposition of a monoclonal immunoglobulin leading to kidney damage. Until recently there was no evidence to guide treatment. We report a case of a patient with PGNMID who responded well to daratumumab.

**Case Description:** This is a 57-year-old female with diabetes of 3 years duration and hypertension. She presented with worsening swelling of a couple weeks duration and was found to have anasarca. Her serum albumin was 1.4 mg/dL, serum creatinine 1.8 mg/dL and had 3-5 red blood cells per high power field in her urine. She was started on intravenous diuretics. Her 24-hour urine protein was 7.3 grams. Her complement levels C3 and C4, ANA, ANCA, hepatitis B and C were negative or normal. The patient's kappa (5.2 mg/dL) and lambda (2.7 mg/dL) free light chains were slightly elevated. Her urine and serum protein electrophoresis did not show a monoclonal protein. A kidney biopsy was done. There was moderate focal segmental mesangial expansion with hypercellularity with no endocapillary hypercellularity. Immunofluorescence (IF) showed moderate diffuse mesangial staining for IgG and C3 with kappa light chain restriction. IF with antibodies for IgG subclasses showed a predominantly IgG1 subclass staining. Electron microscopy revealed electron dense immune-type deposits in the mesangium and a few subepithelial and intramembranous deposits. The patient was diagnosed with PGNMID. A bone marrow biopsy and skeletal survey were negative. She was given rituximab. She was then referred 3 months later for a second opinion due to a continued nephrotic syndrome and decreased kidney function. She proceeded with daratumumab based on Zand et al protocol. After completing the first 8 doses, her creatinine improved to 1.5 mg/dL from 4 mg/dL at time of initial infusion. She continued to have proteinuria until after her 10<sup>th</sup> infusion, where it improved down to 0.6 grams. This was sustained after the 15<sup>th</sup> infusion (0.27 grams). During her treatment course with daratumumab, her side effects included transient nausea and vomiting, back pain, and constipation.

**Discussion:** The patient had complete remission with proteinuria <0.5 gram and improvement in her kidney function.

## FR-PO177

**Looking Beyond the Proteinuria**

Lauren Kring,<sup>1</sup> Alia Hasan,<sup>2</sup> <sup>1</sup>Carilion Clinic, Roanoke, VA; <sup>2</sup>VA Medical Center Salem, Salem, VA.

**Introduction:** Nephrotic syndrome usually raises concern for primary renal disorders such as membranous nephropathy, focal segmental glomerulosclerosis or minimal change disease. A careful history however, must be taken to evaluate for possible malignancy, especially in a patient with normal GFR. Here we present a case of nephrotic syndrome with normal renal function in whom malignancy was initially overlooked.

**Case Description:** A 64 year old white male with history of controlled hypertension and new onset diabetes mellitus, presented with leg swelling and was diagnosed with an acute left leg DVT. The edema also prompted his physician to order a 24-hour urine which showed 18g of proteinuria. Referral was made to Nephrology. He endorsed a 16 pound weight loss, "foamy" urine, right hand and left leg neuropathy for the past 2-3 months. He attributed his neuropathy to diabetes. Labs revealed Hgb 12.1 g/dL, serum creatinine

0.7 mg/dL, albumin 2.9g/dL. Anemia noted for past 4 months. He had mild proteinuria on urinalysis for about 1 year, which worsened 2 months prior; quantification not performed. Hgb A1c was under 6.5. Hepatitis B and C, ANA, dsDNA were negative. Serum protein electrophoresis, immunofixation, and free light chain ratio of 0.67 indicated monoclonal lambda proliferation. Renal biopsy contained 11 glomeruli: 1 globally sclerotic, others normal on light microscopy. Electron microscopy showed a normal basement membrane with 70% foot process effacement. CT imaging had multiple lytic bone lesions and bone marrow biopsy showed 85% plasma cells. He was diagnosed with multiple myeloma (MM) and started on pulse dose steroids, daratumumab (anti CD38) and RVD (lenalidomide, bortezomib, dexamethasone).

**Discussion:** While this patient's nephrotic syndrome was concerning for intrinsic renal disease, he also had new anemia, weight loss, asymmetric peripheral neuropathy and new DVT over a span of 4 months, concerning for underlying malignancy. Light microscopy findings on renal biopsy were consistent with minimal change disease (MCD). MCD is usually associated with hematologic or solid malignancies, but can occasionally be seen in MM. His renal disease therefore was secondary and malignancy related. After starting MM treatment, his proteinuria, edema and neuropathy resolved. This case illustrates the need to assess the patient as a whole and not just focus on one organ or syndrome.

## FR-PO178

**Unusual Course of Paraneoplastic IgA Nephropathy Associated With Squamous Cell Lung Cancer**

Mariam Charkviani, Pingchuan Zhang, Sandra Herrmann. *Mayo Clinic Minnesota, Rochester, MN.*

**Introduction:** Immunoglobulin A nephropathy (IgAN) is a common primary glomerulonephritis, that is characterized by glomerular IgA deposits, however paraneoplastic IgAN has been rarely reported. In this case report we describe an unusual clinical course of patient with squamous cell lung carcinoma that was subsequently diagnosed with IgAN/Henoch-Schönlein purpura (HSP)

**Case Description:** 61-year-old male recently diagnosed with squamous cell carcinoma of the lung was referred for elevation of serum creatinine to 1.49 mg/dl from 0.9 mg/dl. He presented with vasculitic rash on lower extremities, and urinalysis showed acanthocytes and predicted 24-hour proteinuria of 7.8 g. Serologic and infectious workup so as monoclonal screen were negative. He underwent kidney biopsy that revealed diffuse mesangial and endocapillary hypercellularity with segmental fibrinoid necrosis and IgA dominant IF staining, consistent with crescentic IgAN/Henoch Schönlein purpura (HSP) nephritis (**FIG 1**). Immunosuppression was on hold due to active malignancy, and radiation and chemotherapy started. Follow up urinalysis showed less active sediment and decreased proteinuria. He also developed AKI thought to be pre-renal origin and improved with volume. But after cancer therapy changed to Durvalumab his creatinine peaked from 1.6 mg/dL to 2.84 mg/dL and urinalysis showed new sterile pyuria in addition of active sediment. There was concern for immune check point (ICI) induced acute interstitial nephritis (AIN) versus flare of IgA vasculitis. As patient presented with symptoms of ICI induced pneumonitis, Durvalumab was discontinued, and he was started on prednisone. His kidney function gradually improved while on steroids and after completing the course his creatinine was 1.68 mg/dL. Patient remained on remission under active surveillance by oncology for two years.

**Discussion:** Our case describes an unusual course of paraneoplastic IgA /HSP nephropathy and heightens the need for awareness of complications associated with these pathology and immunotherapy cancer agents.

Biopsy images: Light Microscopy and Immunofluorescent staining for IgA

## FR-PO179

**Acute Interstitial Nephritis Secondary to Sarcoid-Like Reaction After Autologous Bone Marrow Transplantation**

Luciana G. Luff,<sup>1</sup> Fernando L. Strufaldi,<sup>1</sup> Livia B. Cavalcante,<sup>1</sup> Renato A. Caires,<sup>2</sup> Francisco Z. Mattedi,<sup>2</sup> Elerson Costalonga,<sup>2</sup> Roberta Scholnik Szor,<sup>2</sup> Veronica T. Costa e Silva,<sup>2</sup> <sup>1</sup>Hospital das Clinicas da Faculdade de Medicina de Sao Paulo, Sao Paulo, Brazil; <sup>2</sup>Universidade de Sao Paulo Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil.

**Introduction:** Sarcoid-like (SL) disease is a systemic inflammatory granulomatous reaction triggered by a known underlying factor, such as immunosuppression. We report a case of acute interstitial nephritis (AIN) in the context of an SL systemic disease associated with humoral immunodeficiency in the post autologous stem cell transplant (ASCT) period.

**Case Description:** A 69-y-old woman diagnosed with non-Hodgkin mantle cell lymphoma was treated with Cyclophosphamide, Doxorubicin, Vincristine, and Prednisone regimen followed by consolidation with ASCT in first complete remission.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

In November 2019, she had Coombs-negative hemolytic anemia and a PET-CT revealed abnormal uptake in mediastinal and supraclavicular lymph nodes(LN). To rule out relapse, LN and bone marrow (BM) biopsies were performed, which demonstrated chronic inflammatory granuloma without necrosis. At this point, serum creatinine was 1.0 mg/dL, and combined hypogammaglobulinemia was observed. In July 2021, the patient was referred to the Nephrology clinic due to an insidious increase in Scr (1.8 > 2.3 > 2.8mg/dL in five months). Albeit discrete proteinuria, no other abnormalities were found. No urinary or systemic complaints were referred. Blood pressure was normal. No edema was detected. Percutaneous renal biopsy demonstrated AIN without granuloma and a negative immunofluorescence. Considering a diagnosis of sarcoid-like disease associated with post-SCT immunodeficiency, prednisone at 1mg/kg/day was started, with decline of Scr to 2.0 mg/dL two weeks later. After two months, methotrexate (10mg/week) was started with wean from steroids. The patient has been followed up with sustained Scr of 1.5mg/dL.

**Discussion:** Acquired immunodeficiencies may be associated with SL granulomatous disease. We postulate that a potential B-cell reconstitution deficiency and consequent hypogammaglobulinemia could create an immunologic environment for a granulomatous disease. This is the first reported acute IN case secondary to SL reaction after an SCT.

Variable	Value (reference range)
Proteinuria	0.7g/day
Hematuria	Absent
Autoimmunity evaluation <sup>1</sup>	Negative
Renal ultrasound	No abnormalities
Serum IgA	48.8 (60-382) mg/dL
Serum IgG	466 (700-1600) mg/dL
Serum protein electrophoresis	Hypogammaglobulinemia
Serum Immunofixation	Absence of abnormal proteins

<sup>1</sup>Autoimmunity evaluation: antinuclear antibody, Rheumatoid factor, complement (C3, C4).

## FR-PO180

### Anti-PR3 Positive Pauci-Immune Glomerulonephritis Associated With Immune Checkpoint Inhibitor Therapy and Responsive to Corticosteroid and Rituximab

Michelle Cline, Jane M. Doheny, Matthew D. Griffin, Teresa Mchale, Liam O'Neill, David Gorey. *Galway University Hospitals, Galway, Ireland.*

**Introduction:** Immunotherapy with checkpoint inhibitors (CPIs) enables activation of suppressed immune responses against cancer-associated antigens. Due to this mechanism of action, CPIs can trigger immune-related adverse events – including renal impairment. The most common findings on biopsy are acute interstitial nephritis and acute tubular injury. Several cases of pauci-immune glomerulonephritis, most commonly ANCA-negative, have also been reported during CPI therapy.

**Case Description:** A 73 year old man was admitted with hemoptysis, nausea and fatigue 5 days after his first cycle of carboplatin, paclitaxel & pembrolizumab for non-squamous cell lung cancer. Baseline serum creatinine (Scr) was 0.74mg/dL (65µmol/L). AKI was apparent on admission with Scr 1.63mg/dL (144µmol/L), initially considered pre-renal. Deterioration in renal function continued with peak Scr of 4.61mg/dL (408 µmol/L) despite adequate supportive therapy. Serological testing revealed positive assays for cANCA and anti-PR3 (35.0 U/mL). CXR showed new bilateral pulmonary infiltrates. Ultrasound-guided kidney biopsy revealed necrotising and crescentic glomerulonephritis with negative immunofluorescence microscopy, in keeping with a pauci-immune glomerulonephritis. IV Methylprednisolone 2mg/kg was administered for 5 days followed by rituximab infusions (2 x 1g, 2 weeks apart) and oral prednisolone taper. During the following 24 days, hemoptysis and systemic symptoms resolved and Scr progressively improved to nadir of 1.62mg/dL (144µmol/L). CPI therapy was not re-initiated. The patient remains in oncological remission without clinical or serological evidence (currently cANCA negative) of recurrent ANCA-associated glomerulonephritis.

**Discussion:** Anti-PR3+ ANCA-associated pauci-immune glomerulonephritis is an unusual cause of AKI during CPI therapy which, in this case, responded well to corticosteroid and rituximab. This case illustrates the importance of kidney biopsy in assessing and managing renal impairment associated with combined chemotherapy/immunotherapy regimens.

H&E and trichrome stain showing necrotising crescent.

## FR-PO181

### The Use of Rituximab in Treatment of Immune Checkpoint Inhibitor Induced Glomerulonephritis

Sai S. Achi,<sup>1</sup> Amanda Tchakarov,<sup>1</sup> Maen Abdelrahim,<sup>2</sup> Daniel Y. Wang,<sup>3</sup> Van Morris,<sup>4</sup> Ala Abudayyeh.<sup>4</sup> <sup>1</sup>The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX; <sup>2</sup>Houston Methodist Hospital, Houston, TX; <sup>3</sup>Baylor College of Medicine, Houston, TX; <sup>4</sup>The University of Texas MD Anderson Cancer Center, Houston, TX.

**Introduction:** Immune checkpoint inhibitors (ICI) have been shown to induce and exacerbate autoimmune side effects in patients with underlying autoimmune diseases. Immune adverse events of the kidney have been reported in 2-5% cases: majority of which are acute interstitial nephritis and less than 1% are glomerular diseases. Though glomerular disease is rare, it adds further complexity to cancer patients' care. We describe two cases of glomerulonephritis (GN) successfully treated with rituximab and continued ICI with cancer and renal response.

**Case Description:** A 64 year old male with mesothelioma and treated with nivolumab, developed nephrotic range proteinuria after two cycles, and biopsy confirmation of membranous nephropathy with positive antibody to PLA2R. The patient was started on rituximab course, achieved complete renal response, and continued nivolumab for 3 years. The PET/CT imaging continues to depict complete metabolic response and serum Anti-PLA2R negative. The second patient is a 71 year old female with squamous cell cancer of the anal canal who did not respond to cisplatin and 5-FU and was started on nivolumab. After the fourth cycle, she developed nephrotic range proteinuria. Biopsy confirmed minimal change disease, she was treated with a course of steroids and rituximab. She achieved complete remission of her proteinuria and had an excellent cancer response with continued ICI treatment.

**Discussion:** We present two unique cases of membranous nephropathy and minimal change disease in cancer patients after ICI exposure successfully treated and re-challenged on ICI with continued renal and tumor response. Based on a recent systematic review of ICI induced GN, the most frequent GN reported was pauci-immune and renal vasculitis (27%), podocytopathies (24%), and complement 3 GN (C3GN; 11%). There are no current guidelines on treatment of ICI induced GN. Based on our experience in vasculitis and current glomerulopathies, by targeting the B cells implicated in the autoimmune induction, rituximab offers an attractive treatment option and patients can continue ICI and improve overall survival.

## FR-PO182

### Shorter vs. Longer Corticosteroid Duration and Recurrent Immune Checkpoint Inhibitor-Associated AKI

Shruti Gupta,<sup>1</sup> Clara García-Carro,<sup>2</sup> Meghan E. Sise,<sup>3</sup> Maria Jose Soler,<sup>4</sup> David E. Leaf.<sup>1</sup> ICPI-AKI Consortium <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>San Carlos Clinical Hospital, Madrid, Spain; <sup>3</sup>Massachusetts General Hospital, Boston, MA; <sup>4</sup>Vall d'Hebron University Hospital, Barcelona, Spain.

**Background:** Corticosteroids are the mainstay of treatment for immune checkpoint inhibitor-associated acute kidney injury (ICPI-AKI), but the optimal duration of therapy has not been established. Prolonged use of corticosteroids can cause numerous adverse events and possibly decreased progression-free survival among patients treated with ICPIs. We therefore sought to determine whether a shorter duration of corticosteroids was equally efficacious and safe as compared to a longer duration.

**Methods:** We used data from our previously conducted multicenter cohort study of patients diagnosed with ICPI-AKI from 29 centers across 9 countries. We examined whether a shorter duration of corticosteroids (28 days or less) versus a longer duration of corticosteroids (29-84 days) was associated with a higher rate of recurrent ICPI-AKI or death in the 30-day period following completion of corticosteroid treatment.

**Results:** Of 165 patients treated with corticosteroids, 56 (34%) received a shorter duration of treatment and 109 (66%) received a longer duration. Patients in these two groups were similar with respect to age, sex, race, malignancy type, and baseline kidney function. Five of 56 patients (8.9%) in the shorter duration group and 12 of 109 (11%) in the longer duration group developed recurrent ICPI-AKI or died (Log-rank P=0.90) (Figure A). Nadir serum creatinine in the first 14, 28, and 90 days following completion of corticosteroid treatment was similar in the shorter versus longer duration groups (P=0.40, P=0.56, and P=0.89, respectively) (Figure B).

**Conclusions:** A duration of corticosteroids of 28 days or less may be safe for patients with ICPI-AKI. However, the findings may be susceptible to unmeasured confounding and further research from randomized clinical trials is needed.

## FR-PO184

### Hyperphosphatemia as Initial Presentation of Multiple Myeloma

Marco A. Bonilla,<sup>1</sup> Tanazul T. Pariswala,<sup>1</sup> Mahmoud Ali,<sup>2</sup> Antonio Corona,<sup>1</sup>  
<sup>1</sup>Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; <sup>2</sup>Saint Barnabas Hospital, Bronx, NY.

**Introduction:** Hyperphosphatemia is commonly seen in patients with kidney failure. However, in patients with normal kidney function, it can be a clue to underlying dysproteinemia

**Case Description:** A 71-year-old male with a medical history of anemia presented for evaluation of abdominal pain. On presentation vital signs were unremarkable. A physical exam revealed a thin elderly male with temporal wasting. Laboratory evaluation showed hemoglobin of 7.1g/dl, sodium 133mmol/L, K 4.2mmol/L, creatinine 1.4mg/dl, Calcium 8.7mg/dl, albumin 3.3g/dl, total protein 10.3g/dl, Gamma GAP 7g/dl, phosphorus 17.7mg/dl. Further workup is in table 1.

**Discussion:** Our case describes an unusual initial presentation of MM in a patient with severe hyperphosphatemia. Bone marrow biopsy reported plasma cell myeloma with 70% CD138-positive plasma cells, confirming a diagnosis of IgG-kappa-type MM. Spurious electrolyte abnormalities present a challenge for clinicians, pseudo-hyperphosphatemia in patients with MM has been associated with laboratory artifacts. A serum sample from a patient with MM will cause an increase in serum turbidity and its optical density, leading to falsely elevated phosphate levels. After the diagnosis of MM, hyperphosphatemia was attributed to spurious etiology. He started IV corticosteroids for 4 days, with a striking improvement in the phosphorus level (Figure 1). Interventions to lower serum phosphorus in this setting should be avoided if there are normal calcium and kidney function levels. Physicians should be aware that an unexplained hyperphosphatemia might be a diagnostic clue for a paraprotein disease.

Table 1. Further laboratory data

Laboratory	Value	Reference
IFE kappa	68.56 mg/dl	0.33-1.94 mg/dl
IFE lambda	0.39 mg/dl	0.57-2.63 mg/dl
Kappa/Lambda ratio	175.79 mg/dl	0.26-1.65 mg/dl
Quantitative IgG	4175 mg/dl	700-1600 mg/dl
Serum protein Electrophoresis M-spike	3.9 g/dl	
Serum Immunofixation	IgG and Kappa bands.	

## FR-PO183

### It's Not What It Looks Like: Obstructive Nephropathy in a Patient With Cervical Cancer

Christine E. Reed,<sup>1</sup> Sameed K. Lodhi,<sup>2</sup> Vimal K. Derebail,<sup>2</sup> Monica L. Reynolds,<sup>2</sup> Evan Zeitler,<sup>2</sup> <sup>1</sup>The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; <sup>2</sup>UNC Kidney Center, Chapel Hill, NC.

**Introduction:** Genitourinary complications may result from pelvic radiation therapy. We present a patient with history of cervical cancer with radiation-induced inflammation leading to recurrent obstructive nephropathy.

**Case Description:** A 35-year-old woman with history of stage III C1 cervical cancer treated with cisplatin, external beam radiation and brachytherapy presented with flank pain and urinary frequency with acute kidney injury (AKI). Medications included acetazolamide and ibuprofen. Exam revealed BP 150/98, and bilateral flank tenderness. Creatinine was 8.3 mg/dL from baseline 0.6 mg/dL three months prior, just after completing chemoradiation; urine protein-creatinine ratio was 8.1. Renal ultrasound revealed only mild bilateral hydronephrosis. With lack of clear etiology, she was empirically treated with intravenous steroids for suspected NSAID-related acute interstitial nephritis which improved creatinine rapidly (Figure). Kidney biopsy revealed acute tubular necrosis and steroids were discontinued. She was readmitted 3 days later for recurrent flank pain and AKI. Cystoscopy revealed bladder erythema with bullous edema obstructing the ureteral orifices. Prednisone was restarted with a taper, with initial improvement of creatinine but then recurrent AKI. Bilateral percutaneous nephrostomy tubes were placed, followed by ureteral stents with stabilization of creatinine.

**Discussion:** We report a case of severe radiation-induced ureteral and bladder inflammation leading to recurrent obstructive nephropathy three months after radiation. Unique aspects include the early onset, involvement of both ureters and bladder, lack of significant hydronephrosis on imaging and profound initial response to steroids. A high index of suspicion for radiation-related obstructive nephropathy should persist, despite an absence of overt hydronephrosis, when evaluating AKI in patients with prior pelvic radiation.

## FR-PO185

## Haplo-Storm Induced AKI

Marco A. Bonilla, Abhishek Nimkar, Kenar D. Jhaveri, Ruthee Bayer, Steven Fishbane. *Northwell Health, New Hyde Park, NY.*

**Introduction:** Cytokine release syndrome(CRS) can occur after allogeneic blood or marrow transplantation, but is especially prevalent after HLA-haploidentical (haplo) peripheral blood transplantation (PBT). This is termed haplo-storm. Here we report a case of AKI associated with haplo-storm.

**Case Description:** A 67 year-old male with medical history of WM transformed to lymphoma was admitted for a haplo-identical peripheral blood stem cell transplant (PBST) from his son. He received an immunosuppressive/preparative regimen consisting of fludarabine, cyclophosphamide and IVIG prophylaxis. Day 1 post-transplant, he developed rigors, fever, tachycardia, nausea and shortness of breath. Clinically, there was concern for Haplo-storm. On day 2, AKI was noted. Vital signs remarkable for blood pressure of 155/95 mmHg, afebrile. Physical Exam was remarkable for encephalopathy, coarse breath sounds and sacral edema. Laboratory evaluation showed serum creatinine of 1.98mg/dl(baseline 1.0mg/dl). White blood cell count of <0.1 K/uL, hemoglobin of 7.2g/dl, Platelet count of 8 K/uL. Electrolytes were within normal limits. Alkaline phosphatase of 195 U/L, lactate dehydrogenase 369 U/L, phosphorous 4.8 mg/dl, uric acid 7.1mg/dl. Urinalysis was remarkable for trace protein, large blood with 461 RBC per high field power. A spot urine protein/creatinine ratio of 2.7g/g. No nephrotoxic agents, contrast agent or hypotension as observed. Kidney sonogram ruled out obstruction. Engraftment had not occurred ruling out engraftment syndrome. Tocilizumab 560mg IV X1 was administered. He was presumed to have Haplo-storm induced AKI. His kidney disease was managed with intravenous diuresis to a negative net fluid balance, further doses of cyclophosphamide were held. His kidney function improved within 7 days back to baseline. Dialysis was not necessary.

**Discussion:** CRS is a common complication of patients undergoing haplo-identical PBT; as high as 89% of patients. Data on Haplo-storm, a form of CRS induced AKI in HSCT is limited. Nephrologist should be aware of the risk of AKI in patients undergoing haplo-PBT, complicated by haplo-storm.

Timeline of AKI

## FR-PO186

## AKI Post SARS-CoV-2 Vaccine in Patients Treated With an Immune Checkpoint Inhibitor (ICPi): Immune Double Whammy!

Richard Baker,<sup>1</sup> Kinjal Gosalia,<sup>2</sup> Kenar D. Jhaveri,<sup>2</sup> Prakash S. Gudsoorkar.<sup>1</sup>  
<sup>1</sup>University of Cincinnati College of Medicine, Cincinnati, OH; <sup>2</sup>Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, New York, NY.

**Introduction:** Immune check point inhibitors (ICPi) have become the first line treatment for most of the cancers and have shown promising results. Vaccine has mitigated the spread of COVID-19 infection, however there are no reported cases in literature of precipitation of AKI in patients treated with ICPi. We describe 3 cases of vaccine induced AIN in patients treated with ICPi. The plausible explanation is amplification of autoimmunity from SARS-CoV-2 vaccine under the influence of ICPi.

**Case Description:** **Pt 1:** 55 year old man on pembrolizumab for lung adenocarcinoma (b/l SCr 1.1 mg/dL) came with AKI (SCr 7.65 mg/dL) after he received first dose of Pfizer SARS-CoV-2 vaccine a week prior to admission. COVID19 PCR was negative. Kidney biopsy showed AIN. ICPi was stopped and oral prednisone (1 mg/kg) was started. SCr declined sharply. Steroid was tapered over 7 months, SCr improved to 1.7 mg/dL. Rechallenge with ICPi was deferred. **Pt 2:** 68 year old female was on ipilimumab for metastatic melanoma. 10 days after her first dose of Pfizer SARS-CoV-2 vaccine she developed AKI, SCr 3.4 mg/dL (b/l 1.3 mg/dL). COVID19 PCR was negative. Kidney biopsy showed AIN. ICPi was stopped and oral prednisone (1mg/kg) was started. At 5 months her SCr was 1.6 mg/dL on prednisone 5 mg qd, however she died from sepsis and multiorgan failure. **Pt 3:** 65 year old female with h/o bladder cancer on pembrolizumab developed AKI, SCr 2.18 mg/dL (b/l 0.8 mg/dL). 3 weeks prior she got a booster dose of Pfizer SARS-CoV-2 vaccine. COVID19 PCR was negative. ICPi was discontinued. CRP was 40 mg/dL (was < 3mg/dL prior) and urine retinol binding protein to creatinine (uRBP/ Cr) ratio was 3797 mcg/g Cr (normal < 190). Patient declined kidney biopsy. Kidney function returned to baseline in 6 weeks without steroids. The cause of AKI was presumed to be AIN based on the elevated uRBP/Cr ratio.

**Discussion:** A strong immune response from SARS-CoV-2 vaccine combined with an uninhibited immune system from ICPi may have led to an amplification of autoimmunity leading to AIN. We suggest, extra surveillance in patients receiving ICPi after SARS-CoV-2 vaccination is justified, and investigation into the amplification of T-lymphocyte

response from highly immunogenic vaccines in patients receiving ICPi will throw more light on the immunopathogenesis.

## FR-PO187

## Methotrexate Deja Vu: The Solution Is in the Volume!

Fatima Ayub, Yazan A. Bashtawi, Nithin Karakala. *University of Arkansas System, Little Rock, AR.*

**Introduction:** Methotrexate (MTX) has a broad range of antitumor activity. Acute methotrexate toxicity rarely presents as a renal failure. We, hereby present a case of MTX-induced acute renal failure with evidence of MTX-induced tubular injury.

**Case Description:** 74 years old male with a past medical history of hypertension, presented to the emergency department with complaints of altered mentation and recurrent falls. He had a 3-month history of cognitive decline, unsteady gait, and mechanical falls. Over the course of 3 days prior to the presentation, his wife noticed him to be drowsier. Brain imaging showed a lesion in the right frontal lobe followed by a biopsy of the lesion that demonstrated diffuse large B cell lymphoma. He was subsequently started on a chemotherapy regimen with MTX. Following the third dose, the patient developed acute hypoxic respiratory failure with acute kidney injury. Serum creatinine of 4.7 mg/dL (Baseline: 0.9 mg/dl) and a serum MTX level of 107 uMol/L was consistent with MTX toxicity. Urine microscopy revealed MTX crystals. Chemotherapy was discontinued and he underwent emergent hemodialysis (HD) for the management of MTX toxicity. Serum MTX levels after the first dialysis treatment was 74 uMol/L which increased back to 87 uMol/L within 24 hours of the first HD session. He underwent three daily sessions of HD due to the continuous rebound of MTX levels after each session. After his fourth dialysis treatment MTX level was 2.4 uMol/L.

**Discussion:** MTX-induced renal failure is a medical emergency because methotrexate is mainly eliminated by the kidneys. Renal damage is due to the precipitation of methotrexate in the tubules leading to tubular injury. Drug precipitation can often be prevented by hydration and alkalization of the urine. It is important to note that the volume of distribution of MTX is 1L/Kg. There is a high risk of rebound in serum levels of substances/drugs that have a large volume of distribution after short dialysis sessions. It is extremely important to understand the pharmacokinetics like volume of distribution, and protein binding to optimize the dialysis treatment.

## FR-PO188

## Identification of Pathologic Grading-Related Gene Modules Associated With Kidney Renal Clear Cell Carcinoma Based on Analysis of the Gene Expression Omnibus and The Cancer Genome Atlas

Weijian Xiong, Ying Li, Wu L. Li, Gao Xuan. *Chongqing Hospital of Traditional Chinese Medicine, Chongqing, China.*

**Background:** Renal cell carcinoma (RCC) originates from the renal epithelium and is the most common type of renal cancer with a poor prognosis. As the pathogenesis of kidney renal clear cell carcinoma (KIRC) has not been elucidated, which is necessary to be further explored.

**Methods:** An expression analysis dataset (GSE126964) was downloaded from the GEO database. Differentially expressed genes (DEGs) between KIRC and normal tissue samples were identified using edgeR and limma analysis. Based on the systematic biology approach of WGCNA, a gene co-expression network was constructed to screen potential biomarkers and therapeutic targets of this disease. Gene ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment were performed in the DAVID database. Kaplan-Meier Plotter was used to identify the hub genes associated with overall survival (OS) time of KIRC patients.

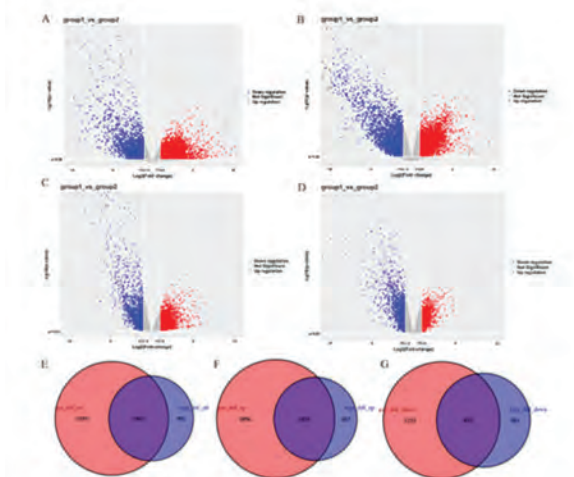

**Results:** A total of 1863 DEGs were identified between the two datasets. Ten co-expressed gene modules were identified using the WGCNA method. GO and KEGG analysis findings revealed that the most enrichment pathways included Notch binding, cell migration, cell cycle, cell senescence, apoptosis, focal adhesions and autophagosomes. Twenty-seven hub genes were identified, among which FLT1, HNRNP, ATP6V0D2, ATP6V1A, and ATP6V1H were positively correlated with the OS rate of KIRC patients.

**Conclusions:** In conclusion, DEGs present in both KIRC and normal kidney tissues, which can be considered as the KIRC biomarkers.

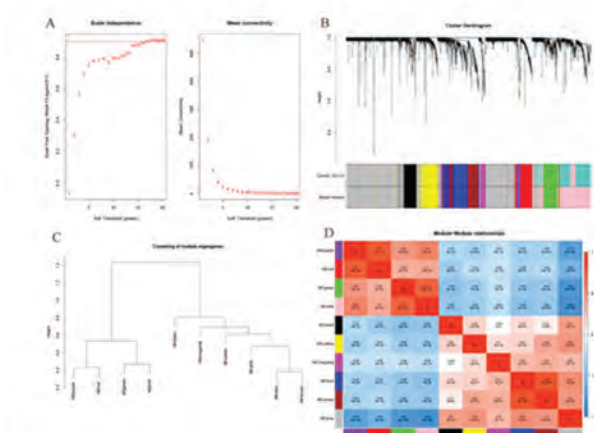

**Funding:** Government Support - Non-U.S.

FR-PO189

### Lung Cancer Induces Kidney Fibrosis and Primes the Kidney for Cisplatin-Induced Nephrotoxicity

Andrew Orwick, Sophia M. Sears, Mark A. Doll, Parag P. Shah, Levi J. Beverly, Leah J. Siskind. *University of Louisville, Louisville, KY.*

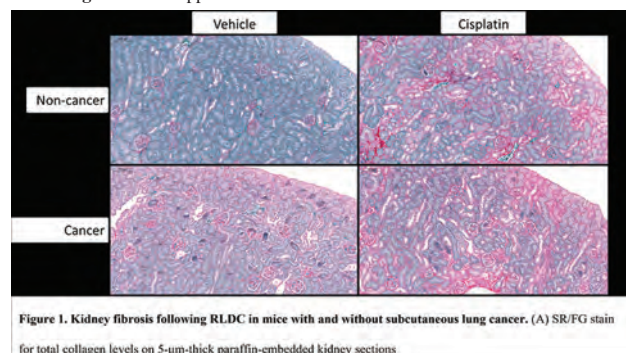

**Background:** Cisplatin is a common first-line treatment for many solid organ tumors. However, its effectiveness is restricted by dose-limiting nephrotoxicity. Thirty percent of cancer patients treated with cisplatin develop acute kidney injury (AKI), which requires a cessation in treatment. There are no treatment options to prevent or treat cisplatin-induced kidney injury. Historically the models used to study cisplatin-induced AKI involve a single high dose of cisplatin and do not include the co-morbidity of cancer. Our lab designed a low-dose repeated cisplatin model that results in the development of kidney fibrosis and chronic kidney disease (CKD). We hypothesized that including the comorbidity of lung cancer will potentiate the cisplatin-induced fibrosis and CKD.

**Methods:** Eight- to ten-week-old B6;129 mice were randomly assigned into four treatment groups: 1. non-cancer + vehicle, 2. non-cancer + cisplatin, 3. cancer + vehicle, 4. cancer + cisplatin. In the cancer groups, 10,000 lung adenocarcinoma cells were injected subcutaneously seven days prior to the start of cisplatin treatment. Cisplatin or saline was administered via intraperitoneal injection once a week for four weeks. Animals were euthanized 72 hours following their final cisplatin injection.

**Results:** Tumor-bearing vehicle control mice had elevated kidney injury markers, reduced markers of kidney function, and increased kidney fibrosis compared to non-tumor vehicle-treated mice. Cisplatin-induced kidney fibrosis was significantly worsened in tumor-bearing mice compared to mice without tumors.

**Conclusions:** The presence of lung tumors is sufficient to alter kidney biology, induce fibrosis, and reduce renal function, independent of cisplatin treatment, and importantly sensitized the kidneys to cisplatin-induced nephrotoxicity. Understanding the tumor-kidney crosstalk may provide mechanistic insights and uncover novel therapeutic targets for preventing and treating cisplatin-induced AKI and CKD.

**Funding:** NIDDK Support

FR-PO190

### Clinicopathologic and Proteomic Characteristics of Intratubular Cytoplasmic AL-Amyloidosis

Vincent Javaugue,<sup>1,2</sup> Alejandro Best Rocha,<sup>3</sup> Samar M. Said,<sup>2</sup> Dominick Santoriello,<sup>4</sup> Jean Hou,<sup>5</sup> Surendra Dasari,<sup>2</sup> Jason D. Theis,<sup>2</sup> Julie A. Vrana,<sup>2</sup> Ibrahim Batal,<sup>4</sup> Christopher P. Larsen,<sup>3</sup> Glen S. Markowitz,<sup>4</sup> Vivette D. D'Agati,<sup>4</sup> Ellen D. Mcphail,<sup>2</sup> Nelson Leung,<sup>2</sup> Samih H. Nasr.<sup>2</sup>  
<sup>1</sup>Centre Hospitalier Universitaire de Poitiers, Poitiers, France; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>3</sup>Arkana Laboratories, Little Rock, AR; <sup>4</sup>Columbia University, New York, NY; <sup>5</sup>Cedars-Sinai Medical Center, Los Angeles, CA.

**Background:** AL-amyloid deposits have been described in all compartments of the kidney. However, intratubular cytoplasmic AL amyloidosis (ITC-AL) is exceedingly rare and only described in few case reports.

**Methods:** We retrospectively reviewed the pathology archives at Mayo Clinic, Columbia University, Arkana Laboratories and Cedars-Sinai Medical Center from 2006-2021 for ITC-AL.

**Results:** Twenty-one patients (71% female, 58% Caucasian, median age 65 years) were included (0.003% of renal amyloidosis). Nineteen presented with AKI and 2 with CKD stage 3, without evidence of Fanconi syndrome. By light microscopy, the intracytoplasmic amyloid inclusions were black on silver stain, PAS-negative and trichrome-blue. They were identified in both proximal and distal tubular cells (n=12), in proximal tubular cells alone (n=5) or distal tubular cells alone (n=4). Ultrastructurally, these inclusions appeared membrane-bound consistent with intralysosomal localization. Concurrent cast nephropathy was present in 18 cases (amyloidogenic in 15). By immunofluorescence, amyloid deposits stained for lambda (n=18) or kappa (n=3). No patient had glomerular or interstitial amyloid deposits while 2 had vessels involvement. Extrarenal amyloid deposits were found in 3 cases. Proteomic analysis of kidney amyloid deposits identified a single light chain variable gene segment in all tested cases (IGLV1-47 in 2, IGLV1-44 in 1 and IGLV3-21 in 1). None had the glomerulopathic IGLV6-57. The underlying hematologic condition was multiple myeloma in 13/13 cases (symptomatic in 11). Patients were treated with bortezomib- (n=11) or lenalidomide-based (n=2) regimens followed by autologous stem cell transplant in 2. After a median follow-up of

14 months (range 1-51), 1 died one month after diagnosis, 4 progressed to ESKD (3 of them died) and 6 had partial recovery of kidney function.

**Conclusions:** ITC-AL occurs mostly concurrent with cast nephropathy and thus presents with AKI. Some cases are associated with extrarenal involvement by amyloidosis. Whether the amyloid fibrils are formed within the cells from reabsorbed light chains or result from phagocytosis of already formed intratubular luminal fibrils remains to be determined.

FR-PO191

AA Amyloidosis Associated With Cancers

Joyita Bharati,<sup>1,2</sup> Tanazul T. Pariswala,<sup>1</sup> Hassan Izzedine,<sup>3</sup> Kenar D. Jhaveri.<sup>1</sup>  
<sup>1</sup>Northwell Health, New Hyde Park, NY; <sup>2</sup>Post Graduate Institute of Medical Education and Research, Chandigarh, India; <sup>3</sup>Hopital des Peupliers, Paris, France.

**Background:** AA amyloidosis commonly results from chronic inflammatory conditions. Data on cancer associated AA amyloidosis is lacking.

**Methods:** We performed a descriptive systematic analysis of AA amyloidosis associated with cancers and its treatment. PubMed database was searched for English language literature using keywords- localized AA amyloidosis, systemic AA amyloidosis, cancer, solid cancer, carcinoma, malignancy, hematological malignancy, leukemia, lymphoma, tumors, cancer chemotherapy, cancer immunotherapy, and cancer drugs.

**Results:** Only case reports and case-series were identified. A total of 52 case reports and 3 case series with adequate information were included and a summary of the findings is provided. In two autopsy series evaluating AA amyloidosis, 13 and 7 cases had solid cancers. Renal cell cancer (RCC) was noted in 45.5% and 25% of these cases, the most common solid cancer associated with AA amyloidosis. In addition, 20 clinical cases of RCC were reported to be associated with AA amyloidosis. All of these were localized renal tumors, except 1 case with metastatic disease. Clear cell carcinoma was the most common histology of RCC associated with AA amyloidosis. There were case reports (1 or more) describing other solid cancers with AA amyloidosis like- lung cancer (6), gastrointestinal stromal tumors with high mitotic activity (2), sarcoma (2), uterine leiomyosarcoma (1), bladder carcinoma (2), ovarian carcinoma (1), and basal cell carcinoma of skin (3). Patients with solid cancers and AA amyloidosis frequently presented with nephrotic syndrome and kidney dysfunction rather than symptoms from the tumor directly. Among hematological malignancies, 12 cases of clonal B-cell/plasma cell dyscrasia, 5 cases of lymphoma, 1 case of chronic myeloid leukemia, and 1 case of chronic lymphocytic lymphoma were reported to be associated with AA amyloidosis. Three cases were identified to have immune checkpoint inhibitors, associated AA amyloidosis

**Conclusions:** AA amyloidosis can be associated with underlying solid cancers, hematological cancers, and immunotherapy. AA amyloidosis should be considered in the differential diagnosis for nephrotic syndrome with or without kidney dysfunction in patients with cancers.

FR-PO192

Pro-Inflammatory Urinary mRNA Profile in Allogeneic Stem Cell Transplant Patients With AKI

Victoria Gutgarts,<sup>1,2</sup> Insara Jaffer Sathick,<sup>1,2</sup> Carol Y. Li,<sup>2</sup> Annelie G. Clurman,<sup>1</sup> Supriya Gerardine,<sup>1,2</sup> Michael Scordo,<sup>1</sup> Justine Jorgensen,<sup>1</sup> Jessica M. Abukoush Szczerba,<sup>1</sup> Manikkam Suthanthiran,<sup>2</sup> Thangamani Muthukumar,<sup>2</sup> Edgar A. Jaimes.<sup>1,2</sup> <sup>1</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>2</sup>Weill Cornell Medicine, New York, NY.

**Background:** Allogeneic hematopoietic cell transplantation (allo-HCT) is an effective treatment for hematologic malignancies. However, allo-HCT has risk of acute kidney injury (AKI) in as many as 80% of patients within the first 100 days. The etiology of AKI is multifactorial but experimental studies suggest a role for immune mediated mechanisms which may have therapeutic implications. We hypothesized that the urinary cell mRNA expression of HCT recipients that develop AKI has higher levels of mRNA for genes associated with inflammation and tubular injury compared to those without AKI.

**Methods:** We prospectively studied a cohort of patients undergoing their first allo-HCT at MSKCC. Urine collections were performed at baseline, weekly while inpatient and every 3 weeks until day 100. AKI was defined as  $\geq 7$ -day elevation of  $\geq 1.5\times$  baseline serum creatinine. Urine samples closest to time of AKI and matched samples from patients without AKI were analyzed. Absolute quantification of a panel of mRNAs (T cell marker CD3e, proinflammatory chemokine CXCL10/IP10, tubular markers NKCC2, E-cadherin, VIM, and TGFb1) and 18SrRNA were assessed in the urinary cells by RT-qPCR assay. We calculated the validated CTOT-04 (Suthanthiran et al, N Engl J Med 2013) urinary cell biomarker score.

**Results:** A total of 12 urine samples were analyzed, 6 patients with AKI and 6 patients without AKI. The table below shows the AKI group had a higher median absolute copy number per microgram of mRNA for all the genes tested.

**Conclusions:** Allo-HCT recipients who develop AKI have a urinary cell mRNA profile suggestive of pro-inflammatory mechanisms of injury based on higher level of expression of inflammatory and tubular genes. Ongoing analysis of additional prospectively collected samples will allow further characterization of this profile and may result in novel non-invasive tests for identification of patients at high risk for AKI and precision therapeutics.

Urinary Cell Levels of mRNAs in HCT Recipients With AKI Versus Time Matched Controls Without AKI

	18S rRNA	TGFb1	CD3e	IP10	E-cadherin	NKCC2	Vimentin	CTOT-04 - Three Gene Signature Score (Allograft Rejection Score: <1.213)

FR-PO193

Soluble Interleukin 2 Receptor as a Potential Biomarker for Immune Checkpoint Inhibitor Nephritis (ICI-AIN)

Qiyu Wang,<sup>1</sup> Harish Shanthanu Seethapathy,<sup>1</sup> Rex N. Smith,<sup>1</sup> Ivy A. Rosales,<sup>1</sup> Robert B. Colvin,<sup>1</sup> Sandra Herrmann,<sup>2</sup> Jocelyn Farmer,<sup>1</sup> Meghan E. Sise.<sup>1</sup>  
<sup>1</sup>Massachusetts General Hospital, Boston, MA; <sup>2</sup>Mayo Foundation for Medical Education and Research, Rochester, MN.

**Background:** Soluble interleukin 2 receptor (sIL-2R), a marker of T-cell activation, is used to monitor disease activity for autoimmune conditions and congenital immunodeficiencies. We hypothesize that sIL-2R may be elevated in patients with ICI-AIN and potentially serve as a diagnostic biomarker.

**Methods:** Retrospective cohort study of patients diagnosed with ICI-AIN (histologic or clinical diagnosis) who had sIL-2R measured as part of work-up. We prospectively enrolled 2 control cohorts: 1) Patients receiving ICIs for cancer with normal kidney function ("healthy ICI-treated controls"); 2) Patients not receiving ICIs who were hospitalized with hemodynamic acute kidney injury (AKI). Patients were excluded if they had active infection or received immunosuppression within 2 weeks of sample collection. sIL-2R levels were standardized using the fold change of the upper limit of normal (ULN) of the CLIA-certified assay. Receiver operating curve (ROC) was generated comparing sIL-2R level between "ICI-AIN" and "hemodynamic AKI controls", and "ICI-AIN" and "healthy ICI controls". Using archived biopsy samples, we compared IL2R- $\alpha$  gene expression measured by Nanostring in patients with ICI-AIN (N=22), acute tubular injury (ATI, N=9) and healthy kidney donors (N=11).

**Results:** sIL-2R levels were significantly higher in ICI-AIN (N=21, median 2.5 fold-ULN, IQR 1.9-3.3), compared to "healthy ICI-treated controls" (N=9, median 0.7 fold-ULN, IQR 0.5-0.9) and "hemodynamic AKI controls" (N=6, median 0.9 fold-ULN, IQR 0.7-1.1). (Figure 1) ROC analysis yielded an optimal cut-point of 1.75-fold ULN of sIL-2R for differentiating ICI-AIN and hemodynamic AKI controls, with specificity of 100% (95% CI, 61%-100%) and sensitivity of 81% (95% CI, 60%-92.3%). IL2R- $\alpha$  gene expression was significantly higher in kidney tissue in patients with ICI-AIN compared to ATI and healthy kidney donors. (Figure 2)

**Conclusions:** sIL-2R is a promising biomarker for ICI-AIN that should be validated in future studies with prospective, consecutive sampling.

FR-PO194

Cellular Senescence Is Associated With CKD Progression in Childhood Cancer Patients With Karyomegalic Interstitial Nephropathy (KIN)

Mandy G. Keijzer-Veen,<sup>1</sup> Sebastiaan Knoppert,<sup>2</sup> Floris Valentijn,<sup>2</sup> M.M. van den Heuvel-Eibrink,<sup>3</sup> Gerrit V. Berg,<sup>1</sup> Marc Lilien,<sup>1</sup> Lianne M. Haveman,<sup>3</sup> Marijn F. Stokman,<sup>2</sup> Geert O. Janssens,<sup>2,3</sup> Roel Broekhuizen,<sup>2</sup> Roel Goldschmeding,<sup>2</sup> Tri Q. Nguyen.<sup>2</sup> <sup>1</sup>Universitair Medisch Centrum Utrecht - Locatie Wilhelmina Kinderziekenhuis, Utrecht, Netherlands; <sup>2</sup>Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; <sup>3</sup>Prinses Maxima Centrum voor Kinderoncologie, Utrecht, Netherlands.

**Background:** Patients with KIN show a clinical picture of interstitial nephropathy with enlarged, irregular and hyperchromatic nuclei of tubular epithelial cells (TECs). The histologic pattern was first described in patients with FAN1 mutations with defective DNA

damage repair, but has also been infrequently reported in children treated for childhood cancers with the alkylating agent ifosfamide.

**Methods:** We included the kidney biopsies of all children treated for childhood cancer in the Princess Máxima Center for Pediatric Oncology with progressive CKD with low molecular weight proteinuria of unknown cause between 2018-2021. Features of karyomegaly and senescence were identified in TECs by automated morphometric assessment of nuclear size distribution, and immunohistochemical markers for DNA damage ( $\gamma$ H2AX), cell-cycle arrest (p21+, Ki67-), and nuclear lamina decay (loss of lamin B1).

**Results:** KIN could be diagnosed in all six children, according to the above described features. (Figure 1A-C) The number of p21 positive cells by far exceeded the typically very small numbers of truly karyomegalic cells. P21 positive TECs were found to contain significantly less lysozyme, testifying to defective resorption as an explanation of the consistent finding of LMW proteinuria. Moreover, in the 5 patients with the largest nuclei, the percentage of p21-positive TECs showed strong inverse correlation with change in eGFR from biopsy to last follow-up ( $R^2=0.93$ ,  $p<0.01$ ).

**Conclusions:** Karyomegaly and cellular senescence-associated tubular dysfunction appear to be a more prevalent cause of otherwise unexplained CKD and LMW proteinuria in children treated with ifosfamide. This finding may have important implications for future personalized treatment strategies.

**Funding:** Private Foundation Support

**Figure 1A.** Enlarged nuclei in KIN are Ki67 negative, p21 positive, (B-C) yH2AX positive, and show less LaminB1 staining.

## FR-PO195

### Kidney Intravascular Large B-Cell Lymphoma: A Multi-Institutional Experience

Prerna Rastogi,<sup>1</sup> Audai A. Alrwashdeh,<sup>1</sup> Mohammad Obeidat,<sup>1</sup> Tiffany Caza,<sup>2</sup> Mercury Y. Lin,<sup>3</sup> Christopher P. Larsen,<sup>2</sup> Dao-Fu Dai,<sup>1</sup> <sup>1</sup>The University of Iowa Hospitals and Clinics Department of Pathology, Iowa City, IA; <sup>2</sup>Arkana Laboratories, Little Rock, AR; <sup>3</sup>Cedars-Sinai Medical Center, Los Angeles, CA.

**Background:** Intravascular large B-cell lymphoma (IVLBCL) is an aggressive variant of large B-cell lymphoma, with growth of neoplastic cells within the blood vessels. Kidney involvement is rare. Prognostic features from a multi-institutional retrospective review are presented here.

**Methods:** Kidney biopsies with a diagnosis of kidney IVLBCL were reviewed till Dec 2021. We identified 17 cases with mean age of  $64.7 \pm 7.9$  years with 52.9% (9/17) ♂ and 53 more (total 70) from literature review with mean age  $61.1 \pm 11.4$  (50% ♂). Findings included fever, anemia, acute kidney injury, 88% of our 17 cases, 69% for all, proteinuria in 65% of our cases, 83.3% for all, hematuria in 35.3% of our patients, unclear in others & Nephrotic range proteinuria in 11.7% of our patients & 27.2% of all cases.

**Results:** Of 40 patients with available data, the median & interquartile range of serum creatinine was 1.75 [1.17, 3.25] mg/dL. Biopsy showed glomerular infiltration by neoplastic lymphoid cells (yellow → Fig 1) in 84.6% cases, cells in the tubulointerstitium (56.7%) and peritubular capillaries. Arteries or veins were involved by neoplastic lymphoid cells in 13.11%. Of 58 cases with data 43.1% showed infiltration into bone marrow, liver, spleen, CNS, lungs & skin. IVLBCL expresses mature B-cell antigens, such as CD20, CD79a, PAX-5 & non-germinal center immunophenotype with CD10- and MUM1+. Follow-up data available in 48 patients showed median survival of ~20 months after diagnosis, of which 6 (12.5%) were post-mortem, with extensive extra-renal involvement. Multivariate Cox regression analysis showed extrarenal involvement is a significant predictor of mortality, with HR: 5.97 (95% CI: 1.72, 20.7,  $p=0.005$ ), but not serum Cre: 1.03 (.54, 1.97,  $p=0.9$ ), after controlling for age gender.

**Conclusions:** Kidney IVLBCL is rare, presenting with fever, anemia, AKI, elevated serum creatinine & proteinuria. Median survival is 20 months & extrarenal involvement indicating extensive disease is associated with worse outcome.

## FR-PO196

### Pilot Study of High Dose Intravenous Magnesium in Mesothelioma Patients Receiving Surgery With Hyperthermic Intraoperative Chemotherapy With Cisplatin (HIOCC)

Arunima Mariya Jose,<sup>1,2</sup> David E. Leaf,<sup>1</sup> Shruti Gupta,<sup>1</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Florida State University College of Medicine, Tallahassee, FL.

**Background:** HIOCC, which involves the administration of heated cisplatin solutions during surgical resection of tumors, is associated with a >50% risk of AKI postoperatively. One potential mechanism for cisplatin-associated-AKI (CP-AKI) is the reduced expression and function of magnesium (Mg) transporters in the kidneys. Mg deficiency has been shown to increase renal CP accumulation in proximal tubular cells by downregulating transporters expressed on the apical side of these cells. Administration of Mg restores the expression of these transporters, allowing cisplatin to be secreted into the tubular lumen and then excreted in the urine. We, therefore, aimed to conduct a pilot study testing whether intravenous (IV) Mg reduces the risk of AKI in mesothelioma patients receiving HIOCC.

**Methods:** We conducted a phase 1 pilot study where we administered high doses of IV Mg at 0.5 g/hour for 36 hours (18 g total) in 5 patients receiving HIOCC. The Mg infusion started the night prior to surgery and continued until the morning of postoperative day 1. Serial Mg levels were monitored throughout the infusion. AKI was defined according to the Kidney Disease Improving Global Outcomes criteria as a 1.5-fold rise in serum creatinine (SCr) in the 7 days following the surgery. Adverse events (e.g., flushing, arrhythmia) were recorded.

**Results:** All 5 patients were male, White, with a median age of 74 years (interquartile range, 67-79), and a median baseline SCr of 1.1 mg/dL (IQR, 1-1.1). Among the 5 patients who completed the study, median postoperative Mg levels were 2.4 mg/dL (IQR, 2-2.9) (Figure). None of the 5 patients developed AKI, and no adverse events were reported.

**Conclusions:** IV Mg is safe and well-tolerated, and may be associated with a decreased risk of AKI; however, these findings need to be corroborated by a larger randomized controlled trial.

**Funding:** NIDDK Support

Median Pre- and Postoperative Magnesium Levels (n=5)

## FR-PO197

**High-Dose Methotrexate (HDMTX) Induced Nephrotoxicity: Glucarpidase or Dialysis?**

Abhinaya Sridhar,<sup>1,2</sup> Uzma Malik,<sup>1,2</sup> Aromma Kapoor,<sup>1,2</sup> <sup>1</sup>Westchester Medical Center, Valhalla, NY; <sup>2</sup>New York Medical College, Valhalla, NY.

**Introduction:** HDMTX induced Acute Kidney Injury (AKI) can lead to delayed renal clearance of MTX causing life threatening toxicities. Treatment options include high-flux hemodialysis (HFHD) and Glucarpidase. We report a case of MTX induced AKI which was successfully treated with Glucarpidase.

**Case Description:** 75 year old woman admitted with CNS lymphoma, planned for 6 cycles of HDMTX based chemotherapy. She received 3 cycles with no side effects. Urine pH and MTX levels were monitored with levels peaking at 2.2, 7.7 and 7.5 umol/L with no AKI. During her 4<sup>th</sup> cycle, she was found to have AKI on day 5. Blood work showed BUN 23 mg/dL and creatinine (Cr) 1.46 mg/dL. She had been normotensive with no administration of nephrotoxic medications or contrast except HDMTX. MTX level was found to be 110.5 umol/L. She was started on hydration, sodium bicarbonate and leucovorin was increased. She received one dose of Glucarpidase 50 units/kg, 52 hours after HDMTX infusion with decrease in MTX level to 21.7 umol/L. MTX levels were closely monitored and continued to downtrend. Urine pH levels were monitored to keep pH >7. Patient did not need further doses of Glucarpidase and decision was made to not initiate HD. She was discharged in renal recovery.

**Discussion:** Routine monitoring of MTX levels can lead to early recognition of AKI. Glucarpidase is an enzyme that cleaves MTX into inactive metabolites providing an alternative route for elimination. Case reports describe successful treatment of AKI with its use in addition to leucovorin rescue, hyperhydration and urine alkalization. Our patient was treated successfully with the same regimen with absence of other MTX toxicities. In the above reports, there was no rebound in MTX levels after single dose Glucarpidase as seen in our patient also. Another treatment option is HFHD, but reports show that MTX levels rebound and require repeat sessions. Recently published guidelines recommend the use of Glucarpidase for HDMTX related AKI but MTX levels not corresponding to the algorithm is a limitation to its use. Despite this, we hypothesize that its use can help avoid HD. Randomized controlled trials are warranted to assess its efficacy on clinically relevant outcomes. **Learning objectives** Routine monitoring of MTX levels can lead to early recognition of AKI. Prompt intervention with Glucarpidase can successfully treat AKI with no rebound in MTX levels and eliminate the need for HD.

## FR-PO198

**Immune Checkpoint Inhibitor Induced Multi Organ Sarcoid-Like Reaction**

Ashwin Thatti,<sup>1</sup> Amanda Tchakarov,<sup>1</sup> Maria E. Cabanillas,<sup>2</sup> Ala Abudayyeh.<sup>2</sup> <sup>1</sup>The University of Texas Health Science Center at Houston, Houston, TX; <sup>2</sup>The University of Texas MD Anderson Cancer Center, Houston, TX.

**Introduction:** With the expansive use of Immune Checkpoint Inhibitors (ICI) there has been increasing adverse events that have been recognized. Autoimmune disease induction post ICI exposure has been reported with the more common diseases such as arthritis, myositis, Sjogren's syndrome or vasculitis. A rarer entity is sarcoidosis which has been reported as granulomatous lesions in the lung, lymph nodes and skin. Here we describe two cases of multiorgan ICI induced Sarcoid-Like reactions (SLR) specifically in the kidney.

**Case Description:** Case 1: 62 year old male with history of stage IV metastatic melanoma completed 4 cycles of Ipilimumab/Nivolumab admitted for acute kidney injury (AKI) and shortness of breath (SOB). Serum Creatinine was 2.8mg/dl (baseline 1.2). UA was bland with positive urine eosinophils. A kidney biopsy showed AIN with Necrotizing granulomas. Troponins were elevated and echocardiogram showed a reduced ejection fraction. An endomyocardial biopsy showed cardiac sarcoidosis. He had a new pulmonary nodule, which was biopsies and showed necrotizing granulomatous inflammation. Steroids were started for 3 months, with AKI resolution and improved cardiac function and sarcoid remission. Case 2: 49 year old female with history of stage IV anaplastic thyroid carcinoma and was treated for 4 years prior on dabrafenib/trametinib and pembrolizumab. She developed SOB and CT of the chest showed several pulmonary nodules. A biopsy showed granulomatous inflammation concerning for sarcoidosis. Pembrolizumab was stopped and she was treated with steroids and her SOB subsequently improved. Multiple hypodense lesions over the kidney were seen incidentally on a CT scan a year after steroid treatment, with normal kidney function and bland urine. A kidney biopsy showed chronic and granulomatous interstitial inflammation. She has been in remission from her cancer and sarcoid manifestations.

**Discussion:** We have presented two unique cases of multiorgan sarcoidosis induced after ICI exposure successfully treated with steroids with continued tumor remission. Previous literature about ICI induced SLR has shown that these lesions improve upon discontinuation of ICI and/or antisarcoid treatment. Treatment might not be needed and ICI can be continued if there is no evidence of end organ damage. SLR can mimic disease progression and biopsy of new lesions seen post ICI usage should be considered.

## FR-PO199

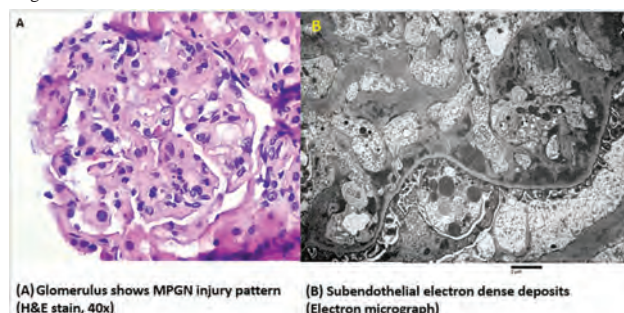

**A Rare Case of Membranoproliferative Glomerulonephritis (MPGN) With Bevacizumab**

Prashamsa Shenoy, Li Li, JingJing Zhang, Thomas Jefferson University, Philadelphia, PA.

**Introduction:** Bevacizumab is an anti-VEGF target chemotherapy often associated with proteinuria, hypertension and thrombotic microangiopathy (TMA). We report a case of immune complex-mediated membranoproliferative glomerulonephritis (IC-MPGN) following bevacizumab therapy.

**Case Description:** A 58-year-old female patient diagnosed with endometrial carcinoma 4 years ago presented with a persistent rise in creatinine (Cr) to 1.4 from 0.7 baseline, while on bevacizumab 15mg/Kg/3 weeks for 10 months. She was previously treated with carboplatin, paclitaxel, docetaxel, bevacizumab and dexamethasone. Her urinalysis showed 1+ proteinuria, sterile pyuria and persistent eosinophilia. Bevacizumab was discontinued and kidney biopsy was pursued. Work up including ANA, ANCA, dsDNA, anti-Ro/ La, complements, hepatitis and HIV serologies were unremarkable. Biopsy revealed thickening of glomerular basement membrane (GBM), endocapillary and mesangial hypercellularity with lobulated pattern consistent with MPGN (Fig A). There was focal double contouring of the GBM but no evidence of fibrinoid necrosis or thrombi. Immunofluorescence (IF) showed capillary wall staining for IgG, IgA, IgM, C3, C1q, kappa and lambda in 2-3+ range. Electron microscopy demonstrated extensive subendothelial and mesangial electron-dense deposits (EDD) with mild podocytopathy (Fig B). The overall features diagnostic of IC-MPGN. She was started on prednisone 40mg, tapered in 3 months with improvement in Cr, proteinuria and remained stable despite switching to pembrolizumab and lenvatinib.

**Discussion:** Bevacizumab is often associated with TMA developing within a year and demonstrates endothelial swelling, mesangiolysis and fibrinoid necrosis. This case had classic IC-MPGN with full house IF and EDD, perplexing us if the culprit was bevacizumab or the solid tumor itself. But her kidney injury was temporally related to bevacizumab and followed discontinuation of dexamethasone suggesting potential development of antibodies to bevacizumab. Therefore, clinicians should be vigilant and practice low threshold for biopsy with patients on bevacizumab for appropriate management.

## FR-PO200

**Minimal Change Disease With Immune Checkpoint Inhibitors**

Rama Kethineni, Ritika Ohri, Marc Barry, Sarah Gilligan, Josephine Abraham. University of Utah Health, Salt Lake City, UT.

**Introduction:** Immune checkpoint inhibitor (ICI)-related acute kidney injury (AKI) occurs in 2-5% of patients treated with these agents. Acute interstitial nephritis is the most common finding on renal biopsy but glomerular disease accounts for approximately 10% of ICI-related AKI. We present a case of minimal change disease secondary to ICI.

**Case Description:** A 72-year-old male with history of testicular cancer s/p orchiectomy and chemoradiation in 2004, nephrolithiasis, GERD, and newly diagnosed metastatic melanoma presented with poor oral intake, cough, and shortness of breath. The patient had been taking omeprazole and was on the 2<sup>nd</sup> cycle of ipilimumab and nivolumab. Labs showed hemoglobin 10.9 mg/dl, Platelets 144, Albumin 1.9 g/dl, BUN 64 mg/dl, and creatinine 2.56 mg/dl from baseline of 1.2 mg/dl. Urinalysis showed protein and 6 RBCs, eumorphic on microscopy. UACR was 7390 mg/g with a UPCr of 9989 mg/g. Serology was negative for ANA, ANCA, HIV, hepatitis with normal C3, C4, and PLA2R 1:10. Renal ultrasound showed no obstruction. Renal biopsy showed minimal change disease with diffuse foot process effacement along with ATN and less than 10% IFTA. His creatinine worsened despite holding chemotherapy to 6.5 with BUN of 150 mg/dl with uremia requiring RRT. Prednisone was initiated at 1 mg/kg with gradual renal recovery and discontinuation of dialysis after 2 sessions. Prednisone was tapered over 4 months with resolution of albuminuria but with new baseline creatinine of 1.5-1.6 mg/dl. He was rechallenged with a Nivolumab-only regimen and developed hepatitis and worsening renal failure.

**Discussion:** Minimal change disease is a rare complication of ICI but should be considered in the differential diagnosis of ICI-related AKI. Treatment with steroids often results in at least partial renal recovery but many questions remain regarding prognosis and re-initiation of ICI.

## FR-PO201

**Immunotherapy-Induced Glomerulonephritis: Whodunit?**

Brian Benes, Kate-Lynn Muir, Kirk W. Foster, Alissa S. Marr, Ketki K. Tendulkar. *University of Nebraska Medical Center, Omaha, NE.*

**Introduction:** Kidney immune-related adverse events are well recognized side effects of immune checkpoint inhibitor therapy. We present a unique case of evolving immune related adverse events with ongoing melanoma therapy.

**Case Description:** A 72-year-old man was referred for evaluation of acute kidney injury after being treated with adjuvant nivolumab for malignant melanoma. Serum creatinine increased from 1.0 mg/dL to 3.1 mg/dL with urine protein/creatinine ratio 0.3 mgTP/mgCR, without hematuria. A presumed diagnosis of acute interstitial nephritis was made based on eosinophiluria. Nivolumab was stopped and he was started on prednisone 60 mg daily and lisinopril. After 1 month, creatinine improved to 1.2 mg/dL. Six months later he was started on talimogene laherparepvec (T-VEC) for progressive melanoma. Four months into treatment, he developed edema and proteinuria (UPCR- 10.5 mgTP/mgCR), with a rise in creatinine to 1.8 mg/dL. Kidney biopsy showed mesangio- and focal endocapillary proliferative glomerulonephritis. Immunofluorescence (IF) was positive for C3 and trace C1q. Electron microscopy had electron dense mesangial deposits. Serum complement levels were normal and functional complements were negative. T-VEC was stopped due to melanoma progression. He was treated with rituximab 1 g weekly for 4 weeks, methylprednisolone IV 1 g daily for 4 days. Proteinuria improved over 6 months to 0.4 with creatinine 1.4 mg/dL.

**Discussion:** Programmed death 1 inhibitors (PD1i) have been described to cause acute tubulointerstitial nephritis (ATIN) and glomerular injury. Improvement after stopping nivolumab and onset of proteinuria after T-VEC administration raises the possibility of T-VEC induced immune mediated effect. ATIN is the most common renal adverse event associated with PD1i (93% in a recent series). Although, C3 glomerulopathy has been reported with nivolumab. Typically, renal injury often occurs within 2-4 weeks of cessation of therapy. T-VEC is an oncolytic virus used in unresectable metastatic melanoma and immune mediated adverse events are less common. Two other case reports of GN associated with T-VEC, one of which had minimal change GN with focal mesangial immune deposition with IgM and C1q on IF have been reported. Delayed onset kidney injury from nivolumab cannot be excluded or these findings could be due to T-VEC. T-VEC should be considered a possible cause of immune adverse events.

## FR-PO202

**Role for Calcineurin Inhibitor in Tyrosine Kinase Inhibitor-induced Focal Segmental Glomerulosclerosis**

Benjamin R. Teruel, Evelyn Bruner, Blathin A. McMahon. *Medical University of South Carolina, Charleston, SC.*

**Introduction:** As the use and indications of anti-angiogenic therapies such as vascular endothelial growth factor (VEGF) and tyrosine kinases inhibitors (TKI's) continues to expand, clinicians will be faced with an increase in adverse kidney events associated with these therapies. Focal segmental glomerulosclerosis (FSGS) and thrombotic microangiopathies are well recognized renal pathologies identified in patients receiving anti-angiogenic therapy. Options to treat the nephrotoxicity induced by these agents include discontinuation or dose reduction of the anti-angiogenic therapy or a trial of corticosteroids (in the case of FSGS).

**Case Description:** We describe a 74-year-old Caucasian man with metastatic papillary thyroid carcinoma who developed nephrotic syndrome, hypertension, and peripheral edema following treatment with Lenvatinib, 20mg. Renal biopsy revealed focal segmental glomerulosclerosis. Partial resolution of proteinuria (>1.0g/g) was achieved via temporary discontinuation of Lenvatinib and treatment with oral prednisone. Subsequently, tumor burden increased off Lenvatinib and a collective decision was made to resume this medication at a lower dose. Unfortunately, proteinuria increased to nephrotic range (>4.0g/g) following resumption of Lenvatinib, 14mg. Over the next three months the patient went into a complete clinical remission of his nephrotic syndrome following administration of the calcineurin-inhibitor, tacrolimus and allowed ongoing concurrent use of Lenvatinib.

**Discussion:** There are many documented cases of TKI-induced FSGS resistant to glucocorticoid treatment. Our case demonstrates that calcineurin inhibitors may have efficacy as a second-line treatment in these instances.

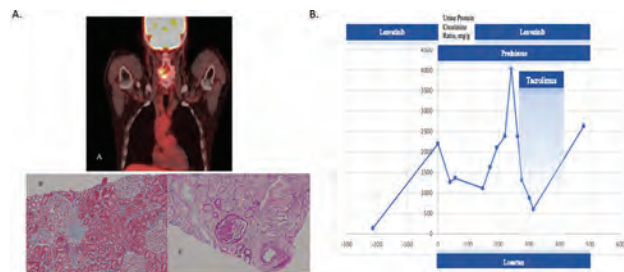

Figure 2: PET and CT sagittal image revealing residual metastatic papillary thyroid carcinoma in C3-C5 vertebrae following surgery and before lenvatinib treatment (A). Light microscopy of renal biopsy (B) with periodic acid-Schiff stain at 20x magnification (B1) and trichrome stain at 100x magnification (B2) showing FSGS.

Figure 3: 24-hour urine protein/creatinine ratio (UPCR) change over time from initial nephrology consultation (0) with key medications spanning the corresponding days of administration.

## FR-PO203

**ANTI-PLA2R Positive Membranous Nephropathy Associated With Atezolizumab: A Case Report**

Diana Oleas, Irati Tapia. *Consorci Sanitari De Terrassa, Terrassa, Spain.*

**Introduction:** Immunotherapy has transformed cancer treatment in advanced malignancies. Increased survival compared with the standard of care has made immunotherapy a fundamental component of oncotherapeutics. Immune checkpoint inhibitors (ICI) trigger a potent stimulus to kill cancer cells. Immune-related adverse events (irAEs) secondary to ICI affect diverse organs. Acute interstitial nephritis is the most frequent kidney irAE. Glomerulopathies, although rare, constitute a more challenging diagnosis and treatment.

**Case Description:** A 72-year-old man with lung adenocarcinoma treated with Bevacizumab and Atezolizumab. During treatment, he developed nephrotic syndrome. A diagnosis of a phospholipase A2 receptor-positive primary membranous nephropathy associated with atezolizumab was made. After failing to respond to steroid therapy, treatment with rituximab was the preferred option. Eight months after being treated with rituximab and ten months after atezolizumab was stopped, the patient maintained preserved renal function and negativization of anti-PLA2R was achieved. Proteinuria declined to half of its initial value five months following anti-PLA2R negativization.

**Discussion:** As we have described, glomerular involvement, like membranous nephropathy, yet not frequent, could cause a high disease burden and affect the oncological and renal outcomes. We believe monitoring for proteinuria during treatment with ICI is crucial to determine an indication for a timely kidney biopsy and treatment.

## FR-PO204

**Panitumumab-Associated IgA Nephropathy With Membranoproliferative and Exudative Features**

Niloufarsadat Yarandi,<sup>1</sup> Mary E. Fidler,<sup>2</sup> Nelson Leung,<sup>1,3</sup> <sup>1</sup>Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; <sup>2</sup>Mayo Clinic Department of Laboratory Medicine and Pathology, Rochester, MN; <sup>3</sup>Mayo Clinic Division of Hematology, Rochester, MN.

**Introduction:** Panitumumab is a monoclonal antibody (MAB) epidermal growth factor receptor (EGFR) inhibitor approved for metastatic colon cancer. EGFR inhibitors can cause tubular, electrolyte disorders and glomerulopathies.

**Case Description:** A 62-year-old male with metastatic colon cancer to the liver developed hypomagnesemia and nephrotic range proteinuria after 2 months of panitumumab. Magnesium 0.6 mg/dL, creatinine 0.72 mg/dL, albumin 3.4 g/dL, proteinuria 16.1 g/24hr, albumin/creatinine 4991 mg/gcr. Urinalysis 51- 100 RBCs(> 25% dysmorphic), 4-10 WBCs, negative nitrite/leukocyte esterase. He required oral and IV magnesium supplements. Amiloride was attempted but resulted in hyperkalemia.

Kidney biopsy revealed IgA nephropathy with exudative membranoproliferative features. Panitumumab was discontinued and prednisone 60 mg daily was started. Proteinuria improved to 6.9 g/24hr within 2 weeks; magnesium normalized.

**Discussion:** Tubular and electrolyte disorders are more common compared to glomerular lesions and are mainly associated with EGFR MABs. The main electrolyte disorder with EGFR inhibitor MABs is hypomagnesemia via renal magnesium wasting. Proliferative IgA crescentic glomerulonephritis (GN), immune-complex GN, and pauciimmune crescentic GN have been reported with EGFR inhibitors. The exact mechanism for nephrotic/nephritic syndrome is not clear. Response to therapy varies from no response to complete response after discontinuing EGFR inhibitor +/- glucocorticoids or other immunosuppressives.

PAS-Jonesx40Endocapillary hypercellularity, segmental neutrophils, segmental glomerular basement membrane double-contouring

#### FR-PO205

##### An Uncommon Cause of Gross Hematuria With Underlying Fibrinolysis Induced by Pulmonary Artery Leiomyosarcoma

Hiroshi D. Hikida, Fouad T. Chebib. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

**Introduction:** Renal arteriovenous (AV) fistulas are an uncommon cause of gross hematuria. In our case presentation, the patient's hematuria rapidly, but temporarily, resolved with two courses of doxycycline. Ultimately, the patient's renal AV fistula was embolized with resolution of the hematuria. This case elucidates an unusual cause of gross hematuria due to renal AV fistula and exacerbated by fibrinolysis caused by a rare malignancy in the pulmonary artery.

**Case Description:** Patient presented to a local clinic with gross hematuria with clots and severe throbbing bilateral flank pain radiating to the groin. He was thought to have prostatitis and was treated with doxycycline which resolved his hematuria but recurred after few days after completion. He presented to our hospital with Hgb 7.4 g/dL and persistent gross hematuria. Abdominal renal imaging and cystoscopy was unrevealing. His workup was consistent with idiopathic fibrinolysis with normal bone marrow biopsy. CT chest revealed nodular opacities but negative comprehensive infectious work up on BAL. The patient ultimately had a renal biopsy performed after which he developed retroperitoneal bleeding that stopped after IR embolization of several bleeding pseudoaneurysms. Renal arteriogram showed evidence of arteriovenous (AV) fistula. His bleeding stopped after initiation of tranexamic acid. Three months later, he developed spontaneous hemoptysis and ipsilateral flank ecchymosis. Subsequent evaluation revealed a large right pulmonary artery mass with FDG-avidity, with ultrasound-guided endobronchial biopsy confirming high-grade pulmonary artery malignancy. He ultimately underwent surgical resection for which surgical pathology revealed high-grade pulmonary artery leiomyosarcoma. Following surgical resection, his coagulopathy improved, and he has had no recurrent bleeding events.

**Discussion:** Studies have shown that underlying malignancy is found in 10-20% of patients with gross hematuria and thus requires systemic evaluation. Diagnosis of renal AV fistulas often require a high-index of suspicion, as their symptoms can vary widely from asymptomatic to gross hematuria, flank pain, and an abdominal mass. Renal artery angiogram is diagnostic gold standard and is required for selective embolization of the fistula as was performed in our patient with a rare underlying malignancy.

#### FR-PO206

##### Plasma Cell Leukemia Masquerading as Acute Myeloid Leukemia: An Unusual Clinical Presentation

Xin Zhang, Song Liu, Kamran Mirza, Maria M. Picken, Vinod K. Bansal, Kavitha Vellanki. *Loyola University Health System, Maywood, IL.*

**Introduction:** Plasma cell leukemia (PCL) is a rare aggressive variant of plasma cell myeloma. Peripheral blood smear morphology can be misleading in the context of acute leukemia like presentation. We present one such unique experience.

**Case Description:** A 64 year old female presented with progressive weakness and fatigue. Work-up revealed acute kidney injury (serum creatinine of 6.8 mg/dl) with nephrotic range proteinuria, hypercalcemia, leucocytosis and 12% of circulating cells with blastoid features on peripheral smear (Figure 1). A preliminary diagnosis of acute myeloid leukemia (AML) was given based on circulating cell morphology, flow cytometry and bone marrow (BM) biopsy findings. Work-up for paraproteinemia subsequently revealed significantly elevated serum free lambda light chains. As co-existence of AML and myeloma is extremely unusual, kidney biopsy was done (Figure 2). While there was some phenotypic overlap with myeloid blasts, subsequent immunohistochemistry of BM biopsy with CD138 staining confirmed the diagnosis of PCL. She has since received targeted chemotherapy with recovery of renal function; currently off dialysis with serum creatinine of 2.6 mg/dl.

**Discussion:** PCL with blastoid morphology is extremely rare and can pose a diagnostic challenge by mimicking acute leukemia. This case illustrates the importance of kidney biopsy in establishing the right diagnosis when clinical features do not correlate with the initial diagnosis.

## FR-PO207

## AKI and “Pseudo-Pyelonphritis” Caused by Immune Checkpoint Inhibitors

Daniel Stalbow,<sup>1,2</sup> Ilya Glezerman,<sup>2,1</sup> Surya V. Seshan,<sup>1</sup> Steven Salvatore,<sup>1</sup> Victoria Gutgarts,<sup>2,1</sup> *Weill Cornell Medicine, New York, NY; <sup>2</sup>Memorial Sloan Kettering Cancer Center, New York, NY.*

**Introduction:** Immune checkpoint inhibitors (ICPIs) have an incidence of renal toxicity that ranges from 1 to 5%. ICPI-associated AKI (ICPI-AKI) presents as asymptomatic rise in serum creatinine. Associated symptoms of dysuria, flank pain, fever and radiologic evidence of renal inflammation are rare.

**Case Description:** Herein we describe three cases (Table below) of biopsy proven ICPI-AKI presenting with dysuria, flank pain and imaging consistent with genitourinary inflammation (Figure below). All patients were empirically treated with antibiotics for suspected infections though urine cultures were negative. Persistent symptoms and rising creatinine led to kidney biopsy which showed acute interstitial inflammation without significant neutrophil infiltration in all three cases. A course of steroids led to the resolution of symptoms and improvement in serum creatinine.

**Discussion:** These cases highlight the complexity of ICPI-AKI that is not limited to laboratory and histology abnormalities but includes symptoms and imaging consistent with inflammation of the genitourinary tract. If overlooked, patients will be mistreated for an infection causing symptoms to persist and a delay in initiation of immunosuppression.

Three cases of ICPI-AKI presenting with dysuria and imaging consistent with genitourinary inflammation

Patient	Cancer	ICPI Type	Baseline Creatinine (mg/dL)	Peak Creatinine at Time of AKI (mg/dL)	Symptoms After Start of ICPI	CT Imaging	Urine Culture	Renal Biopsy Findings	Serum Creatinine (mg/dL)
57F	Breast Cancer	PD-1	0.7	1.8	Dysuria, flank pain, fevers x 1 month	Bilateral perinephric stranding, ureteral thickening, and cystitis	Negative	Active tubulointerstitial nephritis, moderately severe	0.9
62M	Melanoma	PD-1 and CTLA-4	1	4	Abdominal pain x 11 days	Bilateral perinephric fat stranding and ureteral thickening	Negative	Acute tubulointerstitial nephritis	1
46M	Gastric Cancer	PD-1	0.8	3.7	Bilateral flank pain x 7 days	Bilateral perinephric fat stranding and ureteral thickening	Negative	Severe active tubulointerstitial nephritis with granulomatous changes	1.1

Figure: CT findings of bilateral perinephric stranding (yellow arrow) for pts 1-3.

## FR-PO208

## Localized Amyloidosis: The Great Masquerader

Suryanarayanan Balakrishnan, Sushmita Prabhu, Suzanne G. Martin. *Saint Vincent Hospital, Worcester, MA.*

**Introduction:** Amyloidosis is characterized by misfolding of extracellular proteins and deposition in tissues as insoluble fibrils, causing end-organ damage. Localized amyloidosis (LA) without a plasma cell dyscrasia (AL amyloidosis) or chronic inflammation (AA amyloidosis) is rare. LA tends to involve the bladder, upper and lower respiratory tract, skin and eyes. LA presents as a tumor-like lesion, and patients may undergo extensive, and sometimes invasive, testing. LA of the bladder can present with painless hematuria, mimicking urologic malignancy.

**Case Description:** 80M with Stage IIIA CKD, BPH, and atrial fibrillation on warfarin presented with intermittent gross hematuria over many years. Two cystoscopies in the last 5 years were negative for malignancy, with inflammation on biopsy. Labs were reassuring for stable hematocrit and baseline creatinine. Urine sediment revealed nondysmorphic RBCs. Urine protein:Cr ratio was 816mg/gCr. CT abd/pelvis showed diffuse circumferential thickening of the distal right ureter and nodular thickening of the right UVJ. Repeat cystoscopy showed the right ureteral orifice to be surrounded by erythema and thickening, concerning for a ureteral or atypical bladder mass. Biopsy showed chronic inflammation and amorphous, Congo red-positive material consistent with amyloidosis, and he underwent transurethral resection. Immunofixation and serum free light chain ratio were negative for plasma cell dyscrasia. He had no manifestations of amyloidosis in other organs. Proteinuria and creatinine remain stable 8 years later, around 500mg/day and 1.1-1.3mg/dL, respectively.

**Discussion:** Localized bladder amyloidosis may masquerade as malignancy, often presenting with painless gross hematuria and/or lower urinary tract symptoms. Cystoscopy may raise concern for malignancy, and biopsy may only show nonspecific inflammation unless Congo red staining is performed. Securing the diagnosis of amyloidosis can prevent unnecessary procedures. Mass spectrometry is preferred to identify the causative misfolded protein. Primary bladder amyloidosis is rare and systemic

amyloidosis must be excluded. If left untreated, localized bladder amyloidosis can lead to symptoms of obstructive uropathy. Treatment is aimed at transurethral excision of the lesion, and surveillance for recurrence is required. The prognosis is excellent, with only 1% progressing to systemic disease.

## FR-PO209

## Onconeurology, Rise of the Unknowns: Enhertu-Induced Fanconi Syndrome

Pooja Kalantri, Koba A. Lomashvili. *Emory University, Atlanta, GA.*

**Introduction:** Kidney toxicities are associated with increasingly complex and constantly emerging cancer treatment protocols. Data clearly demonstrates that when patients with cancer develop acute or chronic kidney disease, severe fluid and electrolyte abnormalities, outcomes are inferior, and the promise of curative therapeutic regimens is lessened. Here we present a case of a new chemotherapeutic agent and the electrolyte abnormalities that it has caused.

**Case Description:** A 74-year-old woman with metastatic, recurrent ER+/PR-/HER2+ invasive ductal carcinoma of the right breast, status post bilateral mastectomies, chemo, radiation, and hormonal therapies, who, while being on Herceptin/Perjeta maintenance for a year, experienced progression. She was started on Enhertu (Herceptin+Deruxtecan), but due to worsening diarrhea, >12 episodes a day, decreased oral intake and weight loss, was admitted to the hospital. Her blood pressures were soft. Labs showed sodium 132 mmol/L, potassium 2.1 mmol/L, bicarbonate 17 mmol/L, anion gap 6, calcium 7.3 mg/dL, magnesium 1.2 mg/dL, phosphorus 1.3 mg/dL. Abnormalities persisted with improving diarrhea. Urine was positive for protein and glucose, with pH 5. Urine anion gap was negative, but eventually turned positive with improving diarrhea. Transtubular potassium gradient was 8. This was consistent with component of diarrhea causing acidosis, whereas there was also evidence of Fanconi syndrome with glucosuria, proteinuria, and renal potassium and phosphate wasting. The Fanconi syndrome was attributed to the Deruxtecan component of Enhertu, as she was previously on Herceptin. Enhertu was stopped, and her electrolyte abnormalities resolved over a course of 2 months.

**Discussion:** Deruxtecan has been associated with diarrhea (20-30%) and hypokalemia (1-12%) in phase 2 trials. But there has been no mention about Fanconi syndrome. We report a case of reversible Fanconi syndrome due to Enhertu. It is important to recognize this as future doses of this medication may cause poor outcomes in these patients, while the performance status can be improved again by recognizing this reversible cause.

## FR-PO210

## Monoclonal Immunoglobulin Deposition Disease in a Young Female

Divya Sharma Divyadarshini,<sup>1</sup> Gargi Sharma Priamvada,<sup>2</sup> Pingchuan Zhang,<sup>3</sup> Koyal Jain.<sup>2</sup> *<sup>1</sup>Sapthagiri Institute of Medical Sciences and Research Centre, Bangalore, India; <sup>2</sup>University of North Carolina System, Chapel Hill, NC; <sup>3</sup>Mayo Foundation for Medical Education and Research, Rochester, MN.*

**Introduction:** Monoclonal immunoglobulin deposition disease (MIDD) is characterized by deposition of monoclonal immunoglobulin (MIg) along glomerular and tubular basement membranes (GTBM). Prevalence is higher in males with a mean age of 56 years. Light chain deposition disease (LCDD) accounts for 80% of cases with others being heavy chain (HCDD) and rarely light and heavy chain deposition disease (LHCDD). We present a case of rare pathological features of LHCDD presenting at a young age.

**Case Description:** A 34 year previously healthy female presented with hypertensive urgency, renal insufficiency and nephrotic syndrome. Urine protein creatinine ratio was 11 g/g. Urine microalbumin creatinine ratio 5.5 g/g. Serum protein electrophoresis (SPEP) revealed MIg - IgG lambda type, serum free light chain (sFLC) ratio of 0.03. Renal biopsy showed LHCDD with membranoproliferative injury and focal cellular crescents, immunofluorescence showed deposits along GTBM that were nonfibrillar by electron microscopy (Figure). Imaging did not suggest multiple myeloma. Bone marrow biopsy showed only 10% plasma cell population. She was treated with cyclophosphamide, bortezomib and dexamethasone (CyBorD) with improvement in kidney function and proteinuria.

**Discussion:** This case of MIDD, occurring in a very young female, highlights the importance of complete serologic evaluation of individuals with new onset nephrotic syndrome, including SPEP and sFLC. MIDD is associated with multiple myeloma in up to 60% of cases but can occur in absence of hematological malignancy. Kidney is the major target organ in MIDD but about 35% of cases have extrarenal manifestations. Clone-directed chemotherapy with CyBorD or bendamustine is the treatment of choice. The sensitivity of abnormal serum FLC is very high in MIDD, hence is an important marker for both suspicion of disease and remission.

Clockwise: IF IgG, LM – Silver - Diffuse mesangial and endocapillary proliferation with lobular accentuation, IF IgG lambda, EM X4000 – Powdery deposits along TBM

## FR-PO211

### Hypophysitis in a Patient on Pembrolizumab

Jack Luo,<sup>1,4</sup> Kiran Suryadevara,<sup>2</sup> Warda Zaman.<sup>3,1</sup> <sup>1</sup>Alameda Health System, Oakland, CA; <sup>2</sup>St George's University School of Medicine, St George's, Grenada; <sup>3</sup>East Bay Nephrology Medical Group, Oakland, CA; <sup>4</sup>Highland Hospital Internal Medicine, Oakland, CA.

**Introduction:** Pembrolizumab is a PD-1 immune checkpoint inhibitor (ICI) used to treat advanced malignancies that may be unresectable, metastatic, or refractory to other chemotherapy regimens. We report a case of hypophysitis in a 63 year-old Asian female after receiving pembrolizumab for treatment of metastatic urothelial carcinoma.

**Case Description:** A 63 year-old post-menopausal Asian woman presented to the hospital with dizziness, loss of appetite, and generalized fatigue for three weeks. She was found to have a blood glucose level of 55mg/dL. She was on pembrolizumab for 8 months for metastatic urothelial carcinoma. She developed hypothyroidism 3 months after starting pembrolizumab. At presentation, she was hypotensive to 80/55 mmHg, euvolemic on exam, sodium level was 116mmol/L, measured serum osmolality was 246 mOsm/kg; urine osmolality was 312 mOsm/kg and urine sodium was 44 mmol/L. Liver and renal function tests were normal. Serum sodium improved to 118 mmol/L after 1 liter of lactated ringers solution. Blood glucose was 77 mg/dL on initial presentation and varied between 49-100 mg/dL throughout most of the admission. TSH was 4.06  $\mu$ U/ml and cortisol level was <1.0 mcg/dL, ACTH level was undetectable. The patient was started on hydrocortisone 10mg in the morning and 5mg in the evening and fludrocortisone 0.05mg daily. Glucose levels remained within normal limits. All her presenting symptoms resolved. Her history of hypothyroidism and now secondary adrenal insufficiency was suspicious for hypophysitis related to Pembrolizumab. Two weeks after discharge, serum sodium was 143mmol/L and was stable on follow-up labs. In addition, FSH, LH and IGF-1 were checked and were relatively low in her, which are very elevated in post-menopausal women further confirming the hypophysitis. Currently, she is on the same doses of hydrocortisone and fludrocortisone is discontinued. There is plan to restart the Pembrolizumab.

**Discussion:** Hypophysitis is an uncommon side-effect of ICIs, especially PD-1 inhibitors. In a meta-analysis of 31 clinical trials with 7551 patients, the incidence of hypophysitis was only 0.4% with PD-1 inhibitors compared to 3.2% with CTLA-4 inhibitors and 6.4% with combination therapy. Patients may present with nonspecific symptoms such as fatigue, dizziness, and appetite loss, so it is important to have high clinical suspicion for hypophysitis and hormonal deficiencies in patients treated with pembrolizumab.

## FR-PO212

### Thrombotic Microangiopathy Associated With Use of Liposomal Doxorubicin

Claudia M. Brauer Ornelas,<sup>1</sup> Ciara M. Kelly,<sup>2,1</sup> Steven Salvatore,<sup>2</sup> Ilya Glezerman.<sup>2,1</sup> <sup>1</sup>Weill Cornell Medicine, New York, NY; <sup>2</sup>Memorial Sloan Kettering Cancer Center, New York, NY.

**Introduction:** TMA is rare with liposomal doxorubicin and its presentation and prognosis is not well defined in this setting. We report a patient on single agent liposomal doxorubicin who developed TMA.

**Case Description:** 72-year-old female with history of well controlled hypertension (HTN) and retroperitoneal liposarcoma referred to renal service for elevated serum creatinine (SCr) and edema. She underwent resection and left nephrectomy at the time of diagnosis of liposarcoma. Patient was started on liposomal doxorubicin at 40mg/m<sup>2</sup> per cycle (cumulative dose 1240mg/m<sup>2</sup>) 18 months prior to presentation. Her baseline SCr was 1 (0.6-1.1) mg/dL but it has been slowly rising for the past 7 months. She was taking alendronate, amlodipine and levothyroxine. Hydrochlorothiazide was added recently for worsening HTN. Patient appeared comfortable. BP was 166/86 but vital signs otherwise were stable. Exam was unremarkable except for lower extremity edema. Laboratory data revealed SCr of 2mg/dL and nephrotic range proteinuria (4g/day). Urinalysis showed five RBC/HPF. Initial work up showed normal complement level, haptoglobin and urine and serum protein electrophoresis. Hepatitis B and C serologies as well as ANA and ANCA were negative. Lactate dehydrogenase level was elevated 317 (130-250) U/L. aHUS complement panel showed no serologic evidence of complement abnormalities.

CT scan of abdomen and pelvis showed unchanged multifocal recurrent disease and well no evidence of right hydronephrosis. Patient underwent kidney biopsy which showed chronic endothelial injury suggestive of chronic thrombotic microangiopathy involving glomeruli. Liposomal doxorubicin was stopped and SCr peaked at 5.4mg/dl four months after biopsy but gradually improved to a trough of 3.4 mg/dL at last follow up. Nephrotic range proteinuria and edema resolved.

**Discussion:** Liposomal doxorubicin associated TMA is not a well-known potential side effect. There have been two cases of biopsy proven TMA in ovarian cancer patients on single agent liposomal doxorubicin after prolonged exposure. In another case report a patient with liposarcoma of kidney had a prolonged exposure to liposomal doxorubicin and developed TMA leading to hemodialysis. Our patient also had large cumulative exposure indicating that TMA may be dose dependent.

## FR-PO213

### Novel Anti-Cancer Agents and Capillary Leak Syndrome

Tanazul T. Pariswala, Vipulbhai Sakhiya, Rimda Wanchoo, Kenar D. Jhaveri. *Northwell Health, New Hyde Park, NY.*

**Background:** The term capillary leak syndrome (CLS) results clinically in the typical triad of hypotension, edema, and elevated hematocrit. The more severe cases of CLS may present with cardiovascular collapse, shock, and death. Data on CLS associated with novel anti cancer agents is insufficient.

**Methods:** We reviewed the FDA adverse event reporting system (FAERS) quarterly legacy data first quarter 2010 to 4th quarter 2021 for all recently commonly used targeted therapies and immune-checkpoint inhibitors (ICI). Well established chemotherapy agents such as gemcitabine, clofarabine, cyclophosphamide, platinum-based therapy, colony stimulating factors were excluded. CAR-T therapy is well known to cause CLS and hence was excluded. The adverse event terms queried were: capillary leak syndrome, capillary leak and cytokine storm. We reviewed the literature using pubmed, case reports, case series and the registrational studies of anti-cancer agents associated with CLS as well.

**Results:** FAERS reporting system reported 22 cases of CLS in the last 11 years with novel anti cancer agents. The most common class was anti CD20 (rituximab-9 cases), followed by ICIs (6) and then anti VEGF agents(4). Other meds (4) were mainly bortezomib and trastuzumab. The two reported ICIs were ipilimumab and nivolumab. The most common anti VEGF inhibitor was bevacizumab. The literature search revealed anti CD20 (rituximab) being the most common agent with 19 cases reported followed by bortezomib(anti plasma cell agent) with 13 cases. Trastuzumab had 11 cases reported and other rare cases with alemtuzumab(6) and blinatumomab(3). Immune checkpoint inhibitors with specifically nivolumab, there were 4 cases reported.

**Conclusions:** CLS is rare in novel anti cancer agents. Anti CD20 agents such as rituximab seem to be the most common cause of this rare side effect. Other agents such as bortezomib, anti VEGF agents, trastuzumab and ICIs(mainly nivolumab and ipilimumab) can also rarely cause CLS. Oncologist and nephrologists need to be mindful of this rare fatal side effect.

## FR-PO214

### Renal Adverse Events Associated With the Immune Checkpoint Inhibitor Therapy: A Systematic Review and Bayesian Network Meta-Analysis of 96 Randomised Controlled Trials

Shehjar Trisal,<sup>1</sup> Gary K. Low,<sup>1,2</sup> Faraz K. Pathan,<sup>1,2</sup> Muralikrishna Gangadharan Komala.<sup>1,2</sup> <sup>1</sup>University of Sydney - Camperdown and Darlington Campus *Burkitt-Ford Library, Sydney, NSW, Australia;* <sup>2</sup>Nepean Blue Mountains Local Health District, Penrith, NSW, Australia.

**Background:** Immune checkpoint inhibitors (ICI) have revolutionised cancer immunotherapy, improving survival in cancer patients. However, the blockade of immune regulatory sites, CTLA-4, PD-1, and PD-L1 is associated with a range of immune related adverse events (irAE) of which renal irAE occur infrequently and are not regularly reported.

**Methods:** The PRISMA guidelines were used to search for Randomised Control Trials (RCT) reporting severe adverse renal events across five electronic databases from inception to April 2022. This was supplemented with hand searching of major medical journals and the National Clinical Trials registry. A Bayesian network meta-analysis was performed using R version 4.1.0 R for the following outcomes: acute kidney injury (AKI), hypertension (HTN), glomerulonephritis, chronic kidney disease (CKD) and the composite of all acute adverse renal events (AARE) namely AKI, HTN and glomerulonephritis. Network meta-regression was performed to adjust for inconsistencies arising from malignancy subtype.

**Results:** 96 RCTs reported severe grade adverse renal events. The risk of developing acute kidney injury is higher among patients who received PD-1 plus chemotherapy (OR 1.8 [95% CrI 1.3 to 2.4]) and PD-L1 plus chemotherapy (OR 1.90 [95% CrI 1.3 to 2.9]) when compared to standard chemotherapy and placebo (95 studies, 63, 793 participants). The risk of developing an AARE is higher among patients who received PD-1 plus chemotherapy (OR 1.7 [95% CrI 1.1 to 2.4]) and PD-L1 plus chemotherapy (OR 1.7 [95% CrI 1.1 to 2.6]) when compared to standard chemotherapy and placebo (64,409 participants).

**Conclusions:** The combined regimen of PD-1 or PDL-1 + chemotherapy is associated with higher incidence of severe grade AKI and AARE. Prescription of combined therapy will warrant closer monitoring and implementation of preventive strategies/changes to the treatment regimen could be arranged early at the onset of adverse events.

Incidence of Acute Kidney Injury

## FR-PO215

## Real-World Incidence of Kidney Manifestations in Patients Treated With New Tyrosine Kinase Inhibitors

Praveen Ratanasrimetha,<sup>1</sup> Omar Mamlouk,<sup>1</sup> Sai S. Achi,<sup>2</sup> James P. Long,<sup>1</sup> Valda D. Page,<sup>1</sup> Sreedhar A. Mandayam.<sup>1</sup> <sup>1</sup>The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>2</sup>The University of Texas Health Science Center at Houston, Houston, TX.

**Background:** Imatinib was the first FDA approved Tyrosine kinase inhibitor (TKI) and since then there are more than 40 new approved TKI drugs. Multiple studies reported the incidence and clinical characteristics of TKI related nephrotoxicity; however, they were limited to the first approved TKI drugs. Currently, we are relying on FDA adverse reporting system (FARES) data for the newer agents, which is subject to bias. In this study we report our cancer center incidence of acute kidney injury (AKI) and proteinuria as the kidney manifestations associated with certain newer TKI agents.

**Methods:** This is a retrospective cohort study including patients who were treated with the following six most prescribed new tyrosine kinase inhibitors; regorafenib, axitinib, cabozantinib, erlotinib, ponatinib, and ibrutinib from January 2017 to October 2019 at MDA Cancer Center. We collected data related to patient baseline characteristics, concurrent nephrotoxic medication use, serum creatinine, and urine dipstick. We defined acute kidney injury and proteinuria as a rise in serum creatinine more than 50% above the baseline and a positive urine dipstick for protein, respectively, throughout the duration of TKI therapy and up to 45 days of stopping TKI.

**Results:** We identified 2063 subjects. Median age was 63 (SD=12.7) and the overall median duration of TKI therapy was ranging 28-67 days. Around half of the patients were on Ibrutinib. Proteinuria developed in approximately half of the patients (39-61% based on the TKI) and was more prevalent with Regorafenib (61%) vs. Axitinib (39%). 1.5 % of the patients develop AKI during the first 30 days of therapy and 11.1% thereafter. The incidence of AKI was ranging between 10-28% and was highest with Ponatinib (28%) vs. Ibrutinib (10%). In univariate analysis, diabetes and proton pump inhibitors were associated with increased risk of developing proteinuria and AKI, respectively, during TKI therapy.

**Conclusions:** Our study provides a real-world data about the incidence of kidney related manifestation in patients treated with the newer generation of TKI agents. Proteinuria is the predominant kidney manifestation followed by AKI. Incidence of AKI is close to the first generation TKI with exception for ponatinib that had two to three times the risk of AKI.

## FR-PO216

## Glomerular Filtration Rate Equations for Drug Dosing: Discordance by BMI and Age

Beini Lyu,<sup>1</sup> Lesley A. Inker,<sup>2</sup> Alex R. Chang,<sup>3</sup> Thomas D. Nolin,<sup>4</sup> Josef Coresh,<sup>1</sup> Morgan Grams,<sup>5</sup> Jung-Im Shin.<sup>1</sup> <sup>1</sup>Johns Hopkins University, Baltimore, MD; <sup>2</sup>Tufts Medical Center, Boston, MA; <sup>3</sup>Geisinger Health, Danville, PA; <sup>4</sup>University of Pittsburgh, Pittsburgh, PA; <sup>5</sup>New York University, New York, NY.

**Background:** Historically, different methods to estimate glomerular filtration rate (GFR) have been used for drug development, labeling for drug dosing, and clinical practice. Substantial differences in GFR estimated from different equations may prevent optimal drug dosing.

**Methods:** We analyzed 29,564 patients with atrial fibrillation (AF) who had serum creatinine, weight, and height measurements in Geisinger health system between 2005-2019 (mean age 76yrs, mean body mass index [BMI] 29.5 kg/m<sup>2</sup>). We compared differences among three GFR estimates by BMI and age: Cockcroft-Gault estimated creatinine clearance (eCICr; unit: mL/min), CKD-EPI 2021 (eGFR, mL/min/1.73 m<sup>2</sup>), and non-indexed CKD-EPI 2021 (neGFR, mL/min). To quantify potential impact on drug dosing, we estimated the proportion of discordance in recommended rivaroxaban dose by different GFR estimates among patients with eGFR 30-60 mL/min/1.73 m<sup>2</sup>. The FDA label for rivaroxaban recommends a reduced dose in eCICr <50 mL/min.

**Results:** The differences among the three estimates varied by BMI and by age: for example, eCICr was higher than eGFR and neGFR among patients with BMI ≥40 kg/m<sup>2</sup> (mean: eCICr 117.8 mL/min, eGFR 65.8 mL/min/1.73 m<sup>2</sup>, and neGFR 89.4 mL/min);

eCICr was lower than eGFR and neGFR among patients ≥85 years (mean: eCICr 38.6 mL/min, eGFR 51.6 mL/min/1.73 m<sup>2</sup>, neGFR 51.9 mL/min). Rivaroxaban dosing discordance varied by BMI and age as well: for example, among patients with BMI ≥40 kg/m<sup>2</sup>, 40-60% of patients would need a reduced dose of rivaroxaban by eGFR and 15-20% would need a reduced dose by neGFR whereas standard dose would be recommended by eCICr across the age groups (Figure).

**Conclusions:** eCICr, eGFR, and neGFR values could differ substantially depending on body size and age, potentially resulting in substantial drug dosing discordance.

**Funding:** NIDDK Support

## FR-PO217

## Effect of Multiple Doses of Sparsentan on the Single-Dose Pharmacokinetics of Dapagliflozin: Open-Label Drug-Drug Interaction Study in Healthy Adults

Charles Chen,<sup>1</sup> Danlin Cai,<sup>1</sup> Claire E. Winnett,<sup>1</sup> Neeraj Verma,<sup>1</sup> Priscila Preciado,<sup>1</sup> Traver Therapeutics Inc, San Diego, CA.

**Background:** Sparsentan (SPAR) is a novel single molecule Dual Endothelin Angiotensin Receptor Antagonist (DEARA) being investigated for immunoglobulin A nephropathy and focal segmental glomerulosclerosis. Potential drug-drug interactions (DDI) with sodium-glucose co-transporter 2 inhibitors are not known. This phase 1 study examined the effect of multiple doses of SPAR on the pharmacokinetics (PK) of single-dose dapagliflozin (DAPA) and assessed the safety and tolerability of single-dose DAPA when co-administered after multiple doses of SPAR in healthy adults.

**Methods:** This open-label DDI study included Period 1 (Days 1-5; single dose of 10mg DAPA on Day 1, PK sampling pre-dose and up to 96 hours post-dose) and Period 2 (Days 5-14; 800mg SPAR once daily for 10 days with single 10mg dose DAPA co-administered on Day 11, DAPA PK sampling pre-dose and up to 96 hours after Day 11 dosing). To avoid hypoglycemic events, subjects received an oral 20% glucose solution in water with the DAPA dose and every ~15 minutes up to 4 hours post-dose. Plasma concentrations and PK parameters of DAPA and SPAR were summarized. Subjects with evaluable data for both periods were included in an ANOVA mixed model analysis of DAPA AUC<sub>0-t</sub>, AUC<sub>0-inf</sub>, and C<sub>max</sub> following DAPA+SPAR vs DAPA alone. Treatment-emergent adverse events (TEAEs) were summarized.

**Results:** Twenty-two healthy adults were enrolled and 20 completed both study periods. Mean peak and extent of DAPA exposure (C<sub>max</sub> and AUC) values were similar following 10mg DAPA alone and 10mg DAPA+800mg SPAR (Table). TEAEs were reported by 14 (63.6%) subjects. Most frequent were headache (6; 27.3%), nausea (5; 22.7%), and preprandial asymptomatic hypoglycemia (5; 22.7%).

**Conclusions:** Multiple dosing of SPAR did not affect single-dose DAPA PK in healthy adults. Single-dose DAPA co-administered with multiple doses of SPAR appeared to be well tolerated by healthy adults.

**Funding:** Commercial Support - Traver Therapeutics, Inc., San Diego, CA

Plasma Dapagliflozin PK Parameters Following Dapagliflozin+Sparsentan Versus Dapagliflozin Alone

	Dapagliflozin+Sparsentan	Dapagliflozin	GLSMR (%)	90% CI	Intra-subject CV%
AUC <sub>0-t</sub> (ng·hr/mL)	526.1 (n=20)	508.8 (n=20)	103.4	99.9-107.0	6.3
AUC <sub>0-inf</sub> (ng·hr/mL)	565.4 (n=16)	533.7 (n=16)	105.9	103.1-108.9	4.4
C <sub>max</sub> (ng/mL)	79.9 (n=20)	73.9 (n=20)	108.2	96.0-121.8	22.0

## FR-PO218

## Pharmacokinetics and Drug-Drug Interaction of KBP-5074 in Healthy Subjects

Ping Wang,<sup>1</sup> Liu Jinrong,<sup>1</sup> Judy Tan,<sup>1</sup> Jay Zhang,<sup>1</sup> Y. Fred Yang,<sup>1</sup> James C. McCabe.<sup>1</sup> Kbp Biosciences Co Ltd, Jinan, China.

**Background:** KBP-5074, a selective nonsteroidal MRA inhibitor, has a favorable safety profile and significant activity on hypertension and nephropathy in stage 3/4 CKD patients with uncontrolled hypertension. A clinical DDI study was conducted in healthy volunteers to evaluate the effect of a CYP3A4 inhibitor and inducer on the PK of KBP-5074.

**Methods:** This was a phase 1 study to investigate the effect of coadministration of a CYP3A4 inhibitor (itraconazole) and CYP3A4 inducer (rifampin) on the plasma PK of a single dose of KBP-5074 in healthy male and female subjects. 24 subjects 18 to 60 years of age with a BMI of 18.0 to 32.0 kg/m<sup>2</sup> were selected. Serial blood collections were obtained from pre-dose through 240 hours post-dose for analysis of plasma concentrations of KBP-5074.

**Results:** The strong CYP3A inhibitor itraconazole and strong CYP3A inducer rifampin had statistically significant effects on the pharmacokinetics of KBP-5074. The exposures were 1.1 fold and 1.7 fold higher when KBP-5074 was administered in combination with itraconazole based on C<sub>max</sub> and AUC<sub>last</sub>. The median t<sub>max</sub> was reduced

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

(from 4 h to 2h) and geometric mean  $t_{1/2}$  was longer (60.3 h to 125 h) in the presence of itraconazole. When KBP-5074 was administered in combination with rifampin, exposures were decreased approximately 28% and 84% based on  $C_{max}$  and  $AUC_{last}$ . Median  $t_{max}$  was similar (4 hours), but geometric mean  $t_{1/2}$  was shorter (10.9 hours).

**Conclusions:** A strong CYP3A inhibitor (itraconazole) had a weak effect (1.1 to 1.7 fold increase), whereas a strong CYP3A4 inducer (rifampin) had a strong effect (up to 84% decrease) on the clinical pharmacokinetics of KBP-5074. KBP-5074 was well tolerated when administered as a single 0.5-mg dose alone or in combination with itraconazole or rifampin.

**Funding:** Commercial Support - KBP Biosciences PTE Ltd

## FR-PO219

### In Vitro Evaluation of Drug-Drug Interactions of Patiromer With Common Renal and Cardiovascular Drugs

Jörg S. Schmitt,<sup>2</sup> Anna-Lena Steck,<sup>2</sup> Martin Khoeiklang,<sup>2</sup> Carol P. Moreno Quinn,<sup>2</sup> Martin Kretz,<sup>2</sup> Michael Bauer,<sup>2</sup> Lingyun Li,<sup>1</sup> Maria Wilhelm.<sup>2</sup> <sup>1</sup>Vifor Pharma Inc., Redwood City, Redwood City, CA; <sup>2</sup>Vifor Pharma Ltd, St Gallen, Switzerland, St Gallen, Switzerland.

**Background:** Patiromer (PAT) is a non-absorbed potassium binder approved for treatment of hyperkalemia (HK) and has the potential to bind off-target, positively charged molecules in the gastrointestinal tract (GIT), leading to drug-drug interactions (DDIs) with co-administered oral drugs. Generally, separation of administration by 3 hours between PAT and other oral medications is recommended. We sought to further extend the range of medications that can be administered simultaneously with PAT by evaluating drugs used to treat cardio-renal patients with hyperkalemia.

**Methods:** This study utilizes single- and gradient-pH (1.2, 4.5 and 6.8) *in vitro* models mimicking GIT passage to determine DDIs between PAT and 25 cardio-renal drugs. Resultant free test drug concentration was determined by liquid chromatography, and percentage recovery (mean [95% confidence interval]) was calculated from six replicates; <70% recovery with PAT compared with drug alone was deemed a significant DDI.

**Results:** At pH 1.2, <70% (mean [95% confidence interval]) recovery was observed with quinapril (68.0 [67.7–68.2]), telmisartan (9.9 [9.7–10.1]), losartan potassium (46.3 [45.9–46.7]), azilsartan (14.2 [12.8–15.5]), irbesartan (58.1 [57.0–59.2]), olmesartan medoxomil (58.9 [58.2–59.6]), carvedilol (1.3 [1.1–1.5]), nebivolol (5.5 [5.2–5.8]), finerenone (54.8 [54.0–55.6]) and torasemide (44.7 [44.4–45.1]). At pH 4.5, <70% recovery was observed with carvedilol, nebivolol and finerenone (5.4 [5.1–5.7]), 15.8 [14.8–16.7], 69.6 [69.1–70.1], respectively, and at pH 6.8 with telmisartan (10.8 [10.5–11.1]), bisoprolol fumarate (67.6 [66.5–68.6]), carvedilol (1.6 [1.5–1.7]) and nebivolol (6.9 [6.1–7.6]). Binding was associated with charge and lipophilicity. In the gradient-pH model simulating overall GIT passage, >70% recovery of quinapril, losartan potassium, irbesartan, olmesartan medoxomil, azilsartan, finerenone and torasemide was observed.

**Conclusions:** Of the 25 drugs tested, 14 showed ≥70% recovery with PAT. 11 showed <70% recovery with PAT, mostly at pH 1.2. However, 7 drugs with DDIs at pH 1.2 showed no relevant interactions with patiromer at gradient pH, suggesting DDIs at low pH could be reversed as test drugs became neutral or negatively charged in the intestine, where most drugs are absorbed.

## FR-PO220

### Preclinical Pharmacokinetics of a Novel Nicorandil Prodrug

Pramod Gupta, Atul Khare. Unicycive Therapeutics Inc., Los Altos, CA.

**Background:** Nicorandil, a potassium channel activator, is used to prevent or reduce angina. Limitations of nicorandil include serious gastrointestinal side effects and rapid absorption and elimination. A nicorandil prodrug may increase short half-life and improve safety profile of nicorandil. We present pharmacokinetic data in dogs for a novel nicorandil prodrug (UNI-494).

**Methods:** Groups of 3 beagle dogs were administered a single oral dose of 3, 10, or 30mg/kg UNI-494 at a volume of 5mL/kg. Clinical observations were recorded at approximately 1, 1.5, 2, 3, and 24h post-dose. Whole blood samples were collected pre-dose and 0.083, 0.25, 0.50, 1, 1.5, 2, 4, 8, and 24h post-dose to analyze systemic exposure to UNI-494 and nicorandil. Dose and concentration parameters ( $C_{max}$  and AUC) were used to generate linearity plots and calculate the coefficients of determination ( $r^2$ ) and slopes for UNI-494 and nicorandil.

**Results:** Mean  $T_{max}$ ,  $C_{max}$ , and AUC of 3, 10, and 30mg/kg dose groups are displayed in Table 1. For the linearity plots,  $r^2$  values and slopes for dose vs.  $C_{max}$  and dose vs. AUC are shown in Figures 1 and 2, respectively.

**Conclusions:** Nicorandil was rapidly formed from the prodrug UNI-494. Mean  $C_{max}$  for nicorandil was >5-fold greater than that of UNI-494, demonstrating efficient conversion of the prodrug to active drug. The conversion was consistent across dose groups. These results indicate that UNI-494 is a rationally designed drug, and future studies should evaluate this promising treatment in the target population of patients with AKI.

## C<sub>max</sub>, T<sub>max</sub>, and AUC by Dose Group and Analytes

Dose Group (mg/kg)	Analyte	C <sub>max</sub> (ng/mL)	T <sub>max</sub> (Hours)	AUC (Hour*ng/mL)
3	UNI-494	43	0.3	34
	Nicorandil	1,300	0.7	3,400
10	UNI-494	178	0.3	162
	Nicorandil	3,070	1.5	11,400
30	UNI-494	1,500	0.3	1,510
	Nicorandil	7,530	1.3	38,000

Figure 1. Mean  $C_{max}$  of Nicorandil and UNI-494 by UNI-494 Dose After Single Dosing in Dogs  
Mean  $C_{max}$  of Nicorandil and UNI-494 by UNI-494 Dose After Single Dosing in Dogs

### Incidence, Characteristics, and Preventability of Adverse Drug Reactions in Patients With Moderate-to-Advanced CKD

Solene M. Laville,<sup>1,2</sup> Valérie Gras,<sup>1</sup> Julien Moragny,<sup>1</sup> Christian Jacquelinet,<sup>10,6</sup> Christian Combe,<sup>3,4</sup> Denis Fouque,<sup>7,8</sup> Maurice Laville,<sup>7</sup> Carole Ayav,<sup>11</sup> Natalia Alencar de Pinho,<sup>6</sup> Brian Bieber,<sup>9</sup> Benedicte Stengel,<sup>6</sup> Ziad Massy,<sup>5,6</sup> Sophie Liabeuf,<sup>1,2</sup> CKD-REIN study Collaborators <sup>1</sup>Centre Hospitalier Universitaire Amiens-Picardie, Amiens, France; <sup>2</sup>Universite de Picardie Jules Verne, Amiens, France; <sup>3</sup>Centre Hospitalier Universitaire de Bordeaux, Bordeaux, France; <sup>4</sup>Inserm U1026, University of Bordeaux Segalen, Bordeaux, France; <sup>5</sup>Ambroise Paré University Hospital, APHP, Boulogne-Billancourt, France; <sup>6</sup>Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; <sup>7</sup>Claude Bernard University Lyon 1, CarMeN Inserm, Lyon, France; <sup>8</sup>Nephrology department, Lyon Sud University Hospital, Pierre-Bénite, France; <sup>9</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>10</sup>Agence de la biomedecine, La Plaine Saint-Denis, France; <sup>11</sup>Clinical epidemiology, Inserm CIC-EC, Nancy University hospital, Vandoeuvre-lès-Nancy, France.

**Background:** Although adverse drug reactions (ADRs) are recognized as a major problem in the CKD population, few studies have comprehensively investigated ADRs—serious or not—in this population. Our aims were to estimate the incidence of these events according to estimated glomerular filtration rate (eGFR), describe serious ADRs and determine whether they are preventable.

**Methods:** CKD-REIN is a prospective cohort of 3033 nephrology outpatients with a confirmed diagnosis of CKD and an eGFR < 60mL/min/1.73m<sup>2</sup>. ADRs were prospectively identified from hospitalization and medical reports and participant interviews. Experts in pharmacology assessed causality and preventability using validated tools.

**Results:** At baseline, patients' median age was 69, mean eGFR was 33mL/min/1.73m<sup>2</sup>, and the median number of medications per day was 8. During a median follow-up of 4.6 years, 1672 ADRs (among which 488 were serious) occurred in 973 patients, of whom 42% had more than one ADR (incidence rate: all ADRs, 14.2 [13.6–14.9] per 100 person-years (PA); serious ADRs, 4.2 [3.8–4.5] per 100 PA). Among all ADRs, renal and urinary disorders (n=310), gastrointestinal disorders (n=253) and hemorrhages (n=213) were the most common. The incidence rate of serious ADRs in patients with an eGFR <30 was twice as high as in patients with an eGFR ≥ 30mL/min/1.73m<sup>2</sup> (6.0 [5.2;6.7] vs 3.1 [2.7;3.5] per 100 PA). This difference was mainly driven by bleeding events imputed to antithrombotics. Among 488 serious ADRs, 65% were the cause of hospitalization, 31% occurred during hospitalization and 4% were serious but did not require hospitalization. More than 27% of serious ADRs were preventable or potentially preventable (n=132). The most important preventability criterion was inappropriately

high dosage (n=28) and contraindications (n=35) according to the patient's kidney function. Patients were implicated in 22 preventable cases because of medication error (n=14), self-medication (n=6), and other (n=2).

**Conclusions:** ADRs are common in patients with CKD and are a major cause of hospitalization. Many adverse effects are preventable, suggesting the need for better dissemination of guidelines on drug management in patients with CKD.

## FR-PO222

### Delirium in Renal Failure, Not Always Uremia: A Case of Thiamine Deficiency With Wernicke Encephalopathy

Esra Ekiz, Marco Ramos, Prerana R. Rodrigues, Thin Thin Soe, Su M. Yee, Atin K. Shaha, Suhaib A. Andrabi, Leroy Herbert. *New York City Health and Hospitals Corporation, New York, NY.*

**Introduction:** Delirium is an acute confusional state that differs from individual's norm. Thiamine plays role in propagating nerve impulses; its deficiency can present with neurologic symptoms. We report a case of delirium, attributed to uremic encephalopathy, who was found to have thiamine deficiency.

**Case Description:** 67 year-old male with chronic kidney disease, type 2 diabetes, hypertension, polysubstance abuse including nicotine, ethanol, marijuana; admitted to hospital with a fall. Initially, vitals were within normal range, he was drowsy but oriented to three spheres. Physical exam was significant for wheezing on auscultation of lungs and tremors on outstretched hands. Investigations showed blood urea nitrogen 117 mg/dl, creatinine 8.1 mg/dl, high anion gap metabolic acidosis, hypoalbuminemia and anemia. Ethanol level and urine toxicology were negative; ammonia was elevated. Computed tomography of the head revealed no acute intracranial abnormality. Meningitis work-up was negative. Chest x-ray showed bilateral pulmonary opacities. Despite supplemental oxygen, antibiotics, lactulose; sensorium was poor and uremia was thought to be the precipitating factor. After a total of 10 hemodialysis sessions, patient continued to be lethargic and somnolent. Due to history of alcohol use disorder, he was at risk of nutritional deficiencies and high dose thiamine was started with dramatic improvement in sensorium over the course of 24 hours. He became alert, oriented and conversant.

**Discussion:** Delirium is a syndrome of disturbed consciousness or cognitive function developing over a short period of time. Chronic alcohol abuse-induced thiamine deficiency is one of the metabolic causes of altered sensorium, leading to Wernicke's encephalopathy, characterized by mental confusion, ophthalmoplegia and ataxia. All features of the classic triad are present in only one-third of patients. Diagnosis is clinical and is mainly supported by the dramatic response of neurological signs to parenteral thiamine. Azotemia is not always the cause of altered mentation in renal failure. Considering thiamine deficiency in cases with altered mental status is essential in regards to timely management of patients, prevention of complications and efficient use of resources by introduction of a safe, easily accessible medication: ie thiamine.

## FR-PO223

### 5-HT<sub>3</sub> Antagonist Antiemetic Drugs Alter Cisplatin Pharmacokinetics and Risk of Nephrotoxicity

Lauren E. Thompson,<sup>1</sup> Xia Wen,<sup>2</sup> Justine Jorgensen,<sup>3</sup> Jordan Palan,<sup>1</sup> Cathleen Doherty,<sup>2</sup> Brian Buckley,<sup>2</sup> Edgar A. Jaimes,<sup>3</sup> Lauren Aleksunes,<sup>2</sup> Melanie S. Joy.<sup>1</sup> <sup>1</sup>University of Colorado Health, Aurora, CO; <sup>2</sup>Rutgers The State University of New Jersey, New Brunswick, NJ; <sup>3</sup>Memorial Sloan Kettering Cancer Center, New York, NY.

**Background:** Cisplatin, a common chemotherapeutic, causes acute kidney injury (AKI) in up to one-third of patients. Previous reports have indicated that maximum plasma concentration (C<sub>max</sub>) or area under the plasma concentration vs time curve (AUC) of platinum increase risk of AKI. Ondansetron, a commonly co-prescribed 5-HT<sub>3</sub> antagonist antiemetic drug in patients receiving cisplatin-containing chemotherapy, has been associated with enhanced risk of AKI in rodents and retrospective clinical studies. However, to date, there has been no prospective evaluation of AKI risk in patients randomized to different 5-HT<sub>3</sub> antagonist drugs.

**Methods:** As part of study NCT03817970, an initial group of patients (n=23) undergoing their first or second round of cisplatin chemotherapy (≥25 mg/m<sup>2</sup>) were prospectively randomized to one of three antiemetic drugs (ondansetron 8 mg p.o., granisetron 2 mg p.o., or palonosetron 0.25 mg i.v.). Total platinum plasma concentrations were quantified using inductively coupled plasma-mass-spectrometry (ICP/MS). Pharmacokinetic analyses were performed, and parameters were compared based on 5-HT<sub>3</sub>A treatment using one-way ANOVAs with Tukey-Kramer post-hoc tests. All analyses were performed using R and Certara Phoenix™.

**Results:** Patients randomized to receive ondansetron had significantly increased total platinum plasma C<sub>max</sub> levels (normalized by cisplatin dose) compared to patients receiving granisetron (102% increase) or palonosetron (81% increase) (p=0.005). Moreover, ondansetron-treated patients had the highest AUC from 0-2 hours (normalized by cisplatin dose) (granisetron: 83% increase; palonosetron: 40% increase; p=0.147) and the largest average decrease in estimated glomerular filtration rate (eGFR) following cisplatin treatment compared to granisetron (408% decrease) and palonosetron-treated (173% decrease) patients (p=0.170).

**Conclusions:** Cisplatin-treated cancer patients prescribed ondansetron for the prevention of emesis exhibited decreased kidney function when compared to patients receiving granisetron or palonosetron. Future work will expand analyses to include additional patients, urinary excretion of cisplatin, and urinary biomarkers of kidney injury.

## FR-PO224

### Levofloxacin Dosing Recommendations for Home Hemodialysis (HHD)

Soo min Jang,<sup>1</sup> Susan J. Lewis,<sup>3</sup> Bruce A. Mueller.<sup>2</sup> <sup>1</sup>Loma Linda University, Loma Linda, CA; <sup>2</sup>University of Michigan College of Pharmacy, Ann Arbor, MI; <sup>3</sup>University of Findlay College of Pharmacy, Findlay, OH.

**Background:** HHD implementation is challenging due to the lack of drug dosing information for HHD. Recommendations for intermittent HD aren't applicable to HHD due to differences in dialysis frequency, duration, and dialysate volume from intermittent HD.

**Methods:** Using Monte Carlo simulation, we modelled 7-day therapy for 10 HHD settings (A: 3-h diurnal HHD 4X/week @ dialysate volumes of 30L, 40L, 50L; B: 3-h diurnal HHD 5X/week @ 20L, 30L; C: 7-h nocturnal HHD 3.5X/week @ 30L, 50L, 60L; D: 7-h nocturnal HHD 5X/week @ 30L, 60L) based on published pharmacokinetic data and internal demographic information from NxStage Medical, Inc. Many oral levofloxacin regimens were simulated to predict the probability of target attainment (PTA). Clinical breakpoints were 0.5mg/L for E. coli, 1mg/L for P. aeruginosa and 2mg/L for S. pneumoniae. The pharmacodynamic (PD) targets were: AUC<sub>24h</sub>:MIC ≥125 for each 24 h for Gram-negative infections and AUC<sub>24h</sub>:MIC ≥50 for Gram-positive infections. We have aimed to predict the smallest oral levofloxacin doses that achieved PTA >90% for each HHD setting. Maximum daily dosing for oral levofloxacin approved by the U.S. Food and Drug Administration is 750mg daily, hence maximum dose was limited to 750mg daily.

**Results:** Our analyses indicates that no oral levofloxacin regimen reaches PTA of ≥90% on Day 1 for all organisms at all dialysate flows. From Day 2 until Day 7, PTA >98% was achieved for E. coli with 500mg every 24h in all 10 HHD settings at different dialysate volumes. For S. pneumoniae, 750mg every 24h was needed to achieve PD target of ≥90% whereas, 500mg every 24h achieved PTA of ≥83% on Day 2 and PTA of ≥96% from Day 3 until Day 7. For P. aeruginosa, 750mg every 24h was needed to achieve PD target of ≥90% from Day 3 until Day 7.

**Conclusions:** One levofloxacin 500 mg tablet every 24h for E. coli and S. pneumoniae, and 750mg every 24h for P. aeruginosa would reach the PD target by day 2. However, clinical caution is warranted since this levofloxacin dosing recommendation is higher than those used for intermittent hemodialysis.

**Funding:** Commercial Support - Fresenius

## FR-PO225

### Determining Vancomycin Dosing Recommendations in Patients Receiving Home Hemodialysis (HHD) Using Monte Carlo Simulations

Susan J. Lewis,<sup>1</sup> Soo min Jang,<sup>3</sup> Bruce A. Mueller.<sup>2</sup> <sup>1</sup>University of Findlay College of Pharmacy, Findlay, OH; <sup>2</sup>University of Michigan College of Pharmacy, Ann Arbor, MI; <sup>3</sup>Loma Linda University, Loma Linda, CA.

**Background:** HHD is resurging due to clinical benefits and technology advances. Vancomycin is commonly prescribed in end stage kidney disease patients receiving conventional dialysis. HHD utilizes more frequent and/or longer dialysis sessions than standard thrice-weekly hemodialysis and optimal vancomycin doses are likely different for those with HHD. This study was designed to determine optimal vancomycin dosing strategies incorporating therapeutic drug monitoring (TDM) for patients receiving common HHD settings.

**Methods:** Pharmacokinetic models were developed using internal outpatient dialysis patient demographic data and published pharmacokinetic parameters to predict vancomycin disposition in 5,000 virtual patients receiving HHD using Monte Carlo simulations. Many vancomycin doses infused post-dialysis were tested to evaluate the probability of target attainment (PTA) in 10 different HHD regimens (Table). The pharmacodynamic target was a 24-hour area under the curve/minimum inhibitor concentration (AUC<sub>24h</sub>:MIC) ≥400 mg\*h (assuming the MIC of 1 mg/L) since the upper AUC<sub>24h</sub> threshold linked with nephrotoxicity is usually of less concern in this population compared to an AKI population. The smallest vancomycin doses attaining PTA ≥90% during 1-week of therapy were considered optimal initial dosing. Therapeutic drug monitoring (TDM) using a single pre-dialysis vancomycin concentration was developed to individualize subsequent vancomycin doses.

**Results:** Vancomycin doses and TDM schedules that achieved acceptable PTA rates appear in the figure.

**Conclusions:** Optimal vancomycin dosing recommendations for HHD patients differ from those for conventional thrice-weekly hemodialysis. These vancomycin dosing recommendations warrant clinical validation.

**Funding:** Commercial Support - Fresenius

### Ceftazidime Dosing Recommendations in Patients Receiving Various Home Hemodialysis Regimens

Susan J. Lewis,<sup>1</sup> Soo min Jang,<sup>3</sup> Bruce A. Mueller,<sup>2</sup> <sup>1</sup>University of Findlay College of Pharmacy, Findlay, OH; <sup>2</sup>University of Michigan College of Pharmacy, Ann Arbor, MI; <sup>3</sup>Loma Linda University, Loma Linda, CA.

**Background:** Home hemodialysis (HHD) regimens differ from those for typical in-center thrice-weekly hemodialysis in frequency, duration and dialysate volume. In recent years, HHD is increasingly used, but the literature for drug dosing in HHD is sparse. This study was aimed to determine optimal ceftazidime dosing regimens in end stage kidney disease patients with various HHD regimens using Monte Carlo simulation (MCS) techniques.

**Methods:** Pharmacokinetic models were constructed using internal outpatient dialysis patient demographic information and pertinent pharmacokinetic data to predict ceftazidime plasma concentrations in 5,000 virtual patients receiving HHD. MCS was performed to assess the probability of target attainment (PTA) of various ceftazidime doses in 10 different HHD settings (Table). All ceftazidime doses were simulated to be infused post-dialysis. The efficacy target was free serum ceftazidime concentrations above 4 times the minimum inhibitory concentration for at least 60% of the dosing interval ( $fT > 4 \times \text{MIC}$ ;  $\text{MIC} = 8 \text{ mg/L}$  for *Pseudomonas aeruginosa*). The smallest doses attaining  $\text{PTA} \geq 90\%$  of virtual patients during 1-week of therapy were considered optimal to minimize toxicity concerns. The assumption was made that ceftazidime therapeutic drug monitoring services were unavailable.

**Results:** The lowest ceftazidime doses that met PTA goals in  $>90\%$  of virtual patients for ten different HHD regimens are shown in the figure. Required ceftazidime doses differed depending on interdialytic-period (e.g. 1-3 days) and the prescribed dialysate volumes.

**Conclusions:** MCS predicted that HHD patients would require different ceftazidime doses from those recommended for typical thrice-weekly hemodialysis to ensure PTA in  $>90\%$  of virtual patients. Further clinical validation of these findings is necessary.

**Funding:** Commercial Support - Fresenius

### Evaluation of Optimal Cefazolin Regimen in Hemodialysis Patients

Maude Pichette,<sup>1,2</sup> Naoual Elftouh,<sup>1</sup> Jean-François Tessier,<sup>1</sup> Annie-Claire Nadeau-Fredette,<sup>1,2</sup> <sup>1</sup>Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; <sup>2</sup>Universite de Montreal, Montreal, QC, Canada.

**Background:** Cefazolin is commonly used among patients on hemodialysis (HD) to treat gram-positive infections although equipose persists on the optimal regimen in this specific population.

**Methods:** The primary aim of this observational prospective study was to compare free cefazolin plasmatic concentrations between 3 regimens (2-2-3g post-HD / 1g daily / 2g daily) in adult patients from a single center receiving cefazolin between Sept 2020

and Jan 2022. Our secondary aim was to determine if cefazolin levels were above the local minimum inhibitory concentration (MIC) with each regimen. The antibiotic regimen was determined by the patient's treating team (nephrologists and/or microbiologists) independent from the study. Local MIC's for methicillin-sensitive staphylococcus aureus (MSSA) were measured for patients in whom it was available, with 4 times the MIC considered as a therapeutic target according to the literature.

**Results:** 72 cefazolin dosages were obtained from 25 patients, with 15 patients receiving 2-2-3g post-HD, 6 patients treated with 1g daily and 4 patients with 2g daily. The most frequent indications for cefazolin were catheter infections (n=6), cutaneous infections (n=6) and osteitis (n=5). Of note, two patients had endocarditis and 10 patients (40%) had a MSSA bacteremia. Among patients with bacteremia, two patients were treated with 2-2-3g post-HD regimen, 4 received 1g daily and 4 patients had 2g daily. The mean free plasma concentrations of cefazolin were  $23.3 \pm 13.6 \text{ mg/L}$ ,  $33.2 \pm 12.7 \text{ mg/L}$  and  $67.5 \pm 21.6 \text{ mg/L}$  for the 2-2-3g post-HD / 1g daily / 2g daily respectively. The local MICs ranged from 0.25 to 1 mg/L.

**Conclusions:** In all the three regimens, the free plasmatic levels of cefazolin were above the local MIC's. Our data show that a thrice-weekly post-HD regimen should be prioritized in MSSA infection in hemodialysis, especially in outpatient settings, to avoid the need of peripheral access and reduce the time and human resources associated to daily antibiotics.

### Pharmacokinetics of Remdesivir for Treatment of COVID-19 in a Child on Intermittent Hemodialysis

Erika Allred,<sup>1,2</sup> Caitlin E. Carter,<sup>1,2</sup> <sup>1</sup>University of California San Diego, La Jolla, CA; <sup>2</sup>Rady Children's Hospital San Diego, San Diego, CA.

**Introduction:** Remdesivir is FDA approved for treatment (txt) of COVID19 in hospitalized adults and older children but is available only through an FDA EUA in pts  $<12 \text{ yo}$  or  $<40 \text{ kg}$  due to limited safety. Remdesivir is not recommended for use in pts with  $\text{eGFR} < 30 \text{ mL/min/1.73 m}^2$  due to renal excretion and limited data. Children with ESKD have increased morbidity and mortality secondary to COVID-19 and limited txt options. Determining pharmacokinetics (PK) of children on dialysis remains a priority. Here we report the PK of remdesivir and its active metabolite (GS-443902) for txt of COVID19 in a 2 yo on intermittent hemodialysis (IHD).

**Case Description:** A 2 yo male with ESKD on chronic IHD was admitted in December 2021 after developing respiratory distress and hypoxia. SARS-COV-2 PCR was positive and chest x-ray showed viral airway disease. Due to severity of illness, he was treated with 2 doses of intravenous remdesivir (5 mg/kg loading dose after IHD #1 and 2.5 mg/kg after his next IHD 44 hours later.) The plasma concentration of remdesivir quickly decreased from 112 ng/mL to undetectable between 1- and 6-hours post-infusion. GS-441524 levels rose between 1- and 6-hours post-infusion (694 ng/mL to 837 ng/mL) and remained stable at 898 ng/mL 2 days later, prior to the next IHD (fig 1), consistent with minimal clearance between IHD. GS-441524 during IHD was calculated to have an elimination rate constant of  $0.154 \text{ hr}^{-1}$  with a half-life of 4.5 hours during IHD. HD performed prior to the second dose of remdesivir reduced GS-441524 plasma concentration by 37%. We did not observe accumulation of remdesivir, and GS-441524 accumulation was prevented by IHD. The pt was discharged after 4 days and did not have sequelae of txt with remdesivir.

**Discussion:** We report successful and safe txt of a COVID positive IHD dependent toddler with remdesivir. Given limited options for txt of COVID19 in this vulnerable population, additional exploration of remdesivir kinetics is needed to fully understand safety and efficacy.

## Hemodialysis Is More Effective Than Continuous Venovenous Hemodialysis for Treatment of Hypermagnesemia due to Epsom Salt Ingestion

Yazan A. Bashtawi, Fatima Ayub, Joseph H. Holthoff. *University of Arkansas for Medical Sciences, Little Rock, AR.*

**Introduction:** A case of AKI on CKD and hypermagnesemia due to Epsom salt (MgSO<sub>4</sub>) ingestion

**Case Description:** 73 year old male with chronic kidney disease stage 3a who was in chronic use of laxatives presented to ER with generalized weakness associated with hot flushes, nausea and vomiting. He had poor oral intake for several weeks. He takes two tablespoons of Epsom salts daily for constipation, and recently doubled the dose. On arrival vitals showed BP 128/93, P 76, RR 16, O<sub>2</sub> sat 94 %, T 97.5, BMI 15. He had diffuse hyporeflexia. Creatinine (Cr) 3.3 mg/dl; calcium (Ca) 8 mg/dl; Magnesium (Mg) 10.8 mg/dl. PH 7.12, PaCO<sub>2</sub> 28 mmHg, HCO<sub>3</sub> 9 mmol/l Table 1. Urine output >2L/day. Glucose, CK, lactate, ALT, AST, TSH and troponin were normal. ECG showed sinus rhythm (SR), prolonged PR, QRS and QTC intervals. 2 L lactated Ringer's, 4 grams (g) IV Ca gluconate, Lasix 80 mg IV, 40 mEq of potassium chloride IV, and 40 mEq oral were given. 2 hours (hrs) later Mg was 10.4 mg/dl. Patient was shifted to ICU. Treatment repeated and 150 ml/hr normal saline added. 8 hrs later Mg 8.1 mg/dl. ECG showed junctional rhythm. Hemodialysis (HD) was initiated for 3 hrs (Mg 1 mEq/L, 4 k path). Post HD Mg 3.7 mg/dl. For concerns of rebound hypermagnesemia, Continuous Venovenous Hemodialysis (CVVHD) was started (4 k, Mg 1 mEq/L path, rate 25 ml/kg/hr, continuous 30 mmol potassium phosphate infusion every 12 hrs). 18 hrs later his Mg improved to 2.9 mg/dl and treatment terminated figure 1. ECG showed SR with normal PR and QTC intervals. Generalized weakness and hyporeflexia were resolved. He was discharged home 4 days later with baseline Cr and Mg 2.1 mg/dl

**Discussion:** Intermittent hemodialysis resulted in more rapid Mg removal in this patient with renal failure Figure 1. CVVHD may be used as an adjunct therapy for prevention of rebound hypermagnesemia especially when prolonged GI release of ingested magnesium compounds is expected

## FR-PO230

## Erythrocytapheresis in the Management of Acute Sodium Nitrate Toxicity

Nam Ha, Parker K. Hughes, Anubhav Kumar. *UVA Health, Charlottesville, VA.*

**Introduction:** Sodium nitrate, a common food preservative, is increasingly implicated in suicide attempts. Nitrate oxidizes hemoglobin to methemoglobin, which has poor oxygen-binding capacity. At high concentrations, methemoglobinemia leads to cardiovascular collapse. We present a case of life-threatening methemoglobinemia following intentional sodium nitrate ingestion requiring erythrocytapheresis (RBC exchange) and arteriovenous extracorporeal membrane oxygenation (VA ECMO).

**Case Description:** A 27-year-old woman with a history of depression reported to emergency services that she had injected sodium nitrate into her abdomen. On arrival to the emergency department, she was unresponsive, cyanotic, hypotensive, and hypoxic to oxygen saturation of 75%. Methemoglobin level was 86%. She was given methylene blue, intubated with succinylcholine and started on vasopressor and ascorbic acid. Nephrology was consulted for RBC exchange and cardiothoracic surgery for possible serotonin syndrome after methylene blue administration. Patient underwent cannulation to begin VA ECMO. RBC exchange was begun via the ECMO circuit; 2200 mL of red cell volume was exchanged, and methemoglobin level decreased to 5.6%. The patient required no further apheresis therapy and was later decannulated from VA ECMO the next day and eventually transferred for psychiatric care.

**Discussion:** Sodium nitrate ingestion induces cardiovascular collapse via smooth muscle relaxation, compromising venous return. Methemoglobin production occurs via nitrate-mediated oxidation of hemoglobin's ferrous moiety to ferric, impairing oxygen binding and producing hypoxia. Methylene blue may be helpful to reduce ferric iron to ferrous but may be inadequate on its own in cases of extreme poisoning or cardiorespiratory symptoms. Rapid initiation of erythrocytapheresis may be life-saving in these situations, as observed in this case.

## FR-PO231

## Pharmacokinetic (PK) Results From a Phase 3 Trial to Evaluate Pegunigalsidase Alfa Every 4 Weeks (Q4W) in Patients (Pts) With Fabry Disease Previously Treated With Agalsidase Beta or Agalsidase Alfa

Camilla Tøndel,<sup>1</sup> Eric L. Wallace,<sup>2</sup> Rossana Rocco,<sup>3</sup> Einat Almon,<sup>4</sup> Sari Alon,<sup>4</sup> Liora Blinder-Haddad,<sup>4</sup> Raul Chertkoff,<sup>4</sup> David G. Warnock,<sup>2</sup> Stephen Waldek,<sup>5</sup> Antonio Pisani.<sup>6</sup> <sup>1</sup>Haukeland Universitetssjukehus, Bergen, Norway; <sup>2</sup>University of Alabama, Birmingham, AL; <sup>3</sup>Chiesi Farmaceutici S.p.A., Parma, Italy; <sup>4</sup>Protalix Biotherapeutics, Carmiel, Israel; <sup>5</sup>University of Sunderland, Sunderland, United Kingdom; <sup>6</sup>University Federico II of Naples, Naples, Italy.

**Background:** Fabry disease is a lysosomal storage disease caused by X-linked deficiency of alpha-galactosidase-A. Two enzyme replacement therapies (ERTs) are approved for Fabry disease (agalsidase alfa and agalsidase beta) with infusion every 2 wks. We present PK results from a phase 3 trial of pegunigalsidase alfa administered Q4W to pts with Fabry disease previously treated with ERTs.

**Methods:** In this phase 3, open-label, switch-over study, pts aged 18–60y with Fabry disease who had received ERTs for ≥3y (with stable dose for ≥6mo) and had estimated glomerular filtration rate ≥30mL/min/1.73 m<sup>2</sup> received IV infusion of pegunigalsidase alfa 2.0mg/kg Q4W for 52 wks. Blood samples for PK assessment were collected on Day 1 and at Wk 52 at 13 timepoints.

**Results:** 30 pts (24 male, 6 female) enrolled; 29 completed the study and entered the open-label extension (OLE) study. Main PK parameters are shown (Table). From baseline to week 52, pegunigalsidase alfa had a mean C<sub>max</sub> ranging from 35 876.7–46 829.6ng/mL, with t<sub>max</sub> near end of infusion time, and mean t<sub>1/2</sub> ranging from 100–134h. Detectable pegunigalsidase alfa concentrations after each 4-wk dosing interval were above the lower limit of quantitation (19.5ng/mL), ranging from 167.0–301.5ng/mL. Pts with antidrug antibodies (ADAs) at baseline (n=10) had lower AUC<sub>0–last</sub> (1 047 637h•ng/mL) and shorter t<sub>1/2</sub> (41.0h; range: 1.1–136.3h) after 1st infusion and throughout the study vs the overall population.

**Conclusions:** Mean pegunigalsidase alfa concentration at the end of each dosing interval supported Q4W dosing. Long-term clinical outcomes with Q4W dosing are being assessed in the OLE.

**Funding:** Commercial Support - This study was sponsored by Protalix. Medical writing support was provided by Chris Kirk, PhD, on behalf of Oxford PharmaGenesis Inc., Newtown, PA, and funded by Chiesi Inc. The investigators would like to acknowledge the study participants and their caregivers for participating in this study.

**Table** Summary of selected PK parameters for pegunigalsidase alfa Q4W, at baseline and at week 52

Parameter	Baseline (visit 1) <sup>a</sup>		Week 52 <sup>a</sup>	
	Mean (SD) value	Patients, n	Mean (SD) value	Patients, n
C <sub>max</sub> , ng/mL	35 876.7 (11 942.2)	30	46 829.6 (27 865.0)	28
AUC <sub>0-24h</sub> , h·ng/mL	1 757 492.0 (810 170.7)	30	1 990 784.0 (908 259.3)	28
t <sub>max</sub> , h	5.4 (2.2)	30	2.6 (2.1)	28
t <sub>1/2</sub> , h	100.1 (58.3)	30	133.7 (47.8)	26
Range	1.1–212.9		3.9–203.1	
CL <sub>r</sub> , mL/h	290.9 (868.6)	30	217.0 (595.1)	26
V <sub>d</sub> , mL	12 540.3 (6521.1)	30	15 103.0 (5007.9)	26

AUC<sub>0-24h</sub>, area under the concentration-time curve from time zero to last measurable concentration; CL<sub>r</sub>, clearance; C<sub>max</sub>, maximum observed concentration; t<sub>1/2</sub>, terminal elimination half-life; t<sub>max</sub>, time to maximum concentration; V<sub>d</sub>, volume of distribution.  
<sup>a</sup>Infusion length was longer at baseline vs other visits (during which infusions were at steady-state).

## FR-PO232

**Pharmacokinetics and Immunogenicity of Pegloticase in Patients With Kidney Transplants Receiving Pegloticase for Uncontrolled Gout**

Abdul A. Abdellatif,<sup>1</sup> Yan Xin,<sup>2</sup> Jason Chamberlain,<sup>2</sup> Lin Zhao,<sup>2</sup> Katya Cherny,<sup>2</sup> Brad A. Marder,<sup>2</sup> John D. Scandling,<sup>3</sup> Kenneth G. Saag,<sup>4</sup> <sup>1</sup>Baylor College of Medicine, Nephrology and CLS Health, Houston, TX; <sup>2</sup>Horizon Therapeutics plc, Deerfield, IL; <sup>3</sup>Stanford Medicine, Division of Nephrology, Stanford, CA; <sup>4</sup>The University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL.

**Background:** Immunomodulator co-therapy with pegloticase markedly improves the efficacy of pegloticase by reducing its immunogenicity.<sup>1-4</sup> PROTECT (NCT04087720), an open-label, single-arm study in uncontrolled gout patients with a history of kidney transplant (KT) on stable immunosuppressants demonstrated that pegloticase was effective in reducing serum urate (SU) levels, with a high (89%) responder rate, defined as SU < 6 mg/dL for ≥80% of the time during month 6, while preserving key graft function indicators.<sup>5</sup> The objective of this study was to evaluate the pharmacokinetics (PK) and immunogenicity of pegloticase in uncontrolled gout patients with a history of KT on immunosuppression.

**Methods:** Pegloticase (8 mg infusion [IV]) was administered every two weeks (q2w) for 24 weeks. Serum samples for PK and immunogenicity analysis were collected pre- and post-dose at multiple visits.

**Results:** 20 patients received at least 1 dose of pegloticase and were included in the analysis. Measurable pegloticase concentrations were maintained in SU responders through Month 6. Following treatment initiation, the median pre- and post-dose pegloticase concentration ranged from 0.97 to 1.59 µg/mL and 1.57 to 3.60 µg/mL respectively across visits. In contrast, the 2 non-responders both had pre-dose pegloticase concentrations below the limit of quantification (BLQ), and one had a BLQ value post-pegloticase infusion, which was consistent with the immunogenicity results. Pegloticase exposures were higher than those observed with pegloticase monotherapy, which was consistent with the improved PK results observed with methotrexate co-therapy. No infusion reactions or anaphylaxis occurred during the trial.

**Conclusions:** Pegloticase 8 mg IV q2w with standard of care immunosuppressants in transplant patients resulted in a high SU responder rate and improved pegloticase exposure. **References:** 1. ## FR-PO233

**Consumption of Uric Acid in the Gastrointestinal Tract (GI) With Engineered Escherichia coli Nissle as a Potential Treatment for Gout**

Julia Xu,<sup>1</sup> Sharee Pettiford,<sup>1</sup> Sean Cotton,<sup>1</sup> Theodore C. Moore,<sup>2</sup> Vincent Isabella,<sup>1</sup> Mylene Perreault,<sup>1</sup> David Hava.<sup>1</sup> <sup>1</sup>Synlogic, Cambridge, MA; <sup>2</sup>Ginkgo BioWorks, Boston, MA.

**Background:** Elevated circulating levels of uric acid (UA) are associated with an increased risk of developing gout and other chronic diseases such as CKD, T2D, and CVD. Despite advancements in treatment options, gout continues to be characterized by suboptimal quality of care. In healthy individuals, about 70% of circulating UA is metabolized and excreted by the kidneys, while the remaining 30% is processed through the GI tract. Emerging evidence has demonstrated a role for the gut microbiome in degrading UA. Furthermore, a remarkable gut dysbiosis in association with dysregulated host urate degradation has been reported in gout patients. In light of these findings, we engineered a Synthetic Biotic that is capable of degrading UA within the GI tract.

**Methods:** SYN-GOUT is a modified strain of *Escherichia coli* Nissle 1917 engineered to express bacterial and fungal urate oxidase enzymes, as well as to overexpress a urate transporter. The strain converts UA into 5-hydroxyisourate, which then spontaneously degrades into allantoin, a highly soluble and readily eliminated purine derivative.

**Results:** *In vitro*, SYN-GOUT effectively metabolized ~2 mM UA within 120 min, resulting in concomitant increase in its metabolite allantoin. Activity assay showed that SYN-GOUT was effective at consuming UA under hypoxic (2-7% oxygen) conditions, an environment that mimics the gastrointestinal tract. Administration of labeled UA (1,3-<sup>15</sup>N<sub>2</sub>) via intraperitoneal route in mice was associated with appearance of 1,3-<sup>15</sup>N<sub>2</sub>-UA in the small intestine, indicating the existence of an enterorecirculation loop. Finally, urinary UA output decreased more than 2-fold when non-human primates (NHPs) were given a single dose of SYN-GOUT, demonstrating that SYN-GOUT was active *in vivo*.

**Conclusions:** As a novel Synthetic Biotic, SYN-GOUT effectively consumed UA *in vitro*, and remained active under hypoxic conditions. *In vivo*, SYN-GOUT was safe and well-tolerated, and it lowered urinary UA levels in NHPs. The findings that a pool of UA circulates between systemic and GI compartments implies that SYN-GOUT, by consuming UA within the GI tract, has the potential to lower UA systemically. Therefore, SYN-GOUT could be an effective alternative for the treatment of gout, especially in individuals with compromised kidney function.

**Funding:** Commercial Support - Synlogic Therapeutics

## FR-PO234

**Renally Targeted Nanoparticle Drug Therapy for Rhabdomyolysis-Induced AKI**

Jessica F. Hebert,<sup>1</sup> Yoshio Funahashi,<sup>1</sup> Adam C. Munhall,<sup>1</sup> Megan N. Nickerson,<sup>1,6</sup> Mahaba B. Eiwaz,<sup>1</sup> Jonghan Kim,<sup>5</sup> Hak soo Choi,<sup>3,4</sup> Michael Hutchens.<sup>1,2</sup> <sup>1</sup>Oregon Health & Science University, Portland, OR; <sup>2</sup>Portland VA Medical Center, Portland, OR; <sup>3</sup>Massachusetts General Hospital, Boston, MA; <sup>4</sup>Harvard University, Cambridge, MA; <sup>5</sup>University of Massachusetts Lowell, Lowell, MA; <sup>6</sup>Portland VA Research Foundation, Portland, OR.

**Background:** Rhabdomyolysis-induced acute kidney injury (RIAKI) results from excess physical training, crush, or drugs. Specific treatment is lacking. The megalin inhibitor cilastatin is effective in rodent RIAKI, however, achieving inhibition of renal megalin with systemically-administered cilastatin requires a high dose; this could cause off-target effects. To improve efficacy and specificity we tested the hypothesis that a kidney-specific nanoparticle complexed to cilastatin (Cil) and the renoprotective agent dexamethasone (Dex) would ameliorate RIAKI in mice.

**Methods:** The kidney-specific nanoparticle ("H-Dot") is comprised of a poly-epsilon-lysine backbone with moieties supporting targeting and therapeutic domain complexation chemistry and a fluorescent imaging domain. Cilastatin and dexamethasone were complexed to the H-Dot. Cil/Dex/H-Dot was administered to human kidney cells *in vitro*. *In vivo*, pharmacokinetic (PK) parameters were quantified in mice by HPLC. To test efficacy, Cil/Dex/H-Dot or vehicle was administered intravenously to mice subjected to RIAKI.

**Results:** Synthesized Cil/Dex/H-Dots were pure and contained 2:1:1 Cil:Dex:H-Dot ratio. *In vitro* studies demonstrated rapid drug release from the nanoparticle at late endosomal pH and endosomal delivery of Cil with nuclear delivery of Dex. Cil/Dex/H-Dots were exclusively renally filtered. PK demonstrated that kidney-specific H-Dot complexation more than doubled Cil/Dex delivery to the kidney. Efficacy studies in RIAKI-exposed mice demonstrated that loss of renal function was ameliorated 24h after induction of RIAKI in mice which received Cil/H-Dot or Cil/Dex/H-Dot treatment (mean±stdev GFR in Sham: 1111±191, Vehicle: 204±46, Cil/H-Dot 1064±453, Cil/Dex/H-Dot 1074±104, n= 3-6/group, p<0.01 by ANOVA with post-hoc Sidak test for both drugs compared to vehicle).

**Conclusions:** A kidney-specific nanoparticle formulation results in enhanced renal endosomal delivery of complexed drugs, including Cil and Dex. Complexing Cil and Dex to H-Dot nanoparticles ameliorates renal functional loss due to RIAKI in mice. Kidney-specific treatment of RIAKI with Cil/Dex/H-Dot may lead to effective, organ and mechanism-targeted therapy, with potential applications beyond RIAKI.

## FR-PO235

**GSK343 Inhibits EZH2 to Promote MST1 Expression and Confers Neuroprotection in Kidney Failure-Induced Hypercalcemia**

Yaochen Cao,<sup>1,2</sup> Xitong Li.<sup>1,2</sup> <sup>1</sup>Charite Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>Hainan Medical University, Haikou, China.

**Background:** GSK343 is a specific inhibitor of EZH2 which has been highlighted to serve as a potential therapeutic target for kidney diseases. We sought to examine the underlying mechanism of GSK343 in the nerve damage induced by kidney failure-associated hypercalcemia.

**Methods:** We first established an *in vivo* adenine diet-induced CKD model in C57BL/6N mice. After administration of GSK343, oe-EZH2, oe-MST1 and oe-YAP1, disease activity index, serum biochemical indexes, blood calcium and nerve function of mice were evaluated, as well as the expression of M1 marker (iNOS) and M2 marker gene (Arg1). Gain function studies were all employed in renal tubular epithelial cells TCMK-1 to elucidate the mechanism of GSK343/EZH2/MST1/YAP1 in the processes of nerve damage induced by kidney failure-associated hypercalcemia.

**Results:** GSK343 polarized macrophages toward M2 phenotype and thus arrested the resultant nerve damage from kidney failure-induced hypercalcemia. GSK343 reduced the expression of EZH2 and triggered an increase in the expression of MST1. In addition, MST1 overexpression reduced the expression of YAP1, thereby promoting M2 polarization of macrophages and attenuating the nerve damage induced by hypercalcemia. Furthermore, GSK343 promoted macrophages polarized to M2 phenotype and attenuated nerve damage by regulating the EZH2/MST1/YAP1 axis.

**Conclusions:** Overall, our findings suggest that GSK343 may be a novel mechanism underlying the M2 polarization of macrophages and the resultant nerve damage from kidney failure-induced hypercalcemia.

**Funding:** Government Support - Non-U.S.

### Valacyclovir Neurotoxicity in a Patient on Peritoneal Dialysis

Taylor R. Moody, James B. Leonard, Angela H. Lam, Nicholas Husak, Joshua D. King. *University of Maryland Medical System, Baltimore, MD.*

**Introduction:** Valacyclovir is a prodrug of acyclovir often used to treat herpes zoster and herpes simplex. While acyclovir neurotoxicity is well-described in the literature, a recent systematic review identified only 35 cases of valacyclovir neurotoxicity (VAN) through 2021. Patients with advanced age and impaired kidney function are at highest risk of both acyclovir and valacyclovir neurotoxicity. In the absence of hemodialysis (HD), the half-life of valacyclovir in patients with ESKD can be up to 20 hours. Valacyclovir is removed well by HD, but continuous ambulatory peritoneal dialysis (PD) removes only approximately 10% of the drug.

**Case Description:** A 64-year-old man with ESKD on PD after a failed kidney transplant was prescribed valacyclovir 1000 mg three times daily for herpes zoster, exceeding the recommended dose of 500 mg daily. The evening of his first day of therapy, he began to experience confusion. The following day, he presented to a local hospital with hypertension, hyperthermia, hallucinations, and disorientation. Serum laboratory tests and complete blood count were close to baseline; cerebrospinal fluid analysis was notable for mild leukocytosis at 11 WBC/uL. He was admitted to the ICU. The patient's mental status did not improve, and he was persistently hypertensive requiring nicardipine infusion. On hospital day 3 he began receiving PD, but his mental status deteriorated. On hospital day 5 he was started on intermittent HD in combination with his usual PD with dwells every 4 hours. Approximately 4 days after the initiation of HD, mentation substantially improved. No other medical cause of his prolonged encephalopathy was identified, and his altered sensorium was attributed to VAN.

**Discussion:** Valacyclovir is a commonly used drug that is typically well-tolerated, safe, and efficacious; however, in ESKD it may cause substantial encephalopathy. Because this drug is largely renally excreted, patients with impaired kidney function, especially those with ESKD, are at increased risk of toxicity and require substantial dose reduction. Valacyclovir is dialyzable and may require HD to rapidly remove this drug, even in patients on maintenance PD. Delaying initiation of HD, as in this case, may prolong encephalopathy and increase the risk of adverse outcomes.

## FR-PO237

### Effects of KCNN4 Blockade With Senicapoc in Kidney Cell-Based Assays and a Mouse Model of Renal Inflammation and Fibrosis

Peng Zhou,<sup>1</sup> Simon A. Hinke,<sup>2</sup> Cassandre Cavanaugh,<sup>1</sup> Li-Jun Ma,<sup>2</sup> Eugene Myshkin,<sup>1</sup> Neetu Shukla,<sup>2</sup> Thomas A. Natoli,<sup>1</sup> Jose M. Silva,<sup>2</sup> Maria Chiara Magnone,<sup>1</sup> Zhiyong Yang.<sup>1</sup> <sup>1</sup>Janssen Research and Development LLC, Boston, MA; <sup>2</sup>Janssen Research and Development LLC, Spring House, PA.

**Background:** Progressive kidney fibrosis including tubulointerstitial fibroblast proliferation and mesangial matrix expansion is a common manifestation in chronic kidney disease, resulting in end-stage kidney disease. KCNN4 (KCa3.1) is an intermediate-conductance Ca<sup>2+</sup>-activated K<sup>+</sup> channel implicated in immune cell activation, cytokine production, and fibroblast proliferation. Previous studies have shown the pathophysiological relevance of KCNN4 in fibrotic disease.

**Methods:** Here, we explored the pathological role of KCNN4 in renal fibrosis. Specifically, we assessed the impact of a potent and selective KCNN4 inhibitor Senicapoc in kidney cell-based assays, and in a mouse model of renal fibrosis induced by Unilateral Ureteral Obstruction (UUO).

**Results:** *In situ* hybridization and immunohistochemistry showed KCNN4 is expressed mainly in tubular and interstitial cells in human kidney samples. *In vitro*, whole cell patch clamp confirmed the inhibition of K<sup>+</sup> current by Senicapoc (IC<sub>50</sub> ~2nM). In human renal fibroblasts, Senicapoc dose-dependently inhibited TGF-β-stimulated proliferation, but did not inhibit mRNA expression of TGF-β-stimulated fibrotic genes in human renal fibroblast or proximal tubular epithelial cells. *In vivo*, *Kcnn4* expression was upregulated ~20-fold in UUO-induced fibrotic kidney and decreased with anti-TGFβ-1 antibody treatment in UUO model. Senicapoc treatment (100mpk BID, 200mpk QD or BID) at doses much higher than those commonly used in reported literature did not

improve kidney histology or decrease mRNA expression of inflammatory and fibrotic genes in a 10-day mouse UUO model. PK studies showed dramatic decrease in plasma compound exposure levels after repeat dosing when measured at day 3 and thereafter in both mice and rats, potentially indicating insufficient target coverage in the UUO study.

**Conclusions:** In summary, while KCNN4 may play a role in kidney disease, the PK profile of Senicapoc makes it not suitable for target validation studies in rodents. A compound with better exposure profile is needed in order to properly study the effects of KCNN4 blockage in a rodent disease model.

## FR-PO238

### Effect of Ibuprofen on Kynurenic Acid Production and Kynurenine Aminotransferases Activity in Rat Kidneys

Izabela Zakrocka, Wojciech T. Zaluska. *Uniwersytet Medyczny w Lublinie, Lublin, Poland.*

**Background:** Non-steroidal anti-inflammatory drugs (NSAIDs) are widely used analgesics and anti-inflammatory agents. Inhibition of cyclooxygenase, leading to decreased prostaglandin synthesis, is their main mechanism of action, also responsible for NSAIDs renal side effects. Ibuprofen, one of the most popular NSAID, is known to cause acute kidney injury, thus increasing the risk of chronic kidney disease. The metabolite of tryptophan, kynurenic acid (KYNA), is made from L-kynurenine (L-KYN) by kynurenine aminotransferases (KATs). KAT I and KAT II are the best studied KAT isoenzymes. KYNA is a non-selective antagonist of ionotropic glutamatergic receptors. Natriuretic, anti-inflammatory, chronotropic negative and hypotensive properties of KYNA were previously described. The goal of the present study was to examine the effect of ibuprofen, commonly used over-the-counter NSAID, on KYNA production and the activity of KAT I and KAT II, in rat kidney *in vitro*.

**Methods:** The effect of ibuprofen on KYNA production together with KAT I and KAT II activity was examined in rat kidney homogenates *in vitro* after 2 hours incubation in the presence of L-KYN and ibuprofen. The drug was tested at the concentration of 1 μM, 10 μM, 50 μM, 100 μM, 500 μM and 1 mM. KYNA formation during enzymatic reaction was measured with the use of high performance liquid chromatography (HPLC) with fluorometric detector. All applicable international, national and institutional guidelines for the care and use of animals were followed. All procedures performed in this study involving animals were in accordance with the ethical standards of the Local Ethics Committee for Animal Experiments.

**Results:** Ibuprofen at 500 μM and 1 mM decreased KYNA production in kidney homogenates *in vitro* to 78% (P < 0.05) and 46% (P < 0.001) of control value, respectively. At 1 mM concentration ibuprofen lowered renal KAT I activity *in vitro* to 82% (P < 0.05) of control value. Additionally, ibuprofen at 500 μM and 1 mM concentration decreased kidney KAT II activity *in vitro* to 68% (P < 0.05) and 43% (P < 0.05) of control value, respectively.

**Conclusions:** Ibuprofen decreases KYNA synthesis in rat kidney *in vitro* by inhibiting KAT I and KAT II isoenzymes. Results of our study indicate a novel mechanism of ibuprofen's action in the kidney. Its possible relationship with NSAIDs-induced nephrotoxicity needs further clarifications.

## FR-PO239

### When Normal Is Abnormal: Valproate Toxicity With Normal Valproate Serum Level

Juarez R. Braga, Manisha Singh. *University of Arkansas for Medical Sciences, Little Rock, AR.*

**Introduction:** Valproic acid (VPA) is commonly used in clinical practice for the treatment of seizures and other medical conditions. VPA is highly bound to plasma proteins with only a small fraction free in the plasma and responsible for its pharmacological action. However, in patients with hypoalbuminemia, the free fraction of VPA increases which contributes to the risk of neurotoxicity. We present a case of a patient with nephrotic syndrome and total VPA levels within the therapeutic range who developed neurological adverse symptoms.

**Case Description:** A 50-year-old male with history of CKD stage 4, nephrotic syndrome secondary to biopsy-proven diabetic nephropathy, and seizure disorder in use of VPA 1,500 mg two times daily was admitted with altered mental status. On examination, he was disoriented and had tremors and asterixis. His laboratory values were remarkable for creatinine 2.9 mg/dL, eGFR 27 mL/min/1.73 m<sup>2</sup>, BUN 81 mg/dL, and albumin 0.9 g/dL. Total VAP levels were 54 mcg/mL (50-100 mcg/mL). After admission, due to concerns for focal seizures, the dose of VPA was increased to 1,750 mg two times daily and drug monitoring of total VAP levels remained within the therapeutic range. Since symptoms persisted, uremic encephalopathy was considered but deemed unlikely due to the presence of residual kidney function. When levels of free valproate were measured, they revealed a result of 49 mcg/mL (normal 5-15 mcg/mL). Thus, VPA was held with significant improvement in mental status.

**Discussion:** This is a case of neurotoxicity resulting from increased free valproate due to hypoalbuminemia while total VPA levels were normal. Adjustment of the dose of VPA based on total levels led to neurological symptoms. Liver metabolizes VPA but in patients with hypoalbuminemia, free VPA fraction may overwhelm the metabolic pathways, thus increasing the risk for toxicity. Free VPA serum concentrations should be used for therapeutic monitoring in patients with clinically significant hypoalbuminemia. While this assay is not available in many institutions, an albumin-adjusted formula can be used to predict the levels of free VPA. An understanding of pharmacokinetics is important for nephrologists for a rational approach in the investigation and management of drug toxicities.

**Use of Molecular Adsorbent Recirculating System for the Management of Acute Poisoning Without Liver Failure**

Victor E. Serrano-Santiago, Yi Zhao, Roberto L. Collazo-Maldonado. *Methodist Dallas Medical Center, Dallas, TX.*

**Introduction:** Molecular Adsorbent Recirculating System (MARS) is an extracorporeal liver assist device that removes endogenous substances based on the principle of albumin-based dialysis. In addition to its uses in liver failure patients, MARS can be used to remove albumin-bound toxins. We present a case of vasoplegic shock and coma caused by multiple medications that was treated successfully with MARS.

**Case Description:** A 30 y/o woman with significant psychiatric history was admitted for a suicide attempt by intentional overdose. Empty bottles of the following albumin-bound medications were found on the scene: guanfacine, hydroxyzine, lamotrigine, propranolol, sertraline, and ziprasidone. On presentation, she was hypotensive and had bradycardia, bradypnea, and a GCS of 7. The patient was intubated emergently and received activated charcoal, glucagon (2mg), and CaCl<sub>2</sub> (2g). Her blood pressure was supported with norepinephrine infusion and aggressive volume expansion. Poison control recommended seizure precautions and serial electrocardiograms (EKG). Neurological examination without sedation showed a comatose female, pupils dilated and reactive, no motor response to noxious stimulation in all four limbs, weak cough, and no gag reflex. Labs on presentation revealed normal kidney function, acid-base balance, electrolyte levels, and liver function tests. An EKG showed sinus bradycardia (QTc = 432ms) and an electroencephalogram showed moderately severe generalized cerebral dysfunction. Nephrology was consulted, and it was determined that all the ingested medications, except for lamotrigine and hydroxyzine, are highly protein-bound and not dialyzable. MARS therapy was performed for life-threatening vasoplegic shock caused by multiple toxic ingestions. Three hours later, her neurological status and blood pressure improved, and norepinephrine was discontinued. She completed 12 hours of MARS therapy with no complications. The next day, she was successfully extubated, her mental status returned to baseline, and she was hemodynamically stable. The patient was discharged to an inpatient psychiatric unit on hospital day four.

**Discussion:** This case demonstrated MARS is a feasible treatment for patients without liver failure, and that it can be a promising therapy option for those with acute poisoning from protein-bound drugs.

## FR-PO241

**Pharmacokinetics of the Novel Nonsteroidal Mineralocorticoid Receptor Antagonist KBP-5074 in Individuals With Moderate Hepatic Impairment**

James C. McCabe, Vincent Benn, Jay Zhang, Y. Fred Yang. *Kbp Biosciences Co Ltd, Jinan, China.*

**Background:** KBP-5074 is a selective nonsteroidal mineralocorticoid receptor antagonist. This study assessed the effect of moderate hepatic impairment on the pharmacokinetics, safety, and tolerability of KBP-5074.

**Methods:** This was an open, nonrandomized, multicenter, study investigating the PK, safety, and tolerability of a single oral dose of 0.5 mg KBP-5074 to male and female subjects with moderate hepatic impairment (Child-Pugh B score 7-9) compared to normal healthy subjects. Twelve subjects (6 subjects with moderate impairment and 6 matched healthy control subjects) were enrolled. All subjects received a single oral dose of 0.5 mg KBP-5074 on Day 1 after an overnight fast of  $\geq 10$  hours. Each healthy control subject was matched by age ( $\pm 10$  years), BMI ( $\pm 20\%$ ), and sex to a moderate hepatic impairment subject. Serial blood collections were obtained through 264 hours postdose for plasma levels of KBP-5074. Plasma protein binding was analyzed and safety and tolerability were monitored.

**Results:** Following a single oral dose of 0.5 mg, KBP-5074 was steadily absorbed with median  $T_{max}$  values of 4.00 and 3.00 hours, respectively. After reaching  $C_{max}$ , the disposition of KBP-5074 appeared to be biphasic. The geometric mean  $t_{1/2}$  values for the moderate hepatic impairment group and normal healthy control group were 75.6 and 65.7 hours, respectively. Systemic exposure to KBP-5074 as assessed by AUC was 23.5% to 26.6% lower in subjects with moderate hepatic impairment versus healthy subjects, whereas  $C_{max}$  was 41.2% lower. KBP-5074 was determined to be  $>99.7\%$  bound to proteins in plasma. Given the low percentage of unbound drug, it was not deemed appropriate to calculate the PK parameters for unbound drug. KBP-5074 was safe and well tolerated in all participants.

**Conclusions:** Small decreases of AUC and  $C_{max}$  upon systemic exposure to KBP-5074 in subjects with moderate hepatic impairment demonstrate low hepatic extraction and is consistent with the observation that KBP-5074 is cleared predominantly in the gastrointestinal tract vs the kidney. Considering the long half-life and small decrease in AUC and  $C_{max}$ , a dose adjustment does not appear to be warranted in patients with moderate hepatic impairment.

**Uric Acid Crystal Deposition Triggers Tubule Dilation in Normal Kidneys and Cystogenesis in Polycystic Kidney Disease (PKD)**

Sebastian Strubl,<sup>1,2</sup> Nickolas J. Holznecht,<sup>1</sup> Jacob A. Torres,<sup>1</sup> Brina A. Aceves,<sup>1</sup> Margaret Schimmel,<sup>1</sup> David A. Asplund,<sup>1</sup> Bradley C. Kroes,<sup>1</sup> Sita Arjune,<sup>2</sup> Roman-Ulrich Mueller,<sup>2</sup> Peter C. Harris,<sup>3</sup> Thomas Weimbs.<sup>1</sup> <sup>1</sup>University of California Santa Barbara, Santa Barbara, CA; <sup>2</sup>Uniklinik Köln, Köln, Germany; <sup>3</sup>Mayo Clinic Minnesota, Rochester, MN.

**Background:** We have previously reported that renal CaOx crystals are commonly cleared from normal kidneys by reversible tubule dilation but can accelerate disease progression in a PKD rat model. Since ADPKD patients also have a high risk for uric acid (UA) crystal deposition we investigated the impact of UA crystals on PKD disease progression in animal models.

**Methods:** To investigate reversible tubule dilation and signaling activity in normal kidneys upon UA crystal deposition we treated wild-type Sprague Dawley rats with a diet supplemented with uric acid and the uricase inhibitor oxonic acid. To investigate the impact of UA crystal deposition on PKD disease progression we used the same dietary treatment in the HanSPRD model and in heterozygous Pkd1<sup>+/+</sup> rats.

**Results:** We report that, in normal kidneys, renal UA crystals lead to reversible tubule dilation and subsequent crystal clearance similar to CaOx crystals. We observed similar activation of the mTOR and Stat3 pathways in dilated renal tubules as described previously. UA crystal deposition accelerated ADPKD disease progression and fibrosis in the HanSPRD model. Furthermore, UA crystal deposition induced cystogenesis in a novel heterozygous Pkd1 rat model.

**Conclusions:** These results indicate that reversible tubule dilation as a renoprotective clearance mechanism applies to multiple crystal types including UA crystals. For the first time, we show that renal crystals can not only accelerate PKD disease progression but even induce de-novo cystogenesis in an orthologous, heterozygous PKD1<sup>+/+</sup> model. The latter result suggests that a second-hit somatic mutation is not necessary for cystogenesis. Rather, a heterozygous germline mutation in one PKD1 allele combined with a renal insult by tubular micro-crystals is sufficient to induce cystogenesis. These results have significant implications for the clinical management of individuals with ADPKD.

## FR-PO243

**Ferritin as an Inflammatory Molecule in Autosomal Dominant Polycystic Kidney Disease**

Johnny Dinh Phan,<sup>1</sup> Nicole Sommer,<sup>1</sup> Mackenzie Thornton,<sup>1</sup> Mercedes B. Mcgonigle,<sup>1</sup> Subhashini Bolisetty,<sup>2</sup> Darren P. Wallace,<sup>1</sup> Madhulika Sharma.<sup>1</sup> <sup>1</sup>University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS; <sup>2</sup>The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.

**Background:** Despite approval of tolvaptan as the first drug in the treatment of autosomal dominant polycystic kidney disease (ADPKD), there is an unmet need for new drugs. We need drugs with greater efficacy and new drug targets that could enhance discovery of novel drugs. We have recently reported that ferritin is ectopically expressed in cyst lining cells and macrophages of ADPKD patients and an orthologous mouse model of PKD. Ferritin has previously been shown to activate the inflammatory NF-kappa B pathway in acute kidney injury. Since ferritin is also an acute phase reactant expressed in macrophages, we determined whether ferritin has an inflammatory role in ADPKD cells.

**Methods:** We treated primary cyst lining ADPKD and normal kidney epithelial (NHK) cells with ferritin and apoferritin to determine the effects on cell proliferation and inflammatory pathway, MAPK-NF-kappa B. We also studied the effects of ferritin deletion in collecting ducts of PKD mice. We used cell culture and Western blots to study ferritin expression in bone marrow derived macrophages in PKD mice.

**Results:** We found that cyst lining epithelial from ADPKD patients have increased capacity of extracellular ferritin uptake when compared to normal human kidney cells. Ferritin uptake was associated with increased expression of pERK and phosphorylated p65 (Nuclear factor kappa B (NF-kappa-B p65/RelA), suggesting activation of inflammatory signaling pathways. When we labeled cystic mouse PKD kidneys, we found that macrophages close to the epithelial cells expressed ferritin. We hypothesized that macrophages release ferritin which cyst epithelia cells can uptake to mediate inflammation in ADPKD kidneys. Consistent with that isolated bone marrow derived macrophages of PKD mice showed increased ferritin levels. We also show the effects of ferritin deletion in collecting ducts of a PKD mouse model. Our data suggest that ferritin may mediate a cross talk between cyst epithelial cells and macrophages.

**Conclusions:** We found that macrophages in the ADPKD kidneys express ferritin. ADPKD cyst lining cells have increased capacity for uptake of ferritin, which results in elevation of inflammatory pathway and may be responsible for aggravation of disease. Thus ferritin inhibition in cyst lining cells may constitute a therapeutic target.

## FR-PO244

**Divergent Injury Effects of Cisplatin Treatment on Promoting Cyst Formation in Adult Pkd2 Mutant Mouse Model**

Zhang Li,<sup>1</sup> Sreelakshmi Cherakara, Reagan S. Andersen, Bradley K. Yoder. *The University of Alabama at Birmingham School of Medicine, Birmingham, AL.*

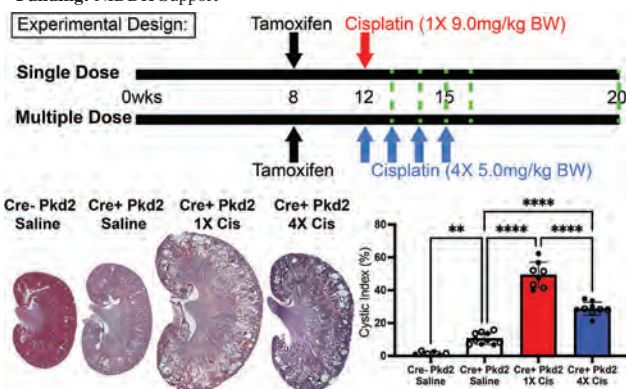

**Background:** Cisplatin is a widely used antitumor drug with severe nephrotoxic side effects, which could result in acute or chronic kidney injury depending on the dosage. Links between cyst formation and renal injuries have been reported in multiple PKD animal models, but the effect of cisplatin-induced injury on cyst formation has not been investigated. Here we evaluate the effect of two different regimens of cisplatin treatment on renal injury and cyst formation in *Pkd2* mutant mouse models.

**Methods:** Adult-induced *Pkd2* mutant mice were treated with either a single dose (9 mg/kg) or four weekly doses (5 mg/kg each) of cisplatin by IP injection to induce acute or chronic renal injury models, respectively (Experimental Design in **Figure**). Mice were euthanized 8 weeks after initial cisplatin treatment for analysis. Renal injury (SOX9 and KIM1), proliferation (Ki67), apoptosis, fibrosis, macrophage accumulation, and cystic index were analyzed using immunofluorescence, FACS and histology approaches.

**Results:** Both cisplatin treatment regimens accelerate cyst formation in mutant mice relative to saline-treated controls. The cystic index is increased in mutant mice with acute injury model compared to chronic injury model (**Figure**). More important, kidneys from mice receiving a single cisplatin treatment had less fibrosis and macrophage accumulation but increased cell proliferation compared to the multiple cisplatin treatment group. The injury response between the two cisplatin treatment approaches is currently being investigated.

**Conclusions:** These data show that cisplatin treatment caused renal injury and enhanced cyst formation in *Pkd2* mutant kidney, and that the cisplatin protocol could be used as an alternative injury method to accelerate cyst formation in cystic kidney disease models. Additionally, these data suggest that acute and chronic injury models have distinct effects on cystic index, fibrosis, and cell proliferation.

**Funding:** NIDDK Support

Cisplatin-induced injury accelerates cyst formation in *Pkd2* mutant kidney

## FR-PO245

**CD206+ Resident Macrophages: A Candidate Biomarker for Renal Cystic Disease Activity in Preclinical Models and Patients With Autosomal Dominant Polycystic Kidney Disease**

Zhang Li,<sup>1</sup> Kurt Zimmerman,<sup>2</sup> Sreelakshmi Cherakara,<sup>1</sup> Phillip H. Chumley,<sup>1</sup> Courtney J. Haycraft,<sup>1</sup> Reagan S. Andersen,<sup>1</sup> Mandy J. Croyle,<sup>1</sup> E.J. Aloria,<sup>1</sup> Isis Thomas,<sup>1</sup> Hanan Chweih,<sup>1</sup> Kristin L. Simanyi,<sup>1</sup> James F. George,<sup>1</sup> Michal Mrug,<sup>1</sup> Bradley K. Yoder.<sup>1</sup> *The University of Alabama at Birmingham, Birmingham, AL; <sup>2</sup>The University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

**Background:** Age and renal injury are drivers of renal cystogenesis in PKD mouse models. Since macrophage depletion attenuates injury-induced cystogenesis and macrophage differentiation state is age and injury-dependent, we speculated that a developmental/injury-regulated macrophage subset may influence renal cyst formation.

**Methods:** We analyzed macrophage populations during renal maturation and their associations with cystogenesis rates in conditional *Pkd2* mutant mice. We tested the relevance of these associations by depleting macrophages using the congenital *Cx3cr1* null mice. We also assessed parallels between the cystogenic activity-associated macrophage subset and disease activity in patients with ADPKD.

**Results:** CD206+ macrophages are enriched in juvenile but not adult wild type mouse kidneys. This correlates with the rapid- to slow-onset cystogenesis that occurs in *Pkd2* mutant mice with juvenile- vs adult-induction. While CD206+ macrophages are minimal in a normal adult kidney, they accumulate around the cysts in non-injured adult-induced *Pkd2* mutants. Using *Cx3cr1* null mice, we reduced macrophage number, including CD206+ macrophages, and this resulted in a significant reduction of cyst severity in non-injured adult-induced *Pkd2* mutant kidneys. The number of CD206+ resident macrophage-like cells also increased in kidneys from ADPKD patients, and their urinary content correlated with the rate of renal function loss in a small ADPKD patient cohort (**Figure**).

**Conclusions:** These data indicate that CD206+ macrophage numbers increase during periods of rapid cyst formation in *Pkd2* mutant mice. Depletion of macrophages attenuates cystogenesis in non-injured adult-induced *Pkd2* mutants. CD206+ macrophages also accumulate in human ADPKD kidneys, and their urine excretion could serve as a disease activity biomarker.

**Funding:** NIDDK Support

The number of CD206+ macrophages is increased in ADPKD patient kidneys, and their urinary content correlate with eGFR decline among patients.

## FR-PO246

**Automated Detection and Quantification of Individual Collagen Fibers in a Mouse Model of Polycystic Kidney Disease**

Caroline R. Sussman, Heather L. Holmes, Peter C. Harris, Michael F. Romero. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

**Background:** Histological assessment of fibrosis is a standard tool for evaluating PKD. The most commonly used stains are Trichrome or Picrosirius red (PSR), which are imaged using brightfield to calculate a percent positive tissue area (cystic index). These stains are limited by variability due to specimen handling and analysis. PSR emits a red fluorescent signal, which can be used to automatically detect and analyze individual fiber characteristics and determine fiber density.

**Methods:** Four-month-old *Pkd1*RC/RC mice were compared to *Pkd1*+/+ (WT). All mice were F1 progeny from a 129/C57BL6J cross. Following euthanasia, kidneys were fixed in 4% PFA, cryosectioned, stained with PSR, and images were obtained using brightfield and fluorescent imaging. Tissue area and fibrotic index were determined using ImageJ, and individual collagen fibers were automatically detected, and metrics determined using CT-FIRE fiber detection software (LOCI; Madison, WI). Statistical measurements were obtained using PRISM (GraphPad Software, Inc.).

**Results:** Standard brightfield imaging showed a significantly higher fibrotic index in RC/RC than WT. Analysis of individual fibers by CT-FIRE indicated this was most likely due to an increase in fiber density rather than fiber width. Fiber density was significantly higher in female RC/RC vs WT ( $4275 \pm 254$  vs  $3423 \pm 102$  fibers/mm<sup>2</sup> respectively (mean  $\pm$  SEM),  $p=0.03$  by ANOVA,  $n=3-9$ ) and trended higher in males and overall ( $4328 \pm 203$  vs  $3667 \pm 230$  fibers/mm<sup>2</sup> respectively (mean  $\pm$  SEM),  $p=0.05$  by ANOVA,  $n=6-17$ ). Frequency histograms showed broader distribution of collagen fiber width in RC/RC with a significantly greater percentage of fibers in the lowest quartile. No significant differences were seen in fiber length, straightness, or angle. Overall, fiber width had a bell-shaped distribution, with almost half of fibers having intermediate width, fiber length was skewed towards shorter lengths and straightness was skewed towards being straighter. Fiber angles were more evenly distributed from 0-180 degrees with slightly greater prevalence of angles closer to 90 degrees.

**Conclusions:** These data demonstrate the potential of CT-FIRE software to provide more objective, higher resolution information about collagen during PKD. Future studies will determine whether it can provide insight into collagen dynamics preceding cysts.

**Funding:** NIDDK Support, Private Foundation Support

## FR-PO247

**High-Fat Feeding in Pkd1 RC/RC Mice Associates With Upregulation of Haver1 and Immune Activation**

Ioan-Andrei Iliuta,<sup>1,2</sup> Xuewen Song,<sup>2</sup> Amirreza Haghighi,<sup>3,2</sup> Ning He,<sup>2</sup> Fatemeh Nasri,<sup>1</sup> James W. Scholey,<sup>1,2</sup> York P. Pei.<sup>1,2</sup> *<sup>1</sup>University Health Network, Toronto, ON, Canada; <sup>2</sup>University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; <sup>3</sup>Brigham and Women's Hospital, Boston, MA.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited nephropathy worldwide and an important cause of end-stage renal disease. The effects of overweight on ADPKD are unclear, although recent clinical research suggests increased body mass index might be an independent risk factor for disease severity. In addition, high-fat feeding aggravated cystic disease in two orthologous mouse models of ADPKD, possibly in association with impaired fatty acid oxidation in the cystic epithelium. We explored the effects of a high-fat diet (HFD) in young *Pkd1* RC/RC mice, a hypomorphic model of ADPKD characterized by slow progression of cystic disease similarly to human ADPKD.

**Methods:** Since *Pkd1* RC/RC mice exhibit sexual dimorphism, with females showing more severe cystic disease, we assigned 20 females and 20 males in a 1:1 ratio to either a HFD, with 60% of calories derived from fat, or a carbohydrate-rich "normal diet" (ND), with 10% of calories derived from fat. Mice were started on the diets at 2 months of age and sacrificed at 7 months of age. We then assessed kidney weight and volume, histology and histomorphometry, biochemistry, and gene expression. In addition to microarray analysis, we performed gene-set enrichment using Enrichr.

**Results:** HFD compared to ND feeding associated with increased kidney volume (p<0.0001) and cystic index (p=0.001) in females, but it did not associate with reduced kidney function. In the kidneys of females fed a HFD compared to a ND, we identified: (1) upregulation of Haver1 (FDR p=0.0009), a pro-inflammatory biomarker of renal tubular injury; (2) enrichment in pathways involved in innate and adaptive immunity, with a majority of these genes upregulated in our dataset; (3) enrichment in EP300 (adjusted p=8.7\*10<sup>-21</sup>), a transcriptional co-activator of cell proliferation, which was upregulated in our dataset; (4) enrichment in PPARα (adjusted p=8.5\*10<sup>-10</sup>), a major regulator of fatty acid oxidation, which was downregulated in our dataset; and (5) evidence of macrophage accumulation on immunohistochemistry (p=0.07).

**Conclusions:** HFD feeding in female *Pkd1* RC/RC mice aggravated the kidney cyst burden, in association with a transcriptomic profile suggesting early-stage inflammatory kidney injury and inhibited fatty acid oxidation.

**Funding:** Government Support - Non-U.S.

FR-PO248

Refining the Developmental Window That Determines Different Kinetics of Cystogenesis After Pkd2 Inactivation in Mice  
Dacia Outada, Terry J. Watnick. *University of Maryland School of Medicine, Baltimore, MD.*

**Background:** Classic Autosomal Dominant Polycystic Kidney Disease (ADPKD) is caused by mutations in *PKD1* or *PKD2*. In mice, early inactivation of *Pkd1* results in rapid and severe cyst formation within 2 weeks. In contrast, inactivation of *Pkd1* in adult kidneys yields slow cystic progression over several months. A detailed time course of *Pkd1* inactivation revealed that the switch in the kinetics of cyst formation occurs between postnatal day (P) 13 and P14. Although it is assumed that a similar switch occurs for *Pkd2* the kinetics of cyst formation in *Pkd2* has never been described. Here we inactivate *Pkd2* at different time points to define the critical window that determines the kinetics of cyst formation after *Pkd2* depletion.

**Methods:** We used the *Pkd2*<sup>fl/fl</sup>; *Pax8*<sup>Cre</sup>; *Tet-O-Cre* mouse model and induced Cre recombinase with doxycycline at different time points (from P10 to P15). We harvested kidneys at 10 days and at 60 days after inactivation. To determine the severity of cystogenesis we analyzed kidney-to-body weight ratio (KW/BW ratio) and cystic index (CI). We performed immunofluorescence staining (IF) using segment-specific markers and performed Masson's Trichrome staining and IF and western blot (WB) to detect fibrosis.

**Results:** Gross examination and histopathological analysis revealed that kidneys inactivated at P10 and harvested at P20 were the largest and most cystic, while kidneys inactivated at and after P14 showed KW/BW ratio and CI closest to non-induced pups at the same age. In contrast, mild dilation of distal tubules was observed in kidneys induced at P14 and harvested at P24. Only a small number of cysts was detected in kidneys induced at P15 and harvested at P25, but if harvested at P60 males showed massive cyst formation in both the proximal and distal tubules while females showed few scattered distal cysts. We could not detect collagen depositions in kidneys induced at P15 and harvested at P60 but we observed an increased number of myofibroblasts around cysts and increased expression of α-SMA by WB especially in males indicating that although fibrosis was not observed remodeling of extracellular matrix proteins had been initiated.

**Conclusions:** Our study revealed that the critical developmental window that determines the kinetics of cysts formation in mouse models is similar for both *Pkd1* and *Pkd2* genes. Research Supported by NIDDK-U54DK126114

**Funding:** NIDDK Support

FR-PO249

Raising Serum Uric Acid With a Uricase Inhibitor Worsens Polycystic Kidney Disease in Rat and Mouse Models  
Daniel Atwood,<sup>1</sup> Ozgur A. Oto,<sup>1,3</sup> Anjana Chaudhary,<sup>1</sup> Charles L. Edelstein.<sup>1,2</sup> *<sup>1</sup>Istanbul Universitesi Istanbul Tip Fakultesi, Istanbul, Turkey; <sup>2</sup>XORTX Therapeutics Inc, Calgary, AB, Canada; <sup>3</sup>University of Colorado Health, Aurora, CO.*

**Background:** Humans are predisposed to gout because they lack uricase that converts uric acid to allantoin. In rodents uricase converts uric acid to allantoin and uricase inhibition raises serum uric acid. The aim of the study was to determine whether raising serum uric acid with the uricase inhibitor oxonic acid (OXO) was associated with worse PKD.

**Methods:** Orthologous models of human PKD were used. PCK rats, a Pkhd1 gene model of ARPKD and Pkd1<sup>RC/RC</sup> (RC) mice, a hypomorphic Pkd1 gene model. OXO 750 mg/kg by mouth in rats from day 21-84 of age and 300 mg/kg IP in mice from day 50-120 of age was used. Uric acid and allantoin were measured by LC/MS-MS. Creatinine was measured by HPLC. Males and females were analyzed together. 12 pro-inflammatory cytokines were measured by MesoScale technology.

**Results:** On IHC staining, xanthine oxidase (that converts xanthine to uric acid) was strongly present in normal tubules in PCK rats. In pharmacokinetic studies in rats, there was a 5-fold increase in serum uric acid 2 hrs after OXO 100 mg/kg (IP or orally), that returned to normal in 8 hrs. OXO resulted in decreased allantoin in PCK rats. In PCK rats and RC mice, OXO resulted in a significant increase in serum uric acid, 2 kidney/body weight ratio (2K/BW) (%), cyst index (% of kidney that was cystic on cross sections) and creatinine (Table). OXO resulted in an increase in pro-inflammatory cytokines in the serum in RC mice.

**Conclusions:** Increasing serum uric acid by inhibiting uricase with OXO results in an increase in kidney weight, cyst index, creatinine in PCK rats and RC mice Potential mechanisms of increased cyst growth that will be investigated include crystal deposition causing tubular dilatation, increased reactive oxygen radicals and pro-inflammatory cytokines/chemokines causing tubular cell proliferation and endothelial injury.

**Funding:** Veterans Affairs Support, Commercial Support - XORTX Therapeutics Inc

Turning the Kidney Into a Lymphoid Organ  
Daniel Atwood,<sup>1</sup> Ozgur A. Oto,<sup>2,1</sup> Anjana Chaudhary,<sup>1</sup> Charles L. Edelstein.<sup>1</sup> *<sup>1</sup>University of Colorado Denver School of Medicine, Aurora, CO; <sup>2</sup>Istanbul Universitesi Istanbul Tip Fakultesi, Istanbul, Turkey.*

**Background:** Pkd1<sup>RC/RC</sup> mice (RC), a hypomorphic Pkd1 mouse model of ADPKD, have suppressed kidney autophagy (Atwood, Edelstein et al. Cell Signal. 2020). We hypothesized that knocking out autophagy (ATG7) in the kidney in aged mice would induce cyst growth. The first aim of the study was to breed kidney-specific autophagy knockout (ATG7<sup>-/-</sup>) mice.

**Methods:** ATG7<sup>-/-</sup> mice were generated using a renal tubule specific cadherin Cre-Lox system. IHC was done with the VectaStain ABC kit. Staining quantitation was done using macros on the Aperio Imagescope. TLT #, size, and index was obtained from H&E sections using an NIS Element macro.

**Results:** 400d ATG7<sup>-/-</sup> mice had no cysts and normal kidney function. Surprisingly, large tertiary lymphoid tissues (TLT)(up to 9%) of the area of the kidney were seen in ATG7<sup>-/-</sup> kidneys. There was increased TLT size, number, and index in ATG7<sup>-/-</sup> vs. WT (Table). TLTs are ectopic lymphoid tissues composed of lymphocyte aggregates that develop de novo in nonlymphoid organs. TLTs form after tissue injury, infection, or chronic inflammation in various kidney diseases. The phenotype of TLTs in ATG7<sup>-/-</sup> was confirmed by the presence of T cell(CD3, 4, and 8), and B cell(CXCL13, CD21) markers and intense proliferation(PCNA) in the TLTs. There was also large amount of staining for pS6(mTORC1), an inducer of proliferation, in the TLTs. PKD kidneys have chronic inflammation which is known to promote the formation of TLTs. There was increased number, size, and index of TLTs in kidneys from RC mice(Table). There was intense proliferation of T cells and increased pS6 (mTORC1) staining in the TLTs in RC kidneys. Treating RC mice with the mTOR inhibitor Torin2(10 mg/kg IP) from 50-120d virtually eliminated TLTs.

**Conclusions:** The following novel findings are described: The presence of numerous, large and discrete TLTs in aged tubule-specific ATG7<sup>-/-</sup> kidneys, intense pS6 (mTORC1) in TLTs in ATG7<sup>-/-</sup> kidneys, first description of the presence of TLTs in PKD kidneys, and virtual elimination of TLTs by treatment of RC mice with an mTOR inhibitor. These data suggest a previously undescribed relationship between suppressed autophagy, activation of mTORC1 and the formation and growth of TLTs.

**Funding:** Veterans Affairs Support

Unbiased RNA-Sequencing Analysis of PKD2<sup>-/-</sup> Proximal Tubular Epithelial Cells Reveals Stabilization of Primary Cilia by Polycystin-2  
Courtney E. Vishy, Benjamin S. Freedman. *University of Washington, Seattle, WA.*

**Background:** Polycystic kidney disease (PKD) is commonly caused by loss of function mutations in *PKD2*, encoding the transmembrane protein polycystin-2 (PC2). PC2 is primarily an ER-resident protein, with a smaller pool localizing to the primary cilium. However, whether and how PC2 affects primary cilium structure and function remains unclear. To complement animal and organoid models of PKD, cell biology models and unbiased approaches are needed to clarify the mechanistic role of PC2 at the primary cilium and develop targeted therapeutics.

**Methods:** CRISPR-Cas9 was applied to generate 5 isogenic pairs of *PKD2*<sup>-/-</sup> and control porcine proximal tubular epithelial cells. 8 biological replicates per genotype were subjected to bulk RNA-sequencing. Gene-ontology (GO) enrichment and differential expression analyses were performed. Transcript abundance of select genes was measured by qPCR and protein abundance by immunoblot. Primary cilia morphology and cellular attachment were visualized by time-course immunofluorescence microscopy. *PKD2*<sup>-/-</sup> hPSC-derived kidney organoids were treated with a the HDAC6 inhibitor tubacin across a range of doses and monitored for cyst formation, live/dead staining, and LDH release toxicity assay.

**Results:** GO term analysis yielded cilium organization as the most downregulated and mitotic cell cycle as the most upregulated. In *PKD2*<sup>-/-</sup> cells, IFT88 had decreased abundance, while the cell cycle associated α-tubulin deacetylase HDAC6 had increased abundance. Upon dissociation and replating, *PKD2*<sup>-/-</sup> cells showed accelerated ciliary disassembly followed by delayed ciliary assembly. Enhanced cell cycle progression occurred only upon cellular dissociation after an initial delay in cellular attachment. Pharmacological inhibition of HDAC6 reduced the number of cysts formed and cyst area in *PKD2*<sup>-/-</sup> organoids even at low doses and without detectable toxicity.

**Conclusions:** PC2 stabilizes cilia after cell dissociation, which promotes cell attachment and inhibits cell cycle progression. These phenotypes are transient and not observed at steady state, possibly explaining why they have not been noticed previously. The isogenic cell biology model presented here thus provides new insight into the dynamics of the polycystin proteins and molecular phenotypes associated with PKD suggesting a new treatment approach to inhibit PKD cystogenesis.

### Tracking Polycystin2 In Vivo Using a Novel Engineered Pkd2-HALO Allele

Courtney J. Haycraft,<sup>1</sup> Mandy J. Croyle,<sup>1</sup> Laura Lambert,<sup>1</sup> Patricia Outeda,<sup>2</sup> Hangxue Xu,<sup>1</sup> Juling Zhou,<sup>1</sup> Phillip H. Chumley,<sup>1</sup> Kelsey R. Clearman,<sup>1</sup> Feng Qian,<sup>2</sup> Michal Mrug,<sup>1</sup> Pamela V. Tran,<sup>3</sup> Stephen C. Parnell,<sup>3</sup> Terry J. Watnick,<sup>2</sup> Bradley K. Yoder.<sup>1</sup> PKD Research Resource Consortium <sup>1</sup>The University of Alabama at Birmingham School of Medicine, Birmingham, AL; <sup>2</sup>University of Maryland School of Medicine, Baltimore, MD; <sup>3</sup>University of Kansas School of Medicine, Kansas City, KS.

**Background:** ADPKD, one of the leading causes of end stage renal disease, is due to mutations in the genes *PKD1* or *PKD2*, which encode for polycystin1 or polycystin2, respectively. While the genes involved were identified several decades ago, research is ongoing to understand their functions and how disruption leads to renal cyst development. Studies focused on trafficking and localization of polycystin2 (PC2) are hindered by the difficulty in antibody generation, low-level expression of the endogenous protein, and inability to track the protein in live cells.

**Methods:** To expand the reagents available to the PKD research community and accelerate studies of PC2 function, the PKD RRC used CRISPR/Cas9 to target HALO to the C-terminus of the endogenous mouse *Pkd2* gene.

**Results:** Mice homozygous for the engineered *Pkd2*-HALO allele are viable and have no overt renal cysts at three months of age indicating that the PC2-HALO protein is functional. Initial studies using western blot from tissues harvested from heterozygous mice showed expression of the PC2-HALO protein in brain and kidney lysates. Additionally, we have begun testing the functionality of the HALO ligand *in vivo* and in primary cells cultured from the mouse line. We confirmed, using a HALO-ligand in heterozygous primary cultured cells, the presence of fluorescent labeling of the fusion protein in the primary cilium of the renal epithelium. Additional characterization of this novel mouse resource is ongoing.

**Conclusions:** This mouse will provide an invaluable resource to analyze PC2 function, trafficking, and turnover *in vivo*.

### Active BRAF Inhibits LKB1-AMPK Signaling and Acetyl-CoA Carboxylase Phosphorylation and Increases Renal Fibrosis in a Model of Polycystic Kidney Disease

Yan Zhang, Emily A. Daniel, Archana Raman, Gail Reif, Stephen C. Parnell, Darren P. Wallace. *University of Kansas Medical Center, Kansas City, KS.*

**Background:** Dysregulated fatty acid oxidation (FAO) in renal epithelial cells contributes to fibrosis in chronic kidney disease. Evidence has shown that reprogrammed metabolism causes reduced FAO in polycystic kidney disease (PKD), and factors that enhance FAO attenuate disease progression in PKD mice. Liver kinase B1 (LKB1) is the main kinase regulating AMP-activating protein kinase (AMPK) and its downstream target acetyl-CoA carboxylase (ACC), an essential rate-limiting enzyme for FAO. Previously, we showed that BRAF, a kinase upstream of MEK-ERK signaling, is the central intermediate for cAMP-induced proliferation of PKD cells. Collecting duct (CD) expression of active BRAF (BRAF<sup>V600E</sup>, a common activating mutation) was sufficient to induce cyst formation in wildtype mice as early as 3 weeks of age, resulting in a novel model of PKD, and accelerated cystic disease in *Pkd1*<sup>RC/RC</sup> mice. Constitutively active BRAF in melanoma cells inhibits AMPK signaling through phosphorylation of LKB1 at Ser 428, an important inhibitory site. We hypothesize that active BRAF leads to ERK-dependent inhibition of LKB1-AMPK signaling, ACC dephosphorylation, and dysregulated FAO, contributing to renal fibrosis in PKD.

**Methods:** To investigate the effect of BRAF on renal fibrosis, mice expressing a conditional BRAF<sup>V600E</sup> were bred with *Pkhd1-Cre* mice to express active BRAF in CD (Braf<sup>CD</sup> mice). At 10 weeks, we collected Braf<sup>CD</sup> kidneys and examined renal fibrosis, macrophage accumulation, and levels of phosphorylated LKB1 (P-LKB1) and ACC (P-ACC).

**Results:** Expression of active BRAF caused an accumulation of immune cells, determined by staining with the macrophage marker CD68, extensive interstitial fibrosis, and increased levels of blood urea nitrogen, indicating a decline in renal function. CD expression of BRAF increased ERK phosphorylation, as expected, and phosphorylation of LKB1 at Ser 428. There were also striking decreases in ACC and P-ACC levels, which have been shown to reduce FAO, leading to increased matrix production and fibrosis.

**Conclusions:** In a novel model of renal cystic disease, BRAF activation of MEK-ERK caused phosphorylation of an inhibitory site on LKB1, leading to decreased AMPK phosphorylation of ACC and increased fibrosis. We propose that ACC is a potential therapeutic target to reduce fibrosis in PKD.

## FR-PO254

### Comparative Transcriptomics of PKD1 Downregulation and PKA Upregulation or Downregulation

Xiaoyan Li, Xiaofang Wang, Li Jiang, Peter C. Harris, Xiaogang Li, Vicente E. Torres. *Mayo Clinic Minnesota, Rochester, MN.*

**Background:** Constitutive activation of PKA by a kidney specific knock-out of *Prkar1a*, encoding the regulatory 1α subunit, induces a cystic phenotype in wild-type mice and aggravates polycystic kidney disease (PKD) in *Pkd1*<sup>RC/RC</sup> mice (AJP Renal Physiol 313:F677, 2017) whereas constitutive inhibition of PKA by kidney specific expression of R1α subunits unable to release catalytic subunits in the presence of cAMP ameliorates PKD in the same model (JASN PMID: 35236775, 2022).

**Methods:** RNA sequencing of wild-type, constitutively activated PKA (CA-PKA) wild-type, *Pkd1*<sup>RC/RC</sup>, CA-PKA *Pkd1*<sup>RC/RC</sup>, and constitutively inhibited PKA (CI-PKA) *Pkd1*<sup>RC/RC</sup> kidneys was performed to compare the effects of PKA activation and *Pkd1* downregulation on gene expression. Differential gene expressions and pathways were identified using DESeq2 and GStats package, respectively.

**Results:** 15,983 transcripts with more than 10 reads were identified. Thirty-six percent (5,710) and 22% (3,574) were differentially expressed (adjusted P<0.05) in CA-PKA and *Pkd1*<sup>RC/RC</sup> kidneys respectively compared to wild-type kidneys; 2,674 (47%) differentially expressed transcripts (DETs) in CA-PKA were also differentially expressed in *Pkd1*<sup>RC/RC</sup> kidneys; log2 fold DET changes were highly and positively correlated (Figure 1). Fifty-six percent (9,005) and 19% (3,063) transcripts were differentially expressed in CA-PKA *Pkd1*<sup>RC/RC</sup> and CI-PKA *Pkd1*<sup>RC/RC</sup> kidneys respectively compared to *Pkd1*<sup>RC/RC</sup> controls; 2,252 (25%) DETs in CA-PKA *Pkd1*<sup>RC/RC</sup> were also differentially expressed in CI-PKA *Pkd1*<sup>RC/RC</sup> kidneys; log2 fold DET changes were inversely correlated (Figure 2). DETs in CA-PKA wild-type, *Pkd1*<sup>RC/RC</sup>, CA-PKA *Pkd1*<sup>RC/RC</sup>, and CI-PKA *Pkd1*<sup>RC/RC</sup> kidneys compared to their controls included 46, 26, 66 and 25% respectively of 351 PKA-dependent out of 10,190 analyzed transcripts in mouse cortical collecting duct cells (PNAS 114:E8875, 2017)

**Conclusions:** This comparative transcriptomic analysis supports the importance of cAMP and PKA signaling in the pathogenesis of PKD and identifies additional therapeutic targets.

**Funding:** NIDDK Support

## FR-PO255

### Loss of Cross-Talk Between Polycystin 1 and LSD1 Promotes Cyst Growth Through Interaction With Ataxia Telangiectasia Mutated and Phase Separation Mechanism in Autosomal Dominant Polycystic Kidney Disease

Xiaoyan Li, Xia Zhou, Ewud Agborbesong, Xiaogang Li. *Mayo Clinic Department of Internal Medicine, Rochester, MN.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is caused by genetic mutations of *PKD1/PKD2*. Although diverse epigenetic regulators promote cyst growth in ADPKD through regulating cystic cell proliferation, apoptosis and ciliogenesis, and targeting dysregulated epigenetic regulators attenuates cyst growth in *Pkd1* mutant mouse models, however, a direct connection between polycystin(s) and epigenetic mechanisms and how epigenetic regulators are regulated in ADPKD kidneys remain elusive.

**Methods:** To understand the role of lysine specific demethylase (LSD1) in cyst growth *in vivo*, we treated *Pkd1*<sup>Int1</sup> and *Pkd1*<sup>RC/RC</sup> mice with LSD1 specific inhibitor ORY-1001 (400 μg/kg) by intraperitoneally (IP) injection. To establish a direct interaction between polycystin 1 (PC1) and LSD1, and an interaction between LSD1 and ataxia telangiectasia mutated (ATM), we performed co-immunoprecipitation (Co-IP) assays in *Pkd1* wildtype and mutant renal epithelial cells.

**Results:** We found that the expression of LSD1 was upregulated in kidneys in *Pkd1* mutant mice and ADPKD patients and targeting LSD1 with its inhibitor delayed cyst growth as seen by decreased cystic index, kidney weight (KW)/body weight (BW) ratios, blood urea nitrogen (BUN) levels and cell proliferation, and increased cystic cell apoptosis in *Pkd1* mutant mice (all *p* < 0.05). The molecular mechanisms of LSD1 in regulating cyst growth include: 1) the interaction with PC1, which decreases the stability and activity of LSD1 when PC1 is present, but loss of PC1 results in the upregulation of LSD1, 2) the interaction of LSD1 with its novel substrate, ATM to regulate the demethylation and activation of ATM, resulting in cyst growth in ADPKD kidneys, 3) the compositions of two intrinsic disordered regions (IDRs) in LSD1 amino acid sequence, suggesting the potential of LSD1 to form phase separation droplets, and 4) the formation of LSD1 phase separation droplets in cystic epithelial cells in kidneys from *Pkd1* mutant mice and ADPKD patients but not in wild type tissues.

**Conclusions:** This is the first study, 1) to establish a direct association of PC1 with an epigenetic regulator LSD1 in renal epithelial cells, and 2) to identify that ATM is a novel substrate of LSD1 to promote DNA damage response. In addition, LSD1 mediated phase-separation also promotes cyst growth in ADPKD.

### Single Gene Mutations in Pkd1 or Tsc2 Alter Extracellular Vesicles Production and Trafficking

John J. Bissler,<sup>1,2</sup> Prashant Kumar,<sup>6,2</sup> Fahad Al-Zadjali,<sup>7</sup> Ying Yao,<sup>2</sup> Alexis Hofherr,<sup>4</sup> Michael Kottgen,<sup>4,5</sup> Darshan Mehta,<sup>6</sup> Kenneth W. Gross,<sup>3</sup> <sup>1</sup>St. Jude Children's Research Hospital, Memphis, TN; <sup>2</sup>The University of Tennessee Health Science Center College of Medicine, Memphis, TN; <sup>3</sup>Roswell Park Comprehensive Cancer Center, Buffalo, NY; <sup>4</sup>Albert-Ludwigs-Universität Freiburg, Freiburg im Breisgau, Germany; <sup>5</sup>Centre for Integrative Biological Signaling Studies, Freiburg im Breisgau, Germany; <sup>6</sup>US FDA National Center for Toxicological Research, Little Rock, AR; <sup>7</sup>Sultan Qaboos University, Muscat, Oman.

**Background:** Patients with autosomal dominant polycystic kidney disease (ADPKD) and the cystic disease associated with tuberous sclerosis complex (TSC) are born with normal or near normal kidneys that later develop cysts and prematurely lose function. Both renal cystic diseases appear to be mediated, at least in part, by disease promoting extracellular vesicles (EVs) that can induce genetically intact cells to participate in the renal disease process.

**Methods:** We used centrifugation and size exclusion chromatography to isolate the EVs for study. We characterized the EVs using tunable resistive pulse sensing, dynamic light scattering, transmission electron microscopy and western blot analysis. We performed EV trafficking studies using a dye approach in both tissue culture and in vivo studies.

**Results:** We have previously reported that loss of the *Tsc2* gene significantly increased EV production and here demonstrate that the loss of the *Pkd1* gene also significantly increases EV production. Using a cell culture system, we also show that loss of either the *Tsc2* or *Pkd1* gene results in EVs that exhibit an enhanced uptake by renal epithelial cells and a prolonged half-life, possibly further accentuating the EV dose effect. Loss of the primary cilia significantly reduces EV production in renal collecting duct cells. We document that EVs from cells that have loss of polycystin-1 have greatly altered kinetics and a profound effect on the EV half-life, possibly impacting the duration of EV cargo effect on the recipient cell.

**Conclusions:** These results demonstrate the interplay between primary cilia and EVs and support a role for EVs in polycystic kidney disease pathogenesis.

### Generation of Mice Expressing an N-Terminal SNAP-Tagged Pkd1 Allele

Stephen C. Parnell,<sup>1</sup> Pamela V. Tran,<sup>1</sup> Heather A. Riddle,<sup>1</sup> Wei Wang,<sup>1</sup> Courtney J. Haycraft,<sup>2</sup> Patricia Outeda,<sup>3</sup> Bradley K. Yoder,<sup>2</sup> Terry J. Watnick,<sup>3</sup> Darren P. Wallace,<sup>1</sup> James P. Calvet,<sup>1</sup> PKD Research Resource Consortium <sup>1</sup>University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS; <sup>2</sup>The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL; <sup>3</sup>University of Maryland School of Medicine, Baltimore, MD.

**Background:** ADPKD missense mutations that impair intracellular trafficking of polycystin-1 (PC1) indicate that PC1 undergoes complex regulation and interacts with various proteins to mature and reach its cellular destinations. However, a lack of antibodies that reliably detect endogenous PC1 and the inability to analyze PC1 trafficking in live cells have limited our understanding of the interplay between PC1 function and localization. To facilitate the *in vivo* visualization of PC1 trafficking and co-immunoprecipitation of multiprotein complexes, we have engineered mice that express endogenous PC1 with an N-terminal SNAP tag.

**Methods:** For proof-of-concept studies, a cDNA construct expressing N- and C-terminally tagged PC1 (<sup>SNAP</sup>PC1<sup>CLIP</sup>) was transfected into HEK293T cells. <sup>SNAP</sup>PC1<sup>CLIP</sup> was detected by Western blot and localized in live cells using SNAP ligand, followed by immunostaining for the ciliary marker, ARL13B. Subsequently, a homologous repair construct encoding SNAP fused in-frame with the first exon of *Pkd1* was injected into C57BL/6J pronuclei for homology driven repair using CRISPR technology. PCR and sequencing were used to screen pups for correct insertion of SNAP into the *Pkd1* locus. RT-PCR and matings with *Pkd1*<sup>Y</sup> and *Pkd1*<sup>RC</sup> hypomorphic mutant mice were used to examine *Pkd1*<sup>N-SNAP</sup> expression and PC1<sup>N-SNAP</sup> functionality.

**Results:** <sup>SNAP</sup>PC1<sup>CLIP</sup> localized around the nucleus (likely the endoplasmic reticulum) and in the cilium of HEK293T cells, demonstrating that PC1-N-SNAP can exit the Golgi and traffic to the cilium. *Pkd1*<sup>N-SNAP</sup> mosaic founders were produced and a stable line with confirmed integration was identified. *Pkd1*-N-SNAP mRNA was transcribed in multiple tissues. At 16 weeks of age, *Pkd1*<sup>N-SNAP/V</sup> and *Pkd1*<sup>N-SNAP/RC</sup> compound heterozygotes appeared normal, suggesting that the *Pkd1*<sup>N-SNAP</sup> allele is functional.

**Conclusions:** *Pkd1*<sup>N-SNAP</sup> mice express the tagged *Pkd1* allele and the tag does not appear to impair PC1 function. Future experiments will test SNAP ligands in primary cells and kidneys of live mice to visualize intracellular trafficking of PC1<sup>N-SNAP</sup>. These mice should enable novel investigation of the regulation of intracellular trafficking and the cellular functions of PC1.

**Funding:** NIDDK Support

## FR-PO258

### Autophagy Is Dynamically Dysregulated Along the Pathogenesis of Autosomal Dominant Polycystic Kidney Disease

Andrew M. Lavin, Ping Zhu, Peter C. Harris, Xiaolei Xu, Xueying Lin. *Mayo Clinic Research Rochester, Rochester, MN.*

**Background:** Abnormal autophagy has been noted in various models of PKD. However, a consensus is lacking and treatment targeting autophagy gives rise to contradictory results, underscoring the complexity of functions of autophagy in PKD. Here, we conducted a detailed analysis of autophagy dysregulation in a mouse model of ADPKD.

**Methods:** *Pkd1*<sup>RC/RC</sup> mouse that contains a disease variant, *PKD1* p.R3277C, was crossed into a transgenic *Tg(EGFP-Lc3)* reporter mouse. Autophagy was assessed at different time points during the disease progression via western blotting, immunofluorescence staining, and qPCR. To measure autophagic flux, BafA1, an inhibitor of autophagosome-lysosome fusion, was used.

**Results:** At 1 month of age when total kidney weight/body weight ratio (2KW/BW) in *RC/RC* mice was only doubled compared with wild-type animals, LC3-II proteins were accumulated at a steady state and failed to further accumulate in the presence of BafA1, indicating insufficient autophagic flux. GFP-LC3 puncta were mainly detected in the non-cystic PT tubules, suggesting autophagy dysregulation was more likely a primary defect to *Pkd1* mutation than secondary to cyst formation. Essential autophagy proteins such as Becln1, Atg7, and Lamp2 were normally expressed while Tfeb, a transcription factor implicated in the autophagic flux regulation and oncogenic proliferation, was specifically downregulated in the PT tubules. At 6 months when 2KW/BW in the *RC/RC* mice was 5-6 times higher than wild-type controls, steady state LC3-II levels were elevated and autophagic flux was recovered. Becln1, Atg7, Lamp2, and Tfeb were all overexpressed, and Tfeb nuclear localization was significantly increased in both the PT and CD tubules.

**Conclusions:** We found dynamic autophagy dysregulation in the *Pkd1*<sup>RC/RC</sup> mouse model of ADPKD, i.e., impaired cargo clearance in the early phase, and adaptive/maladaptive autophagy activation in the later phase, and a spatial- and temporal-dependent dysregulation of Tfeb. Our study suggests a time-dependent mechanism that needs to be considered when developing an autophagy-based therapy for ADPKD.

## FR-PO259

### Assessing the Therapeutic Potential of Readthrough of Nonsense

#### Mutations in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Elizabeth K. Dillinger,<sup>1</sup> Peter C. Harris,<sup>2</sup> <sup>1</sup>Mayo Clinic Graduate School of Biomedical Sciences, Rochester, MN; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN.

**Background:** ADPKD is a common cause of ESKD, and truncating mutations are associated with more severe disease. Over 25% of catalogued *PKD1* and *PKD2* mutations are nonsense type, truncating mutations. Readthrough of nonsense variants resulting in full length wildtype or missense containing proteins is a promising treatment for this type of mutation. We hypothesize that readthrough therapies may result in an increase in PKD1 and PKD2 protein, polycystin-1 and -2 (PC1/PC2), and hence, decrease the severity of cystic disease.

**Methods:** Using a dual-fluorescent, short fragment, *in vitro* assay, and flow cytometry we determined the effect of various readthrough treatments on a catalogue of *PKD2* nonsense mutations. After determining which treatments have the best efficacy on the *PKD2* mutations we are further investigating the effects of these treatments on the level of readthrough, trafficking and localization of full length PC2 and the PC1/PC2 complex formation using a novel *in vitro* assay.

**Results:** We have assayed five PKD2 nonsense variant in detail that contain the three different stop codons and different flanking sequences and have found a dramatic difference in the level readthrough depending on the sequence. We have also added 5 mM caffeine to the culture media which increases the rate of readthrough by diminishing nonsense mediated decay, although alone did not promote readthrough. For the nonsense variant p.Trp414\*, with the nonsense codon TGA C, levels of readthrough of ~28% were recorded with 1800ug/ml of gentamycin, that is promoted to ~38% with the addition of caffeine. In contrast, the nonsense variant p.Gln768\*, codon TAA G, had readthrough of only ~6%, that was not further boosted with caffeine. Analysis of treated MEFs from a mouse mimicking the Gln768\* variant showed minimal readthrough. The level of readthrough with the compounds G418 or ataluren for p.Trp414\* were not as effective as gentamycin.

**Conclusions:** Our studies indicate that readthrough may be a feasible means to increase the level of functional polycystin protein in ADPKD and so a therapy worthy of consideration. However, selecting the best drug and patients based on the specific stop codon may dramatically alter the efficacy.

**Funding:** NIDDK Support

## FR-PO260

### Longitudinal Characterization of Mitochondrial and Metabolic Changes in Autosomal Dominant Polycystic Kidney Disease

Jamie Zheng, Cassandra Trask, Marie C. Hogan, Vicente E. Torres, Peter C. Harris, Alfonso Eirin, Maria V. Irazabal. *Mayo Clinic, Rochester, MN.*

**Background:** Metabolic dysregulations and mitochondria abnormalities are implicated in the pathogenesis of autosomal dominant polycystic kidney disease (ADPKD), but reports differ between studies, and there are no longitudinal studies that determine the timing of these alterations through the disease. This study aimed to determine the longitudinal mitochondrial and metabolic changes in a slowly progressive *Pkd1* mouse model (*Pkd1*<sup>RC/RC</sup>) and patients with ADPKD.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Methods:** We analyzed the kidney metabolome of *Pkd1<sup>RC/RC</sup>* mice and WT controls (n=5 males and 5 females/group) at 1, 2, 4, 6, 8, 12, and 16 months (m, renal failure) using <sup>1</sup>H NMR, and mitochondrial characteristics in kidneys and urine from the same animals at 1, 6, and 16m using electron microscopy, RNAseq, and qPCR. Disease severity and progression were evaluated by kidney weight/body weight (KW/BW), cystic index (CI), fibrotic index (FI), and BUN. We collected urine and blood from 40 well-characterized, young, early-stage (<40 years, eGFR>90 ml/min/1.73m<sup>2</sup>) patients with ADPKD and 20 age and sex-matched controls for metabolomics and mtDNA analyses. Abdominal MRIs were acquired for kidney volume.

**Results:** KW/BW and CI were higher in *Pkd1<sup>RC/RC</sup>* from 1m and FI from 4m, but BUN was similar until 8m. Metabolic changes were present throughout the disease, but the metabolic profile varied at different stages. At 1m, kidney mitochondria resembled the typical appearance of WT controls, but the mitochondria number was lower in *Pkd1<sup>RC/RC</sup>*. Changes in mitochondria area and matrix density became apparent as the disease progressed. The mitochondrial genetic profile in *Pkd1<sup>RC/RC</sup>* versus WT differed at 1, 6, and 16m. However, functional analysis revealed distinct changes at different stages of the disease. In urine, the mtDNA copy number was lower at 1m, but unexpectedly, it increased with disease progression. Analyses of human urine and plasma samples are still ongoing.

**Conclusions:** ADPKD is associated with metabolic dysregulations and mitochondria abnormalities throughout the disease. However, the abnormalities observed were different in the early, middle, and late stages of the disease. These findings have significant implications for treating patients with ADPKD and suggest that different therapeutic strategies might be beneficial throughout the disease.

## FR-PO261

**Loss of Intestinal Pkd1 Does Not Alter Epithelial Cell Integrity or Inflammation in Early Autosomal Dominant Polycystic Kidney Disease**  
Rande S. Sedaka, Shinobu Yamaguchi, Sejal Sanjay Shinde, Jung-Shan Hsu, Takamitsu Saigusa. *The University of Alabama at Birmingham, Birmingham, AL.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited progressive kidney disorder, manifested by a germline *PKD1* mutation in nearly 80% of patients. Polycystin-1 (PC-1), the protein encoded by *PKD1*, is critical to maintaining renal epithelial cell adhesion. However, its expression along the intestines and its role in intestinal epithelial cell barrier function have yet to be elucidated. Considering the gut is the largest source of inflammatory cells in the body, and macrophage infiltration precedes accelerated cyst growth in kidney-specific *Pkd1* knockout (*Pkd1KO*) mice, we hypothesized that loss of intestinal *Pkd1* would lead to decreased intestinal epithelial cell integrity and increased inflammation, potentially preceding renal inflammation.

**Methods:** Plasma, kidney, and intestines were collected from 9-12 week old male and female conditional *Pkd1KO* (CAGG-creER; tamoxifen-induced at 5-6 weeks) and flox (control) mice. Intestinal permeability was detected via a fluorescein isothiocyanate-dextran assay. Tissue was utilized for RT-PCR and immunohistochemistry, while plasma was used to measure monocyte chemoattractant protein-1 (MCP-1).

**Results:** Kidney/body weight ratio was significantly elevated in *Pkd1KO* compared to flox mice. No genotype differences were observed in colon or small intestine/body weight ratio. *Pkd1* expression was significantly decreased in the kidney, duodenum, jejunum, ileum, proximal colon, and distal colon of *Pkd1KO* compared to flox mice. Despite these deficiencies, there were no differences in kidney, ileum, or colon epithelial integrity genes (*Ocln*, *Ptk2*, *Cldn1*, *Tjp1*, *Dsg2*, *Cdh1*), inflammatory genes (*Csf1*, *Il1b*, *Ccl2*, *Il6*, *Tnfa*, *Tgfb1*, *Muc2*), intestinal damage, plasma MCP-1, or small intestinal permeability between genotypes. However, colonic endothelial integrity marker, *Plvap*, was significantly elevated in *Pkd1KO* compared to flox mice, with a trended increase in *Cdh5* and *Cgn* and decrease in colonic permeability.

**Conclusions:** Although *Pkd1* expression is downregulated along the entire intestinal tract in our ADPKD mouse model, it does not appear that intestinal epithelial integrity or inflammation are altered at this early timepoint preceding renal inflammation. Elevated endothelial integrity marker expression suggests improved colonic barrier function in *Pkd1KO* mice.

## FR-PO262

**CD74 Promotes Cyst Growth and Interstitial Fibrosis in Autosomal Dominant Polycystic Kidney Disease**  
Xia Zhou, Xiaoyan Li, Ewud Agborbesong, Xiaogang Li. *Mayo Clinic Minnesota, Rochester, MN.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is a genetic disorder characterized with cyst formation, inflammation and renal fibrosis. CD74 has been recognized as a transmembrane receptor for the cytokine macrophage migration inhibitory factor (MIF). Our previous study has reported that MIF is an important regulator of cyst growth in ADPKD possibly through binding with CD74 to activate ERK, PI3K-Akt, NF-kappa B and AMPK pathways to regulate the cell proliferation and survival. However, whether and how CD74 by itself regulates cyst growth and interstitial fibrosis remains elusive.

**Methods:** To understand the role of CD74 *in vivo*, we generated *Pkd1<sup>flox/flox</sup>; CD74<sup>-/-</sup>; Pkhd1-Cre* mice. To explore the mechanisms mediated by CD74 in regulating cyst growth, inflammation and renal fibrosis, we knocked down CD74 with siRNA and inhibited MIF with its inhibitor ISO-1 in renal epithelial cells and fibroblasts.

**Results:** We found that CD74 were upregulated in *Pkd1* mutant cells and kidneys, and knockout of *CD74* delayed cyst growth as seen by decreased cystic index, kidney weight/body weight ratios, blood urea nitrogen levels in *Pkd1<sup>flox/flox</sup>; Pkhd1-Cre* mice. Deletion of CD74 decreased proliferation and increased apoptosis of cyst lining epithelia, reduced the recruitment of macrophages in pericyclic and interstitial areas, and ameliorated interstitial fibrosis. Knockout of CD74 decreased mRNA levels of MCP-1, TNF alpha, MIF and CD44 as well as fibrotic markers, including Col I, Col III, and fibronectin. In addition, we found that knockdown of CD74 by siRNA decreased the expression of those cytokines, CD44, and fibrotic markers in *Pkd1* mutant renal epithelial cells and renal fibroblasts. Our ChIP assay indicated that CD74 regulated the transcription of those genes through binding on their promoters, supporting a feedback loop between MIF and CD74. Furthermore, we found that inhibition of MIF with its inhibitor ISO-1 decreased the phosphorylation of ERK, Akt and S6, and blocked the phosphorylation of Smad3 induced by TGF beta in renal fibroblasts.

**Conclusions:** CD74 promotes cyst growth and renal interstitial fibrosis in ADPKD. This study identifies novel transcriptional targets of CD74, including cytokine and fibrotic markers, which will help in understanding of essential pathways regulating cystic cell growth and survival, the recruitment of macrophages and the activation of renal fibroblasts in ADPKD.

IIS-Fundación Jiménez Díaz-Universidad Autónoma Madrid, Madrid, Spain; <sup>3</sup>Genetics and Developmental Biology of Kidney Diseases, Health Research Institute of Santiago de Compostela (IDIS), Santiago de Compostela Clinical Hospital Complex (CHUS), Santiago de Compostela, Spain; <sup>4</sup>Department of Internal Medicine, Yale School of Medicine, New Haven, CT; <sup>5</sup>Red de Investigación Renal (REDinREN), Madrid, Spain.

**Background:** Autosomal Dominant Polycystic Kidney Disease is a genetic disease caused by *PKD1* or *PKD2* mutations, which codify for the Polycystin-1 and Polycystin-2 proteins, respectively. ADPKD prevalence is among 1:800 and 1:1000 of live births and is characterized by fluid-filled renal cysts, leading to end-stage renal disease (ESRD). During this process the production of chemokines, cytokines and growth factors by epithelial cells, interstitial fibroblasts and inflammatory cells, such as macrophages, increases. Preclinical studies have described GREMLIN as an important mediator of chronic kidney disease, which could have usefulness as urine biomarker. However, there are no studies about GREMLIN in polycystic kidney disease.

**Methods:** In an orthologous murine model of polycystic kidney disease (*Pkd1<sup>cond/cond</sup>*, Tam-Cre<sup>+/+</sup>) we studied the role of GREMLIN and potential downstream signaling (activation of its receptor VEGFR2 and the Notch pathway) in different stages of renal cystic progression. The polycystic phenotype was induced in lactating mice by administering tamoxifen to the mother on postnatal days 10 and 11, causing a deletion in *Pkd1* gene. Studies were performed taking into account different sacrifice points: at 18, 30 and 45 days. In urine and kidney tissue samples from ADPKD patients, GREMLIN levels were evaluated.

**Results:** In *Pkd1<sup>-/-</sup>* mutant mice, *grem-1* renal expression (the gene encoding GREMLIN protein) was increased from 18 days, with a significant upregulation at 30 days. *Grem-1* overexpression was associated with progressive cysts expansion and detriment in renal function measured by BUN. These results were confirmed at the protein level by western blot. Immunohistochemistry revealed positive GREMLIN staining since pre-cystic tubuloe epithelial cells, which remained elevated in the tubules at later times. Positive GREMLIN expression was observed in biopsy samples of cysts from ADPKD patients as well as GREMLIN protein presence in urine samples. In the polycystic model, GREMLIN induction was correlated with VEGFR2 activation in the same tubular segments. Cyst formation was also associated with activation of NOTCH1 and NOTCH3.

**Conclusions:** GREMLIN expression in murine and human polycystic kidney suggests that it may be an important mediator of renal damage progression in ADPKD.

**Ouabain Treatment Increases Cyst Progression in a Slowly Progressive Autosomal Dominant Polycystic Kidney Disease Mouse Model**  
Jordan Trant, Gladis S. De Blanco, Jeff P. Mcdermott, Gustavo Blanco. *The University of Kansas Medical Center, Kansas City, KS.*

**Background:** Renal cyst progression in Autosomal Dominant Polycystic Kidney Disease (ADPKD) is highly dependent on agents circulating in blood. We have previously shown that one of these agents is the hormone ouabain. By binding to its cell surface receptor Na,K-ATPase (NKA), ouabain triggers a cascade of signal transduction events in the cells, which enhances ADPKD cystogenesis via two main mechanisms: increased cell proliferation and enhanced fluid secretion of the cystic renal tubular epithelial cells. These effects were obtained using *in vitro* models of ADPKD. Here, we determined the effects of ouabain *in vivo* using an ADPKD mouse model.

**Methods:** Ouabain (0.3 mg/g) or saline was injected intraperitoneally to wildtype (WT) mice and a slowly progressive ADPKD model (RC/RC mice). Ouabain was administered daily, starting at postnatal day 9 and for 1-5 months. Kidney weight to body weight ratio (KW/BW), blood urea nitrogen (BUN), percent of cystic area (% cyst area), and kidney fibrosis were then measured.

**Results:** Ouabain treatment significantly increased the % cyst area in RC/RC mice compared to saline-injected controls at all time points. The KW/BW was also augmented in RC/RC mice at 3, 4, and 5 months of treatment. There were no differences observed between male and female mice, and these effects were not seen in WT mice. BUN values were not affected by ouabain in either of the groups tested. Between 1 and 5 months, ouabain significantly increased fibrosis in the RC/RC mice compared with the saline-injected controls.

**Conclusions:** These findings demonstrate that ouabain stimulates kidney cyst progression in ADPKD not only *in vitro*, but also *in vivo*. Since the dose of ouabain that we used is within the reported normal physiological range, our results support the idea that circulating levels of this hormone could be contributing to cyst progression in ADPKD patients.

## FR-PO265

### Electrophysiological Characterization of Polycystin-2 Mutants With Disease-Associated Missense Mutations in the Channel's Pore Loop

Tobias Staudner, Linda Geiges, Christoph Korbmacher, Alexandr V. Ilyaskin. *Friedrich-Alexander-Universitat Erlangen-Nurnberg Institut fur Zellulare und Molekulare Physiologie, Erlangen, Germany.*

**Background:** In ~15% of patients with autosomal dominant polycystic kidney disease (ADPKD) mutations of polycystin-2 (PC2) are causative for the disease. PC2 belongs to the family of transient receptor potential (TRP) channels characterised by six transmembrane segments (S1 - S6) and a pore loop between S5 and S6. Here we investigated the effects of three disease-associated pore loop mutations (F629S, C632R, and R638C) on PC2 ion channel properties.

**Methods:** Pore mutations F629S, C632R, or R638C were introduced into wild-type PC2 (PC2<sub>WT</sub>) or two PC2 *gain-of-function* (GOF) constructs (PC2<sub>F604P</sub> or PC2<sub>L677A/N681A</sub>) using site-directed mutagenesis. PC2 constructs with or without pore mutations were heterologously expressed in *Xenopus laevis* oocytes for functional analysis using the two-electrode voltage clamp technique. PC2-mediated Na<sup>+</sup> inward currents were elicited by divalent cation removal. Monovalent cation selectivity and Ca<sup>2+</sup> permeability were assessed.

**Results:** In contrast to PC2<sub>WT</sub>, expression of PC2 with F629S, C632R or R638C pore mutations produced no detectable baseline Na<sup>+</sup> inward currents. These findings are consistent with a *loss-of-function* effect of the pore loop mutations on baseline PC2 activity. Importantly, F629S, C632R and R638C also completely abolished the ion channel function of the GOF construct PC2<sub>F604P</sub>. This finding suggests that pore loop mutations disturb the gating mechanism associated with the F604P GOF mutation. Interestingly, the R638C mutation reduced but did not abolish Na<sup>+</sup> inward currents mediated by the GOF construct PC2<sub>L677A/N681A</sub>. Importantly, the R638C mutation significantly altered monovalent cation selectivity of PC2<sub>L677A/N681A</sub> and completely abolished its Ca<sup>2+</sup> permeability. Interestingly, introducing the corresponding mutation R518C in the closely related polycystin-2L1 channel rendered it impermeable to Ca<sup>2+</sup> without affecting its Na<sup>+</sup> permeability.

**Conclusions:** PC2 pore loop mutations abolished baseline PC2 ion channel function and also the function of the GOF channel PC2<sub>F604P</sub>. This suggests that pore mutations disturb PC2 channel gating. Moreover, our findings highlight an important role of R638 in monovalent cation selectivity and Ca<sup>2+</sup> permeability of PC2. Supported by a grant from IZKF Erlangen (F8).

## FR-PO266

### Lipophilic Methanethiosulfonate (MTS) Reagents Inhibit Ion Channel Function of Polycystin-2 With a Gain-of-Function Mutation (F604P)

Linda Geiges, Tobias Staudner, Christoph Korbmacher, Alexandr V. Ilyaskin. *Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany.*

**Background:** Polycystin-2 (PC2) mutations account for approximately 15% of reported cases of autosomal-dominant polycystic kidney disease (ADPKD). As a member of the transient receptor potential (TRP) ion channel family, PC2 features a typical structure with 6 membrane-spanning segments (S1–S6). No specific activators or inhibitors of PC2 have been described to date. Interestingly, covalent modification of N-terminal cysteines is a known activation mechanism of another TRP channel, TRPA1. Therefore, we hypothesized that a similar regulatory mechanism may exist in PC2.

**Methods:** PC2 mutants were generated by site-directed mutagenesis and functionally expressed in *Xenopus laevis* oocytes. PC2 currents were measured using the two-electrode voltage clamp technique. For covalent cysteine modification, several structurally different methanethiosulfonate (MTS) reagents were applied in the bath. In particular, the effects of positively charged MTSET and MTSEA and lipophilic MTS reagents (methyl-, ethyl-, propyl- and benzyl-MTS) were investigated.

**Results:** Application of these MTS reagents did not result in an activation of wild-type PC2. To investigate a possible effect of MTS reagents on the channel in an open state, we used two recently discovered *gain-of-function* (GOF) PC2 mutants (PC2<sub>F604P</sub>

or PC2<sub>L677A/N681A</sub>). Importantly, we found that lipophilic but not positively charged MTS reagents strongly inhibited PC2<sub>F604P</sub>. The inhibitory effect could not be reproduced in the structurally related TRPML3 channel containing a corresponding GOF mutation (A419P). The GOF mutant PC2<sub>L677A/N681A</sub> was not sensitive to any of the tested MTS reagents. The inhibitory effect of methyl-MTS was preserved after mutating all four cysteines in the channel's N-terminus. Interestingly, replacing the C593 residue in the S4-S5 linker by serine or alanine resulted in a complete loss of PC2<sub>F604P</sub> function, mimicking the inhibitory effect of lipophilic MTS reagents.

**Conclusions:** We identified lipophilic MTS reagents as inhibitors of PC2<sub>F604P</sub> ion channel function. Moreover, C593 in the S4-S5 linker appears to be a crucial residue for PC2 activity. These new findings may lead to a better understanding of PC2 gating mechanisms and promote the development of pharmacological PC2 modulators. Supported by a grant from IZKF Erlangen (F8)

**Funding:** Government Support - Non-U.S.

## FR-PO267

### SMYD3 Regulates Cyst Growth and Ciliogenesis in Autosomal Dominant Polycystic Kidney Disease

Ewud Agborbesong,<sup>1</sup> Xia Zhou,<sup>1</sup> Xiaoyan Li,<sup>1</sup> Xiaogang Li.<sup>2</sup> *Mayo Clinic Minnesota, Rochester, MN; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is a genetic disorder that results in renal cyst formation with the eventual loss of renal function. In addition, ADPKD is associated with abnormal primary cilia function. Yet the regulation of cystogenesis and ciliogenesis in ADPKD are not fully known. Deregulation of epigenetic modulators has emerged as a common etiological factor in ADPKD. How epigenetic modifiers regulate cystogenesis and ciliogenesis remains unclear. We investigated the role of the histone methyltransferase, SMYD3, on cyst growth and ciliogenesis in ADPKD.

**Methods:** To investigate the role and mechanism of SMYD3 on cyst growth and ciliogenesis in ADPKD, we generated double conditional knockout *Pkd1<sup>fl/fl</sup>; Smyd3<sup>fl/fl</sup>; Ksp-Cre* mice. To further define the mechanisms, we knocked down Smyd3 with shRNA and siRNA, and performed immunostaining, western blot, qRT-PCR and chromatin immunoprecipitation analysis in renal epithelial cells and tissues.

**Results:** Smyd3 was upregulated in *Pkd1* mutant mouse and human ADPKD kidneys, and its knockout reduced cyst growth as seen by decreased cystic index, KW/BW ratios, BUN levels, and cyst lining epithelial cell proliferation in *Pkd1* mutant mice. This decreased cyst growth correlated with shortening of cilia in *Pkd1* mutant kidney tissues. We found that Smyd3 is located at the centrosome and its depletion disrupted centrosome integrity and decreased recruitment of basal body components such as Cep164 and Ttbk2. We further found that Smyd3 interacted with Ttbk2 and  $\alpha$ -tubulin, and via methylation of  $\alpha$ -tubulin regulated microtubule stability which contributed to ciliogenesis. Also, Smyd3 regulated the transcription of ciliary genes by binding to their promoters, and regulated the activation of PKD associated signaling pathways including Erk, Stat3, NF- $\kappa$ B and  $\beta$ -catenin. In addition, Smyd3 played a crucial role in the activation of the hedgehog signaling pathway in renal epithelial cells.

**Conclusions:** Smyd3 is a novel basal body constituent that regulates centriole assembly and ciliogenesis through its interactions with novel binding partners and transcriptional regulation of ciliary genes. The activation of Smyd3 mediated cilia dependent hedgehog and PKD signaling pathways associated with cell proliferation promotes cystogenesis, providing a novel link between cyst growth and cilia formation and function in ADPKD.

## FR-PO268

### The Polycystin-1 C-Terminal Tail (CTT) Suppresses Cystic Disease: Elucidating the Underlying Mechanisms

Laura Onuchic, Valeria Padovano, Giorgia Schena, Vanathy Rajendran, Xiaojian Shi, Ke Dong, Nikolay P. Gresko, Hongying Shen, Stefan Somlo, Michael J. Caplan. *Yale School of Medicine, New Haven, CT.*

**Background:** Mutations in *PKD1*, which encodes polycystin-1, account for ~78% of autosomal dominant polycystic kidney disease (ADPKD) cases. We have previously shown that transgenic CTT expression in the *Pkd1<sup>fl/fl</sup>; Pax8<sup>rtTA</sup>; TetO-Cre* ADPKD mouse model suppresses cystic phenotype and preserves renal function. We have also shown that this suppression is dependent on an interaction between CTT and Nicotinamide Nucleotide Transhydrogenase (NNT). NNT is a mitochondrial enzyme that modulates NAD(P)(H) levels. In the present study, we assessed CTT-dependent changes in both redox modulation and NNT enzymatic activity. Furthermore, we expressed CTT in a non-inducible, early and rapidly progressing ADPKD mouse model.

**Methods:** Mice were generated on C57BL/6N ("N"; NNT-competent) and C57BL/6J ("J"; NNT-deficient) backgrounds. Kidney NAD(P)(H) levels were determined by targeted LC-MS. NNT enzymatic activity was measured with a spectrophotometric assay. ADPKD mice +/- CTT, in which Cre expression is driven by the *Pkd1* promoter, were generated by crossing "J"-*Pkd1<sup>fl/fl</sup>; Pkd1-Cre* with "N"- and "J"-CTT-expressing *Pkd1<sup>fl/fl</sup>; Pax8<sup>rtTA</sup>; TetO-Cre* mice.

**Results:** "N" cystic CTT-expressing mice exhibited an ~3-fold increase in NADPH/NADP<sup>+</sup> and an ~2.5-fold increase in NADH/NAD<sup>+</sup> ratios when compared to CTT-negative littermates. CTT expression on the "J" background did not affect either ratio. We detected a 20% decrease in NNT enzymatic activity in "N" cystic mice compared to "N" WT controls. Interestingly, CTT expression in "N" cystic mice rescued enzymatic activity to the same level observed in "N" WT controls. Finally, CTT expression in the

*Nnt*-heterozygous F1 progeny (*J-Pkd1<sup>fl/fl</sup>;Pkh1-Cre* x *N-Pkd1<sup>fl/fl</sup>;Pax8<sup>rtm</sup>;TetO-Cre+CTT*) led to a 25% decrease in kidney-to-body weight ratio. As expected, CTT expression in the “J” *Nnt*-deficient F1 progeny did not suppress cystic disease.

**Conclusions:** While the directionality of the reaction catalyzed by NNT in the context of ADPKD remains to be determined, it is likely that CTT-dependent modulation of mitochondrial redox and NNT activity contributes to disease suppression. Furthermore, we confirmed CTT-dependent disease suppression in a second *Pkd1*-KO model, which supports the idea that this small fragment may open the doors to the exploration of gene therapy approaches.

## FR-PO269

### Deep Learning Allows Automated Analysis of Cystogenesis in Novel *Xenopus* Animal Models for Autosomal Polycystic Kidney Disease

Thomas Naert, Soeren S. Lienkamp. *Universitat Zurich, Zurich, Switzerland.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is caused by mutations in *PKD1* or *PKD2* and has an unmet need for new drugs and therapeutic targets. Ideally, these are identified in clinically relevant vertebrate disease models amenable to screening efforts. Further, genome editing simplifies the generation of new animal models for congenital disorders. However, the detailed and unbiased phenotypic assessment of altered embryonic development remains a challenge.

**Methods:** We employ targeted and unilateral CRISPR/Cas9 editing in order to inactivate *pkd1* or *pkd2* in the *Xenopus* developing vertebrate kidney. Cystogenesis is then visualized by whole-mount immunostaining, fluorescent stereomicroscopy, mesoSPIM light-sheet microscopy and advanced U-Net deep learning image processing for automated, unbiased and rapid scoring of kidney pathological states in two and three dimensions.

**Results:** CRISPR/Cas9 genome engineering in *pkd1* and *pkd2* elicited cystic malformations in developing renal tubules two-days post-fertilization ( $p < 0.001$ ). We observed cystogenesis across different developmental stages by leveraging an image processing pipeline for automated scoring of ADPKD in *Xenopus* embryos using deep learning approaches. Using a combination of segmentation and classification deep learning architectures allowed for automated size measurement of kidneys, as well as a qualitative analysis of cystic hallmarks. Our models correlated well with an independent expert on test data ( $n_{\text{test}} = 120$ ;  $r = 0.96$ ;  $P < 0.001$ ). Next, using tissue clearing and light-sheet microscopy approaches, we extended to three-dimensional analysis of cystogenesis. Here we showed that three-dimensional kidney size quantification can be achieved.

**Conclusions:** By combining light-sheet microscopy and deep learning we provide a framework for higher-throughput and in-depth characterization of novel models for autosomal polycystic kidney disease.

MesoSPIM light-sheet microscopy allows for whole-embryo imaging of *Xenopus tropicalis* embryos. Wild-type (top) embryos develop normal kidneys, *pkd1* mutants (bottom) reveal cystogenesis.

## FR-PO270

### The Transcriptional Regulator AP-2 $\alpha$ Maintains the Tubular Diameter of Renal Collecting Ducts in Adult Mice

Janna Leiz, <sup>1,2</sup> Shuang Cao, <sup>3,1</sup> Felix Boivin, <sup>1,2</sup> Christian Hinze, <sup>3,1</sup> Kai M. Schmidt-Ott, <sup>3,1</sup> Molecular and Translational Kidney Research <sup>1</sup>Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>Max-Delbrück-Centrum für Molekulare Medizin in der Helmholtz-Gemeinschaft, Buch, Germany; <sup>3</sup>Medizinische Hochschule Hannover, Hannover, Germany.

**Background:** The transcriptional regulator AP-2 $\alpha$ , encoded by the Tfp2a gene, is part of the AP-2 transcription factor family. Heterozygous missense mutations of TFP2A in humans result in branchio-oculo-facial syndrome (BOFS), which is associated with renal anomalies in about 35 % of patients. Recent studies demonstrated that mice with a collecting duct-specific knockout of AP-2 $\alpha$  display a progressive tubular dilation of medullary collecting ducts. Molecular mechanisms resulting in these renal anomalies are still unknown.

**Methods:** Mice carrying a collecting duct-specific knockout of AP-2 $\alpha$  (Hoxb7:Tfp2a<sup>fl/fl</sup>) were generated. In addition, inner medullary collecting duct (IMCD3) cells were engineered to harbour a CRISPR/Cas9-induced knock out of AP-2 $\alpha$ . Deregulated genes were identified by bulk and single-nucleus mRNA-sequencing and validated by in situ hybridization.

**Results:** Histomorphological analyses of our mouse model confirmed a progressive tubular dilation of outer medullary collecting ducts in adult mice over a period of six months. Integrative analysis of single-nucleus and bulk RNA-sequencing for kidneys

of 3-months-old Hoxb7:Tfp2a<sup>fl/fl</sup> mice and littermate controls indicated deregulated expression of genes associated with cell adhesion and WNT signaling pathways. Identical pathways were deregulated in AP-2 $\alpha$ -deficient IMCD3 cells when compared to controls. Genes deregulated in AP-2 $\alpha$ -deficient collecting ducts included the tight junction component Cldn8 and the Wnt signaling factor Wnt9b. Their decreased mRNA expression was confirmed by in-situ hybridization. Both genes have previously been implicated in the development of renal anomalies and defects in tubulogenesis.

**Conclusions:** Taken together our study indicates that AP-2 $\alpha$  is essential for the maintenance of tubular diameter and epithelial differentiation in collecting ducts of adult mice, providing insights into potential molecular mechanisms causing renal defects observed in BOFS.

## FR-PO271

### CDK7-CDK6-FIP5 Phosphorylation Cascade Controls Axoneme Polyglutamylation and Polycystin Signaling in Primary Cilia

Kai He, Xiaobo Sun, Jinghua Hu. *Mayo Clinic Minnesota, Rochester, MN.*

**Background:** ADPKD is mainly caused by mutations in *PKD1* or *PKD2*, which encodes Polycystin 1 (PC1) and Polycystin 2 (PC2) respectively. PC1 and PC2 co-localize to **primary cilia** of kidney epithelial cells and have been proposed to form a receptor/channel complex to sense environmental cues. Recently studies suggested that many PKD mutations, especially the non-truncation mutations, cause defects in ciliary localization but not the channel activity of polycystins complex. Therefore, understanding how polycystins are targeted to and maintained in primary cilia would shed light on the etiology of ADPKD. **Tubulin polyglutamylation** is a spatiotemporal post-translational modification which predominantly occurs on cilia axoneme. We recently unveiled that axoneme polyglutamylation is essential for controlling the ciliary localization and dosage of PC2. Thus, axoneme polyglutamylation could be a novel target for enhancing the ciliary function of polycystins and treatment for ADPKD. However, the regulatory mechanism underlying proper axoneme polyglutamylation remains poorly understood.

**Methods:** Kinases library screen. Biochemistry and Molecular biology approaches. Cell biology approaches. *in vitro* and *ex vivo* models of renal cystogenesis

**Results:** Here, we report that a ciliary CDK7-CDK6-FIP5 phosphorylation cascade specifically suppresses axoneme polyglutamylation by blocking the cilia impact of glutamylases TTL5 and TTL6. Excitingly, pharmacologic inhibition of CDK6 by Abemaciclib effectively restores axoneme polyglutamylation and ciliary levels of PC2 in *Cep41* and *Armc9*-deficient cells, the Joubert syndrome genes whose mutations cause axoneme hypoglutamylation. Interestingly, CDK6 is abnormally upregulated in human ADPKD cells, renal tubules of ADPKD mouse model (*Pkd1<sup>RC/RC</sup>* mice), and ADPKD patients. Remarkably, pharmacologic inhibition of CDK6 significantly suppressed the cyst growth in *in vitro* and *ex vivo* models of renal cystogenesis.

**Conclusions:** Our study reveals the regulatory mechanism of axoneme polyglutamylation and ciliary polycystin signaling, and suggests CDK6 as a potential therapeutic target for ADPKD.

**Funding:** NIDDK Support, Private Foundation Support

## FR-PO272

### Role of CFTR in Autosomal Dominant Polycystic Kidney Disease

Liudmila Cebotaru, Murali K. Yanda. *Johns Hopkins University, Baltimore, MD.*

**Background:** Autosomal dominant kidney disease is the most common dominant genetic renal disorder in humans leading to significant health care costs. It is associated with the slow but relentless formation of multiple renal cysts driven by cAMP-dependent fluid secretion leading to considerable patient morbidity. CFTR is known to be involved in secreting fluid in ADPKD through its localization in the apical membrane. We showed that the CFTR corrector, VX-809 relocates CFTR to the basolateral membrane creating an absorptive phenotype. Thus, the plasma membrane is the expected site where CFTR functions. Here, we show that CFTR unexpectedly is located in primary cilia and plays a role in cilia length.

**Methods:** We used a combination of mouse models employing a conditional knockout of *pkd1* and a mouse model bearing the R3277C mutation in PC1. We labelled kidneys with anti-CFTR, PC2 and anti-acetylated  $\alpha$ -tubulin antibodies, the latter a common marker of the primary cilium. We also conducted immunoprecipitation studies.

**Results:** We showed using confocal microscopy that CFTR can be found in the cilium of normal mice and is reduced in both *pkd1* and RC/RC mice. We found the same pattern for PC2. Interestingly colocalization of CFTR, PC2 and acetylated  $\alpha$ -tubulin is restored by VX-809. We triple-labeled kidney sections to determine if CFTR and PC2 colocalize within the cilium. Surprisingly, CFTR and PC2 were co-localized to the cilia in normal and cystic kidneys treated with VX-809, but there was much less co-localization in the cystic kidneys. We asked whether CFTR and PC2 can move together within the cell via a close association. Our results showed that the two proteins are able to bind to one another. We next asked whether the absence of CFTR in a null mouse had any impact on cilia. To our surprise, the cilia length was about twice as long in the CFTR null mice compared to wt-CFTR containing controls. Finally, we determined, if PC2's location in the primary cilium is altered in CFTR-null mice and found that the colocalization is decreased in CFTR-null mice.

**Conclusions:** These data suggest that CFTR does play a role in cilia both in impacting its length and the location of PC2.

**Funding:** NIDDK Support

## FR-PO273

**A Quantitative Proteomic Study of Tolvaptan Treatment in an Orthologous Mouse Model of Autosomal Dominant Polycystic Kidney Disease: What Remains Altered?**

Laura Nuñez-Gonzalez,<sup>6</sup> Adrian Cordido,<sup>1,6</sup> Marta Vizoso,<sup>1</sup> Fernando Gómez García,<sup>1</sup> Susana Bravo,<sup>3</sup> Cándido D. Rodríguez,<sup>1,5</sup> Alberto Ortiz,<sup>2</sup> Miguel A. García-Gonzalez,<sup>1,4</sup> <sup>1</sup>*Genetics and Developmental Biology of Kidney Diseases. Health Research Institute of Santiago de Compostela (IDIS), Santiago de Compostela Clinical Hospital Complex (CHUS), Santiago de Compostela, Spain;* <sup>2</sup>*Jimenez Diaz foundation. School of Medicine, Autonomous University of Madrid (UAM), Madrid, Spain;* <sup>3</sup>*Proteomic Platform. Health Research Institute of Santiago de Compostela (IDIS), Santiago de Compostela Clinical Hospital Complex (CHUS), Santiago de Compostela, Spain;* <sup>4</sup>*Galician Public Foundation of Genomic Medicine, Santiago de Compostela Clinical Hospital Complex (CHUS), Santiago de Compostela, Spain;* <sup>5</sup>*Nephrology Service, Santiago de Compostela Clinical Hospital Complex, Santiago de Compostela, Spain;* <sup>6</sup>*Department of Internal Medicine, Yale School of Medicine, New Haven, CT.*

**Background:** Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a monogenic inherited disorder caused by mutations in *PKD1* and *PKD2* genes, with a prevalence of 1:800 live births. It is characterized by the presence and progressive development of fluid-filled cysts leading to end-stage renal disease. A specific antagonist of vasopressin receptor type 2 in the distal tubules of the nephron (Tolvaptan) has been approved for ADPKD treatment. Although Tolvaptan mechanism of action has been described, its underlying molecular mechanisms are not well characterized. Our study is mainly focused on the understanding of those Tolvaptan hidden molecular mechanisms, in order to also understand, the remain altered pathways.

**Methods:** Quantitative proteomics based on SWATH-MS technology were performed comparing proteomes of kidneys from polycystic kidney disease (PKD) murine model: Pkd1<sup>cond/cond</sup>;Tam-Cre<sup>-/-</sup>. Mice were subdivided in three groups: Wild Type, Mutant and Tolvaptan-treated mutant animals.

**Results:** In this study, tolvaptan showed an amelioration of renal function measured by BUN, as well as diminution in cystic index and number of cysts. Through quantitative proteomics, we identified a list of 327 proteins with an adjusted p-value below 0.05 and two-fold cut-off which were found to be modified after tolvaptan treatment in comparison to mutant animals and 433 proteins in tolvaptan-treated group in comparison with wild type animals. In both differential proteomes tolvaptan treatment has shown a differential expression in the cluster of respiratory electron transport and ATP synthesis by proteins of the inner membrane of mitochondria, which could indicate a reduction in the oxygen necessities after the treatment. This effect can reduce hypoxia in cystic environment, which in turn can be responsible for some of the beneficial effects of the drug.

**Conclusions:** This work identified novel molecular pathways modified after tolvaptan treatment such as diminution in oxygen necessities and downregulation of proteins responsible for ATP synthesis. These modifications elucidate crucial aspects of tolvaptan treatment, unmasking novel alternative or complementary treatment strategies for ADPKD.

## FR-PO274

**Protein 4.1O Binds to Polycystin-1, Activates Ubiquitination, and Inhibits Polycystin-1 Signaling**

Theresia Vienen, Eva Koenigshausen, Lars C. Rump, Lorenz Sellin. *Heinrich-Heine-Universität Dusseldorf, Dusseldorf, Germany.*

**Background:** The majority of ADPKD patients have a PKD1 gene mutation. PKD1 codes for Polycystin-1 (PC-1). Cyst formation is caused by altered renal tubular cell proliferation and migration. Protein 4.1 family members are actin adaptors, which link plasma membrane receptors to the actin cytoskeleton. Protein 4.1O (FRMD3) is a candidate gene for diabetic nephropathy. Furthermore, protein 4.1O has properties of a tumor suppressor. This study investigates the molecular and cellular properties of protein 4.1O as a potential ADPKD modifier and therapeutic target.

**Methods:** PC-1 full-length and truncation mutants were transiently expressed. PC-1 interaction with protein 4.1O and its truncation mutants were investigated. Truncation mutants cover the N- and C-terminal domains of protein 4.1O (Band 4.1, FERM, actin-binding domain and coiled coil domain). The modulation of the PC-1 signaling properties by protein 4.1O were investigated in luciferase assays for c-myc and TEAD. FRMD3 core promoter regions were cloned into luciferase reporter and its activation by PC-1 was investigated. Ubiquitination assays investigated the influence of protein 4.1O on ubiquitination of itself and other proteins.

**Results:** Coimmunoprecipitations show an interaction of protein 4.1O to PC-1. The C-terminus of PC-1 interacts with isoforms of protein 4.1O (201, 204, 207). The truncation mapping and isoform alignment identifies a potential leucine zipper domain in protein 4.1O as the C-terminal binding domain to PC-1. The N-terminal FERM domain and the C-terminal domain of protein 4.1O are each by themselves sufficient to mediate PC-1 interaction. Protein 4.1O silences the PC-1 mediated transactivation of c-myc and hippo signaling (TEAD). PC-1 activates the protein 4.1O promoter. Furthermore, protein 4.1O enhances ubiquitination and is polyubiquitinated.

**Conclusions:** Both, the FERM domain and C-terminal domain, containing the coiled coil domain, of protein 4.1O interact with the PC-1 C-terminus. The protein 4.1O interaction inhibits the PC-1 mediated activation of c-myc and hippo signaling.

PC-1 activates the promoter of protein 4.1O and mediates silencing of PC-1 signaling. Furthermore, protein 4.1O enhances ubiquitination and its own polyubiquitination. In summary, protein 4.1O shows features of an anti-cystogenic protein and might be an ADPKD modifier.

## FR-PO275

**Effect of Enalapril in a Novel Human Orthologous Rat Model of Autosomal Recessive Polycystic Kidney Disease With Salt-Sensitive Hypertension**

Aya Yoshimura,<sup>1</sup> Eriko Matsuyama,<sup>1</sup> Takashi Watanabe,<sup>1</sup> Miwa Sakata,<sup>1</sup> Takahiro Shirozu,<sup>1</sup> Masanori Kugita,<sup>1</sup> Kanako Kumamoto,<sup>1</sup> Akiko Takizawa,<sup>2</sup> Melinda R. Dwinell,<sup>2</sup> Masumi Hirabayashi,<sup>3</sup> Tamio Yamaguchi,<sup>4</sup> Kazuo Takahashi,<sup>1</sup> Shizuko Nagao.<sup>1</sup> <sup>1</sup>*Fujita Health University, Toyoake, Japan;* <sup>2</sup>*Medical College of Wisconsin, Milwaukee, WI;* <sup>3</sup>*National Institute for Physiological Sciences, Okazaki, Japan;* <sup>4</sup>*Suzuka University of Medical Science, Suzuka, Japan.*

**Background:** One of the causes of hypertension in autosomal recessive polycystic kidney disease (ARPKD) is enhanced salt reabsorption in the collecting duct with increased expression of ENaC (Kaimori et al. 2017), which is targeted by the renin receptor in angiotensin II-induced hypertension (Peng et al. 2017). Recently, the SS-PCK novel rat model of ARPKD with salt-sensitive hypertension was established by introducing the *pkhd1* gene from the PCK rat onto the Dahl salt-sensitive (SS) background. In the current study, we investigated pathophysiological characteristics of SS-PCK rats, and the effect of ACEI treatment on hypertension and renal disease progression.

**Methods:** PCK and Sprague Dawley (SD) rats were obtained from Charles River, and SS and SS-PCK rats were from Medical College of Wisconsin. Males were given standard chow with normal salt level. Furthermore, Enalapril was administered in SS-PCK rats from 5 to 16 weeks of age. Blood pressure, serum urea nitrogen (SUN) and creatinine (Cre) were measured and kidneys were provided for histology (H&E, PAS and sirius red stains), immunohistochemistry (Ki67 and TGF-β) and immunoblotting (α-, β-, γ-ENaC subunits) analyses.

**Results:** At 18 weeks of age, blood pressure level was higher in SS-PCK rats compared to either PCK, SS or SD rats. Renal expression of ENaC subunits in SS-PCK was higher than in PCK, SS or SD rats. In SS-PCK compared with PCK, Ki67 expression, kidney weight/body weight and cyst area/section were lower, whereas severe glomerular sclerotic area was higher. Enalapril treatment in SS-PCK ameliorated hypertension, renal cyst formation and glomerulosclerosis, with reduction of Cre, SUN, fibrotic area, and expression level of renal ENaC subunits, Ki67 and TGF-β.

**Conclusions:** Current findings suggest that the novel rat model of ARPKD with salt-sensitive hypertension could be useful to determine the mechanism of disease progression. By using this strain, it is speculated that ACEI may have a therapeutic potential in ARPKD with salt-sensitive hypertension by reducing ENaC expression.

**Cilk1 Deficiency Induces Cyst Formation and Abnormal Ciliary Trafficking via Klc3**

Je Yeong Ko, Gyueong Rah, Jong Hoon Park. *Sookmyung Women's University, Yongsan-gu, Seoul, Republic of Korea.*

**Background:** Ciliogenesis-associated kinase 1 (CILK1), also known as intestinal cell kinase (ICK), is localized in the basal bodies of cilia and regulates ciliary transport. Mutations in the CILK1 gene induces various ciliopathies, including endocrine-cerebro-osteodysplasia syndrome and juvenile myoclonic epilepsy; however, the mechanism underlying the ciliary defect in the CILK1-deficient kidney has not been elucidated.

**Methods:** We generated mice with specific deletion of Cilk1 in renal collecting duct and performed yeast-two-hybrid assay to identify a novel ciliary regulator in Cilk1-deficient model.

**Results:** CILK1 deficiency results in polycystic kidney disease (PKD) and abnormal ciliary trafficking in cyst lining cells. We identified a novel ciliary regulator, kinesin light chain 3 (KLC3), which promotes ciliary trafficking and cyst progression in CILK1 deficient PKD. KLC3 overexpression induced ciliary recruitment of IFT-B and EGFR, which contributed to the ciliary defect involved in cyst progression. Reduction in KLC3 restored abnormal ciliary trafficking and inhibited cyst progression caused by CILK1 deficiency, indicating that KLC3 is a ciliary regulator related to cyst progression in CILK1 deficient PKD.

**Conclusions:** We found that CILK1 deficiency leads to PKD accompanied by abnormal ciliary trafficking via KLC3 overexpression. These results provide new insight into the pathogenesis of CILK1 deficient PKD model.

FR-PO277

**Ion and Metabolite Composition of Cystic Fluid From a Rat Model of Autosomal Recessive Polycystic Kidney Disease (ARPKD)**  
Christine A. Klemens,<sup>1</sup> Marharyta Semenikhina,<sup>2</sup> Lashodya V. Dissanayake,<sup>1</sup> Oleg Palygin,<sup>2</sup> Alexander Staruschenko.<sup>1</sup> <sup>1</sup>*USF Health Morsani College of Medicine, Tampa, FL;* <sup>2</sup>*Medical University of South Carolina, Charleston, SC.*

**Background:** Polycystic kidney disease results in fluid-filled cysts in the kidney and is responsible for ~10% of all end-stage renal disease cases. Implementation of ‘omics’ techniques leads to increased understanding of pathogenic changes in many diseases. While several studies have assessed kidney, plasma, and urine metabolites from both human and rodent kidneys, none have explicitly looked at the composition of cyst fluid. This study aimed to reveal ARPKD renal fluid components, which might be critical for understanding cyst formation.

**Methods:** We used the PCK rat model of ARPKD to simultaneously collect blood from the aorta, urine from the bladder, and cystic fluid directly from renal cysts of male and female rats (12-14 wks). Solute osmolality and electrolyte concentrations were measured. Cyst fluid untargeted metabolomic profiling was performed using LC/MS and analyzed using Metaboanalyst and Ingenuity Pathway Analysis.

**Results:** The cyst fluid osmolality was significantly lower than urine (430.8 ± 12.0 vs 1215 ± 99 mOsm) but above the typical plasma range (275-290 mOsm). The cyst fluid also had a distinct electrolyte composition relative to plasma and urinary values. The concentrations of Na<sup>+</sup> (23.7 ± 1.2 mM) and Cl<sup>-</sup> (65.5 ± 2.1 mM) in the cystic fluid were significantly lower than plasma or urinary levels. However, K<sup>+</sup> (95.2 ± 3.1 mM) was significantly increased compared to blood but not distinct from urinary concentrations. There were no differences observed between male and female cyst electrolytes. Omics analyses indicate that the predominant non-lipid molecule in the cyst fluid were amino acids, while fatty acids and isoprenoids were the most represented lipid chemical classes. KEGG Pathway Analysis determined the top metabolic pathways associated with cyst fluid composition included: Tryptophan, Tyrosine, and Alanine/Aspartate/Glutamate. Significant differences between male and female cyst fluid composition were observed (1,304 compounds upregulated and 1,214 compounds downregulated in males vs females).

**Conclusions:** Kidney cyst fluid has a distinct electrolyte composition. Additionally, amino acids are the most represented chemical class, and a better understanding of how their presence in cyst fluid influences cyst development may lead to potential intervention strategies.

FR-PO278

**Disruption of Cystin Myristoylation Causes Autosomal Recessive Polycystic Kidney Disease (ARPKD)**  
Chaozhe Yang,<sup>1</sup> Naoe Harafuji,<sup>1</sup> Ljubica Caldovic,<sup>2,3</sup> Zsuzsanna M. Bebek,<sup>4</sup> Natalie Burrill,<sup>5</sup> Erum A. Hartung,<sup>5</sup> Julie Moldenhauer,<sup>5</sup> Lisa M. Guay-Woodford.<sup>1,2</sup> <sup>1</sup>*Children’s National Hospital Center for Translational Research, Washington, DC;* <sup>2</sup>*Children’s National Hospital Center for Genetic Medicine Research, Washington, DC;* <sup>3</sup>*The George Washington University School of Medicine and Health Sciences, Washington, DC;* <sup>4</sup>*The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL;* <sup>5</sup>*The Children’s Hospital of Philadelphia, Philadelphia, PA.*

**Background:** Approximately 80% of patients with typical autosomal recessive polycystic kidney disease (ARPKD; MIM 263200) have pathogenic variants in *PKHD1*, and *DZIP1L* variants account for less than 1% of the remainder. In mice, renal disease resulting from mutations in *Cys1* (encoding cystin), but not in either *Pkhd1* or *Dzip1l*, closely phenocopies human ARPKD.

**Methods:** Identification and clinical characterization of successive fetuses from a consanguineous union with *CYS1* mutations and ARPKD phenotype. *In silico* analysis of mammalian cystin genes to identify putative functional domains. Analysis of mouse *Cys1* by mutagenesis, fluorescence staining, affinity purification/mass spectrometry, and phosphorylation/dephosphorylation assays.

**Results:** Exome sequencing of the affected siblings and parents revealed *CYS1* c.4G>A as a homozygous variant in both fetuses, which is predicted to disrupt the G2 myristoylation site within the cystin MGxxxSx N-terminal myristoylation motif. In mouse cell lines, we have confirmed that the G2 site is myristoylated and glycine-to-alanine substitution at G2 disrupts cystin ciliary localization (Tao 2009). Sequence alignment of 97 mammalian cystin protein sequences identified a conserved arginine-rich stretch of amino acids flanked by serine-8 and -17 residues. Serine-17 (S17) is a predicted phosphorylation target, suggesting that cystin membrane association is regulated by a myristoyl-electrostatic switch mechanism. Treatment with 8-bromo-cAMP attenuated the ciliary localization of endogenous cystin, but did not directly alter S17 phosphorylation, indicating a role for other cAMP-dependent kinase pathways, e.g. EPAC. In addition, we identified protein phosphatase PPM1A as a cystin-interacting protein and demonstrated that sanguinarine (a PPM1A inhibitor) regulates the phosphorylation status of cystin S17. Finally, we demonstrated that cystin interacts with  $\alpha 1$ ,  $\alpha 2$ , and  $\beta 2$  importin subunits, suggesting that the importin complex mediates cystin trafficking between the cilium and nucleus.

**Conclusions:** Our data provide further evidence that *CYS1* mutations cause ARPKD and provide new insights about the role of regulated ciliary trafficking in ARPKD pathogenesis.

FR-PO279

**Cardiac Hypertrophy in Rodents With Polycystic Kidney Disease (PKD) Before the Onset of Hypertension**  
Ozgur A. Oto,<sup>1,2</sup> Daniel Atwood,<sup>2</sup> Anjana Chaudhary,<sup>2</sup> Charles L. Edelstein.<sup>2</sup> <sup>1</sup>*Istanbul Universitesi Istanbul Tip Fakultesi, Istanbul, Turkey;* <sup>2</sup>*University of Colorado Health, Aurora, CO.*

**Background:** The aim of the study was to determine whether there is cardiac hypertrophy (CH) before hypertension (HTN) in rodents and to further detail cardiac structure/function in the heart in Pkd1<sup>RC/RC</sup> (RC) mice.

**Methods:** 12wk old PCK rats, a Pkhd1 gene model, and 120d RC mice, a hypomorphic Pkd1 gene model, were studied. A noninvasive tail-cuff system was used to measure BP. A Vevo 2100 was used for Echocardiography/ mitral Doppler measurements

**Results:** Heart weight/body weight (HW/BW) was increased in PCK rats at 12wks. HTN develops at 16wks in PCK rats. HW/BW was increased in RC mice before the onset of HTN (table). We previously described increased mTORC1/2/suppressed autophagy in the heart in 70d RC mice. mTORC1/ autophagy play a role in the CH, so we detailed cardiac structure/ function in RC mice. There was cardiac hypertrophy: increased intra-ventricular septum (IVS) and left ventricular wall (LVW) thickness. On echo there was increased LV mass, decreased ratio of peak velocity of early/ late filling of mitral inflow (grade 1 diastolic dysfunction) and decreased LV diastolic volume. Interestingly in 270dRC mice the cardiac dysfunction was different. There was severe Grade 4 diastolic dysfunction (increased E/A ratio) indicating restrictive filling of the LV. Normal ejection fraction fractional shortening indicated heart failure with preserved EF.

**Conclusions:** There was increased heart weight, CH, increased LV mass, grade 1 diastolic dysfunction, in RC mice before the onset of HTN. Factors other than HTN like increased mTORC1/2/ suppressed autophagy may contribute to causing CH in PKD mice.

FR-PO280

**Metformin Worsens Kidney Function and Has No Effect on Cyst Growth in the PCK Rat Model of Autosomal Recessive Polycystic Kidney Disease (ARPKD)**  
Ozgur A. Oto,<sup>1,2</sup> Daniel Atwood,<sup>2</sup> Anjana Chaudhary,<sup>2</sup> Charles L. Edelstein.<sup>2</sup> <sup>1</sup>*Istanbul Universitesi Istanbul Tip Fakultesi, Istanbul, Turkey;* <sup>2</sup>*University of Colorado Health, Aurora, CO.*

**Background:** Metformin (MET) has shown mixed results in reducing cyst growth in mouse models of PKD and in humans. Lactic acidosis has been suggested as a cause of the lack of efficacy of MET on cyst growth. The effect of MET on cyst growth in rat models of PKD is not known. The aim of this study was to determine the effects of MET on cyst growth, kidney function, mTOR signaling and lactate levels in a rat model of ARPKD

**Methods:** Male PCK rats, a Pkhd1 gene mutation model of human ARPKD were studied. PCK rats were treated with either vehicle (VEH) or metformin (300 mg/kg, IP) from 28-84 d of age. Autophagy and mTOR proteins were analyzed by quantitative immunoblot analysis (Relative densitometry units-RDU). BUN was measured with a urea assay kit (BioAssay Systems). Serum creatinine was measured by HPLC. Lactate levels were measured by an L-Lactate assay Kit (EnzymFluo). Cyst index was analyzed by a NIS Elements macro

**Results:** During the study 2 MET-treated rats died. Two kidney weight was not affected by MET (3.0 vs 3.1±0.4, p=0.6). Two kidney/body weight ratio (2K/BW) was high in MET group but there was significant weight loss. Cystic indexes were similar in both groups (3.7±1.9, 3.7±2.08, p=0.9). There was a significant increase in BUN and creatinine levels in MET group. MET is known to activate AMPK, suppress mTORC1 and induce autophagy. AMPK (pAMPK; 0.7 vs 1.3, ns), mTORC1 (pS6; 0.4 vs 0.8, ns) and mTORC2 (pAktS473) was not suppressed by MET (0.8 vs 0.5; ns) and conversion of LC3-I to LC3-II (a marker of autophagy) was not affected by MET (0.9 vs 1.6; ns). Lactate levels were significantly higher in MET group

**Conclusions:** A standard dose of MET did not slow cyst growth. MET increased lactate levels and was nephrotoxic (increased BUN and Creatinine). In conclusion, the study suggests that human studies of MET in PKD may be complicated by nephrotoxicity and that MET dosing should be carefully chosen in human PKD studies. Studies of a dose-response of MET on cyst growth, kidney function, lactate levels and mTOR/autophagy are underway in PCK rats

**Cleavage of Pkhd1 Results in a Small Fragment That Localizes and Functions Within Mitochondria**

Rebecca V. Walker, Anthony R. Maranto, Patricia Outeda, Hangxue Xu, Terry J. Watnick, Feng Qian. Qian lab University of Maryland Baltimore, Baltimore, MD.

**Background:** Autosomal recessive polycystic kidney disease (ARPKD) is caused by mutations in *PKHD1* encoding FPC, and is characterized by severe renal cystogenesis in neonates, yet mouse models do not fully recapitulate the human phenotype.

**Methods:** We use mouse models, biochemistry, cell models, and proteomics to reveal novel cleavage fragments of FPC and their effect on enhancing cystogenesis in *Pkhd1* mutant cyst-sensitized mice.

**Results:** We describe how *Pkhd1* mutation modifies a *Pkhd1* uncleavable mutant (*Pkhd1<sup>V</sup>*), enhancing the cystic phenotype in kidney and pancreas, and revealing some elusive functions of FPC. FPC displays differential cleavage to produce fragments of unknown function. We identify several of these cleavage fragments and describe the mitochondrial localization of one small C-terminal fragment, induced by a newly identified mitochondria localizing signal presented in the fragments. Mitochondrial proteomics revealed that mice lacking FPC have significant changes compared to Wt. Finally, we show that deletion of just the C-terminal fragment of FPC ( $\Delta$ CT) is sufficient to enhance the renal cystic phenotype of the PC1 cleavage mutant but does not result in the pancreatic cystogenesis seen in other *Pkhd1* mutants on this background.

**Conclusions:** Our results suggest that the C-terminus of FPC plays an important role in preventing cystogenesis via a novel mitochondria specific function.

**Funding:** NIDDK Support, Private Foundation Support

**Mice With a Genomic Deletion of Pkhd1 Exons 3-67 Have Minimal Renal Manifestations but Evidence of Transcriptional Network Changes by snRNA Sequencing**

Yu Ishimoto,<sup>1</sup> Luis F. Menezes,<sup>1</sup> Fang Zhou,<sup>1</sup> Teruhiko Yoshida,<sup>1</sup> Patricia Outeda,<sup>2</sup> Terry J. Watnick,<sup>2</sup> Gregory G. Germino.<sup>1</sup> <sup>1</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>2</sup>University of Maryland School of Medicine, Baltimore, MD.

**Background:** Autosomal recessive polycystic kidney disease (ARPKD) is caused mostly by mutations in *PKHD1*. We previously generated a mouse with a genomic deletion of exons 3-67 of murine *Pkhd1*. While *Pkhd1<sup>del3-67/del3-67</sup>* kidneys are somewhat enlarged and show no obvious morphological or histological changes. We and others have previously reported kidney cysts in ARPKD models, suggesting that compensatory pathways might prevent cystogenesis. We therefore investigated transcriptomic changes in *Pkhd1<sup>del3-67/del3-67</sup>* kidneys and controls, using single-nuclei RNA-sequencing (snRNAseq).

**Methods:** We sampled kidneys from three male 4-weeks old *Pkhd1<sup>del3-67/del3-67</sup>* and three littermate controls. After quality control filtering, we analyzed a total of 83,322 cells, with a median number of ~4000 transcripts/cell.

**Results:** Clusters of cells representing most nephron epithelial cell types had *Pkhd1* expression. Grouping similar cell types and re-clustering, we observed no differences between mutant and control samples. Within each cell type, multiple genes distributed across the genome had significant p-value changes but most had minimal fold-change differences, and we found no evidence of significantly dysregulated pathways by gene-set enrichment analysis. Using network analysis, we inferred transcriptional networks and scored genes based on their connectivity. We found evidence that a few pathways were significantly changed in different nephron segments, including some with transcriptional regulator activity. To investigate consistent changes in all nephron segments, we derived a consensus network including only gene-gene interactions present in all segments. Within this network, we identified genes with multiple connections (hubs) that were differentially expressed and showed changed in connectivity between mutants and controls, suggestive of re-wiring. Pathway enrichment analysis of likely re-wired differentially expressed hubs identified ubiquitin-conjugation as a major change in *Pkhd1* mutants, consistent with previous results.

**Conclusions:** *Pkhd1<sup>del3-67/del3-67</sup>* kidneys showed no obvious morphological changes or compensatory transcriptional profiles. Network analyses, however, identified possible re-wiring of ubiquitin-conjugation pathway.

**Funding:** NIDDK Support

## FR-PO283

**Conserved Glycine Rich (G8) Domains in Zebrafish Fibrocystin-L (FPC-L) Paralogs Identify a Tractable Experimental System for Functional Studies of PKHD1-Encoded FPC**

Ashima Gulati,<sup>1</sup> Matthew R. Swift,<sup>2</sup> Eric Glasgow,<sup>2</sup> Lisa M. Guay-Woodford.<sup>1</sup> <sup>1</sup>Children's National Research Institute, Washington, DC; <sup>2</sup>Georgetown University, Washington, DC.

**Background:** Functional evaluation of FPC, the major protein underlying ARPKD is limited because rodent models do not recapitulate the human renal phenotype. Homology analyses and phylogenetic expression identify FPC-L encoded by *PKHD1L1* as the likely ancestral protein to *PKHD1*-encoded FPC. We compared the homology of FPC predicted domains with its ancestral protein, FPC-L. While zebrafish lack FPC, the phylogenetic conservation of specific N-terminal domains in FPC-L, suggests that zebrafish could serve as a tractable system to investigate domain-specific motifs relevant to FPC function.

**Methods:** Informatics analysis: FPC-L, FPC identity/similarity scores across evolutionary timescale. Zebrafish embryo FPC-L expression: whole mount *in situ* hybridization for *pkhd1l1.1* and *pkhd1l1.2*.

**Results:** FPC-L and FPC share two conserved glycine-rich G8 domains that are relatively unique to these protein families. The first G8 domain spanning 122 amino acids exhibits two times the identity (50% identical, 63% similar) when compared to overall human FPC-L and FPC homology (25% identity, 44% similarity). FPC-L zebrafish paralogs are widely expressed at various stages during embryonic development in a reproducible pattern (Figure). FPC-L expression mirrors that of *pkd2* and other ciliary proteins that are widely expressed at a low level in most zebrafish tissues.

**Conclusions:** The conservation of two unique G8 domains in FPC and its ancestral protein, FPC-L, over the evolutionary span of vertebrate aquatic to terrestrial transition supports the biologic relevance of these domains. Zebrafish present a tractable experimental model to interrogate the function of these highly conserved domains, and provide new insights into the functional biology of FPC-L and FPC N-termini.

#### Pathogenic STAT3 Activation in Cystic Kidney and Bile Duct Epithelia of Murine *Pkhd1*-Knockout

Wolfgang H. Ziegler, Julia Fox, Hanna Burmester, Susanne Hahnenstein, Dieter Haffner. *Medizinische Hochschule Hannover, Hannover, Germany.*

**Background:** Loss of fibrocystin function causes autosomal recessive polycystic kidney disease (ARPKD) associated with epithelial defects, cyst formation and fibrosis of kidney and liver. In the mouse model, liver defects are developing independent of gender, while kidney defects are restricted to female mice. Study of fibrocystin function in mouse kidney is hampered by mild cyst development and late onset. Here, we re-analyze the kidney and liver phenotype in *Pkhd1*-knockout mice of different age in a defined background strain and observe distinct hallmarks of disease development and fibrocystin related signaling.

**Methods:** Targeted mutation *Pkhd1*-knockout mice in BALB background were maintained within the line. Kidneys and livers of male and female animals, homozygous and heterozygous for the *Pkhd1*-knockout allele as well as wildtype, were analyzed histologically at 8 weeks and 3 to 9 months of age, with serum and urine samples taken before preparation. We compare signaling in cystic epithelia of both organs to behavior of epithelial cell lines with and without fibrocystin expression.

**Results:** At 6 and 9 months of age, relative kidney and liver weights were massively increased in homozygous female *Pkhd1*-knockout mice as compared to heterozygous and wildtype controls. In kidneys, cyst formation at the corticomedullary border led to a significantly increased cystic index in knockout mice associated with pronounced macrophage recruitment and fibrosis peaking at 9 months. In addition, proliferation markers were significantly enhanced and pronounced nuclear localization of phosphorylated STAT3 observed in cyst lining epithelia. In liver, ductal plate malformation and fibrotic remodeling were present already at 3 month of age and independent of gender. Induction of STAT3-dependent signaling was addressed in cystic mouse tissue and in stimulated *Pkhd1*-knockout cell lines with respective controls.

**Conclusions:** Maintenance in defined BALB background leads to a murine *Pkhd1*-knockout model showing progressive cyst formation in liver and kidneys associated with fibrosis and inflammation. Highly activated STAT3 signaling was observed associated with epithelial defects. The *Pkhd1*-knockout mouse allows analysis of disease related mechanisms and appears suitable for testing of pharmacological interventions.

**Funding:** Government Support - Non-U.S.

### FR-PO285

#### Polycystins Are Required for Renal Tubulointerstitial Fibrosis

Yanzhe Wang, Ming Wu, Chaoyang Ye. *Shuguang Hospital, ShangHai, China.*

**Background:** Renal fibrosis is the common pathway of various chronic kidney diseases progressing to end stage renal failure. Polycystin-1 (encoded by PKD1 gene) and polycystin-2 (encoded by PKD2 gene) form a transmembrane complex and function as a stress sensor, which is located in the primary cilia. Polycystins are involved in the disease condition of different organs. Mutation of PKD genes causes autosomal dominant polycystic kidney disease and deletion of polycystin attenuates heart injury induced cardiac fibrosis. The role of polycystins in renal tubulointerstitial fibrosis is currently unclear.

**Methods:** Unilateral ureteral obstruction (UUO), unilateral ischemia-reperfusion injury (UIRI), aristolochic acid or folic acid induced mouse models of renal fibrosis were established for this study.

**Results:** Here we showed that polycystin-2 is up-regulated in these three mouse models of renal fibrosis and tightly correlated with the expression of collagen-I in a time dependent manner. Treatment with triptolide inhibited the expression of polycystin-2 and pro-fibrotic markers in UUO and UIRI models. Moreover, triptolide or PKD2

siRNA inhibited the expression of polycystin-2 and pro-fibrotic markers in vitro. Using Pkd2 conditional knockout mice, we showed that genetic deletion of Pkd2 reduced the expression of pro-fibrotic markers in UUO kidneys. Polycystin-1 was also up-regulated in renal fibrotic models and conditional deletion of Pkd1 reduced the expression of pro-fibrotic markers in UUO or folic acid induced fibrotic kidneys. Furthermore, the expression of the methyltransferase EZH2 is positively correlated with the expression of polycystins in fibrotic kidneys. Conditional knockout of EZH2 attenuated the anti-fibrotic responses induced by Pkd1 deletion in UUO kidneys.

**Conclusions:** In conclusion, polycystins are up-regulated in fibrotic kidneys and promote renal tubulointerstitial fibrosis through up-regulation of EZH2, suggesting that primary cilia are required for renal tubulointerstitial fibrosis.

### FR-PO286

#### Injury-Induced Renal Fibrosis Promotes Cystogenesis and Cyst Growth in Adult Mice With Autosomal Dominant Polycystic Kidney Disease

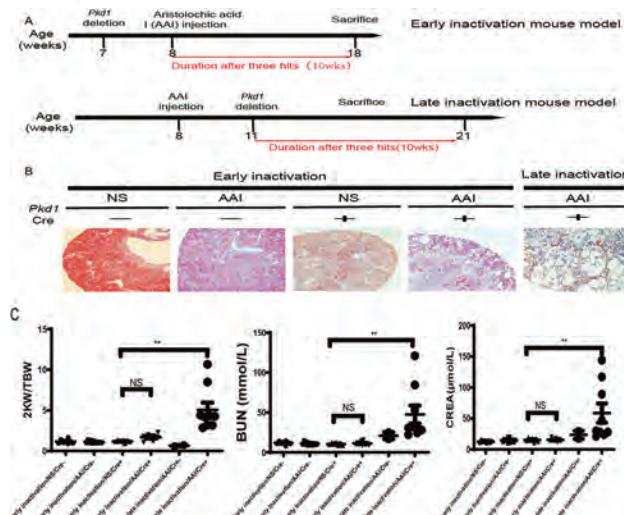

Yanzhe Wang, Ming Wu, Chaoyang Ye. *Shuguang Hospital, ShangHai, China.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most frequent inherited kidney disease caused by mutations in *PKD1* or *PKD2* gene. Enhanced fibrosis is correlated with the accelerated renal function decline and kidney growth in the late stage of ADPKD patients. However, the role of fibrosis in ADPKD remains unclear.

**Methods:** We established renal fibrosis by toxic (aristolochic acid I, AAI; 1,2-dichlorovinyl-cysteine, DCVC) or surgical (unilateral ischemia reperfusion injury, UIRI) injuries which was prior to *Pkd* gene inactivation in adult mice.

**Results:** Here we showed that renal cysts were induced in adult Pkd1 or Pkd2 mice with pre-established renal fibrosis. Recovery of renal fibrosis at three weeks after UIRI retarded cystogenesis in Pkd1 mice. Enhanced renal fibrosis by repeated toxic injuries accelerated renal cyst growth in Pkd1 mice. We further showed that the rate of cyst formation at the early stage of adult Pkd1 mice was decided by the baseline level of renal fibrosis. Finally, we showed that conditional knockout of EZH2 attenuated renal fibrosis and cyst growth in Pkd1 mice with established renal fibrosis.

**Conclusions:** We conclude that fibrosis is a driving force for renal cyst formation and growth in adult kidneys and inhibition of renal fibrosis through targeting EZH2 might be a new therapeutic strategy for ADPKD.

## FR-PO287

## Role of Glutamine Transporter Slat3 in Promoting Polycystic Kidney Disease

Shinobu Yamaguchi, Randee S. Sedaka, Sejal Sanjay Shinde, Jifeng Huang, Jung-Shan Hsu, Takamitsu Saigusa. *The University of Alabama at Birmingham School of Medicine, Birmingham, AL.*

**Background:** Disease severity of polycystic kidney disease (PKD) is influenced by diet. High protein (HP) diet is one of the most recognized PKD progression-accelerating factors. Dietary protein is catabolized into amino acids (AA) and delivered to the kidney, activating the mTOR pathway and renal hypertrophy. Renal hypertrophic signaling superimposed in PKD mice increases immune cell response, inflammation and accelerates cyst growth. We hypothesize that the cystogenesis-promoting effects of HP diet are caused by increased delivery of specific AA to the kidney, ultimately activating the immune cell response and accelerating cyst growth.

**Methods:** Adult tamoxifen-inducible *Pkd1*<sup>fllox/fllox</sup> mice with and without Cre (CAGG-ER2) were given tamoxifen to induce gene deletion. Two weeks later, mice were fed either a high (HP; 60%), normal (NP; 18%) or low (LP; 6%) protein diet (all isocaloric 3.7kcal/g, restricted to 2.8g/day) for 1 week. Mice were then euthanized and tissues were used for histology, immunofluorescence (IF), RT-PCR and Western blot. Kidney tissue was cell sorted to isolate tubular epithelial cells for RNA sequencing.

**Results:** *Pkd1* knockout (*Pkd1* KO) mice fed a HP diet for 1 week had increased kidney weight/body weight ratio and cystic area compared to NP or LP fed counterparts. However, there were no differences in the number of renal macrophages, pro-inflammatory cytokines, or markers of proximal tubular injury at this early stage. RNA sequencing of renal tubular epithelial cells from *Pkd1* KO mice fed a HP- compared to NP- or LP diet revealed increased gene expression of sodium-glutamine transporter *Slat3* and gluconeogenesis marker *Pepck1*, confirmed by RT-PCR. *Slat3* expression by IF along cyst-lining tubular epithelial cells, as well as pS6 protein abundance, increases in HP- compared to LP diet fed *Pkd1* KO mice. Urinary ammonia, a byproduct of glutamine, was elevated in *Pkd1* KO mice fed a HP- compared to NP- or LP diet.

**Conclusions:** One-week feeding with HP- compared to NP- or LP diet increased the expression of glutamine transporter *Slat3*, gluconeogenesis, mTOR and cyst growth prior to increases in macrophage number and cytokines in *Pkd1* KO mice. Glutamine in dietary protein may accelerate cyst growth through *Slat3* during early stages of PKD.

## The Renal Circadian Clock Is Disrupted in Autosomal Polycystic Kidney Disease

Abeda Jamadar,<sup>1</sup> Lauren G. Douma,<sup>2</sup> Michelle L. Gumz,<sup>2</sup> Reena Rao.<sup>1</sup> <sup>1</sup>University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS; <sup>2</sup>University of Florida, Gainesville, FL.

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease. Based on a never-before described observation of unusually high night-time activity in the *Pkd1*<sup>R277C</sup> (RC/RC) mouse model of ADPKD, we examined their circadian rhythms. Circadian rhythms are intrinsic cyclical ~24-hour oscillations in behavior and physiology, which at the molecular level are regulated by circadian clock proteins that regulate gene expression. The circadian clock regulates renal functions, which are disrupted in some kidney diseases. Here we examined the renal circadian rhythms in ADPKD.

**Methods:** Circadian oscillation of clock proteins was examined in RC/RC and wild type (WT) mouse kidneys; and in *Pkd1* gene knockout mouse renal proximal tubular cells (PT-*Pkd1*<sup>-/-</sup>) and inner medullary collecting duct cells (IMCD3-*Pkd1*<sup>-/-</sup>) and controls (PT-*Pkd1*<sup>+/+</sup> and IMCD3-*Pkd1*<sup>+/+</sup> cells). For real-time visualization of circadian dynamics in ADPKD kidneys, bioluminescence rhythms were measured in kidney tissue explants from RC/RC and WT mice expressing *Per2*<sup>Luciferase</sup> gene. Diurnal rhythms of urine output and water intake were also measured in RC/RC and WT mice.

**Results:** PT-*Pkd1*<sup>-/-</sup> and IMCD3-*Pkd1*<sup>-/-</sup> cells showed significantly disrupted oscillations of multiple clock genes, including *BMAL1*, *CLOCK*, *CRY1* and *Per2* when compared to control cells which displayed clock gene oscillations at 20-24h intervals. We found significant differences in mRNA levels of multiple clock genes in RC/RC mouse

kidneys, compared to WT controls. In particular, both mRNA and protein levels of *Per2* showed significant difference between WT and RC/RC kidneys. While the WT-*Per2*<sup>Luciferase</sup> kidney tissue explants showed persistent bioluminescence rhythms, lower-amplitude rhythms with shorter circadian periods were found in RC/RC-*Per2*<sup>Luciferase</sup> kidney explants. We also found significant differences in diurnal rhythms of urine output and water intake in RC/RC mice compared to WT mice.

**Conclusions:** This study shows for the first time that (A) cultured renal tubular epithelial cells are good oscillators, but *Pkd1* gene deletion disrupts the circadian clock gene rhythms of tubular epithelial cells, the very cells that form cysts, and (B) circadian rhythms of clock genes as well as renal functions are disrupted in RC/RC mouse kidneys. Renal circadian rhythms are thus disrupted in ADPKD.

## Mechanisms of Cystogenesis by Cd79a-Driven, Conditional mTOR Activation in Mouse Developing Nephron

Linh N. Tran,<sup>1</sup> Satoshi Matsuda,<sup>1</sup> Huong Quynh Tran Thuy,<sup>1</sup> Katsuhiko Yoshizawa,<sup>2</sup> Hiroyasu Tsukaguchi.<sup>1</sup> <sup>1</sup>Kansai Ika Daigaku Fuzoku Hirakata Byoin, Hirakata, Japan; <sup>2</sup>Mukogawa Joshi Daigaku, Nishinomiya, Japan.

**Background:** Polycystic kidney diseases (PKD) are a common genetic disorder arising from developmental and/or postnatal processes. Defects of primary cilia and/or their signaling pathways, e.g., mTOR pathways, underlie the pathogenesis. However, how mTOR regulates tubular integrity remains unclear. To define the role of mTOR pathway in cyst formation, we studied phenotypes of in-house PKD mouse model (*Cd79a-Cre;Tsc1*<sup>fl</sup>, thereafter *Cd79a-Tsc1* KO). The Cre mediated-*Tsc1* depletion driven by *Cd79a*, the known B cell receptors, allowed a unique conditional mTORC1 activation along the distal nephron after embryonic E16.

**Methods:** Paraffin kidney sections were stained with PCNA and TUNEL, a marker of proliferation and apoptosis, respectively. The activation of mTORC1 and mTORC2 was evaluated by the phosphorylation of ribosomal protein S6<sup>S240/244</sup> and Akt<sup>S473</sup>, respectively.

**Results:** *Cd79a-Tsc1* KO kidney recapitulated human ADPKD pathology. Cysts appeared initially from the distal nephron by postnatal 2 weeks and developed global PKD by 4 weeks. Early cysts were of several cell types, either lined by cuboidal, hypertrophic cells with karyocytomegaly, or flattened, dedifferentiated epithelium with luminal cell exfoliation. In *Cd79a-Tsc1* KO tubules, epithelial cells continued to proliferate even after physiological nephrogenesis of postnatal 2 weeks, while apoptosis was hardly seen until later tumorigenic stage after 9 weeks. Overactivation of mTORC1 was found in part but not all cyst-lining cells and occasionally regardless of *Tsc1* depletion, suggesting the non-autonomous mechanisms of the cystogenesis. Elongation of cilia and disorientation of cell intercalation as well as oriented cell division were seen in pre-cystic, developing tubules, indicating the defective cilia-related planar polarity.

**Conclusions:** Our results indicate that PKD phenotypes arising from overactivation of mTORC1 in early developing nephron closely resemble those of the primary cilia disorder ADPKD, suggesting two conditions share the common mechanisms. Cystogenesis are likely triggered at early developmental stage of tubulogenesis shaping the optimal tubule diameter through coordinated proliferation with polarity.

## FR-PO290

## Combined Transcriptome and Metabolome Profiling in a Mouse Model of Tuberous Sclerosis Complex Renal Cystic Disease

Kamyar A. Zahedi,<sup>1,2</sup> Sharon L. Barone,<sup>1,2</sup> Marybeth Brooks,<sup>1,2</sup> Manoocher Soleimani.<sup>1,2</sup> <sup>1</sup>University of New Mexico Health Sciences Center, Albuquerque, NM; <sup>2</sup>New Mexico VA Health Care System, Albuquerque, NM.

**Background:** Tuberous sclerosis complex (TSC) is an autosomal recessive disorder that is caused by mutations in hamartin (TSC1) or tuberin (TSC2) and affects over a million individuals worldwide. In the kidney, TSC is associated with the development of cysts and angiomyolipomata, which damage the renal parenchyma and lead to renal failure. The cyst development and expansion in principal cell specific *Tsc1* knockout mice (*Tsc1*-cKO/*Aqp2* Cre; *Tsc1*cKO) is dependent on the expansion of A-intercalated cells and diminution of principal cells. In order to identify the mRNA and metabolome changes associated with cystogenesis in TSC renal disease, we compared the transcriptome and metabolome of kidneys from 28 days old wildtype (Wt) and *Tsc1*cKO mice.

**Methods:** The transcriptome and metabolome of 28 days old Wt and *Tsc1*cKO were analyzed and compared.

**Results:** There were significant changes in the levels of 14 metabolites in the kidneys of *Tsc1*cKO mice compared to their Wt counterparts. These included reductions in the levels of a number of amino acids (e.g., Gly, Ile, Leu, Trp and valine). We also observed significant decreases in creatine, NADH, inosine, UDP-galactose, GTP and myoinositol levels in the kidneys of *Tsc1*cKO mice. Transcriptome analysis revealed 540 mRNAs that were up regulated and 131 mRNAs that were down regulated in *Tsc1*cKO compared to Wt mice. Enrichment analysis revealed these to belong to pathways associated with collecting duct acid secretion, mTOR signaling, metabolism of amino acids as well as AMPK and AKT signaling.

**Conclusions:** Metabolome changes point to altered energy production and storage (e.g., Leloir and phosphagen pathways), signal transduction (e.g., lipid signaling) and protein synthesis pathways. The reduced amino acid levels point to their consumption in response to unregulated cell proliferation. This is supported by RNA-seq data which point to an active mTOR signaling pathway. The induction of mTOR signaling is a result of TSC1 deletion in principal cells and a phosphor-inactivation of TSC (experimental

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

data) in genotypically normal A-intercalated cells. Alterations in other metabolites and mRNAs are also indicative of changes in oxidative phosphorylation, protein synthesis, posttranslational modification, proton transport and injury to the cortex in the kidneys of *Tsc1cKO* mice.

## FR-PO291

### The Endocannabinoid System Mediates Cystogenesis in Tuberous Sclerosis Kidney Disease

Oded Volovelsky,<sup>1</sup> Eden Abergel,<sup>2</sup> Morris Nechama,<sup>2</sup> Hadass Pri Chen.<sup>1</sup> *Hadassah University Medical Center, Jerusalem, Israel.*

**Background:** Tuberous Sclerosis Complex disease (TSC) is caused by an inactivating mutations in *TSC* genes, leading to mTOR pathway hyperactivation. CKD secondary to angiomyolipoma and renal cysts is a leading cause of morbidity in TSC. The endocannabinoid (eCB) system is involved in kidney pathophysiology. Its ligands act mainly through endocannabinoid receptors, CB1R and CB2R. Here we aimed to explore eCB ligands and receptors involvement in TSC cystic kidney disease.

**Methods:** We used a TSC mouse model with *TSC1* deletion in nephron progenitor cells as well as HK2 cell line with *TSC1* deletion using Crispr/cas9. eCB system characterization was performed by measuring the expression of its enzymes and receptors using western blotting, immunohistochemistry, and immunofluorescence staining of kidney sections, real-time PCR for RNA expression and liquid chromatography/online tandem mass spectrometry analysis for ligand level measurements.

**Results:** eCB ligands level in TSC kidneys changed significantly with an elevation of *N*-arachidonoyl ethanolamide and a decline in 2-arachidonoyl levels compared to control. These changes in the eCB ligands were associated with perturbations in the expression level of enzymes involved in their biosynthesis and degradation. The expression and protein level of CB1R was upregulated, and down regulated for CB2R, in *TSC1* mouse model and *TSC1* null HK2 cell. Furthermore, incubation of HK2 cells with CB1R antagonists, prevented the mTOR pathway hyperactivation and an LPS-induced increase in TNF $\alpha$  and IL-6 expression, implying attenuation in cell signaling and an anti-inflammatory mechanism responsible for the beneficial effect of CB1R antagonists.

**Conclusions:** *TSC1* deletion in the kidney modifies the eCB system, including ligands, enzymes, and receptors profile. The role of the endocannabinoid system in cystic kidney disease may be mediated by mTORC1 activity and inflammation. CB1R inhibition may ameliorate these TSC associated cell signaling with a beneficial therapeutic potential.

## FR-PO292

**Planar Cell Polarity Effector Fuzzy in Actin Regulation and Ciliogenesis**  
Rita K. Kalot,<sup>1,2</sup> Sima Babayeva,<sup>2</sup> Elena Torban.<sup>1,2</sup> *<sup>1</sup>McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada; <sup>2</sup>Research Institute of the McGill University Health Centre, Montreal, QC, Canada.*

**Background:** Ciliopathies are disorders caused by mutations in the genes controlling cilia assembly and function. Clinical characteristics of ciliopathies include multi-organ syndromes or organ-specific anomalies, including small and/or cystic kidneys. Planar cell polarity (PCP) effector proteins are major regulators of ciliogenesis since defects in either Fuzzy, Wdpcp, or Inturned cause abnormal cilia formation and pleiotropic syndromes. In vertebrates, PCP effectors recruit important ciliary proteins to the ciliary base. Our recent data indicate that Fuzzy interacts with p190A (ArhGap35), a RhoA GAP that suppresses actin polymerization at the ciliary base, and recruits it to the base of the primary cilium, indicating a potential role of Fuzzy and other PCP effectors in actin regulation at the base of the cilium. Therefore, we aim to understand the role of PCP effector-mediated actin regulation in ciliogenesis and ciliopathies.

**Methods:** Ciliation in mouse embryonic fibroblasts (MEF) was assessed by immunofluorescence. Fuzzy-p190A interaction was identified by co-immunoprecipitation. Co-localization of Fuzzy and p190A at the basal body was visualized by Immunofluorescence in Fuzzy<sup>-/-</sup> and control cells. RhoA activity was assessed by Rhotekin G protein-binding domain-eGFP biosensor in mutant and control cells. Cilia rescue experiments were done using RhoA kinase inhibitors in Fuzzy mutant MEFs and mouse kidney explants.

**Results:** Knockout of Fuzzy drastically reduces cilia formation in MEFs, however, ciliogenesis in the mutant MEFs and embryonic kidney explants was rescued by ROCK inhibitors. Fuzzy recruits p190A to the ciliary base, where the latter likely prevents excessive actin polymerization and promotes ciliogenesis. Indeed, we detected excessive activation of RhoA (regulator of actin polymerization) at the basal body in Fuzzy<sup>-/-</sup> MEFs and excessive polymerization in the Fuzzy<sup>-/-</sup> kidney tissues.

**Conclusions:** Overall, this study has established the link between Fuzzy and major actin regulator p190A during ciliogenesis. This suggests that Fuzzy regulates actin polymerization at the basal body and thereby may control ciliary trafficking. Identifying additional actin-regulating components downstream of PCP effectors at the ciliary base may help identify novel potential drug targets for the treatment of ciliopathies.

## FR-PO293

### The Ciliary Phosphoinositide Pathway Regulates the Level of Polycystins in Cilia

Chuan Chen,<sup>1</sup> Jinghua Hu,<sup>1</sup> Kun Ling,<sup>1</sup> Mayo Clinic Minnesota, Rochester, MN.

**Background:** ADPKD is a progressive genetic disorder which is mainly caused by mutations in the *PKD1* and *PKD2*. The dosage of functional polycystins strongly correlates with the disease severity. However, molecular mechanisms underlying the trafficking and maintenance of PC1/PC2 in cilia remain unclear. Phosphoinositides (PIs) are a group of signaling phospholipids that regulate membrane trafficking. Abnormal phosphoinositide metabolism correlates with variant human diseases, including polycystic kidney. Recent studies showed that PI(4)P and PI(4,5)P<sub>2</sub> exhibit unique compartmentalization in the ciliary membrane and regulate ciliary trafficking and signaling, suggest the PI pathway may function in the trafficking of polycystins.

**Methods:** We use small molecule inhibitors and location-directed protein expression to manipulate the PI contents in the context of cilia, and then determine the ciliary level of PC1 and PC2 using IF and immunoblotting. We use the IMCD3 3D spheroid model and embryonic kidney culture to mimic cystogenesis. We use the FlpIn system to generate several patient mutations of PC1 and PC2.

**Results:** We found that approaches increasing the ciliary PI(4,5)P<sub>2</sub> significantly increase the PC2 level in cilia in normal cells and cells carrying ADPKD mutations, such as *GANAB* and *PKD1* p.R3277C. By generating more patient mutations using FlpIn system, we discovered the ciliary level of several mutated polycystins can be also restored by increasing the PI(4,5)P<sub>2</sub> level. More importantly, increasing PI(4,5)P<sub>2</sub> in cilia reduces the cystic burden in the ADPKD disease model. Cyst index analysis indicated that our specific inhibitor significantly reduced the cyst formation both *in vitro* and *ex vivo*, and moderately reduced *in vivo*. In addition, this inhibitor showed no obvious effect on phosphorylated AKT or ERK expression, suggested that the impaired cystogenesis observed in the inhibitor groups very likely resulted from the recovered ciliary level of polycystins.

**Conclusions:** ADPKD is the most prevalent inherited progressive kidney disease with potential lethality. However, the effective treatment of ADPKD is extremely limited. We found that manipulating the ciliary PI pathway as well as their products significantly increases the ciliary dosage of polycystins, and exhibits suppression effects on renal cystogenesis. These results suggest that the ciliary PI pathway could be a novel therapeutic target for ADPKD.

## FR-PO294

**Early Cyst Formation Leads to the Development of an Inflammatory Microenvironment and Tissue Remodeling in Polycystic Kidney Disease**  
Anubhav Chakraborty,<sup>1</sup> Stephen C. Parnell,<sup>1</sup> Yan Zhang,<sup>1</sup> Emily A. Daniel,<sup>1</sup> Archana Raman,<sup>1</sup> Gail Reif,<sup>1</sup> Darren P. Wallace.<sup>1</sup> *University of Kansas Medical Center, Kansas City, KS.*

**Background:** Polycystic kidney disease (PKD) is a genetic disorder characterized by the formation and growth of numerous fluid-filled cysts. BRAF, a kinase that activates MEK-ERK signaling, is a central intermediate for cAMP-induced cell proliferation and cyst growth in PKD. Recently, we showed that collecting duct (CD)-specific expression of active BRAF<sup>V600E</sup>, a common activating mutation (BRAF<sup>CD</sup>), was sufficient to induce renal cyst formation in an otherwise normal mouse. A key pathological feature of PKD is the development of interstitial inflammation and fibrosis, leading to a decline in renal function. Our hypothesis is that cyst formation induces an inflammatory microenvironment early in renal cystic disease.

**Methods:** To examine changes in gene expression due to cyst formation, we performed RNA sequencing on 3-week-old cystic kidneys from BRAF<sup>CD</sup> mice and *Pkd1*<sup>RCRC</sup> mice, an orthologous slowly progressive model of PKD. Kidneys from 3-week-old wildtype mice were used as controls. Pathway analysis was used to identify common pathways affected during initial cyst formation due to active BRAF-MEK-ERK signaling and mutated *Pkd1*.

**Results:** We found that 566 out of 641 differentially expressed genes (DEGs) in the BRAF<sup>CD</sup> kidneys were also changed in the *Pkd1*<sup>RCRC</sup> kidneys (out of 840). Enrichment analysis indicated that inflammation, cytokine response, tissue fibrosis, and remodeling were some of the top activated pathways and cellular functions (FDR < 0.05; Z-score > 2). 88 of the 566 common DEGs were identified as inflammatory genes (Fold Change  $\geq$  1.5; FDR < 0.05), including elevated expression of tumor necrosis factor- $\alpha$  (TNF $\alpha$ ), toll-like receptor 8, and interleukin-34. The renal tubule injury marker neutrophil gelatinase-associated lipocalin (NGAL, LCN2) and tissue remodeling factors such as MMP-7, mucins (MUC5B, MUC15), lipase family member K, glutathione peroxidase 5, and protease inhibitors (cystatin-11 and -12, serine peptidase inhibitor) were also upregulated.

**Conclusions:** Renal cyst initiation due to active BRAF or mutated *Pkd1* was associated with elevated gene expression of markers for inflammation and tissue remodeling prior to the overt cystic disease, suggesting that cystic cells contribute to early development of an inflammatory microenvironment.

**Time-Restricted Feeding Outperforms Periodic Fasting Head-to-Head in Slowing and Reversing Progression of Polycystic Kidney Disease in the Han:SPRD Rat Model**

Jacob A. Torres, Nickolas J. Holznecht, David A. Asplund, Bradley C. Kroes, Sebastian Strubl, Margaret Schimmel, Thomas Weimbs. *University of California Santa Barbara, Santa Barbara, CA.*

**Background:** We previously reported that interventions that induce the state of ketosis, including caloric restriction, time-restricted feeding, ketogenic diet and extended fasting, ameliorate or reverse polycystic kidney disease progression in animal models. We had found that time-restricted feeding was highly effective in juvenile Han:SPRD rats and that a 48-hour extended fast induced apoptosis in cystic epithelia. To expand on those findings, we now compared, head-to-head, periodic 48-hour fasting against a daily 16:8 time-restricted feeding regimen in both juvenile and adult Han:SPRD rats.

**Methods:** Juvenile and adult Han:SPRD rats were fasted weekly for 48 hours and then given ad libitum access to food for 5 days before being fasted again for 48 hours. This was repeated for 5 weeks from age 3 weeks to 8 weeks in juveniles and for 4 weeks in adults from age 8 weeks to 12 weeks. For daily time-restricted feeding, rats were given ad libitum access to food for 8 hours a day and were fasted for the remaining 16 hours. This was performed in adult rats from weeks 8 weeks to 12 weeks of age.

**Results:** All treatments led to a decrease in serum creatinine and markers of cystic disease progression. The beneficial effects of daily time-restricted feeding significantly exceeded that of periodic 48-hour fasting, leading to a partial reversal of established renal cystic disease in adult rats.

**Conclusions:** These results suggest that daily time-restricted feeding is a more potent intervention than periodic fasting. This study has important implications for translation into the clinic for the dietary management of individuals with ADPKD and the design of future clinical studies to assess outcomes of such interventions.

## FR-PO296

**Changes in Tubule Flow During Renal Cyst Development**

Isis Thomas, Hanan Chweih, Courtney J. Haycraft, Zhang Li, Mandy J. Croyle, Kristin L. Simanyi, Bradley K. Yoder. *The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.*

**Background:** Polycystic kidney disease (PKD) is an inherited disorder where cysts develop in the kidney leading to renal failure. Cyst development results from mutations in ciliary localized proteins, PC1 and PC2 (encoded by the *Pkd1* and *Pkd2* genes, respectively), or due to loss of the cilium (e.g., in *Ift88* mutants). It is currently unknown whether flow is disrupted prior to or after cyst initiation, or whether tubule flow is important in maintaining the cells' differentiation state. While the function of the cilium in the kidney remains enigmatic, one proposed role is as a mechanosensor that detects changes in flow through the tubule lumen.

**Methods:** We propose that the loss of *Pkd2* leads to changes in the nephron associated with abnormal injury responses, cyst formation, and alterations in tubule flow. In this study we evaluate tubule flow during cyst initiation and progression to determine when tubule flow is altered and whether changes in flow lead to an increase in cell injury in adult induced *Pkd2* mutant mice. *Pkd2* mutant mice were induced by IP injection of tamoxifen at 8 weeks of age. Dextran absorption was analyzed by fluorescence activated cell sorting (FACS) and immunofluorescence (IF) with LTA (proximal tubules) and additional nephron segment markers.

**Results:** At 6- and 12-weeks following tamoxifen induction, dextran absorption was still detected in proximal tubules (presence of dextran+/LTA+ cells) of mutant mice. Additionally, we observed a decrease in LTA+ cells and an increase in dextran+/LTA- cells in *Pkd2* mutants at 6 weeks post induction via FACS suggesting that at this stage flow is maintained. Decreased numbers of LTA+ cells in *Pkd2* mutant samples suggest either a loss or dedifferentiation of proximal tubule cells prior to cyst formation. Visualization of dextran flow through the tubules in live samples confirmed that tubule flow is still present. We will utilize IF staining for proximal tubule (HNF4a), injured (SOX9), and proliferating (Ki67) cells to analyze changes throughout cyst development.

**Conclusions:** Overall, our data shows that flow through the tubules is not affected in early cystogenesis, but cellular alterations, such as loss of LTA staining occur early in *Pkd2* mutant mice.

**Funding:** NIDDK Support

## FR-PO297

**Polycystin-2 Like 1 in Renal Cyst Formation**

Ario Mohammadi,<sup>1</sup> Ahmad Jaser,<sup>1</sup> Aashish Dahal,<sup>1</sup> Lydia J. Liang,<sup>1</sup> Jing Zhou.<sup>1,2</sup> *<sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA.*

**Background:** Polycystin-2 (PC2), encoded by PKD2 gene is a member of the transient receptor potential (TRP) family of non-selective cation channels. Mutations in PKD2 gene cause autosomal dominant polycystic kidney disease (PKD). Polycystin-L (also called polycystin-2L1, Pkd2L1) is a Ca2+-activated non-selective cation channel with high sequence identity to polycystin 2 and is permeable to Ca2+, K+ and Na+. We have previously shown that polycystin-L is expressed primary cilia of hippocampal

neurons in the brain. In the kidney, PCL is detected on the primary cilium of epithelial cells similar to other members of the polycystin family.

**Methods:** Genetic crossing of gene-targeted mice were used to determine the resulting phenotypes. Histology, morphometric analyses and immunostaining were used to measure cystic index and cilium length.

**Results:** To determine whether polycystin-L plays a role in the kidney, we inactivated polycystin-L by gene targeting. Disruption of polycystin-L led to increased hippocampal and thalamocortical excitability, however their kidneys are phenotypically normal, which is in striking contrast with Pkd2 knockout mice that develop severe polycystic kidney disease. To determine whether polycystin-L modulates polycystic kidney disease in orthologous model of ADPKD, we created Pkd2. Pkd1 double knockout mice. We observed a reduction in kidney/body weight ratio and cystic index in a subset of double knockout mice. Cilia length measurements showed Pkd2. Pkd1 double knockout mice have shorter cilia than Pkd2 single knockout mice.

**Conclusions:** Disruption of both PkdL and Pkd2 in mice does not worsen the PKD phenotype in Pkd2 single knockout mice. In a significant portion of mice, there is a reduction in polycystic kidney disease severity in double knockout mice when compared with that in Pkd2 single knockout mice.

## FR-PO298

**A scRNAseq Approach to Define Early Events in Cyst Formation and Stepwise Transformation**

Sara Clerici, Daniel Spies, Alessandra Boletta. *IRCCS Ospedale San Raffaele, Milano, Italy.*

**Background:** We have previously generated and described a mouse model carrying kidney-specific inactivation of the *Tsc1* gene using a Cadherin16-Cre line (KspCre). The peculiarity of the *Tsc1<sup>fl/fl</sup>;KspCre* model is that it develops a slowly progressive cystic kidney disease model, triggered by mTORC1-dependent downregulation of polycystin-1 (PC-1), which progressively transform into cystadenomas and carcinomas (Pema et al, Nat Comms, 2016; Drusian et al, Cell Reports, 2018). As they transform, the renal lesions lose the expression of tubule-specific markers.

**Methods:** In order to track all KO cells within the kidney, we generated *mT/mG; Tsc1<sup>fl/fl</sup>;KspCre* mice. Indeed, only KspCre expressing cells would excise mTomato (mT) in favor of mGFP (mG), while the surrounding tissue ubiquitously expresses mTomato. Mutants were characterized through histological and immunofluorescent analyses. Single cell suspension from control and mutant kidney was obtained through mechanical and enzymatic dissociation with Miltenyi kits and validated by flow cytometry confirming viability and aggregates requirements for single-cell sequencing.

**Results:** Histological characterization of *mT/mG; Tsc1<sup>fl/fl</sup>;KspCre* confirmed the progression from cysts (at P20) to cystadenomas and carcinomas (at P50 and P80) with the previously reported frequency. Furthermore, careful characterization of the *mT/mG; Tsc1<sup>fl/fl</sup>;KspCre* revealed that cystic structure, papillae, cystadenomas and carcinomas displayed mG-positivity in all lesions of all stages of the phenotype. A dissociation protocol was set up obtaining 75% viability in both control and mutant kidneys. Flow cytometry confirmed the 25-30% mG+ cells expected in controls, which expanded to 65% in mutant kidneys, in line with the robust proliferation observed in these mutants. scRNAseq analysis of control mT/mG and *mT/mG; Tsc1<sup>fl/fl</sup>;KspCre* kidneys is being set-up at different time points (P10, precystic; P20 cystic; P50 and P80 transformed).

**Conclusions:** We generated a mouse model allowing to separate and study *Tsc1* mutant cells and the surrounding healthy tissue in a mouse model of progressive cysts and renal cell carcinoma (RCC) development. Single-cell sequencing analysis will help defining early versus late events in cystogenesis and in transformation towards RCC.

## FR-PO299

**Primary Cilia Respond to Nutrients Availability and Favor Glutamine Utilization During Metabolic Stress**

Maria Elena Steidl,<sup>1,2</sup> Elisa Agnese Nigro,<sup>1</sup> Anne K. Nielsen,<sup>1,2</sup> Matteo Lampis,<sup>1,3</sup> Laura Cassina,<sup>1</sup> Christine Podrini,<sup>1</sup> Roberto Pagliarini,<sup>1</sup> Marco Chiaravalli,<sup>1</sup> Valeria Mannella,<sup>1</sup> Ming Yang,<sup>4</sup> Giovanna Musco,<sup>1</sup> Christian Frezza,<sup>4</sup> Alessandra Boletta.<sup>1</sup> *<sup>1</sup>IRCCS Ospedale San Raffaele, Milano, Italy; <sup>2</sup>Universita Vita Salute San Raffaele, Milano, Italy; <sup>3</sup>Eidgenossische Technische Hochschule Zurich, Basel, Switzerland; <sup>4</sup>Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany.*

**Background:** Autosomal Dominant Polycystic Kidney Disease (ADPKD) represents the most common renal ciliopathy. Our group demonstrated that ADPKD is characterized by a metabolic rewiring that involves increased glycolysis, glutaminolysis, fatty acid synthesis, and decreased oxidative phosphorylation (OXPHOS) and fatty acid oxidation. Given that the polycystins localize to cilia, but also to other locations, we wondered what is the contribution (if any) of cilia in regulation of the bioenergetic demand of cells.

**Methods:** Cilium-ablated *Ift88* KO MEFs and IMCD3 cells were generated by CRISPR/Cas9 technology. NMR and LC-MS analyses were used to measure extracellular and intracellular metabolites. Seahorse assays were performed to measure mitochondrial respiration parameters. Immunofluorescence analyses were performed to measure primary cilium length both *in vitro* and *in vivo* in response to various nutrients.

**Results:** We found that cilium-ablated cells do not display overt differences compared to controls in cellular growth or mitochondrial respiration under complete medium conditions. However, NMR and LC-MS metabolomics under the same culture conditions revealed subtle differences between cilium-ablated cells and controls in metabolites

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

involved in glucose and glutamine-related pathways and in the TCA cycle. Interestingly, we found that nutrients deprivation drives a drastic primary cilium elongation, with an effect much stronger than simple serum deprivation. Physiological levels of glutamine, but not glucose, caused re-shortening of cilia both *in vitro* and *in vivo*. Furthermore, when exposed to glutamine supplementation under nutrients deprivation, cilium-ablated cells display significant abnormalities in the intracellular levels of glutamine, aspartate, and asparagine, suggesting an altered glutamine utilization under metabolic stress. We also found that this effect was mTOR-independent, but likely mediated by glutamine fueling of the TCA cycle.

**Conclusions:** Our results reveal that the primary cilium is involved in the response to nutrients availability and the usage of glutamine. These important findings could shed light on the role of primary cilium both in physiological and pathological contexts.

## FR-PO300

### Polycystin 1 Ciliary Localization Is Controlled by Chemo- and Mechano-sensitive Signaling Processes That Involve the Machinery of GPCR Desensitization

Nikolay P. Gresko, Michael J. Caplan. *Yale University, New Haven, CT.*

**Background:** Most cases of autosomal dominant polycystic kidney disease (ADPKD) are caused by loss of function mutations in the PKD1 and PKD2 genes, which encode polycystin-1 (PC1) and polycystin-2 (PC2), respectively. PC1 is a 460kD multi-spanning membrane protein that undergoes several proteolytic cleavages, one of which occurs at G protein coupled receptor proteolytic site in the N terminus and at least two of which release C-terminal fragments. PC1 and PC2 proteins localize to the primary cilium and contribute to cellular mechano-sensation and, also form a cation-permeable heterotetrameric channel. Recent studies demonstrate that PC1 can function as an atypical GPCR for Wnt ligands.

**Methods:** Immunofluorescence

**Results:** Here we report that the receptor activity of PC1 controls its ciliary localization. PC1 receptor function can be induced by ligand or by mechanical stimuli. Bending of the primary cilium have been shown to induce the release of extracellular ATP. We find that extracellular ATP reduces PC1 ciliary localization and that the effects of mechanical stimuli on the ciliary localization of PC1 may be mediated at least in part by extracellular ATP. Consistent, we show that constitutively active PC1 receptor construct is absent from the primary cilia whereas a constitutively inactive PC1 construct resides stably in the primary cilia. When we block GPCRs desensitization with  $\beta$ -arrestin inhibitor barbadin, we observe active PC1 construct accumulation in the cilium. We also examined the surface localization of the full length PC1 protein co-expressed with PC2 and found that extended Wnt9b ligand treatment or mechanical stimuli both lead to reduced presence of the full length PC1 protein at the cell surface and in the primary cilium, a process that can be disrupted by inhibition of  $\beta$ -arrestin.

**Conclusions:** Taken together, our data suggest that PC1 localization is regulated by physiological stimuli, including ligand binding and mechanical stress, through a mechanism that is similar to the receptor desensitization processes that regulate GPCR localization. Furthermore, the ATP released in response to mechanical stimuli appears to contribute to these desensitization mechanisms, resulting in removal of PC1 from the primary cilium.

### Selective mTORC1 Inhibitors Block Cystogenesis in a Human Kidney Organoid Model of Polycystic Kidney Disease

Ramila E. Gulieva, Benjamin S. Freedman. *University of Washington, Seattle, WA.*

**Background:** The mammalian target of rapamycin complex (mTORC) pathway is activated in kidneys with PKD, and is therefore a promising target for therapy development. There are two mTORC complexes, mTORC1 and mTORC2. Recent work has developed selective mTORC1 inhibitors (mTORC1i), which have fewer side effects than compounds that inhibit both mTORC1 and mTORC2. Whether such compounds can affect PKD cystogenesis, however, has not yet been determined. We set out to test this in human kidney organoids with mutations in *PKD1* or *PKD2*, which form cysts in a PKD-specific way.

**Methods:** *PKD1*<sup>-/-</sup> or *PKD2*<sup>-/-</sup> iPSCs were differentiated into kidney organoids, placed in suspension for 9 days until cysts formed, and transferred into 96-well plates (one cyst/well). Compounds were introduced at different concentrations (0.1 to 30  $\mu$ M), including two selective mTORC1i (ORG1, ORG2), everolimus, vehicle and untreated controls. Phase contrast images were taken of each organoid on multiple days for 14 days to measure changes in cyst size. In parallel, cultures of organoids were used to assess markers of mTOR activity (P-p70S6, P-S6RP, P-AKT). LDH activity and live/dead staining were used to measure toxicity.

**Results:** All mTORC1 inhibitors produced dose-dependent reductions in cyst growth over the course of the experiment. Everolimus and ORG1 had statistically significant effects, whereas ORG2 was less efficacious. All mTORC inhibitors significantly decreased phosphorylation of mTOR targets S6RP and p70s6. P-AKT was decreased only in everolimus treatments but not in ORG1 and ORG2 treated organoids, reflecting selectivity of mTORC1i. Live/dead assay measured on day 14 indicated that everolimus is toxic at 10  $\mu$ M and 30  $\mu$ M, ORG1 at 30  $\mu$ M, and for ORG2 no sign of toxicity was identified.

**Conclusions:** We have established a model of drug treatment in PKD organoids to predict therapeutics that can slow cyst growth. Findings in organoids demonstrated efficacy of mTORC inhibitors for PKD, which was consistent with the ability of this

class of drugs to slow cyst growth in pre-clinical models. This helps to validate the use of organoids for studying PKD and screening potential therapeutics. An exciting finding is that novel selective mTORC1i compounds show efficacy and target engagement at non-toxic doses. These data provide proof of concept for further studies in animals and eventually humans.

### Canonical Correlation Analysis to Identify Single Nucleotide Polymorphisms in CKD

Amy J. Osborne, Agnieszka Bierzynska, Gavin I. Welsh, Moin Saleem, Ian C. Campbell. *University of Bristol, Bristol, United Kingdom.*

**Background:** Genetic risk for chronic kidney disease (CKD) is associated with the two complementary kidney function biomarkers, estimated glomerular filtration rate (eGFR) and blood urea nitrogen (BUN). Within this context, genome-wide association studies (GWASs) have identified single nucleotide polymorphisms (SNPs) associated with each biomarker, as well as SNPs likely relevant for kidney function based on their effect size directions. However, it has not yet been investigated which SNPs show a joint statistical association with, or shared genetic basis for, both kidney function biomarkers considered together in a multivariate analysis.

**Methods:** To identify SNPs correlated with both eGFR and BUN jointly, we applied canonical correlation analysis (CCA) to two CKD genotype datasets (European ancestry NURTURE-CKD and Salford Kidney Study) and *metaCCA* to the wider context of three larger publicly available GWAS summary statistics datasets (European ancestry CKDGen, United Kingdom Household Longitudinal Study, and BioBank Japan). SNPs that showed a significant correlation with both eGFR and BUN, using Bonferroni-correction, were gene-annotated based on location (AnnoVar) and kidney tissue expression quantitative trait loci (eQTL; QTLizer). Functional enrichment and gene overlap was assessed.

**Results:** For the CKDGen European ancestry dataset, of the 122 SNPs previously reported as likely relevant for kidney function by Wuttke et al. 2019, we found that 97 SNPs (80%) showed a significant correlation with both eGFR and BUN jointly using *metaCCA*. For the *metaCCA*-identified pruned SNPs that were in exons or kidney tissue eQTL-associated, the genes showed significant functional enrichment for proximal tubule transport, low molecular weight proteinuria, abnormal renal physiology and renal tubular atrophy, and others. Between the *metaCCA*-identified genes for the CKDGen (54 genes) and BioBank Japan (7 genes) datasets, despite the genetic ancestry difference, three genes overlapped (*FGF5*, *GOSR2*, *MUC1*). For the two smaller CCA-analysed datasets, the top SNPs showed p-values < 9E-3 but none were significant based on the Bonferroni correction. Gene annotations for these top SNPs overlapped with some *metaCCA*-identified genes, including *SLC7A9* and *GATM*.

**Conclusions:** This powerful methodology identifies novel SNPs correlated with kidney function in CKD.
