**Results:** A previously healthy 6-year-old girl with no family history of kidney disease presented with worsening edema. Lab results at admission included serum creatinine 1.25 and albumin 1.2, and urinalysis with 2+glucose, 3+protein, and 1+blood. Biopsy showed 70% global glomerulosclerosis with 50-60% interstitial fibrosis with negative immunofluorescence. She did not respond to 4 weeks of high dose prednisone and transitioned to tacrolimus. CTN4 and ITGB4 mutations were found in her nephrotic syndrome genetic panel and tacrolimus was discontinued. Her serum creatinine rose quickly to 5.8 and protein loss was uncontrollable, therefore bilateral nephrectomy was performed 8 months after presentation. The patient received a kidney from her mother 1 month later, and the graft is fully functional to date. scRNAseq revealed 15 clusters and cluster 10 was annotated as podocytes based on expression of the genes specific to podocytes described in KIT. While expression of some of the podocyte-specific genes (*NPHS2*, *PODXY*, *SRGAP2B*, *CCN2*, *CLIC5*, *ATP10A*) were preserved, other genes (*FYN*, *NTNG1*, *CDC14A*, *ALS2CL*) were not detected in the patient dataset. The diseased kidney also expressed genes that are not expressed in the healthy kidney. The most highly differentially upregulated genes only in the diseased kidney include *MGP*, *TAGL*, *RGS5*, *TPM2* and *ADIRF*. Extracellular matrix genes were also significantly increased in diseased podocytes. Switch in classes of GPCR genes was also observed (Q and O in healthy and D, A, K in diseased podocytes).

**Conclusions:** Genes identified by scRNAseq implicate potential therapeutic targets for children with genetic podocytopathy.

**Funding:** NIDDK Support

### Reduction of Systemic Inflammation by Notch3 Inhibition in HIV-Associated Nephropathy

Mackenzie Thornton,<sup>1</sup> Nicole Sommer,<sup>1</sup> Mercedes B. McGonigle,<sup>1</sup> Johnny Dinh Phan,<sup>1</sup> Tao Wang,<sup>2</sup> Pravin C. Singhal,<sup>3</sup> Timothy A. Fields,<sup>1</sup> Madhulika Sharma,<sup>1</sup> *<sup>1</sup>University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS; <sup>2</sup>The University of Manchester, Manchester, United Kingdom; <sup>3</sup>Northwell Health, New Hyde Park, NY.*

**Background:** Anti-retroviral therapy (ART) suppresses HIV-associated Nephropathy (HIVAN) but does not protect from continuous generation of viral proteins and inflammation. We need therapies that inhibit viral replication and inflammation simultaneously to avoid progression into chronic kidney disease (CKD). We have previously shown that pan Notch inhibition ameliorated disease progression in the Tg26 mouse model of HIVAN. Here, we determined specifically the role of Notch3 pathway in HIVAN pathogenesis.

**Methods:** We labelled renal sections from HIVAN patients and mouse model (Tg26) for Notch3 via immunohistochemistry. We determined if HIV-1 induces Notch3 activation. We generated Tg26 mice with global Notch3 knockout (Tg-N3KO) and characterized the kidneys, followed by RNA sequencing. Macrophage-podocyte interactions were then studied. Soluble TNF alpha levels were evaluated using ELISA.

**Results:** Notch3 was activated in glomerular, tubular and interstitial cells of HIVAN biopsies and Tg26 mice. Notch3 expression was induced when podocytes were transfected with HIV-1 construct. Genetic knockout of Notch3 (N3KO) in Tg26 (Tg-N3KO) mice resulted in a significant increase in the life span. This was associated with marked improvement in glomerular and tubular injury and renal function. A striking reduction in infiltrating immune cells was observed. RNA sequencing and validation data indicated a marked reduction of macrophage markers in Tg-N3KO mice versus Tg26 mice. We then isolated and cultured bone marrow derived macrophages from Tg26 and Tg-N3KO mice and found that Notch3 and Notch ligands, Jagged 1 and Delta like 4 (Dll4) were markedly upregulated in Tg26 mice. N3KO normalized them. Conditioned macrophage media

from BMDM derived from Tg26 mice resulted in Notch activation of podocytes. Finally, Notch3 deletion not only affected the kidneys but reduced the systemic expression of soluble inflammatory factor tumor necrosis factor alpha (TNF-alpha).

**Conclusions:** Notch 3 deletion in HIVAN model reduced kidney injury, improved renal function, reduced macrophage infiltration and reduced systemic TNF alpha levels which may collectively be responsible for the increase life span of the Tg26 mice. Thus, inhibition of Notch3 may constitute an attractive therapeutic strategy in HIV related CKDs.

## SA-PO746

### Podocyte Expression of the Human PLA2R1 Causes Immune-Mediated Membranous Nephropathy in Mice

Nicola M. Tomas, Silke Dehde, Catherine Meyer-Schwesinger, Larissa Seifert, Renke Lucas, Sarah Köllner, Ming Huang, Tobias B. Huber, Gunther Zahner. *Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

**Background:** Antibody-mediated autoimmune pathologies like membranous nephropathy (MN) are difficult to model, particularly in the absence of target antigen expression in typical model organisms such as mice and rats, which is the case for PLA2R1, the major autoantigen in this disease.

**Methods:** We generated a mouse line expressing the full-length human PLA2R1 specifically in podocytes (hPLA2R1-positive mice). Mice were characterized during the first weeks of life using urinary albumin measurements, serum analyses, light microscopic and immunofluorescence microscopy as well as electron microscopy. The mouse line was also crossed to *Rag2*<sup>-/-</sup> mice, which lack mature B and T lymphocytes.

**Results:** Human PLA2R1-positive mice were healthy after birth. Beginning from the age of three weeks, however, mice developed a nephrotic syndrome with progressive albuminuria and hyperlipidemia. This was preceded by the development of anti-PLA2R1 antibodies, which primarily bound the PLA2R1 extracellular domains that are also recognized by patient autoantibodies (CysR, CTLD1, CTLD7/8). After disease onset, histological analyses in hPLA2R1-positive mice revealed the typical morphological signs of MN with granular glomerular deposition of murine IgG in immunofluorescence and subepithelial electron-dense deposits in electron microscopy. Importantly, hPLA2R1-positive *Rag2*<sup>-/-</sup> mice did neither develop anti-PLA2R1 antibodies nor proteinuria.

**Conclusions:** Our work demonstrates that podocyte expression of human PLA2R1 in mice can induce immune-mediated, PLA2R1-associated MN.

**Funding:** Government Support - Non-U.S.

## SA-PO747

### THSD7A Cleavage Is Mediated by the Proprotein Convertase Furin In Vitro

Larissa Seifert, Silke Dehde, Renke Lucas, Gunther Zahner, Nicola M. Tomas. *Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

**Background:** Thrombospondin type 1 domain-containing 7A (THSD7A) is a pathogenic autoantigen in membranous nephropathy (MN). It is prominently expressed on podocytes in humans and rodents, where it is located at the basal aspects of foot processes and it likely plays a role in podocyte adhesion. When expressed recombinantly e.g. in HEK cells, THSD7A is cleaved in the N-terminal region.

**Methods:** Purified, recombinantly expressed THSD7A was analyzed by mass spectrometry (MS). Following MS analysis, we applied site directed mutagenesis to further narrow down the cleavage site. We tried two additional approaches to confirm our data and identify the protease that we assumed to be responsible for the cleavage. First, we tested a specific inhibitor and second we added the recombinant commercial available protease to uncut protein, to see whether it is processed.

**Results:** Mass spectrometry revealed a cleavage of THSD7A in the polybasic region of the fourth TSP-1 domain. The cleavage site was located between two cysteins forming a disulfide bond, leading to adherence of the fragments even after cleavage of the peptide backbone. The identified site corresponded to the cleavage motif of proprotein convertases (PCs). Base substitution of one Arginin to Alanin within the cleavage site completely abolished the proteolytic processing. Adding an inhibitor, which dominantly inhibits the PC furin, to the cell culture medium of THSD7A expressing HEK cells achieved the same effect. Conversely, adding recombinant furin to uncut THSD7A led to cleavage of the protein.

**Conclusions:** The PC furin cleaves THSD7A in the fourth TSP-1 domain in vitro. Whether this processing also occurs in vivo and is related to the biological function of THSD7A needs to be investigated.

**Funding:** Government Support - Non-U.S.

## SA-PO748

### Podocyte Autophagy and Cell Survival Is Regulated by the Circadian Clock Gene

Lulu Wang, Lei Jiang, Junwei Yang. *Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

**Background:** The circadian clock is a ubiquitous system in mammals which synchronizes cellular, tissue, and systemic biological functions with 24-hour environmental cycles. CLOCK (Circadian locomotor output Cycles protein kaput) is a core component of the molecular clocks. It contains a BHLH-PAS domain and forms a heterodimer with BMAL1 (Brain and Muscle Arnt-like 1), acting in the positive branch of the circadian transcription/translation feedback loop. Previous study had identified

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

that the intrinsic circadian clock BMAL1 in podocytes controls glomerular filtration rate. Little is known about the *Clock* and podocytes. The study aimed to explore the effects of *Clock* on podocytes.

**Methods:** In vitro, the primary podocyte was used to elaborate the role of *Clock* on podocytes by knockdown of *Clock* by siRNA. Chromatin immunoprecipitation (CHIP) sequence was employed to detect association between *Clock* and autophagy. In vivo, we made mouse sleep fragmentation to constructed circadian rhythm disorder model. The podocyte specific *Clock* knockout mice (podocyte-*Clock*<sup>-/-</sup>) were also constructed.

**Results:** Loss of *Clock* caused podocyte death. There was an increased urinary albumin excretion and podocytes injury in Podocyte-*Clock*<sup>-/-</sup> mice compared to control mice. We also found that sleep fragmentation led to the loss of circadian clock oscillation, the fusion of foot processes and albuminuria. CHIP-seq and qPCR analysis confirmed that *Clock* bonded to the promoter of *Becn1* and *Atg12*. Circadian rhythms disorder impaired autophagy, which promoted podocyte death.

**Conclusions:** Our study revealed the critical role of *Clock* circadian rhythm in podocyte. Mechanistically, *Clock* dependent circadian autophagy is indispensable for podocyte to adapt stress response or nutrient metabolism.

**Funding:** Government Support - Non-U.S.

### Oxysterol-Binding Protein Like 7 Deficiency Leads to Decreased Autophagic Flux, Increased Lipid Droplet Accumulation, and Apoptosis in Podocytes

Jeffrey D. Pressly,<sup>1,2</sup> Sandra M. Merscher,<sup>1,2</sup> Alessia Fornoni.<sup>1,2</sup> <sup>1</sup>University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL; <sup>2</sup>Peggy and Harold Katz Drug Discovery Center, Miami, FL.

**Background:** Previously we demonstrated that OSBPL7 protein levels are decreased in podocyte models of chronic kidney disease (CKD). OSBPs are involved in cholesterol transfer from the endoplasmic reticulum (ER) to the Golgi, cholesterol efflux, and autophagy. OSBPL7 is a lipid transfer protein that transfers cholesterol for PI4P at subcellular membrane sites that contains an oxysterol binding domain (OSBD), a PH domain, and an FFAT motive. It remains unknown if OSBPL7 deficiency contributes to dysregulated lipid trafficking, leading to a decrease in podocyte viability.

**Methods:** OSBPL7-V5 construct was purchased from Addgene, and mutated constructs carrying deletions in the FFAT and PH domains of OSBPL7 were generated by PCR mutagenesis. Overexpression of OSBPL7 (deletion) constructs was achieved using Eugene HD (Promega) following manufacturer-recommended transfection protocols. Whole-cell lysates were collected from siOSBPL7 and scOSBPL7 podocytes and analyzed for LC3 and GATE-16 protein expression by western blot. LD number was determined using Opera high content screening system and Columbus analysis software. Apoptosis was measured using the ApoTox-Glo Apoptosis Assay (Promega).

**Results:** OSBPL7 deficiency in siOSBPL7 podocytes leads to decreased autophagic flux with increased levels of LC3 cleavage and decreased levels of GATE-16. siOSBPL7 podocytes demonstrate increased lipid droplets compared to scOSBPL7 podocytes. Overexpression of full-length OSBPL7 is sufficient to protect siOSBPL7 podocytes from apoptosis. However, overexpression of an OSBPL7 construct with a deletion of the FFAT domain failed to rescue the effect on apoptosis, implicating the FFAT domain as imperative for the antiapoptotic effects of OSBPL7 in podocytes.

**Conclusions:** OSBPL7, i.e., the FFAT domain of OSBPL7, is necessary for the proper function of and viability of podocytes. OSBPL7 deficiency leads to decreased autophagic flux, lipid accumulation, and podocyte injury. The decreased autophagic flux may contribute to lipid droplet accumulation, resulting in lipotoxicity in podocytes deficient in OSBPL7. Future studies will address the role of OSBPL7 in lipophagy and the role of lipophagy in CKD, which may lead to the identification of novel therapeutic targets for the treatment of this prevalent and costly disease.

### SMPDL3b Modulates STING Activation in Podocytes

Matthew Tolerico,<sup>1,2</sup> Antonio M. Fontanella,<sup>1</sup> Shamroop Kumar Mallela,<sup>1</sup> Margaret Z. Gurumani,<sup>1,2</sup> Judith T. Molina David,<sup>1</sup> George W. Burke,<sup>3</sup> Sandra M. Merscher,<sup>1</sup> Alessia Fornoni,<sup>1</sup> Alla Mitrofanova.<sup>1,3</sup> <sup>1</sup>University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL; <sup>2</sup>University of Miami Department of Molecular and Cellular Pharmacology, Miami, FL; <sup>3</sup>University of Miami Department of Surgery, Miami, FL.

**Background:** Chronic kidney disease (CKD) is a major health problem with no definitive cure. Podocytes are specialized glomerular cells that maintain kidney filtration and are injured in CKD. Recent studies show that sphingomyelin phosphodiesterase acid-like 3b (SMPDL3b) is important for podocyte function and regulates innate immunity in macrophages. The stimulator of interferon genes (STING), a component of the innate immune system that detects cytosolic DNA, has been shown to regulate inflammation in mouse models of CKD. We tested the hypothesis that altered SMPDL3b expression leads to podocyte injury through chronic activation of STING.

**Methods:** Illumina sequencing RNA data analysis, qRT-PCR and Western blot were used to characterize immortalized human podocytes with knockdown (siSMP) or overexpression (SMP OE) of SMPDL3b. c-diAMP, a STING specific agonist, treatment (10µM) was performed for 24h. Glomeruli isolated from 8-week-old mice with podocyte specific Smpdl3b deficiency (pSMP<sup>fl/fl</sup>) or overexpression (pSMP<sup>tg</sup>) were used to evaluate STING activation. pSMP<sup>fl/fl</sup> and pSMP<sup>tg</sup> mice were injected I.P. with a single dose of c-diAMP, 25mg/kg or 5% DMSO and sacrificed 72h after injection, following by urinary

albumin-to-creatinine ratio (ACR), histological and serum analyses. Two-tailed t-test or One-Way ANOVA followed by Tukey's post-test were used to detect statistical changes.

**Results:** Illumina RNAseq analysis revealed altered DNA sensing pathways in SMP OE podocytes. siSMP podocytes have reduced phospho and total STING, while SMP OE podocytes have increased phospho and total STING compared to control podocytes. Treatment with c-diAMP resulted in increased STING phosphorylation in control and siSMP podocytes, but not in SMP OE cells. Glomerular STING was significantly decreased in pSMP<sup>fl/fl</sup> mice and increased in pSMP<sup>tg</sup> mice. While both pSMP<sup>fl/fl</sup> and pSMP<sup>tg</sup> mice do not develop proteinuria at the baseline, treatment with c-diAMP resulted in increased ACR in pSMP<sup>tg</sup>, but not in pSMP<sup>fl/fl</sup> mice.

**Conclusions:** Our data indicate that SMPDL3b overexpression leads to STING activation in podocytes *in vitro* and STING-dependent proteinuria *in vivo*. Targeting SMPDL3b in the podocytes may represent a novel approach to regulate podocyte innate immunity and to improve renal outcomes in patients with CKD.

## SA-PO751

### Steroid-Resistant Minimal Change Disease Induced by Waldenstrom Macroglobulinemia

Tin T. Pham,<sup>1,4</sup> Allison Carilli,<sup>2</sup> Christine A. Vanbeek,<sup>3</sup> Jorge I. Martinez Osorio,<sup>2</sup> <sup>1</sup>HCA Healthcare Graduate Medical Education, Orlando, FL; <sup>2</sup>Orlando VA Healthcare System, Orlando, FL; <sup>3</sup>AmeriPath Inc, Oklahoma City, OK; <sup>4</sup>University of Central Florida, Orlando, FL.

**Introduction:** Waldenstrom's macroglobulinemia (WM) is an IgM-secreting B-cell lymphoproliferative disorder associated with a variety of renal manifestations. Glomerular pathology in WM most commonly occurs because of direct monoclonal protein deposition resulting in light chain amyloidosis, cryoglobulinemic glomerulonephritis, or non-cryoglobulinemic membranoproliferative glomerulonephritis. Minimal Change Disease (MCD) rarely develops in the setting of non-Hodgkin lymphomas (NHLs) including WM. We present a case of steroid resistant MCD induced by WM requiring the use of cytotoxic agents with successful remission achieved of nephrotic syndrome.

**Case Description:** 67-year-old man, with history of hyperlipidemia was evaluated for acute onset of anasarca, asthenia, and weight gain of 40 lbs. He had heavy proteinuria (12 grams), hypoalbuminemia (1.0 grams/dL), and normal serum creatinine level (1.1 mg/dL). Serum protein electrophoresis showed 2 M spikes (one IgM kappa, one IgM lambda). Serum free light chain ratio was normal at (1.42). PCR for gene mutation was positive. Bone marrow biopsy revealed a mildly hypercellular bone marrow (60%) with involvement by a B-cell lymphoproliferative disorder. Renal biopsy showed MCD. He was started on prednisone 80 mg that was tapered to 60 mg over 4 months. However, he had persistent fatigue, lower extremity edema, and ongoing proteinuria (7 to 14 grams). On repeat renal biopsy, there was extensive podocyte foot process effacement, consistent with MCD. The treatment was transitioned to 6 cycles of rituximab, cyclophosphamide, and corticosteroids. The patient reported remarkable improvement in fatigue and lower extremity edema by the middle of his treatment. After finishing the full treatment course, he had complete resolution of proteinuria, stable serum creatinine (1.1 mg/dL), and normalization of serum albumin (3.8 g/dL).

**Discussion:** MCD is a rare renal manifestation of WM. Although the lesion is not due to direct monoclonal protein deposition, it may be related to other factors secreted by the tumor. MCD in the setting of NHL is often steroid-sensitive. However, this case demonstrates that cytotoxic agents and monoclonal antibodies may be required to achieve complete remission.

## SA-PO752

### Don't Miss Mesalamine! Mesalamine-Induced Focal Segmental Glomerulosclerosis in a Patient With Ulcerative Colitis

Andrea R. Linares. Department of Kidney Medicine Cleveland Clinic Florida, Weston, FL.

**Introduction:** Renal manifestation in UC and Crohn's disease is not uncommon. It's suggested to be a combination of genetic factors, infectious agents, bacterial endotoxins, and immune complex depositions. The most frequent renal disease in patients with IBD are nephrolithiasis, TIN, GN, and amyloidosis. Mesalamine is a 5-ASA compound which is the mainstay drug for UC. It is known to cause hypersensitivity reactions which may even cause aggravation of UC.

**Case Description:** We present a case of a 23 year old male with a history of UC for 8 years who went to the ED for worsening generalized edema for 3 days. His UA with 3+ protein and no RBCs. UPCR was 7.2 and albumin 1.6 g/dL. Nephrology was consulted for nephrotic syndrome. IV diuresis was started for anasarca. The patient had been taking mesalamine for many years and did not have recent UC flare ups. He did not have history of premature birth, hypertension, or obesity, and had normal kidney size. Urine microscopy showed oval fat bodies. Serological work up was significant for elevated ESR, + MPO and +PR3 antibodies. HIV, CMV, EBV, and parvovirus B19 were negative. A native kidney biopsy was done and it revealed negative IF findings and evidence against active immune complex mediated GN. EM confirmed diffuse podocyte effacement and ultimately glomerular tip lesion variant Focal Segmental Glomerulosclerosis. The patient was started on immunosuppression with corticosteroids, RAAS blockade with ARB, Calcium/ Vitamin D supplementation, PPI, diuretics, and salt restriction. With close outpatient monitoring and tapering of steroids, the patient's proteinuria and edema improved. He continues to follow up with GI and will pursue other treatments for UC once steroids have been completely tapered.

**Discussion:** IBD renal manifestations are usually associated with disease activity and improve with remission of bowel inflammation. Lack of viral causes or UC activity, as well as positive MPO and PR3 antibodies, was more suggestive of a drug induced reaction.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

Mesalazine is renally excreted and the most common reported kidney related adverse reactions is acute or chronic interstitial nephritis due to hypersensitivity reaction usually occurring in the first 6 months of use. Mesalazine induced FSGS must be considered in the differential early on presentation of a patient with nephrotic syndrome to ensure adequate and appropriate treatment to preserve kidney function.

## SA-PO753

### Effects of Hyperuricemia on the Progression of Salt-Sensitive (SS) Hypertension in Dahl SS Rats

Lashodya V. Dissanayake,<sup>1,2</sup> Adrian P. Zietara,<sup>1,2</sup> Vladislav Levchenko,<sup>1</sup> Oleg Palygin,<sup>3</sup> Alexander Staruschenko.<sup>1,4</sup> <sup>1</sup>University of South Florida, Tampa, FL; <sup>2</sup>Medical College of Wisconsin, Milwaukee, WI; <sup>3</sup>Medical University of South Carolina, Charleston, SC; <sup>4</sup>VA James A Haley Hospital, Tampa, FL.

**Background:** Uric acid (UA) is a purine metabolite that has shown both oxidative and antioxidant properties. Increased plasma levels of UA (hyperuricemia) have been associated with hypertension and chronic kidney disease. Variations in dietary salt intake affect plasma and urine UA levels and may be involved in blood pressure and renal function control. We explore conditions of induced mild hyperuricemia and a high salt diet on the development of hypertension using Dahl SS rats, a model of salt-sensitive (SS) hypertension, and chronic administration of oxonic acid. Oxonic acid is a uricase inhibitor that prevents the breakdown of UA further into more soluble allantoin.

**Methods:** 8-week-old Dahl SS male rats were implanted with telemeters. After recovery, BP measurements were collected for 4 days on a 0.4% NaCl diet and switched to either a 4% NaCl diet or a 2% oxonic acid + 4% NaCl diet (treatment, N=4-6) for 3 weeks. Rats were euthanized, and tissue, plasma, and urine were collected for the following analysis.

**Results:** Treatment with oxonic acid for 3-weeks increased plasma UA 5-fold (0.25±0.01 vs. 1.37±0.06 mg/dl, control vs. treated) while decreasing the urine UA excretion (0.33±0.01 vs. 0.19±0.01 UA/Cre). Elevated UA plasma levels were associated with significantly attenuated progression and magnitude of SS hypertension (mean arterial pressure: 159±1 vs. 137±1 mmHg, control vs. treated). Total body weight (TBW) and kidney weight/TBW ratio did not differ. The treatment group had a lower heart weight/TBW ratio (3.98±0.03 vs. 3.64±0.02). Overall, electrolyte homeostasis did not vary between the groups; however, urine Ca<sup>2+</sup> excretion was significantly lower in the treatment group (1.48±0.09 vs. 0.43±0.06 Ca<sup>2+</sup>/Cre).

**Conclusions:** The present study indicates that the increase in UA plasma levels attenuates the progression of SS hypertension. These results may suggest that UA homeostasis may be involved in the regulation of oxidative stress and has a protective effect against salt-induced hypertension.

## SA-PO754

### Salt Sensitivity Is Modulated by Lanosterol Synthase rs2254524 Polymorphism

Sipontina Faienza,<sup>1,2</sup> Lorena Citterio,<sup>2</sup> Elisabetta Messaggio,<sup>2</sup> Laura Zagato,<sup>2</sup> Chiara Lanzani,<sup>2</sup> Marco Simonini,<sup>2</sup> Paolo Manunta.<sup>2</sup> Genomics of Renal Diseases and Hypertension Unit <sup>1</sup>Università Vita Salute San Raffaele, Milano, Italy; <sup>2</sup>IRCCS Ospedale San Raffaele, Milano, Italy.

**Background:** The blood pressure (BP) response to different salt intakes, the so-called salt sensitivity, is more frequent in hypertensive patients compared to the general population. Elevated levels of the steroid hormone Endogenous Ouabain (EO) have been associated with hypertension (HT) and salt sensitivity. We characterized the missense variation rs2254524 (Val642Leu; V642: C variant; L642: A variant) of the Lanosterol Synthase (Lss), a gene coding for a key enzyme in steroid biosynthesis, since AA patients on a low salt diet showed a greater reduction in BP compared to the LSS CC and only CC patients had an increase in plasma EO after the low salt protocol. Hence, we hypothesized that LSS could affect salt-sensitive HT by regulation of EO biosynthesis.

**Methods:** We generated a knock-in mouse model carrying the Lss rs2254524 SNP expression ubiquitously to test our hypothesis. Male mice were fed with a Normal Salt Diet (NSD; 0.5% NaCl), High Salt Diet (HSD; 4% NaCl), or Low Salt Diet (LSD; 0.03 % Na) for 15 days and BP was measured by the BP-2000 Blood Pressure tail-cuff system, in conscious trained mice.

**Results:** Lss AA mice were viable, healthy, and undistinguishable phenotypically from the WT Lss CC. However, the Lss mRNA and protein levels were reduced in the adrenal glands of mutated mice at 3 months and in the kidneys at 6 months of age, whereas no differences were observed at 12 months of age. At baseline, the Lss AA polymorphism affected kidney weight, normalized to body weight, that was significantly enlarged at 3 and 12 months of age, compared to its WT counterpart. Moreover, the Systolic BP (SBP) in Lss WT mice showed a progressive increase at 9 and 12 months of age that was not observed in Lss AA mice. At 3 months, only the AA mice showed a significant SBP reduction after LSD compared to NSD, and upon HSD was observed an SBP increase in AA, but not in CC mice, just at 12 months of age. Moreover, the 12 months mice in HSD showed cardiac hypertrophy, a common feature in hypertensive patients.

**Conclusions:** Extensive studies are still ongoing, but the new Lss mouse model resembles the salt-sensitive HT together with heart hypertrophy observed in hypertensive patients and provides a good model to prove our hypothesis.

**Funding:** Government Support - Non-U.S.

## SA-PO755

### Dendritic Cell-Specific JAK2 Contributes to Salt-Sensitive Hypertension via the Epithelial Sodium Channel

Mohammad Saleem,<sup>1</sup> Luul Aden,<sup>1,2</sup> Ashley L. Pitzer,<sup>1</sup> Jeanne A. Ishimwe,<sup>1</sup> Fernando Elijovich,<sup>1</sup> Cheryl L. Laffer,<sup>1,2</sup> Suman Pakala,<sup>1</sup> Paul D. Kastner,<sup>1</sup> Thomas R. Kleyman,<sup>3</sup> Annet Kirabo.<sup>1</sup> <sup>1</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>2</sup>Vanderbilt University, Nashville, TN; <sup>3</sup>University of Pittsburgh, Pittsburgh, PA.

**Background:** Salt-sensitivity of blood pressure is an independent predictor for death due to cardiovascular disease. We recently found that the epithelial sodium channel (ENaC) on dendritic cells mediates NADPH oxidase-dependent formation of immunogenic isolevuglandin (IsoLG)-protein adducts leading to inflammation and salt-sensitive hypertension. We hypothesized that expression of JAK2 specifically in antigen presenting myeloid cells contributes to salt-sensitive hypertension in an ENaC dependent mechanism.

**Methods:** We used both bulk and single cell transcriptome profiling using RNA-Seq analysis in human antigen presenting cells. We also performed molecular and flow cytometric immune phenotyping along with radio telemetry blood pressure and heart rate monitoring in mice with specific deletion of JAK2 in CD11c+ cells (JAK2 KO). To induce salt sensitivity of blood pressure in otherwise salt resistant C57BL/6 mice, L-NAME was given in drinking water for 2 weeks followed by 3 weeks of high salt treatment.

**Results:** Transcriptomic analyses in human myeloid antigen presenting cells revealed that high salt treatment in vitro and in vivo upregulates genes of the JAK/STAT pathway, and the downstream regulators including the suppressor of cytokine signaling (SOCS) genes. JAK2 KO mice developed blunted hypertension (124.2 vs 137.2 mmHg, SE=3.84, P=0.02) and reduced heart rate compared to the wildtype littermates during L-NAME/high salt treatment. JAK2 KO mice exhibited less infiltration of effector memory T cells (TEM) in kidney and spleen, with profound reduction in inflammatory markers IL-17a and IFN-gamma in CD4+ and CD8+ T cells in spleen. Moreover, there was less aortic infiltration of CD11c+ cells with less expression of CD86, and less production of IsoLGs and IL1-beta in JAK2 KO mice. These mice also exhibited less monocyte/macrophage infiltration in the kidneys and less volume retention in response to high salt-feeding. We also found that salt-induced expression of ENaC subunit g, and serum/glucocorticoid regulated kinase 1 (SGK1) were reduced in the CD11c+ cells.

**Conclusions:** These results indicate that dendritic cell JAK2 plays an important role in salt-sensitive hypertension through an ENaC-dependent mechanism.

**Funding:** Other NIH Support - 1K01HL130497-01, 5R01HL147818-22, 1R03HL155041-01, 1R01HL144941-01A1

## SA-PO756

### Resident Renal Dendritic Cells Respond to Salt-Sensitive Hypertension via ToneBP, Leading to Increased Interleukin 6

Masaaki Yoshigi,<sup>1</sup> Kennedy Cunliffe-Koehler,<sup>1</sup> Amity F. Eaton,<sup>2</sup> Harini Srinivasan,<sup>1</sup> Dennis Brown,<sup>2</sup> Maria A. Battistone,<sup>2</sup> Brandi M. Wynne.<sup>1</sup> <sup>1</sup>University of Utah Health, Salt Lake City, UT; <sup>2</sup>Harvard Medical School, Boston, MA.

**Background:** During hypertension, dendritic cells (DCs) have been shown to activate immune cells and secrete cytokines, such as IL-6. DCs also form an intricate network within the renal cortex. Tonicity-Responsive Enhancer Binding Protein (ToneBP) is a transcriptional regulator of the cellular response to hypertonicity. ToneBP plays a role in the stress response in immune cells. We hypothesize that rDCs respond to increased sodium and salt-sensitive hypertension (SS HTN) via ToneBP, leading to increased IL-6 levels.

**Methods:** To test this hypothesis, mice lacking a functional CX<sub>3</sub>CR1 chemokine receptor (CX<sub>3</sub>CR1<sup>EGFP+/+</sup>) were used. CX<sub>3</sub>CR1 is required for DC localization to the kidney; thus these mice have a renal-specific DC-depletion. Mice were subjected to increased dietary salt (HS, 4%) or normal chow, in addition to a SS HTN model; 2 weeks L-NAME followed by 1-2 weeks of wash-out and then HS chow for the remainder of the study. Pro-inflammatory cytokines using meso-scale design (MSD)(n=3-8) in serum samples. Kidney tissue was used to determine IL-6 mRNA and ToneBP levels (n=4).

**Results:** Renal-dendritic cell depleted mice had a trending increase in ToneBP mRNA expression following HS (2-3weeks), which was significantly increased (2.39 fold change, p<0.0001) during SS HTN. SS HTN rDC-depleted mice had significantly reduced renal ToneBP expression (1.47 fold change, p<0.05) as compared to SS HTN Wt. When looking at IL-6 levels, we observed reductions in renal IL-6 levels (1.5 fold change) in SS HTN rDC-depleted mice compared to SS HTN Wt, with similar trending reductions in serum IL-6 levels.

**Conclusions:** Here, we show that resident renal DCs may be a primary contributor to the renal osmotic stress response by ToneBP, as shown by the considerable reductions in ToneBP mRNA following SS HTN in rDC-depleted mice. In addition, we observed similar reductions in renal and serum IL-6 levels. These data suggest that during SS HTN, DC-mediated ToneBP may contribute to the pro-inflammatory cytokine responses by innate immune cells.

**Kidney-Specific CAP1/Prss8-Deficient Mice Maintain ENaC-Mediated Sodium Balance Through an Aldosterone Independent Pathway**

Elodie Ehret,<sup>1</sup> Yannick Jäger,<sup>1</sup> Frederique Ino,<sup>1</sup> Marc P. Maillard,<sup>2</sup> Edith Hummler,<sup>1</sup> Simona Frateschi.<sup>1</sup> <sup>1</sup>Université de Lausanne Faculté de biologie et de médecine, Lausanne, Switzerland; <sup>2</sup>Centre hospitalier universitaire vaudois Service de néphrologie et d'hypertension, Lausanne, Switzerland.

**Background:** The channel-activating protease 1 (CAP1/Prss8) is a glycoposphatidylinositol-anchored protein and is part of the membrane bound serine protease family. *In vitro* studies revealed CAP1/Prss8 as an activator of the epithelial sodium channel (ENaC). This channel, localized in the distal part and the collecting duct of the nephron, is involved in the maintenance of the electrolytic homeostasis by reabsorbing sodium from the lumen towards the blood. Na<sup>+</sup> deprivation normally results in a rise of plasma aldosterone thereby increasing ENaC activity. It is hypothesized that ENaC is proteolytically cleaved by channel-activating proteases furin and CAP1/prostasin.

**Methods:** To test whether CAP1/Prss8 is required for renal ENaC activation, tubular nephron-specific CAP1/prostasin knockout mice (Prss8<sup>lox/lox</sup>; Pax8-rtTA<sup>tg/+</sup>; TRE-LC1<sup>tg/0</sup>) and control mice were exposed to a low Na<sup>+</sup> diet. Physiological parameters including urinary Na<sup>+</sup> and K<sup>+</sup>, plasma electrolytes, aldosterone levels and renin activity were measured. ENaC activity was determined by benzamil-induced natriuresis.

**Results:** Upon Na<sup>+</sup> deprivation, no changes in Na<sup>+</sup> and K<sup>+</sup> was observed in CAP1/Prss8 knockout mice.  $\alpha$ - or  $\gamma$ ENaC subunit cleavage pattern did not differ. Interestingly, although plasma aldosterone concentration was significantly decreased in CAP1/Prss8 knockout mice, ENaC activity was similar between the two groups, suggesting that the production of aldosterone is uncoupled from the renin-angiotensin system in CAP1/Prss8 knockout mice.

**Conclusions:** In summary, we were able to show that *in vivo*, CAP1/Prss8 was not required for ENaC proteolytic activation. Our experiments revealed that the lack of CAP1/Prss8 uncoupled ENaC activation from the classical renin-angiotensin-aldosterone stimulation on Na<sup>+</sup> restriction. This study reveals a complex regulation of ENaC function including aldosterone-dependent and independent mechanisms.

## SA-PO758

**High Tissue Sodium Associates With Insulin Resistance in Prehypertensive Obese Individuals**

Lale A. Ertuglu, Melis Sahinoz, Elvis A. Akwo, Andrew Guide, Thomas G. Stewart, Mindy Pike, Cassianne Robinson-Cohen, Meena S. Madhur, David G. Harrison, Talat Alp Ikizler. *Vanderbilt University Medical Center, Nashville, TN.*

**Background:** High tissue sodium (Na<sup>+</sup>) accumulation plays a role in the development of hypertension by activation of inflammatory and metabolic pathways. We sought to determine if tissue Na<sup>+</sup> content is associated with insulin sensitivity (IS) in patients with early hypertension, a known metabolic derangement commonly observed in patients with kidney and cardiovascular disease.

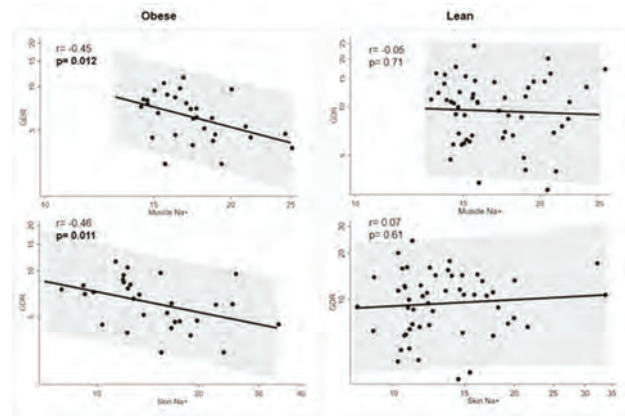

**Methods:** Tissue Na<sup>+</sup> accumulation and IS were assessed in 83 participants with early hypertension (SBP 120 - 139 mmHg or DBP 70 - 89 mmHg) using <sup>23</sup>NaMRI and hyperinsulinemic euglycemic clamp technique. Glucose disposal rate (GDR) was used as the marker of IS. High-sensitivity C-reactive protein (hsCRP) and interleukin 6 (IL-6) were used as markers of inflammation.

**Results:** GDR did not significantly associate with tissue Na<sup>+</sup> in the entire cohort. In subgroup analysis according to obese vs lean, GDR significantly associated with muscle and skin Na<sup>+</sup> among the obese ( $\beta = -1.11$ , 95% CI = -1.99, -0.24 and  $\beta = -0.45$ , 95% CI = -0.83, -0.07 for muscle and skin Na<sup>+</sup>, respectively) but not in lean participants. Among obese participants, there was significant effect modification by the inflammatory markers. The changes in GDR per unit changes in tissue Na<sup>+</sup> were greater at higher levels of hsCRP ( $p = 0.03$  and  $0.01$  for muscle and skin Na<sup>+</sup>, respectively) and IL-6 ( $p = 0.05$  and  $0.01$  for muscle and skin Na<sup>+</sup>, respectively). This was not observed in lean participants.

**Conclusions:** Our data show a significant negative association between muscle and skin Na<sup>+</sup> and IS in the obese, but not in lean individuals with early hypertension. Systemic inflammation may play a key role in the relationship between tissue Na<sup>+</sup> and IS.

**Funding:** NIDDK Support, Private Foundation Support

Characteristic	Overall (n=83)	Obese (n=30)	Lean (n=53)	P-value
Age (years)	48 (36, 58)	49 (38, 58)	48 (34, 55)	0.44
Female, n (%)	56 (67.5)	21 (70)	35 (66)	0.81
African American origin (%)	34 (41)	15 (50)	34 (64.2)	0.25

## SA-PO759

**Tissue Sodium Content and Intramuscular Adipose Tissue Accumulation in Individuals With Early Hypertension**

Lale A. Ertuglu, Melis Sahinoz, Elvis A. Akwo, Andrew Guide, Thomas G. Stewart, Mindy Pike, Cassianne Robinson-Cohen, Meena S. Madhur, David G. Harrison, Talat Alp Ikizler. *Vanderbilt University Medical Center, Nashville, TN.*

**Background:** High tissue sodium (Na<sup>+</sup>) accumulation has been associated with the development of hypertension through activation of inflammatory pathways. Hypertension is also linked with increased adiposity. Whether tissue Na<sup>+</sup> plays a role in this relationship remains unknown. We hypothesized that excess tissue Na<sup>+</sup> in the muscle could lead to intramuscular adipose tissue (IMAT) deposition and that pro-inflammatory characteristics of tissue Na<sup>+</sup> mediate this effect in individuals with early hypertension.

**Methods:** IMAT and Na<sup>+</sup> accumulation in the skin and muscle were measured using <sup>1</sup>H- and <sup>23</sup>Na- MRI imaging of the calf in 83 subjects with early hypertension (systolic blood pressure between 120 and 139 mmHg, or a diastolic blood pressure 70 and 89 mmHg). Blood samples were collected for high-sensitivity C-reactive protein (hsCRP) and interleukin 6 (IL-6) measurements.

**Results:** Median age was 48, with 68% female and BMI 27.5 kg/m<sup>2</sup>. Median muscle and skin Na<sup>+</sup> were 16.6 (IQR: 14.9-19) and 12.6 (IQR: 10.9-16.6) mmol/L, respectively. Median IMAT was 1.3 mL. IMAT was positively correlated with muscle and skin Na<sup>+</sup> ( $r = 0.38$ ,  $p < 0.001$  and  $r = 0.48$ ,  $p < 0.001$ , respectively). There was a significant effect modification of the relationship between IMAT and skin Na<sup>+</sup> by the inflammatory markers in models adjusted for age and sex. The effect of skin Na<sup>+</sup> on IMAT volume increased at high levels of inflammatory markers ( $p = 0.03$  and  $0.01$  for hsCRP and IL-6, respectively).

**Conclusions:** Our data show that high tissue Na<sup>+</sup> concentrations in both skin and muscle associate with increased IMAT, suggesting an adipogenic effect. Systemic inflammation may play a key role in the relationship between skin Na<sup>+</sup> and IMAT, potentially through high sodium-induced systemic inflammatory activation in the skin.

**Funding:** NIDDK Support, Private Foundation Support

The interaction between hsCRP and muscle sodium for the association with IMAT.

## SA-PO760

**Altered Transsulfuration Metabolic Pathway Under GSTM1 Deficiency in Hypertension**

Yves T. Wang, Luoqing Chen, Timothy J. Beane, Nhu Nguyen, Thu H. Le. *University of Rochester Medical Center, Rochester, NY.*

**Background:** Glutathione S-transferase  $\mu$ -1 (GSTM1) belongs to the superfamily of GSTs that are phase II antioxidant enzymes regulated by nuclear factor erythroid 2-related factor 2 (Nrf2). In humans, homozygous carriers of the common *GSTM1(0)* null allele are deficient of the enzyme and its activity and have increased risks of chronic kidney disease (CKD) progression. Global *Gstm1* knockout (KO) mice have increased renal superoxide levels, inflammation, and kidney injury in angiotensin II-induced hypertension (Ang II-HTN). While the upstream regulation of GSTM1 has been delineated, its downstream effects are poorly understood.

**Methods:** We took a metabolomic approach using the service of Metabolon (Morrisville, NC) to perform unbiased, global metabolic profiles of kidney tissues of wild-type (WT) and *Gstm1* KO mice at baseline and after 4 weeks of Ang II-HTN via miniosmotic pump at 1000 ng/kg/min (n=6/group). For confirmation, targeted metabolomics was performed using an LC-MS/MS in negative ion mode. Total hydrogen sulfide ( $H_2S$ ) levels were measured using the formation of methylene blue method (n $\geq$ 6/group).

**Results:** Among the 926 profiled metabolites, levels of several metabolites of the transsulfuration pathway (TSP) and downstream cysteine metabolism were different between WT and *Gstm1* KO mice. Targeted analysis of metabolites in and downstream of the TSP showed that cystathionine was significantly increased in KO vs. WT kidneys in both baseline (3.5-fold, p=0.013) and Ang II-HTN (4.3-fold, p=0.001). Metabolites upstream of cystathionine were not different. Downstream metabolites were unchanged at baseline, but were all reduced ( $\log_2$  (KO/WT) < -0.4) in Ang II-HTN, though the differences of individual metabolites were not statistically significant. Levels of  $H_2S$ , a bioactive end product of the TSP, were significantly reduced in KO kidneys (21.6 $\pm$ 2.9 vs. 28.6 $\pm$ 4.9 nmol/kidney, p<0.01).

**Conclusions:** Our preliminary data suggest that GSTM1 modulates the balance of  $H_2S$ , a gaseous molecule that has emerged as an important modulator of cell metabolism and signaling with pleiotropic effects, including potent anti-oxidant, anti-inflammatory, and vasodilatory functions. Delineation of the impact of GSTM1-TSP- $H_2S$  axis in disease states has important therapeutic implications in kidney and cardiovascular diseases in the context of precision and individualized medicine.

## SA-PO761

**Circulating Monocytes From Patients With Primary Aldosteronism Display Exhaustion on Lipopolysaccharide Stimulation**

Marta Kantauskaite, Blanka Duvnjak, Claudia Schmidt, Fabian Srugies, Thilo Kolb, Eva Koenigshausen, Lars C. Rump, Johannes Stegbauer. *Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany.*

**Background:** Aldosterone excess present in primary aldosteronism (PA) plays a critical role in the development of endothelial dysfunction, oxidative stress and chronic inflammation, which contributes to aggravated hypertensive organ damage. According to animal studies, aldosterone-induced immune cell activation directly contributes to vascular injury. As the monocytes are the main immune cells interacting with vascular wall during the injury, we proposed that patients with PA would demonstrate activated monocytes.

**Methods:** Monocytes from patients (N=9) before and 3 months after the treatment (N=9) and healthy individuals (N=6) were seeded into 96-well plates at 200000 cell/well in RPMI 1640 Dutch-modified culture medium (PAN Biotech) with supplements. After 4 hour rest time the cells were exposed to 10 ng/ml Lipopolysaccharides (LPS) O111:B4 from E.coli for 24 hours. After the incubation supernatants were collected for cytokine, chemokine and growth factor measurements using Bio-Plex Pro Human Cytokine 17-plex Assay. Clinical and laboratory data were collected from patients records.

**Results:** Before the treatment PA patients displayed significantly higher concentrations of following cytokines and growth factors than healthy controls: G-CSF, IFN- $\gamma$ , TNF- $\alpha$ , IL-6, IL-10, IL-8, IL-17, MCP-1. Moreover, before the treatment Aldosterone-Renin-Quotient (ARQ) correlated positively with IL-6 (r 0.667, p=0.05) and MCP-1 (r 0.883, p=0.002). After the treatment was initiated, we have observed normalized blood pressure (median 139/85mmHg vs 130/80mmHg, p<0.05) and significantly lower ARQ (83 (59 – 261) vs 13(3.6 -9.4), p<0.05). In addition, cytokine levels in monocyte supernatants normalized and reached levels similar to healthy controls. Upon the stimulation with LPS, PA patients demonstrated a blunted immune response whereas the treatment restored the cytokine response upon LPS stimulation. Moreover, lower IL-6 (r -0.766, p=0.27), TNF- $\alpha$  (r -0.802, p=0.017) and G-CSF (r -0.719, p = 0.045) concentration upon LPS stimulation was associated with higher diastolic blood pressure.

**Conclusions:** Patients with primary aldosteronism demonstrate higher cytokine levels at a steady state and a type of reversible endotoxin tolerance upon stimulation which might contribute to the increase in blood pressure.

**Funding:** Government Support - Non-U.S.

## SA-PO762

**Insights Into the Role of Atrial Natriuretic Peptide in Mitochondria-Mediated Metabolism in Salt-Sensitive (SS) Hypertension**

Aleksandra Zamaro,<sup>1</sup> Alena Cherezova,<sup>1</sup> Regina F. Sultanova,<sup>2</sup> Ryan Schibalski,<sup>1</sup> Mark Domondon,<sup>1</sup> Morgan J. Spicer,<sup>1</sup> Anna Nikiforova,<sup>2</sup> Mikhail Fomin,<sup>1</sup> Courtney J. Christopher,<sup>3</sup> Shawn R. Campagna,<sup>3</sup> Krisztian Stadler,<sup>4</sup> Daria Ilatovskaya.<sup>1</sup> <sup>1</sup>Augusta University, Augusta, GA; <sup>2</sup>Medical University of South Carolina, Charleston, SC; <sup>3</sup>University of Tennessee Knoxville, Knoxville, TN; <sup>4</sup>Pennington Biomedical Research Center, Baton Rouge, LA.

**Background:** Salt-sensitive (SS) hypertension (SS-HTN) is associated with decreased levels of Atrial Natriuretic Peptide (ANP), and is accompanied with renal mitochondrial dysfunction. Although ANP has been proposed as a modulator of mitochondrial bioenergetics, its role in renal mitochondrial function in SS hypertension is unclear. The present study was aimed at identifying renal metabolic pathways affected in the condition of ANP deficiency modeled in a Dahl SS rat.

**Methods:** Dahl SS wild type (WT) and ANP knockout (KO) rats were placed on a 0.4% NaCl normal salt (NS) diet, or a 4% NaCl high salt (HS, to induce hypertension) for 21 days. Metabolic profiles of renal cortices were generated using UHPLC-HRMS, and metabolites were identified by retention time exact mass using MAVEN and MetaboAnalyst software. IPA was used to identify pathways of interest. Mitochondrial membrane potential, production of H<sub>2</sub>O<sub>2</sub> and respiration were measured on isolated renal cortical mitochondria.

**Results:** 133 mitochondria-associated metabolites were identified in the kidney cortices. When KO and WT groups were compared on NS, in the KO we observed increased abundance of amino acids and their metabolites (p<0.01) as well as uric acid cycle metabolites (citrulline, ornithine, acetylglutamine, p<0.01). Furthermore, we report elevated products of glycolysis in the KO (phosphoenolpyruvate, p<0.01, pyruvate, p<0.05), and significantly lower abundance of purines (ADP, GMP, UMP, p<0.01). Interestingly, KO tissues exhibited low levels of NAD<sup>+</sup> and NADP<sup>+</sup> (p<0.01). We observed similar metabolic processes in the WT rats when HS diet rats were compared to NS diet fed rats. Studies on isolated mitochondria revealed a decrease in membrane potential accompanied with higher OCR and superoxide production in the KO animals on both NS and HS diets, vs WT groups.

**Conclusions:** It can be surmised that lack of ANP in the Dahl SS rats triggers a potential renal glycolytic shift and activation of catabolic pathways. These data support the notion that changes in ANP levels modulate mitochondrial bioenergetics in SS-HTN, and further studies of the related pathways will lead to a discovery of novel therapeutics.

**Funding:** Other NIH Support - HL148114

## SA-PO763

**Revealing Novel Signaling Pathways Affected in Glomeruli During Salt-Sensitive Hypertension**

Fabiha Anwar,<sup>1</sup> Daria Lysikova,<sup>1</sup> Ryan Schibalski,<sup>1</sup> Mark Domondon,<sup>2</sup> Margarita Shamatoval,<sup>1</sup> Krisztian Stadler,<sup>3</sup> Denisha R. Spires,<sup>1</sup> Daria Ilatovskaya.<sup>1</sup> <sup>1</sup>Augusta University, Augusta, GA; <sup>2</sup>Medical University of South Carolina, Charleston, SC; <sup>3</sup>Pennington Biomedical Research Center, Baton Rouge, LA.

**Background:** Salt-sensitive hypertension (SS-HTN) is defined by an increase in blood pressure resulting from an elevated salt intake; it is characterized by the development of hypertensive glomerulosclerosis. There is a gap in knowledge regarding factors that might contribute to glomerular damage in SS-HTN. The goal of this study was to assess the transcriptomic changes that accompany glomerulosclerosis in SS-HTN.

**Methods:** 8-week-old Dahl Salt Sensitive rats were fed a normal (0.4% NaCl, NS) or high salt diet (4% NaCl, HS, to induce hypertension) for 3 weeks. At the endpoint, glomeruli were obtained from the cortex using differential sieving. Total mRNA was isolated from the glomeruli and subjected to NextGen sequencing; transcriptomic data was analyzed using IPA software. The cutoff value for the experimental fold-change (EFC) was 1.5; p value < 0.05 was considered significant.

**Results:** 149 genes were found to be differentially expressed in glomeruli from HS and NS diet fed rats (107 and 42 were down- and up-regulated). We recorded changes in several signaling pathways: GPCR signaling was suppressed, including leptin/melanocortin, AMPK/mTOR, and ERK/MAPK pathways (Elf3 (EFC 1.8); Mc4r (-5.0), Gator2 (-4.3), Azgpl1 (-3.6), Lepr (-2.9), Nr4a1 (-2.4), Pki (-2.5), Rgs2 (-1.8)). We report changes in calcium regulation (Calb (1.6), Cav2.1 (-3.6), Prkce (-3.0), Carf (-2.2), Ip3kb (-1.8)), cellular metabolism (Ltc4s (2.3), Apobec1 (1.5), Sdr42e1 (1.5), Acaca (-3.2), Fads3 (-2.6), Sdhaf3 (-2.3), Ren (-1.9), Cox14 (-1.7), Cyp4f2 (-1.6), Mgl1 (-1.6) Cyp2d22 (-1.5), Ch25h (-1.5), Gnpda2 (-1.5)), immune response, apoptosis, and inflammation (Mrc1 (1.5), NfkB (-2.8), Xiap (-2.8), Fcgr2a (-2.7), Marco (-2), Hla-a (-1.7)), as well as fibrosis and cell proliferation (Myl3 (1.7), Cend2 (1.5), Fmn13 (-3.5), c-Rel (-2.8), Cdk13 (-1.8), Cdkn1b (-1.6), Wnt5a (-1.6)), and solute transporters (Slc14a1 (2.8), Slco1a1 (-2.2), Slc2a10 (-1.7), Slc38a3 (-1.7), Slc6a6 (-1.6), Slc38a6 (-1.5)).

**Conclusions:** We revealed here novel gene networks affected in glomeruli during SS-HTN. Alignment of this data with other existing 'omics analyses is necessary to provide further insight into the development of hypertensive glomerulosclerosis.

**Funding:** Other NIH Support - HL148114

## SA-PO764

**Endothelial Cell-Specific G2APOL1 Expression Induces Hypertension via STING and NLRP3 Pathways**

Bibek Poudel, Joseph Wahba, Allison Vassalotti, Archana Raman, Junnan Wu, Katalin Susztak. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

**Background:** Genetic studies showed an association between ApolipoproteinL1 (APOL1) high risk (G1/G2) genotype and hypertension (HTN) and hypertensive kidney disease (H-CKD). The causal role of APOL1 in the development of HTN and H-CKD is not fully understood.

**Methods:** In the human kidney, APOL1 is highly expressed in endothelial cells and podocytes. We generated endothelial and podocyte-specific inducible G0 and G2 APOL1 transgenic mice by crossing the TRE-G2APOL1 and TRE-G0-APOL1 mice with the endothelial-specific Cdh5tTA and podocyte-specific (NPHS1rtTA) transgenic mice. We induced APOL1 expression by doxycycline diet. In the Cdh5tTA/TRE-G2APOL1 and control mice, we performed uni-nephrectomy (UNX) at five weeks of age and kept mice on a 4% salt diet for 12 weeks. Blood pressure was monitored by the tail-cuff method. To understand the role of the inflammasome (*NLRP3* and *GSDMD*) and the cytosolic nucleotide sensor (STING) in disease development, we crossed the *STING*, *NLRP3*, and *GSDMD* knock-out mice with the Cdh5tTA/TRE-G2APOL1 animals.

**Results:** Podocyte-specific G2APOL1 transgenic mice developed severe HTN only after proteinuria and renal damage was observed, likely representing a secondary HTN. Systolic, diastolic, and mean arterial blood pressure was mildly but significantly higher in Cdh5tTA/TRE-G2APOL1 mice compared to control mice. Cdh5tTA/TRE-G2APOL1 mice also developed a slight increase in urinary albumin/creatinine ratio and renal fibrosis after the animals became hypertensive. Hypertension, renal fibrosis, and proteinuria were ameliorated in *STING*, *NLRP3*, and *GSDMD* knock-out Cdh5tTA/TRE-G2APOL1 mice compared to Cdh5tTA/TRE-G2APOL1 mice. Our preliminary data indicate an increased cytosolic leakage of mitochondrial DNA in Cdh5tTA/TRE-G2APOL1 mice, which is likely responsible for the *STING*, *NLRP3*, and *GSDMD* activation in the Cdh5tTA/TRE-G2APOL1 mice.

**Conclusions:** EC-specific G2APOL1 transgenic mice developed mild salt-sensitive hypertension and renal damage, indicating the causal role of G2APOL1 in hypertension and hypertensive kidney disease, while podocyte-specific G2APOL1 was associated with secondary hypertension. This project was supported by DK105821.

**Funding:** NIDDK Support

## SA-PO765

**The Clinical Conundrum of Secondary Hypertension in Young Adults: A Case of Extreme Renin Elevation Associated With Coarctation of the Aorta**

Rohit K. Gupta, Elizabeth Taber-Hight. *Indiana University School of Medicine, Indianapolis, IN.*

**Introduction:** Hypertension may affect 1 in 8 young adults between 20-40 years of age. In the year 2000, worldwide prevalence of hypertension was estimated as 12.7% in men and 7.4% in women between 20-29 years of age and 18.4% in men and 12.6% in women between 30-39 years of age. Uncontrolled hypertension at a young age is associated with complications such as cardiovascular disease, cerebrovascular accidents and increased mortality that persist into late adulthood. This underscores the need to evaluate hypertension, including secondary causes, in young adults.

**Case Description:** A 27 year-old woman was referred to our clinic for hypertension. She was diagnosed with hypertension at the age of 10. Her hypertension was well controlled with medications (including azilsartan and metoprolol), but no previous work up for secondary hypertension was available. Labs revealed elevated plasma renin of 11300 pg/ml, normal serum aldosterone of 11.5 ng/dl and an aldosterone-to-renin ratio of <0.1. Contrasted computed tomography (CT) revealed severe coarctation of the aorta (COA) with minimal patent lumen. No renin-secreting tumor or renal artery stenosis was identified. Severe COA was confirmed by invasive aortography.

**Discussion:** This case describes an association between severe COA, extreme plasma renin elevation and hypertension. The mechanism behind renin elevation in this situation is unclear. In addition to severe COA with minimal patent lumen and elevated pressure gradients across the coarcted segment identified by CT angiography and invasive aortography, findings such as “dampened upstroke” by renal arterial doppler and moderately-to-severely reduced ankle-brachial indices suggest that renal hypoperfusion may play a role. Use of the angiotensin II receptor blocker azilsartan to control hypertension likely contributed to some degree of plasma renin elevation and relatively suppressed serum aldosterone. It is also notable that plasma renin remained extremely elevated despite concomitant use of metoprolol. Hypertension was reasonably controlled medically, but the patient ultimately underwent coarctation repair of hemodynamically significant, severe COA.

## SA-PO766

**Identification of a Mechanosensor in Juxtaglomerular Cells for the Regulation of Renin Synthesis and Secretion**

Jin Wei, Jie Zhang, Nikita S. Yadav, Jenna Chan, Kshama Patel, Anish R. Thalakola, Ridham Patel, Fady G. Attalla, Garrett D. Meredith, Ruisheng Liu. *USF Health Morsani College of Medicine, Tampa, FL.*

**Background:** Juxtaglomerular (JG) cells are a group of specialized vascular smooth muscle (VSM) cells but distinguished from VSM cells by the synthesis and secretion of renin. However, the intracellular mechanisms of renin release from JG remain elusive.

**Methods:** We performed single-cell RNA seq on a total of 9815 cells that were derived from renal cortex tissue of C57BL/6J mice.

**Results:** Unbiased clustering analysis demonstrated 12 distinct cell clusters. In particular, a cluster consisting of 284 cells was identified as VSM cells by distinct expression of Acta2 ( $\alpha$ -smooth muscle actin). Moreover, based on the co-expression of Ren1 (renin), 34 JG cells were further distinguished from this cluster of VSM cells. We profiled the transcriptome of these JG cells and correlated it with Ren1. The top 5 genes that were most positively correlated with Ren1 expression were Nr2f1, Akr1b7, Smim15, Gng11, and Sdc1. We also compared the transcriptome between JG cells and VSM cells. The top 5 genes that were most differentially expressed in JG cells vs. VSM cells were Ren1, Sfrp2, Akr1b7, Fam46a, and Sdc1. Thus, Akr1b7 and Sdc1 could be potential candidate genes that participate in the control of Ren1 expression in JG cells. In the present study, we examined the role of Sdc1 (syndecan-1) in the regulation of renin synthesis and secretion in response to perfusion pressure changes with both *in vitro* model of isolated/perfused afferent arteriole (Af-Art) and *in vivo* model of 2 kidneys 1 clip (2K1C). We found that low perfusion pressure through Af-Art increased Ren1 mRNA expression by 140.7 $\pm$ 24.8% while high perfusion pressure decreased the expression by 66.2 $\pm$ 13.1% compared to normal perfusion pressure in WT mice. However, the perfusion pressure alteration-induced changes in Ren1 expression were significantly attenuated in SDC1KO mice (n=4-5; p<0.05). Additionally, 2K1C increased renin expression in low-pressure kidney by 163.3 $\pm$ 48.7%, plasma renin and Ang II concentrations by 118.2 $\pm$ 61.4% and 162.8 $\pm$ 50.2%, and mean arterial pressure by 31.6 $\pm$ 5.7 mmHg. However, the 2K1C-induced changes were significantly reduced in SDC1KO mice (n=5-7; p<0.01).

**Conclusions:** In conclusion, this study demonstrates that syndecan-1 is a key mechano-sensor in JG cells that regulates the renin synthesis and secretion.

**Funding:** Other NIH Support - NHLBI

## SA-PO767

**Spontaneous Renal Artery Dissection**

Khaldoon Aljassani, Rimsha Ali, Taaha M. Mirza. *University of Pittsburgh Medical Center UPMC, Pittsburgh, PA.*

**Introduction:** Renal artery dissection is frequently seen as an extension of aortic dissection, but bilateral Spontaneous Renal Artery Dissection (SRAD) is an extremely rare condition that has only been described in case reports. The clinical presentation is variable and renal infarction is a frequent consequence.

**Case Description:** A 41-year-old male with insignificant past medical history presented with a sudden onset left sided sharp flank pain, 7/10 in intensity, non-radiating, no dysuria, hematuria, frequency. His routine labs on presentation were benign apart from mild elevation in white blood cell count and elevation of creatinine from baseline. CT abdomen with contrast showed left kidney infarction with large thrombus in the left renal artery. Coagulation profile and thrombophilia work up was negative. Heparin infusion was started, the patient's pain and renal function improved, discharged on apixaban. 3 days later he presented with right flank pain with hematuria, face puffiness and lower limb swelling, hypertension. Initial work up showed elevated creatinine, ESR and CRP, LDH, D dimer, mild transaminitis. CT abdomen and pelvis with contrast showed parital right kidney infarct with filling defect in the right renal artery suspicious for a dissection. Patient was started on heparin infusion, steroids and azathioprine. Further autoimmune work up was negative. Peripheral smear, bone marrow biopsy, MRI angiography of the head and neck was normal. IR angiogram of the renal arteries showed bilateral renal artery dissection. A stent was placed in the right renal artery, improving right renal blood flow to the residual right renal parenchyma. No significant flow was identified in the left renal artery.

**Discussion:** SRAD is a rare phenomenon with incidence of 0.05% of all artery dissections (1). Spontaneous bilateral renal artery dissection is an exceedingly rare condition described in case reports. (2, 3) The etiology has not been clearly defined; however Fibromuscular Muscular Dysplasia is noted to be associated with the development of SRAD, which is what we expected as the likely cause in our patient. The presentation of SRAD is variable, usually asymptomatic (C), unless it leads to renal infarction. A CT angiogram can be used to diagnose renal artery dissection as with most dissections. Treatment focused is on surgical revascularization and nephrectomy is only opted for if there is a high infarction burden.

## SA-PO768

### Deletion of AT1a Receptors Selectively in the Proximal Tubules of the Kidney Augments Glomerular Filtration in Male and Female PT-Agr1a<sup>-/-</sup> Mice

Xiao C. Li, Jia L. Zhuo. *Tulane University School of Medicine, New Orleans, LA.*

**Background:** It is well recognized that circulating angiotensin II (Ang II) plays a key role in the regulation of glomerular filtration via activation of AT<sub>1</sub> (AT<sub>1a</sub>) receptors. However, whether Ang II and AT<sub>1</sub> (AT<sub>1a</sub>) receptors in the proximal tubules play an important role in the regulation of glomerular filtration remains unknown.

**Methods:** We tested the hypothesis that deletion of AT<sub>1a</sub> receptors selectively in the proximal tubules augments glomerular filtration in male and female PT-Agr1a<sup>-/-</sup> mice. PT-Agr1a<sup>-/-</sup> mice were generated using the iL-Sgt2-Cre/Agr1a-floxed approach. Two groups of adult male and female wild-type (WT) and PT-Agr1a<sup>-/-</sup> mice were infused with or without a slow pressor dose of Ang II for 2 weeks via an osmotic minipump (~500 µg/kg body wt./day, i.p.). Whole-kidney glomerular filtration rate (GFR) was determined using the transdermal GFR monitoring technique with FITC-sinistrin (MediBeacon, 10 mg/100 g body wt. i.v.).

**Results:** In WT mice, basal systolic blood pressure was 116 ± 3 mmHg, which increased to 146 ± 5 mmHg in response to Ang II infusion ( $P < 0.01$ ). Basal GFR was 160.8 ± 14.4 µl/min in male (n=9) and 149.9 ± 18.4 µl/min in female mice (n.s., n=7). In response to Ang II infusion, GFR was significantly decreased by ~25% to a similar extent in male and female WT mice ( $P < 0.01$ ). By comparison, basal systolic blood pressure was 13 ± 2 mmHg lower in age-matched male (n=13) and female (n=10) PT-Agr1a<sup>-/-</sup> mice ( $P < 0.01$ ). In response to Ang II infusion, systolic blood pressure increased to 128 ± 3 mmHg in male and female PT-Agr1a<sup>-/-</sup> mice ( $P < 0.01$ ). Interestingly, basal GFR was ~20% higher in male (190.6 ± 11.0 µl/min,  $P < 0.05$ , n=10) and ~30% higher in female PT-Agr1a<sup>-/-</sup> mice (203.8 ± 21.5 µl/min,  $P < 0.05$ , n=9) than WT mice, respectively. In response to Ang II infusion, GFR was significantly decreased by ~25% in male PT-Agr1a<sup>-/-</sup> mice (155.9 ± 20.0 µl/min,  $P < 0.01$ , n=10). However, Ang II infusion had no significant effect on GFR in female PT-Agr1a<sup>-/-</sup> mice (191.2 ± 18.8 µl/min, n.s., n=7).

**Conclusions:** Our findings suggest that deletion of AT<sub>1a</sub> receptors selectively in the proximal tubules inhibits AT<sub>1a</sub> receptor-mediated, Ang II-stimulated proximal tubule sodium reabsorption, which increases the end proximal tubule sodium delivery to the macula densa and impairs the tubuloglomerular feedback response in PT-Agr1a<sup>-/-</sup> mice.

## SA-PO769

### Regulation of Edn1 by Its Antisense Long Non-Coding RNA, Edn1-AS

Alexandria Juffre, Lauren G. Douma, Charles S. Wingo, Michelle L. Gumz. *Gumz Laboratory University of Florida, Gainesville, FL.*

**Background:** The peptide hormone endothelin-1 (ET-1) decreases renal sodium reabsorption by inhibiting epithelial sodium channel (ENaC) activity. Dysfunctional regulation of sodium handling can cause hypertension and ET-1 is a therapeutic target. We discovered a long non-coding RNA (lncRNA), Edn1-AS, which is antisense to the Edn1 mRNA. Using CRISPR-modified human proximal tubule cells (HK-2), we previously found that cis over-expression of Edn1-AS (expressed from the same locus as Edn1) resulted in increased ET-1 levels in cultured human proximal tubule cells (HK-2). The goal of this study was to test the effect of trans-overexpression of Edn1-AS (from an exogenous DNA construct) on Edn1 expression. Based on our previous results, we hypothesized that trans over-expressing Edn1-AS in collecting duct cells would increase ET-1 mRNA expression.

**Methods:** Inducible Edn1-AS overexpressing IMCD-3 and mpkCCD cells were generated using Tet-ONE systems (Takara Clontech), which increases Edn1-AS expression after treatment with doxycycline. Edn1-AS lncRNA and Edn1 mRNA levels were determined by strand-specific RT-PCR or qPCR.

**Results:** Similarly to cis over-expression in HK-2 cells, trans over-expression of Edn1-AS in IMCD-3 and mpkCCD cells showed increased Edn1 levels (n=3,  $p < 0.05$  by unpaired t-test).

**Conclusions:** Consistent with our previous results in HK-2 cells, increased Edn1 expression was observed in Edn1-AS overexpressing IMCD-3 and mpkCCD cells. These data suggest that Edn1-AS is a positive regulator of Edn1, regardless of whether Edn1-AS is over-expressed in a cis or trans manner. Subsequent studies will seek to determine the mechanism of action of Edn1-AS on Edn1 expression which may involve chromatin remodeling. Future investigation of Edn1-AS's regulation of Edn1 could lead to the identification of novel therapeutic targets for treatment of hypertension.

### Bone Marrow Indoleamine 2, 3-Dioxygenase Deficiency Attenuates CKD Associated Atherosclerosis

Biaoxin Chai, Vetalise K. Chefor, Lixia Zeng, Dheer Patel, Max Keller, Nancy F. Roeser, Jaeman Byun, Anna V. Mathew. *Mathew Lab, University of Michigan University of Michigan, Ann Arbor, MI.*

**Background:** Non-traditional risk factors like inflammation and oxidative stress play an essential role in the increased cardiovascular disease (CVD) risk prevalent in chronic kidney disease (CKD). Indoleamine 2, 3-dioxygenase (IDO1) catabolizes amino acid tryptophan to kynurenine in immune cells and extrahepatic tissues. IDO1 expression and activity are linked to atherosclerosis and renal function in clinical and experimental models. However, the mechanistic link between bone marrow IDO1 expression and CKD accelerated atherosclerosis is unknown.

**Methods:** Male LDLr<sup>-/-</sup> mice underwent sham surgery or 5/6 nephrectomy (CKD) and were placed on a high-fat/high-cholesterol diet (HFD) for 16 weeks. Tryptophan and kynurenine levels were measured using targeted mass spectrometry in the plasma, urine, and tissues. We designed a metabolic flux study using intraperitoneal injection of <sup>13</sup>C<sub>11</sub> tryptophan to delineate the contribution of decreased renal excretion vs. increased production in specific tissues in CKD mice. We then created a chimeric 5/6 nephrectomized male LDLr<sup>-/-</sup> mice with bone marrow from control and IDO1<sup>-/-</sup> mice, respectively, to demonstrate the role of IDO1 in CKD atherosclerosis. We quantified atherosclerosis with Oil Red-O staining of *en face* aortic sections. We measured changes in macrophage apoptosis, phagocytosis, and cytokine profiles with IDO1 deficiency.

**Results:** CKD mice demonstrate lower circulating tryptophan and increased kynurenine to tryptophan ratio (KTR, marker of IDO activity) at baseline and the end of diet than controls. CKD mice demonstrate increased IDO expression and activity in aortic tissue and bone marrow cells. The metabolic flux study revealed that the CKD mice had increased label in kynurenine pools of vascular and bone marrow tissues confirming increased IDO1 activity in these tissues. IDO1 deficiency in the bone marrow of male CKD LDLr<sup>-/-</sup> mice decreases atherosclerosis compared to CKD mice with intact bone marrow IDO1 expression. Activated human macrophage cultures reveal that IDO1 depletion increases macrophage apoptosis and decreases phagocytosis and cytokines.

**Conclusions:** In summary, IDO1 depletion in the bone marrow of CKD mice decreased atherosclerosis by its action on macrophage apoptosis, phagocytosis, and cytokine profiles.

## SA-PO771

### Activin A Is a Potential Mediator of TGFβ1-Induced Tubulointerstitial Fibrosis

Asfia Soomro, Renzhong Li, Dan Zhang, Kian S. O'Neil, Melissa Macdonald, Bo Gao, Joan C. Krepinsky. *McMaster University, Hamilton, ON, Canada.*

**Background:** Chronic kidney disease (CKD) is a rising health issue in North America, characterized by progressive renal fibrosis often leading to organ failure. TGFβ1 is a central mediator of fibrosis in CKD of diverse etiology, but its direct inhibition is limited by adverse effects. We recently showed in glomerular mesangial cells (MC) that activin A (ActA) mediates TGFβ1 profibrotic effects through regulation of both canonical Smad3 and noncanonical MRTF-A signaling. Here we study the potential role of ActA in the development of tubulointerstitial fibrosis (TIF), a major determinant of kidney function decline in CKD. We further assess the promoter regulation of ActA by TGFβ1.

**Methods:** Renal fibrosis was induced in mice overexpressing (OE) TGFβ1 using 2 models: 5/6 nephrectomy (Nx) and unilateral ureteral obstruction (UUO). UUO mice were treated with a neutralizing ActA antibody to assess effects on fibrosis. Primary mouse MC, human renal proximal tubular epithelial cells (PTEC, HK2) and rat renal fibroblasts (RF) were used. ActA and Activin B (ActB) were inhibited with a neutralizing antibody or follistatin. Transcriptional activity of the ActA promoter was studied using a luciferase reporter plasmid and a series of deletion constructs.

**Results:** TGFβ1 OE augmented fibrosis and activin levels in Nx and UUO. ActA neutralization inhibited Smad3 activation and fibrosis after UUO in wild-type and TGFβ1 OE mice. In both models, ActA and B were significantly increased in tubular cells, which largely colocalized to PTEC identified by megalin. We thus studied the potential role of activins in tubular-fibroblast crosstalk. TGFβ1 increased secretion of ActA and B from HK2 cells, with a greater ActA effect. Media from HK2 treated with TGFβ1 induced RF Smad3 activation and fibrotic responses (matrix synthesis, αSMA induction). These were blocked by follistatin or ActA, but not ActB, neutralization. In MC, we found the -350bp region of the ActA promoter is required for TGFβ1 regulation. Interestingly, a novel CT microsatellite site upstream of this which suppressed promoter activity was also identified.

**Conclusions:** ActA is induced by TGFβ1 and mediates its profibrotic effects, with relevance to both glomerular and TIF. Its inhibition is being evaluated as a novel treatment for fibrosis in CKD.

## SA-PO772

### Loss of Serum and Glucocorticoid Kinase 1 (SGK) in T Cells Abrogates Memory T Cell Formation, Hypertension, and End-Organ Damage

Dina Maaliki,<sup>1</sup> Maha M. Itani,<sup>1</sup> Hala H. Jarrah,<sup>1</sup> Carla El-Mallah,<sup>1</sup> Omar Obeid,<sup>1</sup> Miran A. Jaffa,<sup>1</sup> Hana A. Itani.<sup>1,2</sup> <sup>1</sup>American University of Beirut, Beirut, Lebanon; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN.

**Background:** NaCl concentrates in tissues over time and activates immune cells including T<sub>H</sub>17 cells and dendritic cells, which are known to contribute to hypertension, in a Serum/Glucocorticoid Kinase 1 (SGK1)-dependent fashion. In addition to T<sub>H</sub>17 cells and dendritic cells, memory T cells play a vital role in hypertension genesis. Long-lived memory cells generate a systemic inflammatory response through mobilization to target organs and release of cytokines. To understand the mechanisms by which memory T cells sense salt, we tested the hypothesis that SGK1, an important intracellular sensor of Na<sup>+</sup>, in T cells is necessary for the formation of memory T cells and their mediation of salt sensitive hypertension and organ damage.

**Methods:** We employed mice with T cell-specific deletion of SGK1, SGK1<sup>fl/fl</sup> x tgCD4<sup>cre</sup> mice, and used SGK1<sup>fl/fl</sup> mice as controls. To mimic repeated exposure to hypertensive stimuli, we treated mice with L-NAME (0.5mg/ml) in drinking water for 2 weeks, allowed a 2-week washout interval, followed by a high salt(HS) diet (4% NaCl) for 3 weeks.

**Results:** L-NAME/HS significantly increased blood pressure as well as memory T cell infiltration in the kidney, aorta, and bone marrow of SGK1<sup>fl/fl</sup> mice, as compared to SGK1<sup>fl/fl</sup> x tgCD4<sup>cre</sup> mice. SGK1<sup>fl/fl</sup> mice also demonstrated caused striking albuminuria, cortical fibrosis, cortical ROS generation and increased renal IFN-γ and NGAL expression

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

after L-NAME/HS. Myography studies demonstrated an impaired relaxation in response to acetylcholine but not sodium nitroprusside in mesenteric arterioles from SGK1<sup>fl/fl</sup> mice, but not SGK1<sup>fl/fl</sup> x tg CD4<sup>cre</sup> mice. T cells were sorted and adoptively transferred from the bone marrow of CD45.2 SGK1<sup>fl/fl</sup> x tgCD4<sup>cre</sup> mice or SGK1<sup>fl/fl</sup> controls that had undergone the L-NAME/HS protocol, to recipient CD45.1 mice. Recipient mice were then fed a HS diet for 3 weeks. Strikingly, mice that had received T cells from SGK1<sup>fl/fl</sup> donors exhibited significantly increased blood pressure and renal memory T cell infiltration, compared to mice that had received cells from SGK1<sup>fl/fl</sup> x tgCD4<sup>cre</sup> donors.

**Conclusions:** Our data suggest a new therapeutic target to reduce the formation of hypertension-specific memory T cells, which will protect against hypertension and end-organ damage in response to repeated hypertensive stimuli.

### Histone Deacetylase 9 Contributes to Vascular Calcification in CKD

Lin Xiong, Qiong Xiao, Chen Rong, Yun Tang, Li Wang, Yi Li, Guisen Li. *Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China.*

**Background:** Vascular calcification (VC) is a serious complication of chronic kidney disease (CKD). Unfortunately, there is no effective therapy for VC beyond supportive care due to the complex pathogenesis of VC. Histone deacetylase 9 (HDAC9) could regulate the transdifferentiation of vascular smooth muscle cells in atherosclerotic aortic calcification. However, the role of HDAC9 in VC upon CKD is unclear. The purpose of this study was to investigate the role and mechanism of HDAC9 in VC upon CKD.

**Methods:** Rat aortic smooth muscle cells (RASMCs) were divided into control and calcification group. The calcification group was induced with  $\beta$ -glycerophosphate and CaCl<sub>2</sub>. RASMCs were incubated with Alizarin Red S stain to detect calcification. Real-time quantitative PCR (RT-PCR) and western blotting (WB) were utilized to detect the expression level of HDAC9. 30 male wild-type Wistar rats were randomly divided into six groups (n=5): 4- and 16-week control groups, and 4-, 8-, 12-, and 16-week VC groups. The VC model of CKD in rats was established by 5/6 nephrectomy combined with high phosphorus chow. Rat aortas were collected and stained with alizarin red to detect VC. Subsequently, the expressions of HDAC9 were detected by third generation sequencing and immunohistochemical staining.

**Results:** *In vitro*, alizarin red staining showed the RASMCs in the calcified group had more calcium salt deposition compared with the control group. Both WB and RT-PCR showed the expression of HDAC9 in calcified cells was increased. *In vivo*, alizarin red staining of the aorta showed the vascular calcium deposition in the calcification group was significantly higher than that in the control group. In the third-generation full length transcriptome sequencing of rat aorta, the RNA expression of HDAC9 in calcification group increased gradually from 4 weeks to 12 weeks, and was significantly higher than that in 4- and 16-week control groups; From 12 to 16 weeks, the RNA expression of HDAC9 began to decline, but it was still higher than that of the 4-week and 16-week control groups. Moreover, immunohistochemical staining also indicated the expression of HDAC9 in the aorta of the 12-week calcification group was significantly increased, relative to the 4- and 16-week control groups.

**Conclusions:** Histone deacetylase 9 could contribute to development of vascular calcification in chronic kidney disease.

## SA-PO774

### Olfactory Receptor 558 (Olfr558) Is Required for Sex Differences in Blood Pressure

Jiaojiao Xu,<sup>1</sup> Rira Choi,<sup>1</sup> Helen R. Warren,<sup>2</sup> Kunal Gupta,<sup>1</sup> Lakshmi Santhanam,<sup>1</sup> Jennifer L. Pluznick.<sup>1</sup> *<sup>1</sup>Johns Hopkins University School of Medicine, Baltimore, MD; <sup>2</sup>Queen Mary University of London Barts and The London School of Medicine and Dentistry, London, United Kingdom.*

**Background:** Olfactory receptor 558 (Olfr558) is expressed in the kidney where its functional role is unknown.

**Methods:** Olfr558 was localized using RNAScope. Systolic (SBP), diastolic (DBP), and mean arterial pressure (MAP) was measured in whole-body Olfr558 wild-type (WT) and knockout (KO) via telemetry. Expression was analyzed by qPCR, plasma renin activity (PRA) was measured by ELISA, and vasoreactivity was examined *ex vivo* by wire myography (responses to potassium chloride (KCl), phenylephrine (PE), acetylcholine (ACh), and sodium nitroprusside (SNP) in aortic and mesenteric rings). In females, pulse wave velocity (PWV) and tensile testing were performed. Using UK Biobank data (N~450k), we performed genetic analyses of DBP, testing for sex-interaction effects.

**Results:** Olfr558 localizes to renal vascular smooth muscle cells, including the renal afferent arteriole. It is known that males have a higher BP than premenopausal females in both humans and mice; indeed, we find that Olfr558 WT males (M) had a higher BP than females (F, n=7-9 per group), including MAP (M:101.0±1.6 vs. F:89.0±0.9 mmHg, *p*<0.0001), SBP (M:113±2 vs. F:102±1mmHg, *p*=0.003), and DBP (M: 89±2 vs. F:75±0.1mmHg, *p*<0.0001). These sex differences in BP were absent in Olfr558 KO (MAP M: 96±2 vs. F: 95±1mmHg; SBP M: 110±2 vs. F: 108±2mmHg; DBP M: 81±2 vs. F: 82±2mmHg). However, other sex differences (body weight) are intact in KO, and KO males and females are fertile. In male KOs (n=10-12), kidney renin mRNA was decreased (0.4±0.1 vs WT: 1±0.1 *p*=0.001), as was PRA (201±21 vs WT: 402±15, *p*=0.001); these parameters were unchanged in female KOs. Male KO aortic rings exhibited less constriction to PE, male KO mesenterics exhibited more relaxation to SNP, and female KO aortic rings exhibited more constriction to KCl. KO females have increased PWV (KO: 4.6±0.4 vs WT: 3.2±0.2 m/s, *p*=0.007, n=8-11), but no changes in tensile testing. The OR51E1 (the human ortholog of Olfr558) gene region was recently reported for

association with DBP (PMID 30224653). Our UK Biobank analyses demonstrate a sex-specific effect for the lead variant rs17224476, with effects on DBP differing significantly (*p*=0.01) between men vs women.

**Conclusions:** Olfr558 is required for sex differences in BP in mice. Olfr558 regulates BP in males via renin and vascular reactivity, but via arterial stiffness in females.

**Funding:** Other NIH Support - R56DK107726

## SA-PO775

### Full-Length Klotho and Secretase BACE1 Are Upregulated in Human Hearts From Patients With Advanced CKD

Gayatri Narayanan,<sup>1</sup> Arvin Halim,<sup>1</sup> Neal X. Chen,<sup>1</sup> Sharon M. Moe,<sup>1</sup> Tzongshi Lu,<sup>2,3</sup> Kenneth Lim.<sup>1</sup> *<sup>1</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>2</sup>Brigham and Women's Hospital, Boston, MA; <sup>3</sup>Harvard Medical School, Boston, MA.*

**Background:** Klotho is an anti-aging protein that has demonstrated remarkable cardiovascular-protective effects. Klotho-deficient mice develop extensive cardiovascular disease that resembles advanced CKD patients; conversely Klotho supplementation rescues this phenotype. Klotho is cleaved into several soluble isoforms that constitute its KL1 and/or KL2 ectodomains by proteases ADAM10, ADAM17, and BACE1. To-date, the expression profile and natural history of Klotho and its regulatory enzymes locally in hearts from patients with CKD is largely undefined. Herein, we performed molecular phenotyping of the local Klotho hormonal system in explanted human donor hearts from patients with CKD.

**Methods:** We analyzed human left ventricular tissues from advanced CKD donors (hemodialysis, HD; n=19), patients with hypertension with preserved renal function (HTN; n=11), and healthy controls (CON, n=19) collected in the Cardiovascular Aging in CKD (CAIN) cohort. Hearts were subjected to gross pathologic and molecular analysis, including Masson's Trichrome staining, immunohistochemistry and immunoblotting.

**Results:** HD and HTN hearts exhibited significantly higher heart weight relative to body surface area (BSA) compared to CON hearts (*p*<0.001). HD hearts had significantly thicker left ventricular walls compared to CON hearts (*p*<0.007). There was greater fibrosis staining in HD hearts compared to HTN (*p*<0.008) and CON hearts (*p*<0.001). Significantly, HD hearts exhibited greater upregulation of full-length Klotho compared to HTN (*p*<0.008) and CON hearts (*p*<0.002). There was no significant difference in full-length Klotho expression between HTN and CON hearts (*p*=0.7). Interestingly, we did not detect KL1 and KL2 isoforms in human hearts. Moreover, HD hearts exhibited increased BACE1 (*p*<0.02) compared to HTN and CON hearts. There were no significant differences in ADAM10 or ADAM17 expression in hearts between the three groups (*p*>0.1).

**Conclusions:** Full-length Klotho and BACE1 are upregulated in hearts from advanced CKD patients. These results suggest that increased local Klotho expression may be an adaptive response in advanced CKD. Cleavage of myocardial Klotho may be driven by BACE1 in diseased hearts from patients with CKD. Further studies to elucidate the mechanisms and regulation of myocardial Klotho are warranted.

**Funding:** NIDDK Support

## SA-PO776

### Novel Evidence for an Enhanced Intrarenal Machinery of Estrogen Biosynthesis in the Female Rat Kidney

Victoria L. Nasci,<sup>1</sup> Alison J. Kriegel,<sup>2</sup> Eman Y. Gohar.<sup>1</sup> *<sup>1</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>2</sup>Medical College of Wisconsin, Milwaukee, WI.*

**Background:** Hypertension is more prevalent in men than age-matched premenopausal women. We recently showed that activation of the G-protein coupled estrogen receptor 1 in the renal medulla promotes natriuresis in female (F), but not male (M), Sprague Dawley (SD) rats. Whether renal medullary GPER1 is activated by circulating or locally produced estrogen is unknown. Some extragonadal tissues, such as the brain, express aromatase, the key enzyme in estrogen biosynthesis, which acts locally to convert testosterone to estradiol (E<sub>2</sub>). We hypothesized that the kidneys are capable of producing E<sub>2</sub> and this intrarenal steroidogenic capability is enhanced in F rats.

**Methods:** To test this, we assessed the expression of elements of the estrogen biosynthesis pathway in M and F SD rat kidneys with a focus on the medulla as it plays a major role in sex-related differences in sodium handling.

**Results:** Mass spectrometry (MS) imaging of kidney sections revealed greater abundance for cholesterol sulfate, a substrate which can be used in sex steroid production, in F compared to M kidneys. This sex-specific difference in renal cholesterol abundance was driven by medullary differences (F: 4.98x10<sup>6</sup> ± 0.4 x10<sup>6</sup>; M: 2.2 x10<sup>6</sup> ± 0.2 x10<sup>6</sup> average peak intensity *P*=0.0001). RNA sequencing of the renal inner medulla analyzed via Ingenuity Pathway Analysis revealed that 23% of sequenced transcripts encoding proteins within the estrogen biosynthesis pathway were greater, and 8% were lower, in F vs M rats, suggesting activation of this pathway in F kidneys. Of interest, Cyp19a1, which encodes for aromatase, was 2.7-fold higher in F compared to M inner medulla. Whereas inner medullary expression of Cyp2c11, which encodes an enzyme that converts testosterone to 2 $\alpha$ -OH-testosterone, was 13-fold lower in F vs M. Increasing salt intake promoted Cyp19a1 mRNA expression in F, but not M, inner medulla (*P*=0.04). Using LC-MS, we found greater levels of tissue E<sub>2</sub> within inner medullary tissues of F kidneys compared to M (28.9 ± 7.8 vs 9.3 ± 2.0 pg/ $\mu$ l/mg *P*=0.0323).

**Conclusions:** Overall, our investigation of renal estrogen biosynthesis reveals greater expression of the substrate, key enzyme, and end product as well as pathway enrichment in F compared to M kidneys. This points to the kidney as an extragonadal site for E<sub>2</sub> biosynthesis, which could provide insight into sex-differences in renal disease.

## SA-PO777

**Kidney Specific BMAL1 Knockout Reveal Differences in Circadian Rhythms of Blood Pressure Following a Low Potassium/High Salt Diet**  
Charles B. Drucker, G. R. Crislip, Hannah M. Costello, I. Jeanette Lynch, Charles S. Wingo, Michelle L. Gumz. *University of Florida College of Medicine, Gainesville, FL.*

**Background:** Circadian rhythms are present in various physiologic functions, with irregularities being linked to cardiovascular disease, including hypertension, in humans. Previously, we have shown that knocking out the circadian clock factor BMAL1 in renal distal nephron and collecting duct cells of male mice (KS-BMAL1 KO) led to lower systolic blood pressure (SBP) than control mice (CNTL) with no effect on daily rhythms under a normal diet. Additionally, this effect was increased following a low potassium/high salt diet (OKHS; 4% NaCl). Our goal for this study was to determine if there were any genotype differences in circadian rhythms of SBP following a OKHS diet.

**Methods:** SBP was measured via telemeter implants (N=7-8). KS-BMAL1 KO and CNTL were placed on a normal diet for 3 days, OK diet for 7 days, and then a OKHS diet for 10 days. Cosinor analysis on SBP was performed for each mouse during the last 3 days of normal and OKHS diets to calculate mesor (midline estimating statistic of rhythm), amplitude (the extent of predictable change within a cycle), period (duration of a cycle from peak to peak), and acrophase (time at which the peak of a rhythm occurs). Two-way ANOVA with post-hoc analysis to compare between genotypes following OKHS is provided.

**Results:** As expected, the mesor for SBP was lower in KS-BMAL1 KO compared to CNTL following OKHS ( $p=0.0005$ ). OKHS increased mesor compared to normal diet. There were no differences between genotypes in the period. OKHS diet also had no effect on SBP period. The period ranged from 23.0-24.9 hours. KS-BMAL1 KO had lower amplitude in SBP than CNTL following OKHS ( $p=0.04$ ). Additionally, OKHS increased amplitude compared to normal diet in both groups ( $p<0.0001$ ). There was no difference between genotypes in acrophase, however, OKHS advanced the acrophase in both groups ( $p<0.0001$ ).

**Conclusions:** Treatment with OKHS affects rhythms of SBP by increasing the amplitude and advancing the acrophase, suggesting a role for diet in causing circadian disruption. BMAL1 within distal nephron and collecting duct cells contributes to SBP regulation following OKHS and the amplitude of rhythms.

**Funding:** NIDDK Support, Veterans Affairs Support, Private Foundation Support

## SA-PO778

**Circadian Clock Provides Beneficial Effects Against the Dysfunction in Endothelial Signaling by Regulating Heme Synthesis and Heme Oxygenase-1 Expression**  
Hideyuki Negoro,<sup>1,2</sup> <sup>1</sup>Harvard Medical School, Boston, MA; <sup>2</sup>The Graduate School of Project Design, Tokyo, Japan.

**Background:** The circadian clock is a molecular mechanism that confers 24 hours variations in gene expression and function to regulate many physiological functions. Chronic circadian clock disruption is associated with vascular stiffness and dysfunction in endothelial signaling and responses. Heme is a ligand of REV-ERB $\alpha$  and REV-ERB $\beta$  which modulate circadian rhythms by binding to the ROR region of CLOCK or BMAL1 to suppress the expression of these genes. 5-Aminolevulinic acid (ALA) is the common precursor of heme. The iron ion is inserted into PpIX to form heme in the mitochondria and incorporated into hemoproteins. Heme oxygenase-1 (HO-1) is an intracellular enzyme which catalyzes the oxidation of heme to generate ferrous iron, carbon monoxide, and biliverdin, which is subsequently converted to bilirubin. These products have anti-inflammatory, anti-apoptotic and anti-thrombotic properties. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influence HO-1 which play an important part in the protection of vascular diseases.

**Methods:** Congenic 12- to 16-week-old male, wild-type and Bmal1-KO littermate mice were generated from heterozygote breeding to be used for these studies. We also knocked down Bmal1 to evaluate the protein levels of HO-1 expression in the knocked down cells. To synchronize circadian rhythms, serum stimulations were performed. Cells were also pre-incubated with or without 1 mM ALA and 0.5 mM sodium ferrous citrate (SFC).

**Results:** In aorta from Bmal1 KO mice, there was a reduction in HO-1 expression in mice with a dysfunctional circadian rhythm. Bmal1 KO mice display pre-mature aging to have a dramatic prothrombotic phenotype. This phenotype is linked to the regulation of key risk factors for cardiovascular disease. These include HO-1 which is significantly reduced in Bmal1 KO mice. ALA/SFC co-incubation affected the oscillation and phase of core clock genes and led to increase of HO-1. HO-1 levels followed a circadian pattern, and this pattern was absent in Bmal1 KO mice.

**Conclusions:** These findings indicate that circadian clock provides beneficial effects against the dysfunction in endothelial signaling to promote atherogenesis by regulating Heme synthesis and HO-1 expression. This study establishes a mechanistic connection between Bmal1 and cardiovascular phenotype.

**The Circadian Clock Protein PER1 Mediates Sex-Dependent Effects on Arterial Stiffness**

Ravindra K. Sharma,<sup>1</sup> Joshua Gomes,<sup>1</sup> G. R. Crislip,<sup>1</sup> Hannah M. Costello,<sup>1</sup> Lauren G. Douma,<sup>1</sup> Suraj Krishnan,<sup>1</sup> Kityan Cheng,<sup>1</sup> Rajesh Mohandas,<sup>2</sup> Michelle L. Gumz.<sup>1</sup> <sup>1</sup>University of Florida, Gainesville, FL; <sup>2</sup>LSU Health New Orleans, New Orleans, LA.

**Background:** Increased arterial stiffness is independently associated with adverse cardiovascular events and improvement in pulse wave velocity (PWV), a noninvasive clinical index of arterial stiffness, correlates with better survival. The Circadian Protein Period 1 (PER1) is important to the maintenance of circadian rhythms and regulates a wide array of physiological functions including blood pressure. Lysyl Oxidase (LOX), an extracellular cuproenzyme that mediates collagen crosslinking, is integral to maintain vascular stiffness, and exhibits a circadian pattern of expression. Thus, we hypothesize that disrupted circadian clock function and upregulation of LOX could be a key mechanism for increased vascular stiffness.

**Methods:** Male and female C57BL/6J (15-16 weeks old) global PER1 Knock-out (KO) and WT mice (n=6) subjected to echocardiographic measurement of PWV to evaluate aortic stiffness. Further, cell specific mRNA expression of LOX was assessed in aortic tissue using situ hybridization (ISH). Aortic segments were mounted in ex-vivo wire myograph to analyze changes in vascular reactivity and functions. Finally, morphometric measurements were used to assess structural changes and remodeling in H&E stained aortic sections. Comparisons between groups were made using t-test and p-value <0.05 was accepted as significant.

**Results:** Knockout of PER1 resulted in an increased PWV in male (Con:179 $\pm$ 32, PER1 KO: 306 $\pm$ 47 cm/s,  $p<0.001$ ) but not in female mice (Con:219 $\pm$ 14, PER1 KO: 225 $\pm$ 23 cm/s,  $p<0.80$ ) compared to age matched WT controls. This was associated with an increased LOX mRNA expression (~2.7 fold;  $p<0.01$ ) in the aorta of PER1 KO compared to WT mice. Morphometric analysis showed an increased adventitia thickness (30%;  $p<0.05$ ) in aortas of PER1KO mice. However, vascular functions/reactivity in PER1 KO mice aorta were slightly increased but this did not reach statistical significance.

**Conclusions:** Our findings suggest that disruption of circadian rhythm by deleting PER1 increases arterial stiffness in male but not in female mice. Increased LOX mediated changes in extracellular matrix are at least in part responsible for the pathogenesis of arterial stiffness in these mice. Inhibition of excessive LOX may have therapeutic potential in alleviating pathogenic increased vascular stiffness.

## SA-PO780

**Alterations in Kidney Venous Flow in the Prognosis of Heart Failure**

Faeq Husain-Syed,<sup>1,2</sup> Sharma Singam,<sup>3</sup> Jason K. Viehman,<sup>3</sup> Philip Schulte,<sup>3</sup> Pascall Bauer,<sup>2</sup> Khodr Tello,<sup>2</sup> Manuel Richter,<sup>2</sup> Werner Seeger,<sup>2</sup> Henning Gall,<sup>2</sup> Ardeschir Ghofrani,<sup>2</sup> Horst-Walter Birk,<sup>2</sup> Kianoush Kashani,<sup>3</sup> Claudio Ronco.<sup>4,5</sup> <sup>1</sup>University of Virginia, Charlottesville, VA; <sup>2</sup>Universitätsklinikum Giessen und Marburg GmbH, Giessen, Germany; <sup>3</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>4</sup>Azienda Ospedale Università Padova, Padova, Italy; <sup>5</sup>Ospedale San Bortolo di Vicenza, Vicenza, Italy.

**Background:** Doppler-derived kidney venous flow (KVF) has gained interest as a potential surrogate marker of kidney congestion and adverse outcomes in heart failure (HF). The clinical importance of changes in KVC from baseline remains unclear.

**Methods:** 216 inpatients with HF comprising the whole left ventricular ejection fraction spectrum and diuretic-resistant volume overload were enrolled and underwent spectral Doppler at baseline and after one month. 4 KVF patterns (i.e., continuous, pulsatile, biphasic, and monophasic venous flows) and the kidney venous stasis index (KVSII) were defined. In addition, echocardiography, intra-abdominal pressure (only baseline), kidney function, hormones, and hydration status were assessed on the day of kidney Doppler ultrasonography. We evaluated HF-related morbidity using the cause-specific Cox proportional hazard model for the composite outcome of HF progression (hospitalization for worsening HF, outpatient HF decompensation) and all-cause mortality for 18-months post-discharge.

**Results:** During follow-up, the morbidity/mortality outcome occurred in 126 patients and was independently predicted by baseline KVSII (per 0.1 increase: HR 1.18 [95% CI 1.03–1.35;  $p=0.020$ ]) and KVF patterns (per one pattern increase: HR 1.42 [95% CI 1.04–1.94;  $p=0.026$ ]), respectively. Both an increase of 0.1 in the change from Doppler 1 to 2 KVSII and a single increase in the individual KVF pattern in the change from Doppler 1 to 2 were associated with higher risk of the composite outcome (HR 2.99 [95% CI 2.08–4.32;  $p<0.0001$ ] and HR 6.73 [95% CI 3.27–13.86;  $p<0.0001$ ], respectively).

**Conclusions:** Serial assessment of KVF provides additional prognostic information on worsening HF and death risk-stratification. Changes in KVF may provide a basis for enhanced clinical making in patients with HF.

## SA-PO781

The Activation of BK $\alpha$  Channel Inhibits Cardiac Fibrosis in CKD

Yijin Huang,<sup>1</sup> Momar A. Diop,<sup>1</sup> Shuyang Bian,<sup>1</sup> Faten Hassounah,<sup>2</sup> John W. Calvert,<sup>2</sup> Xiaonan H. Wang,<sup>2</sup> Hui Cai.<sup>2,3</sup> <sup>1</sup>Emory University Emory College of Arts and Sciences, Atlanta, GA; <sup>2</sup>Emory University School of Medicine, Atlanta, GA; <sup>3</sup>VA Medical Center Atlanta, Decatur, GA.

**Background:** Uremic cardiomyopathy contributes to morbidity and mortality in chronic kidney disease (CKD). Our previous study found that activation of the large conductance, calcium-activated potassium channels (BK channels) attenuated renal fibrosis in mice. We hypothesized that upregulation BK channels activity suppresses cardiac fibrosis in CKD.

**Methods:** CKD mice were induced by 5/6 nephrectomy. To enhance BK channel activity, BMS-191011 (10 mg/kg BW), an opener of BK channel, was given by IP injection daily for 8 weeks. Blood pressure was measured using the tail-cuff method. Echocardiogram was used to measure cardiac size and function. Cardiac myoblast cells (H9C2) were used to assess the effects of BK opener (NS1916 10mM) on fibrotic markers and TGF- $\beta$  signaling pathway. The mRNA expression of BK was assayed by RT-PCR. The fibrotic protein markers were measured by western blots or immunohistochemistry (IHC) in the H9C2 cells and cardiac tissues.

**Results:** The expressions of BK $\alpha$  mRNA and protein were decreased and cardiac fibrosis was increased in the heart of CKD mice. Activation of BK channel by BMS-191011 significantly decreased the CKD-induced increase in systolic (116mmHg-CKD/BMS vs 135mmHg-CKD) and diastolic blood pressure (58mmHg-CKD/BMS vs 80mmHg-CKD) compared to the CKD groups. Echocardiogram showed that LV end-diastolic dimension increased in 5/6Nx mice (3.2mm-sham to 4.0mm-CKD), but back to normal after BK opener treatment (3.5mm-CKD/BMS;  $p < 0.01$  vs CKD) along with improving ejection fraction (63.9%-sham, 43.1%-CKD and 53.5%-CKD/BMS;  $p < 0.05$  vs CKD). IHC showed that fibrosis was significantly increased in CKD heart along with increased levels of fibronectin and vimentin, whereas BMS treatment attenuated these changes. In addition, TGF beta decreased BK $\alpha$  level and increased fibronectin and collagen Ia in a dose-dependent manner, whereas NS1916 inhibited the TGF $\beta$ -induced upregulation of fibronectin and collagen I in H9C2 cells.

**Conclusions:** Activation of BK channel by BK channel openers has significantly attenuated cardiac fibrosis in both CKD mice and in cardiac myoblast cells. This study could provide novel therapeutic strategies for treating uremic cardiomyopathy in chronic kidney diseases.

## Distinct Glucose vs. Fructose-Specific Gene Regulation in Small Intestine

Manoocher Soleimani,<sup>1,2</sup> Sharon L. Barone,<sup>1,2</sup> Kamyar A. Zahedi,<sup>1,2</sup> Christos Argyropoulos.<sup>1</sup> <sup>1</sup>University of New Mexico Health Sciences Center, Albuquerque, NM; <sup>2</sup>New Mexico VA Health Care System, Albuquerque, NM.

**Background:** Metabolic syndrome is manifested by visceral obesity, hypertension, and insulin resistance and is highly prevalent in US population. The pathogenesis of hypertension in metabolic syndrome remains speculative. Americans are consuming >300 calories/day of sugar- mostly in the form of fructose and sucrose (a glucose/fructose disaccharide). In addition, Americans are consuming 2-3 times the recommended amount of *salt*. How the interaction between excessive salt, carbohydrates, and their transporters in the small intestine may lead to salt sensitivity of hypertension in metabolic syndrome remains unknown. Increased consumption of sucrose (which hydrolyzes to glucose and fructose) increases systemic blood pressure in rodents. There are distinct pathways mediating the absorption of glucose vs. fructose in the small intestine. Glucose is absorbed primarily via SGLT1; whereas, fructose is primarily absorbed via GLUT5.

**Methods:** Mice were fed a 60% glucose or fructose diet (vs. control) for 2 weeks. RNA seq analysis and expression studies were performed on RNA isolated from mouse jejunum.

**Results:** RNA seq analysis and northern hybridization on jejuna of experimental animals shows significant activation of the mineralocorticoid receptor (MR) in glucose-, but not fructose-fed mice. Glucocorticoid receptor (GR) expression did not change in glucose- or fructose-fed mice. In addition, the expression of SGK1, which regulates the expression of NHE3 and SGLT1 was increased significantly in glucose-fed, but not fructose-fed mice. The expression of 11 $\beta$ -hydroxysteroid dehydrogenase 2 (11 $\beta$ -HSD2), which inactivates glucocorticoids, is decreased in glucose-fed mice, which ensures that glucocorticoids remain active and can efficiently compete for binding with MR. GLUT5 was increased more significantly in fructose-fed, whereas SGLT1 was increased more significantly in glucose-fed mice.

**Conclusions:** Our studies demonstrate that increased glucose consumption activates the MR and SGK1, but downregulates 11 $\beta$ -HSD2 in the small intestine. The upregulation of MR and SGK1 can facilitate further salt absorption via NHE3 and SGLT1 working in parallel and stimulated by glucocorticoids. We propose that increased carbohydrate consumption (including sucrose) can stimulate salt absorption in the small intestine by distinct mechanisms.

## SA-PO783

## Increased Dopamine D1 Receptor (D1R) Phosphorylation due to G Protein-Coupled Receptor Kinase 4 (GRK4) Variant 65L Causes Hypertension

Shaun C. Moore, Daniel A. Yaqub, Laureano D. Asico, Ines Armando, Pedro A. Jose. *The George Washington University, Washington, DC.*

**Background:** Activating variants of the human GRK4 (65R>L, 142A>V, and 486A>V) are involved in the desensitization of the D1R and are associated with hypertension in several ethnic groups. Although GRK4 is essential for the normal desensitization and resensitization of dopamine receptors, certain constitutively active GRK4 variants impair dopamine D1 (D1R) function and natriuretic function. We have reported that global transgenic mice expressing hGRK4 65L have salt-sensitive hypertension.

**Methods:** We have reported that global transgenic mice expressing hGRK4 65L have salt-sensitive hypertension. To avoid the effect of protein overexpression in these transgenic mice, we generated mice globally expressing hGRK4 65L or hGRK4 wild type (WT) by *crispr-cas9*-mediated genome editing in C57Bl/6 mice (hGRK4 65L GE and hGRK4 WT GE).

**Results:** Systolic blood pressure (SBP) in hGRK4 65L GE mice under pentobarbital anesthesia was higher (124 $\pm$ 2 vs 101 $\pm$ 1 mmHg,  $n=5$ /group,  $P < 0.05$ ) than in their littermates not expressing the human gene (GE WT) or mice expressing hGRK4 WT GE. Renal D1R phosphorylation was higher in hGRK4 65L GE than GE WT (112 $\pm$ 2 vs 100 $\pm$ 1%,  $n=3$ /group,  $P < 0.05$ ). To determine the role of the kidney in the salt sensitivity of these mice, we generated mice with kidney-specific (KS) expression of the GRK4 65L (KS hGRK4 65L) by the bilateral ureteral infusion of adeno-associated virus (AAV) vectors carrying hGRK4 65L in GRK4 knockout mice. Mice infused with hGRK4 WT served as controls (KS hGRK4 WT). SBP (under anesthesia) before AAV was similar in both groups. SBP post AAV increased in KS hGRK4 65L (93 $\pm$ 1 vs 117 $\pm$ 4 mm Hg,  $P < 0.05$ ,  $n=4$ ) but not in KS hGRK4 WT (96 $\pm$ 2 vs 105 $\pm$ 6,  $n=5$ ). Renal D1R phosphorylation was higher (170  $\pm$  10 vs 100  $\pm$ 15%;  $n=5$ ,  $P < 0.02$ ) in KS hGRK4 65L than KS hGRK4 WT. We also studied human renal proximal tubule cells (hRPTCs) endogenously carrying GRK4 WT or GRK4 65L. In hRPTCs with GRK4 65L D1R, phosphorylation (204  $\pm$  22 vs 100 $\pm$ 24%,  $n=6$ /group;  $P < 0.05$ ), was increased, relative to hRPTCs with GRK4 WT.

**Conclusions:** Our results show across different mouse models and hRPTCs that the presence of GRK4 65L results in increased D1R phosphorylation and show the vital role of renal D1R in the regulation of blood pressure.

## Afferent Neurons of the Kidney With Impaired Firing Pattern in Inflammation: Role of Sodium and Potassium Currents

Kristina Rodionova,<sup>1</sup> Roland Veelken,<sup>1,2</sup> Karl F. Hilgers,<sup>1</sup> Peter Linz,<sup>1</sup> Christian Ott,<sup>1,2</sup> Roland E. Schmieder,<sup>1</sup> Mario Schiffer,<sup>1</sup> Kerstin U. Amann,<sup>1</sup> Tilmann Ditting.<sup>1,2</sup> <sup>1</sup>Friedrich-Alexander-Universitat Erlangen-Nurnberg Medizinische Fakultät, Erlangen, Germany; <sup>2</sup>Paracelsus Medical Private University Nuremberg, Nuremberg, Germany.

**Background:** Previously, we reported that peripheral neurons with renal afferents involved in sympathetic control exhibit a predominantly tonic firing pattern of higher frequency that is reduced to low frequencies (phasic firing pattern) in renal inflammation (and hypertension). Now, we wanted to test the hypothesis that the reduction in firing activity during inflammation is due to special tonic neurons switching from higher to low frequencies.

**Methods:** Renal subcapsular staining (DiI) for identification of neurons with renal projection (RANs). Cultivated neurons incubated with the chemokine CXCL1 (1,5 nmol/ml) for 12 hours prior to electrophysiology. Current clamp used to characterize neurons as “tonic”, i.e. sustained action potential (AP) firing or “phasic”, i.e. <5 APs upon stimulation. Membrane currents investigated by increasing clamp voltage. Data analyzed: renal vs. non-renal and tonic vs. phasic neurons.

**Results:** Renal neurons exposed to CXCL1 showed a decrease of tonic firing pattern compared to controls (35.6% vs. 57%,  $P < 0.05$ ). Phasic neurons exhibited higher Na<sup>+</sup> and K<sup>+</sup> currents than tonic neurons in controls resulting in shorter APs (3.7 $\pm$ 0.3 vs. 6.1 $\pm$ 0.6 ms,  $P < 0.01$ ). In neurons incubated with CXCL1, Na<sup>+</sup> and K<sup>+</sup> peak currents increased (Na<sup>+</sup>: -969 $\pm$ 47 vs. -758 $\pm$ 47 nA/pF,  $P < 0.01$ ; K<sup>+</sup>: 707 $\pm$ 22 vs. 558 $\pm$ 31 nA/pF,  $P < 0.01$ ) in phasic, but were unchanged in tonic neurons. Incubated phasic neurons showed a much broader range of Na<sup>+</sup> currents [-365 – -1429 nA] vs. [-412 – -4273 nA];  $P < 0.05$ ; similar to tonic neurons.

**Conclusions:** The enlarged number of renal phasic neurons incubated with CXCL1 showed significantly increased membrane currents resembling the broad range of Na<sup>+</sup> currents seen in tonic neurons. These findings suggest that a subgroup of tonic neurons switched to a phasic response pattern in inflammation while other mechanisms become less likely (e.g. recruitment of formerly silent phasic neurons).

## Pericyte Detachment and Interstitial Fibrosis in Dahl Salt-Sensitive Hypertensive (DahlS) Rats

Hiroki Ito,<sup>1,2</sup> Takuo Hirose,<sup>2,1</sup> Shigemitsu Sato,<sup>1</sup> Kazuhiro Takahashi,<sup>2</sup> Takefumi Mori.<sup>1</sup> <sup>1</sup>Tohoku Ika Yakka Daigaku, Sendai, Japan; <sup>2</sup>Tohoku Daigaku Daigakuin Igakuken Kenkyuka Igakubu, Sendai, Japan.

**Background:** Dahl salt-sensitive hypertensive (DahlS) rats have salt-sensitive hypertension and volume-overloaded renal venous congestion with heart failure. We previously reported that pericyte detachment and pericyte-myofibroblast transition (PMT) around the vasa recta were involved in interstitial injury and fibrosis in an artificially induced renal venous congestion model. In the present study, we assessed the relation of pericyte detachment around the vasa recta and PMT with interstitial fibrosis in DahlS rats.

**Methods:** Eight-week-old DahlS rats (Dahl/Mcw) were divided into three groups: normal diet, 4% NaCl diet, and 8% NaCl diet groups, and their kidneys were analyzed after 2 weeks. Total mRNA and protein expression levels were quantified by real-time PCR and western blot, respectively. Tubulointerstitial damage and fibrosis were identified by histological analysis. Furthermore, we evaluated pericyte detachment around the vasa recta by low-vacuum scanning electron microscopy (LV-SEM).

**Results:** The expression of KIM1, a tubulointerstitial damage marker; CNN1 and  $\alpha$ SMA, interstitial fibrosis markers; and TAGLN, a PMT marker; was increased in a salt-dependent manner in DahlS rats. Pericyte detachment around the vasa recta was observed in 4% and 8% NaCl diet groups by LV-SEM.

**Conclusions:** Pericyte detachment and PMT are involved in tubulointerstitial injury and fibrosis of DahlS rats. Renal venous congestion and subsequent physiological changes could have a role in renal damage and fibrosis.

## SA-PO786

## Role of Platelet-Derived Growth Factor (PDGF) in Ex Vivo Aortic Calcification Under Uremic Conditions

Burcu Yesilyurt,<sup>1,3</sup> Li Zhang,<sup>3</sup> Barbara M. Klinkhammer,<sup>3</sup> Julia Moellmann,<sup>3</sup> Patrick Droste,<sup>3</sup> Claudia Goettsch,<sup>3</sup> Willi Jahnke-Dechent,<sup>3</sup> Michael Lehrke,<sup>3</sup> Mathias Hohl,<sup>2</sup> Joachim Jankowski,<sup>1</sup> Dickson W. Wong,<sup>3</sup> Peter Boor.<sup>3,1</sup> <sup>1</sup>Rheinisch-Westfälische Technische Hochschule Aachen, Aachen, Germany; <sup>2</sup>Universitätsklinikum des Saarlandes und Medizinische Fakultät der Universität des Saarlandes, Homburg, Germany; <sup>3</sup>Universitätsklinikum Aachen, Aachen, Germany.

**Background:** Chronic kidney disease (CKD) is associated with an increased risk of developing vascular calcification. Platelet-derived growth factor (PDGF) is involved in vascular development and vasculopathy via effects on vascular smooth muscle cells (VSMCs). It remains unclear whether PDGF might be involved in CKD-associated vascular calcification.

**Methods:** To address this, we adapted an *ex-vivo* calcification model in murine aortas to analyze the effect of uremia and PDGF. We first examined whether aortic calcification is affected by age, sex, genetic background, incubation time-points of calcification medium (3-10days), and various aortic regions (arch, thoracic, suprarenal and infrarenal). Aortas collected from control and CKD mice (induced by an adenine-enriched diet) were calcified *ex-vivo* to examine the effect of CKD conditioning on calcification. Hemodialysate from CKD patients was added to the calcification medium to create the uremic milieu *ex-vivo*. Soluble PDGFR- $\beta$  antibody and Imatinib were used as an inhibitor of PDGFR- $\beta$ . *Ex-vivo* calcification was also performed on the transgenic aorta with tamoxifen-inducible activation of PDGFR- $\beta$  specifically in VSMCs.

**Results:** With these approaches, we observed that longer (10days) incubation in the calcification medium led to an increased calcification in all aortic regions. Aortas from older mice had higher susceptibility to calcify *ex-vivo*, whereas sex and genetic background had no effects. Aortas from CKD mice calcified significantly more than those of healthy mice. Similarly, adding hemodialysate to the calcification medium enhanced calcification, which was significantly diminished upon PDGF signaling inhibition. Additionally, aortas from mice with constitutive PDGFR- $\beta$  activation in VSMCs showed a higher calcification compared to WT mice.

**Conclusions:** Overall, our results suggested that PDGFR- $\beta$  activation in VSMCs is involved in uremic vascular calcification.

**Funding:** Private Foundation Support

## SA-PO787

## Cardiac Radiation Exposure and Coronary Atherosclerosis: An Inflammatory Interplay

Perna R. Nepali,<sup>1</sup> Mickael Mathieu,<sup>1</sup> Sebastien Monette,<sup>1</sup> Yunping Qiu,<sup>3</sup> Irwin J. Kurland,<sup>3</sup> Andreas Rimner,<sup>1</sup> Adriana Haimovitz-Friedman,<sup>1</sup> Edgar A. Jaimes.<sup>1,2</sup> <sup>1</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>2</sup>Weill Cornell Medicine, New York, NY; <sup>3</sup>Albert Einstein College of Medicine, Bronx, NY.

**Background:** Cardiac radiation exposure is a known risk factor for the increased cardiovascular mortality observed in cancer patients receiving thoracic radiation therapy (RT). A better understanding of the mechanisms involved is essential to develop preventive and treatment strategies. In this study we hypothesize that the development of accelerated atherosclerosis after RT is dependent upon inflammatory mechanisms that include the activation of eicosanoid pathways.

**Methods:** Male Apolipoprotein E knockout mice on a high fat diet received 16Gy cardiac RT to the whole or partial (apical or basal) regions of the heart at 9 or 16 weeks (w) of age. Atherosclerotic lesions (H&E) and inflammatory infiltrates (IHC) were assessed 8w post RT. Eicosanoid profile was studied (liquid chromatography mass spectrometry) in the serum of 16w old mice 24 hours post radiation. RNAscope was used to assess LOX mRNA expression post RT.

**Results:** (1) At 8w follow up, mice receiving basal RT at 16w showed a greater number of atherosclerotic lesions in the basal coronary arteries ( $29.33 \pm 5.48$  versus  $9 \pm 2.70$ ) and basal subendocardial vasculature ( $6.66 \pm 0.07$  versus  $0.2 \pm 0.2$ ) as compared to controls. Inflammatory cells (CD45, CD3) and endothelial adhesion molecules were differentially expressed based upon the site of RT. (2) Protective oxidized EPA metabolites (5HEPE and 12HEPE) were decreased after whole RT but increased after basal irradiation compared to whole RT (Table). (3) 12LOX mRNA was significantly elevated in the cardiac lesions of mice after apical RT and there was a trend towards increased 15LOX and 5LOX mRNA expression post whole, basal and apical RT compared to controls.

**Conclusions:** Our results indicate that RT to different regions of the heart results in a distinctive variance in the systemic production of eicosanoids and vascular LOX mRNA expression profile which may mediate or be a compensatory response in the development of accelerated atherosclerosis after RT.

Eicosanoid	No RT	24h whole RT (* versus No RT)	24h Basal RT (* versus 24h Whole RT)
12HEPE	35.38 $\pm$ 6.06	6.42 $\pm$ 1.31 <sup>†</sup>	43.70 $\pm$ 17.23

## Mapping Tubuloglomerular and Myogenic Autoregulation Throughout the Kidney With MRI

Edwin Baldelomar,<sup>1</sup> Jennifer R. Charlton,<sup>2</sup> Shella Keilholz,<sup>1</sup> Cihat Eldeniz,<sup>1</sup> Hongyu An,<sup>1</sup> Kevin M. Bennett.<sup>1</sup> <sup>1</sup>Washington University in St Louis School of Medicine, St Louis, MO; <sup>2</sup>University of Virginia School of Medicine, Charlottesville, VA.

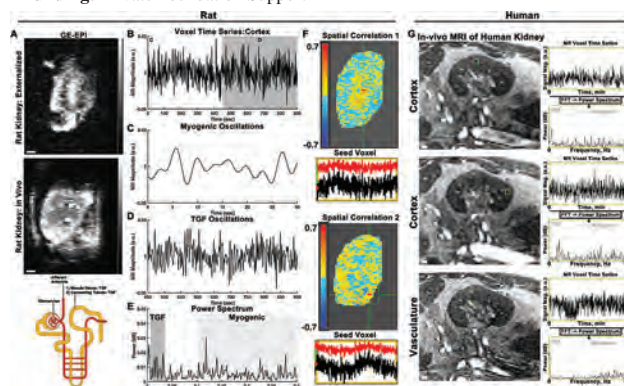

**Background:** Autoregulation is a critical kidney function to protect nephrons, is disrupted in disease, and several autoregulatory mechanisms of perfusion have been observed in animal models, observed by distinct low-frequency oscillations (myogenic ~100mHz and tubuloglomerular feedback, TGF ~10mHz).

**Methods:** *Rat Kidneys* – Sprague Dawley rats (n=4) were anesthetized and left anatomical kidney externalized in three animals. MR Details: Bruker 9.4T MRI; a mouse brain receive only coil; single shot gradient echo echo planar imaging; TE/TR = 13/150ms; resolution = 0.4x0.4x0.4mm<sup>3</sup>; and 15min acquisition time. Vitals were monitored. In two animals, we compared scans with and without saturation bands over renal artery to assess oxygen sensitivity. We imaged one kidney *in situ* without externalization to determine if we could overcome motion. Imaging was repeated after euthanasia. *Human Kidney In Vivo* – A single human volunteer consented for imaging. MR Details: 3T Prisma scanner using a spine and a flex coil; FLASH sequence; TE/TR = 2.27/4.2ms; resolution = 2.5x2.5x2.5mm<sup>3</sup>; and 15min acquisition time. *Post processing* – AFNI and Matlab softwares were used to process and analyze data. Typical pre-processing methods were used.

**Results:** Resting state MRI and spectral analysis revealed spatially variable and distinct bands of frequencies consistent with myogenic and TGF autoregulatory mechanisms (Fig 1). We found evidence of other mechanisms of physiological function at lower frequencies that require further investigation. We observed evidence of spatial correlations in the time course consistent with nephrovascular coupling (Fig 1).

**Conclusions:** A simple and short, non-contrasted MRI scan can be used to detect spatially variable, low- frequency oscillatory changes that appear to be associated with autoregulation of the kidney in both rats and humans. Mapping autoregulatory spectra may be an important, unique biomarker of kidney disease, developmental processes, transplant evaluation, and response to therapies.

**Funding:** Private Foundation Support

SA-PO789

**Association of Maternal Hypertension With Offspring Kidney Function in a Non-Human Primate Model of Spontaneous Hypertension**  
Carol Vincent, Ashton Chen, Kylie Kavanagh, Andrew M. South. *Wake Forest University School of Medicine, Winston-Salem, NC.*

**Background:** Early-life exposure to adverse events can program hypertension (HTN) and kidney disease in childhood and early adulthood but the mechanism is not well understood. The spontaneously hypertensive vervet monkey may provide a novel model for investigating early HTN and related renal target organ damage development.

**Methods:** This is a pilot prospective cross-sectional study of *Chlorocebus spp.* maternal-offspring dyads. We identified 10 HTN mothers based on prior sedated blood pressure (BP) measurements, defined by the 2017 ACC/AHA Guideline using age  $\geq$ 13 years old criteria, and randomly selected offspring to complete each dyad. We 1:2 matched each maternal HTN dyad with a maternal normotension dyad by age and offspring sex. Sedated BP, weight, and labs were obtained on dyads. Our exposures were maternal HTN group and maternal BP measurements. Our outcomes were offspring serum creatinine (SCr) and blood urea nitrogen (BUN). Using generalized linear models, we estimated the associations between the exposures and outcomes.

**Results:** Age range, BP, and sex distribution were similar within the maternal and offspring groups (Table 1). Maternal HTN and BP were not significantly associated with offspring SCr ( $\beta$  0.08, 95% CL -0.1 to 0.26) or BUN ( $\beta$  2.6, 95% CL -3.0 to 8.2).

**Conclusions:** We did not observe an association between maternal HTN and offspring kidney function in maternal-offspring vervet dyads. This could be because offspring of older, less healthy mothers may be too young to show altered kidney function or be due to our small sample size in this pilot study. Next steps include investigating associations of renin-angiotensin system components with offspring BP and organ damage.

**Funding:** Other NIH Support - R01-HL146818, NHLBI K23-HL148394, L40-HL148910, Private Foundation Support

	Hypertensive Mothers N=10	Normotensive Mothers N=5	Offspring of hypertensive mothers N=10	Offspring of normotensive mothers N=5

**Association of Serum Uric Acid With Hypertension Severity and Adverse Cardiac Changes at Baseline in Youth With Primary Hypertension**  
Carol Vincent, Ashton Chen, Andrew M. South. *Wake Forest University School of Medicine, Winston-Salem, NC.*

**Background:** Mechanisms driving hypertension (HTN)-related organ damage in youth with HTN are incompletely understood. Uric acid may be associated with HTN and related target organ damage in youth, but this relationship remains paradoxical due in part to methodological limitations.

**Methods:** This is a secondary analysis of data from a pilot prospective cohort study of youth aged 5–17 years with newly diagnosed primary HTN defined by the AAP Clinical Practice Guideline. Exclusion criteria were diabetes mellitus, chronic kidney disease, heart disease, or non-English or Spanish speaker. Our exposures were serum uric acid (SUA) and SUA standard deviation (SD) from the mean. Our outcomes were blood pressure (BP), BP z-score, left ventricular mass index (LVMI) indexed to height and BSA, and relative wall thickness (RWT). We estimated associations between exposures and outcomes with generalized linear models adjusted for gestational age, birth weight, sex, and body mass index as identified in a directed cyclic graph.

**Results:** Of the 30 participants, mean age was 13.4 years (SD 3.6) with 30% female, 27% Black or African American, and 40% Hispanic or Spanish origin ethnicity. Median SUA was 5.4 mg/dL [IQR 4.9, 7.1]. No participants had left ventricular hypertrophy. Elevated blood pressure was seen in 10%, stage 1 hypertension in 47%, and stage 2 hypertension in 27% of the population. In adjusted analyses, SUA from mean was not associated with systolic BP ( $\beta$  0.18, 95% CL -2.72 to 3.08), diastolic BP ( $\beta$  -1.72, 95% CL -4.35 to 0.92), LVMI g/m<sup>2.7</sup> ( $\beta$  -0.72, 95% CL -3.08 to 1.64), LVMI g/BSA ( $\beta$  -0.61, 95% CL -4.52 to 5.75), or RWT ( $\beta$  -1.77, 95% CL -9.62 to 6.07). SUA was associated with Diastolic BP z-score ( $\beta$  -0.38, 95% CL -0.61 to 0.15).

**Conclusions:** We did not observe associations of SUA with HTN or related heart changes on echocardiogram. Our findings could be reflect that our population did not

have LVH or our small sample size. Ongoing analyses include investigating associations of renin-angiotensin system with target organ damage.

SA-PO791

**Increased Renal Inflammation in Drd5 Knockout Mice Is Associated With Peroxiredoxin-4 Dysfunction**  
Bibhas Amatya,<sup>1</sup> Jacob Q. Polzin,<sup>1</sup> Laureano D. Asico,<sup>1</sup> Ines Armando,<sup>1</sup> Robin A. Felder,<sup>2</sup> Pedro A. Jose,<sup>1</sup> Hewang Lee.<sup>1</sup> <sup>1</sup>*The George Washington University School of Medicine and Health Sciences, Washington, DC;* <sup>2</sup>*University of Virginia Health Sciences Center, Charlottesville, VA.*

**Background:** The dopamine D5 receptor (D<sub>5</sub>R) suppresses inflammation in the central nervous system. However, its role in the regulation of inflammation associated with oxidative stress and hypertension in the kidney is not known.

**Methods:** Protein expression was determined by immunoblotting in D<sub>5</sub>R-expressing cells, treated with pharmacological reagents or transfected with mock or specific siRNA to silence specific genes. Protein-protein interaction was determined by co-immunoprecipitation and co-localization analysis of immunofluorescence images. *Drd5*<sup>-/-</sup> mice were generated, as previously reported.

**Results:** In D<sub>5</sub>R-HEK 293 cells, fenoldopam (FEN, 25 nM/12 hr, n=4), a D<sub>5</sub>-like receptor agonist, increased the expression (158.1 $\pm$ 11.9% vs 100.0 $\pm$ 6.8% basal level, n=6) of peroxiredoxin-4 (PRDX4), an endoplasmic reticulum-localized protein. By contrast, D<sub>5</sub>R protein was decreased in *PRDX4* siRNA-treated D<sub>5</sub>R-HEK293 (58.8 $\pm$ 6.7% vs 100.0 $\pm$ 9.6% basal level, n=4) and -human renal proximal tubule cells (hRPTCs) (60.4 $\pm$ 5.8%, n=4). PRDX4 protein was also decreased in the kidney cortices of *Ddr5*<sup>-/-</sup> mice (*Ddr5*<sup>+/-</sup>: 100 $\pm$ 18%, n=5; *D<sub>5</sub>R*<sup>-/-</sup>: 69 $\pm$ 14%, n=4; P<0.05). FEN increased the co-immunoprecipitation of D<sub>5</sub>R and PRDX4 and their colocalization, particularly in the endoplasmic reticulum. Moreover, silencing *PRDX4*, by its specific siRNA, increased reactive oxygen species (ROS) production and impaired the inhibitory effect of FEN on ROS production in hRPTCs. In D<sub>5</sub>R-HEK 293 cells, siRNA silencing of *PRDX4* also increased the production of tumor necrosis factor (TNF) and interleukin (IL)-1b. The increase in TNF protein in D<sub>5</sub>R-HEK293 cells with silenced *PRDX4* was attenuated by tempol, a superoxide dismutase mimetic, indicating that oxidative stress and downstream inflammation are associated with PRDX4 deficiency and consistent with the increase in NLRP3 inflammasome with PRDX4 silencing (scrambled siRNA: 100 $\pm$ 5.0%, *PRDX4* siRNA: 150.6 $\pm$ 6.0%). The protein expressions of TNF (*Ddr5*<sup>+/-</sup>: 100 $\pm$ 11%, n=4; *D<sub>5</sub>R*<sup>-/-</sup>: 179 $\pm$ 16%, n=4; P<0.05) and IL-1 $\beta$  (*Ddr5*<sup>+/-</sup>: 100 $\pm$ 13%, n=4; *D<sub>5</sub>R*<sup>-/-</sup>: 156 $\pm$ 14%, n=4; P<0.05) were also increased in the kidney cortices of *Drd5*<sup>-/-</sup> mice, relative to *Drd5*<sup>+/-</sup> littermates.

**Conclusions:** The increase in renal inflammation in *Drd5*<sup>-/-</sup> mice is due, in part, to oxidative stress, caused by the impaired interaction between D<sub>5</sub>R with PRDX4.

**CXCL12 and Fractalkine Predict Heart Failure in CKD Patients: The CRIC Study**  
Mariana F. Marques,<sup>1,2</sup> Marta Borges Canha,<sup>1,2</sup> Katherine S. Ravi,<sup>3</sup> Finnian R. McCausland.<sup>3</sup> <sup>1</sup>*Centro Hospitalar Universitario de Sao Joao, Porto, Portugal;* <sup>2</sup>*Faculdade de Medicina da Universidade do Porto, Porto, Portugal;* <sup>3</sup>*Brigham and Women's Hospital, Boston, MA.*

**Background:** Heart Failure (HF) is common and associated with higher mortality in patients with Chronic Kidney Disease (CKD). Inflammation is thought to play a role in HF development, prompting us to explore the association of CXCL12 and fractalkine (T cell and monocyte chemokines, respectively) with incident HF in the Chronic Renal Insufficiency Cohort (CRIC).

**Methods:** This study included 3478 patients with available baseline measurements of CXCL12 and Fractalkine. Multivariable Cox and logistic regression models were fit to assess the association of each biomarker (log-transformed and categories) with baseline B-type Natriuretic Peptide (BNP) levels and Left Ventricular Mass Index (LVMI) measured at year 1, both defined as categorical variables above median, and incident HF.

**Results:** In fully adjusted analyses, higher CXCL12 and fractalkine levels were associated with higher baseline BNP – Odds Ratio (OR) 1.27 [95% Confidence Interval (CI) 1.17 – 1.38] and OR 1.22 [1.11 – 1.34], respectively. Raised CXCL12 and fractalkine were associated with increased LVMI at year 1 of follow-up, independent of patient demographics and renal function – OR 95% CI 1.10 [1.01 – 1.21] and 1.13 [1.03 – 1.24], correspondingly. Both biomarkers predicted incident HF, regardless of patient demographics, renal function, comorbidities, medication and sodium and phosphate levels – Hazard Ratio (HR) 95% CI 1.21 [1.07 – 1.37] for CXCL12 and 1.15 [1.00 – 1.31] for fractalkine. Results were significant only for the highest quartiles of the biomarkers when analysed as categorical variables.

**Conclusions:** Higher levels of CXCL12 and fractalkine are independently associated with higher baseline BNP, LVMI at 1 year, and incident HF hospitalization. Whether interventions that target these pathways can reduce incident HF among patients with CKD remains to be determined.

## A Role of Amphiregulin in PDE3A-Mediated Renoprotection

Anastasiia Sholokh,<sup>1</sup> Brandon J. McMurray,<sup>2</sup> Daniele Y. Sunaga-Franze,<sup>1</sup> Fatimunnisa Qadri,<sup>1</sup> Kerstin Zuehlke,<sup>1</sup> Lajos Marko,<sup>4</sup> Minze Xu,<sup>3</sup> Andreas Patzak,<sup>3</sup> Pontus Persson,<sup>3</sup> Philipp G. Maass,<sup>2</sup> Tatiana A. Borodina,<sup>1</sup> Sylvia Bähring,<sup>4</sup> Michael Bader,<sup>1</sup> Enno Klussmann.<sup>1</sup> <sup>1</sup>Max-Delbruck-Centrum für Molekulare Medizin in der Helmholtz-Gemeinschaft, Berlin, Germany; <sup>2</sup>University of Toronto, Toronto, ON, Canada; <sup>3</sup>Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>4</sup>Max Delbruck Centrum für Molekulare Medizin Experimental and Clinical Research Center, Berlin, Germany.

**Background:** A primary risk factor for chronic kidney disease (CKD) is hypertension. Autosomal-dominant hypertension with brachydactyly type E (HTNB) resembles essential hypertension, but the patients show almost no signs of end-organ damage such as CKD. HTNB is caused by mutations in the phosphodiesterase 3A (PDE3A) gene. Therefore, we hypothesize that HTNB-causing PDE3A-mutations are renoprotective and aim to gain insight into the underlying mechanisms.

**Methods:** Using CRISPR/Cas9 technology, rats expressing PDE3A with a 3 amino acid deletion (PDE3A-Δ3aa) were generated. These animals recapitulate the HTNB phenotype. Rats with a functional PDE3A knockout (Functional Del) were used as an additional control. Inner medulla (IM) and residual kidney (RK) were investigated using biochemical, molecular biological, histological, and physiological approaches. Vasa recta contractility was measured.

**Results:** The overall kidney morphology of the wild-type (WT), PDE3A-Δ3aa, and functional Del rats was similar. As in second-order mesenteric arteries, the media to lumen ratio of renal arteries was significantly increased in PDE3A-Δ3aa rats compared to wild-type. The relaxation of Vasa recta to forskolin was not affected in PDE3A-Δ3aa rats and appeared stronger in functional Del (both vs. WT). The mRNA and protein expression levels of proinflammatory cytokines and fibrosis markers remained at similar levels as in wild-type rats in both IM and RK. However, compared to wild-type animals, collagen levels in IM and RK of PDE3A-Δ3aa and in IM of functional Del rats were significantly increased. Amphiregulin (AREG) is a fibrosis- and thus kidney damage-inducing epidermal growth factor receptor (EGFR) agonist. The mRNA and protein expression levels of AREG were significantly decreased in IM of PDE3A-Δ3aa animals compared to wild-type, while its serum level remained unchanged.

**Conclusions:** Our data reveal that PDE3A mutations protect the kidneys from hypertension-induced damage and suggested that AREG plays a role in the underlying mechanisms.

## Progression of Kidney Disease in Kidney Transplant Recipients With a Failing Graft: A Matched Cohort Study

Ngan Lam,<sup>1</sup> Robert R. Quinn,<sup>1</sup> Alix Clarke,<sup>1</sup> Huda Al-Wahsh,<sup>1</sup> Greg A. Knoll,<sup>2</sup> Fareed Kamar,<sup>1</sup> Rachel Jeong,<sup>1</sup> James A. Kiberd,<sup>1</sup> Pietro Ravani.<sup>1</sup> <sup>1</sup>University of Calgary Cumming School of Medicine, Calgary, AB, Canada; <sup>2</sup>Ottawa Hospital, Ottawa, ON, Canada.

**Background:** Renal function may decline more rapidly in kidney transplant recipients with a failing graft than in people with chronic kidney disease (CKD) of their native kidneys.

**Methods:** We conducted a retrospective, population-based cohort study using linked healthcare databases in Alberta, Canada (2002-2019) to identify kidney transplant recipients with a failing graft, defined as 2 outpatient estimated glomerular filtration rate (eGFR) measurements between 15 and 30 mL/min/1.73 m<sup>2</sup> at least 90 days apart. Recipients were compared to propensity-score matched, non-transplant controls with a similar degree of sustained kidney dysfunction who were followed by a nephrologist. We compared the change in eGFR over time (primary outcome) and the competing risks of kidney failure and death without kidney failure (secondary outcome). We used joint modelling to account for possible informative censoring and the association between time-dependent changes in eGFR (eGFR with 95% confidence limits,  $_{LCL}$ , eGFR $_{UCL}$ ) and the competing events (hazard ratios,  $_{LCL}$ , HR $_{UCL}$ ).

**Results:** We matched 575 transplant recipients to 575 non-transplant controls. For the recipients, the median age was 57 years (interquartile range [IQR] 46-67), 39% were women, and median potential follow-up time was 7.8 years (IQR 3.6-12.1). In the joint model, the eGFR decline over time was similar in the two groups (recipients vs. controls:  $-2.27_{-2.60}^{-1.94}$  vs.  $-2.52_{-2.68}^{-2.21}$  mL/min/1.73 m<sup>2</sup> per year). In the time-to-event sub-model, the hazards for both kidney failure (HR  $_{2.05}^{2.68}$ ) and death (HR  $_{1.23}^{1.61}$ ) were significantly higher for transplant recipients. eGFR decline was associated with kidney failure but not with death.

**Conclusions:** Although kidney function declines at a similar rate in transplant recipients as in non-transplant controls, people with a failing graft have a higher risk of kidney failure and death. Studies are needed to identify preventive measures to improve outcomes in kidney transplant recipients with a failing graft.

**Funding:** Government Support - Non-U.S.

## Long-Term Outcomes of Living Related Kidney Donation for Alport Syndrome Spectrum: A Propensity-Score Matched Analysis

Yasar Caliskan,<sup>1</sup> Ozgur A. Oto,<sup>2</sup> Seda Safak,<sup>2</sup> Safak Mirioglu,<sup>2</sup> Berna Yelken,<sup>3</sup> Arzu Velioglu,<sup>4</sup> Ahmet B. Dirim,<sup>2</sup> Nurana Guller,<sup>2</sup> Abdulmecit Yildiz,<sup>5</sup> Alparslan Ersoy,<sup>5</sup> Aydin Turkmen,<sup>2</sup> Halil Yazici,<sup>2</sup> Krista L. Lentine.<sup>1</sup> <sup>1</sup>Saint Louis University School of Medicine, Saint Louis, MO; <sup>2</sup>Istanbul Universitesi Istanbul Tip Fakultesi, Istanbul, Turkey; <sup>3</sup>Koc Universitesi, Istanbul, Turkey; <sup>4</sup>Marmara Universitesi, Istanbul, Turkey; <sup>5</sup>Bursa Uludag Universitesi, Bursa, Turkey.

**Background:** We examined a cohort of living related donors (LRDs) to recipients with Alport syndrome spectrum (AS) and compared their outcomes with a control group to improve understanding of the clinical course and outcomes of living donation in this context.

**Methods:** LRDs of AS recipients (ASLD group) and propensity score-matched control LDs without any family history of AS (non-ASLD group) were followed for major cardiac events (MACE), death, post-donation eGFR and proteinuria.

**Results:** Long-term outcomes over 12.5 (IQR, 5.0-16.7) years were evaluated in 27 and 29 LDs from ASLD and non-ASLD groups, respectively (Table 1). During follow-up, 5 LDs (18.5%) in ASLD developed MACE after 5.5 (IQR, 4.5-10.3) years, whereas only two LDs in non-ASLD group developed MACE (p=0.19) (Table 1). New-onset hypertension was higher in ASLD (51.9%) compared to the control group (24.2%) (p=0.03). Three donors in ASLD and 2 donors in non-ASLD group who developed new-onset hypertension died during follow-up (p=0.58). MACE rate was significantly higher in donors who developed hypertension after donation (0% vs 33.3%, p<0.001). There were no differences between study groups regarding last eGFR and proteinuria levels (p=0.42 and p=0.26, respectively). When long-term outcomes of donors with COL4A3-5 variants were evaluated, of 6 ASLDs with associated variants only a donor with COL4A3 and another donor with COL4A4 heterozygous variant developed hypertension and MACE (Table 2).

**Conclusions:** Although the risk of kidney disease can be minimised by careful donor evaluation, our findings suggest that hypertension risk after the donation is higher than expected in related donors of recipients with AS.

Table 1. Demographic and follow up characteristics of living related donors of recipients with Alport syndrome spectrum and propensity score matched control donor group.

Characteristics	ASLD Group (n=27)	Non-ASLD Group (n=29)	P value

**Increasing Conversion Rates and Reducing Disparities: Determining Modifiable Predictors Associated With Donating a Kidney**  
Amy D. Waterman,<sup>1</sup> John D. Peipert,<sup>2</sup> Edward A. Graviss,<sup>3</sup> Duc T. Nguyen,<sup>3</sup> Ahmed O. Gaber,<sup>1</sup> Andrea M. Meinders,<sup>1</sup> Linda W. Moore,<sup>1</sup> Francis L. Weng,<sup>4</sup>  
<sup>1</sup>Houston Methodist, Houston, TX; <sup>2</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>3</sup>Houston Methodist Academic Institute, Houston, TX; <sup>4</sup>Cooperman Barnabas Medical Center, Livingston, NJ.

**Background:** Potential living donors (PLD) may present for evaluation but not donate due to modifiable factors that could be intervened upon. From a longitudinal cohort study of 5 transplant centers, we examined how many PLDs of different races/ethnicities actually donated, how many were not ruled out who might still donate, and whether any modifiable factors were predictive of actual living donation (LD).  
**Methods:** From 2017-2020, we surveyed 2184 PLDs about their demographic characteristics, their educational preparedness, LD readiness, and anxiety prior to evaluation. Using EMR review, we followed 1241 PLDs for up to 12 months who were not ruled out to determine whether they donated a kidney. We used multivariable logistic regression models to identify characteristics associated with donating with variable selection conducted using the least absolute shrinkage and LASSO methods.  
**Results:** Of 2184 PLDs, 943 (43.2%) were ruled out for medical reasons, 704 (32.2%) dropped out, 130 (6.0%) were ruled out for modifiable reasons, and 407 (18.6%) donated. At the univariate level, PLDs who were Black (22.8%), Hispanic (22.4%), or of other races/ethnicities (20.6%) were less likely to donate than Whites (40.3%) and Asians (43%), with multilevel modeling revealing that Hispanics [OR: 2.25; 95% CI: 1.29, 3.95] remained less likely to donate than Whites after controlling for other factors (Table). Multivariate modeling also revealed that PLDs who had spoken to the kidney patient about donating, read information, and were in the Action Stage of readiness were 1.5-2.4 times more likely to donate.  
**Conclusions:** Interventions focused on increasing living donors' readiness and preparedness may reduce drop-out and increase the number of PLDs converting to actual LD.  
**Funding:** Other NIH Support - NIMHD - National Institute on Minority Health and Health Disparities

SA-PO797

**Understanding Anxiety in Potential Living Donors and Its Association With Actual Donation**  
Amy D. Waterman,<sup>1</sup> Ariella Maghen,<sup>2</sup> Wendy Balliet,<sup>3</sup> Francis L. Weng,<sup>4</sup> Edward A. Graviss,<sup>1</sup> Duc T. Nguyen,<sup>1</sup> Alexis Bobu,<sup>1</sup> Ahmed O. Gaber,<sup>1</sup> John D. Peipert,<sup>5</sup> <sup>1</sup>Houston Methodist, Houston, TX; <sup>2</sup>Community Memorial Health System, Ventura, CA; <sup>3</sup>Medical University of South Carolina, Charleston, SC; <sup>4</sup>Cooperman Barnabas Medical Center, Livingston, NJ; <sup>5</sup>Northwestern University, Evanston, IL.

**Background:** Potential donors (PDs) considering Living Kidney Donations (LD) may experience emotional distress surrounding donation and consequently drop out. Using longitudinal cohort data, we examined anxiety at onset of donor evaluation, characteristics associated with higher anxiety, and whether higher anxiety was associated with actual LD.  
**Methods:** PDs from 5 transplant centers were surveyed on their attitudes, knowledge of LD, and a PROMIS® 4-item anxiety short form (normative T score mean of 50, higher scores mean higher anxiety). Participants were followed up to 12 months from evaluation to determine if they donated. Multivariable logistic regression models were used to identify characteristics associated with mild anxiety or higher (T score ≥55) and LD.  
**Results:** 2184 individuals were surveyed, of which 407 (18.6%) donated a kidney. Participants were White (50.3%), female (61.5%). The median T-score was 46.8 (IQR: 39.4, 54.8); 19.7% (n=424) had T scores ≥55. Anxiety T-scores did not vary by race/ethnicity (p=0.77). Lack of support for donation [odds ratio (OR): 2.25; 95% CI: 1.29, 3.95], having a close familial recipient (OR: 1.72; 1.07, 2.79), and other factors were associated with higher anxiety (Table 1). Compared to those with less anxiety, those patients with higher anxiety were more likely to report that they would prefer that someone else donate (19% vs. 7.5%, P<.001) and had a 39% reduction in odds of actually donating (OR: 0.61; 95% CI: 0.38, 0.97).

**Conclusions:** Higher anxiety, particularly when the kidney recipient is a family member, was associated with a reduced likelihood of LD. PROMIS Anxiety should be considered as a screening tool for PD along with LD tailored interventions to reduce anxiety and support withdrawal from donation.  
**Funding:** Other NIH Support - NIMHD

SA-PO798

**Prevalence and Predictors of Suboptimal Kidney Donor Profile Index (KDPI) and Estimated Post-Transplant Survival (EPTS) Mismatches in Kidney Transplant Recipients**  
Sarah Chen, Barbara A. Grimes, Charles E. McCulloch, Flavio Vincenti, Elaine Ku. *University of California San Francisco, San Francisco, CA.*

**Background:** Under the current Kidney Allocation System, longevity matching of transplant candidates with deceased donor organs occurs through matching of the Kidney Donor Profile Index (KDPI) to the Estimated Post-Transplant Survival (EPTS). Our objective was to explore predictors and outcomes of population with large mismatches in KDPI and EPTS (defined in Figure).  
**Methods:** Adults who received deceased donor transplantation between 2015-2019 according to the USRDS were included. Logistic regression models were used to identify predictors of a high KDPI/low EPTS or low KDPI/high EPTS match (Figure) in separate models. Candidate predictors included demographic, comorbidity, and laboratory data. To confirm if these mismatches had differential graft outcomes, we examined the risk of graft loss in each of these groups compared to those with closer categories of matching between KDPI and EPTS.  
**Results:** Table 1 shows predictors of the two mismatch types. Results were similar when highly sensitized (calculated panel reactive antibody>80%) or repeat transplant recipients were excluded. In Cox models, we found the expected outcomes: higher risk of graft loss for high KDPI/low EPTS mismatched population (HR 1.62; 95% CI 1.36–1.94) and lower risk of graft loss for low KDPI/high EPTS mismatched population (HR 0.46; 95% CI 0.37–0.58).  
**Conclusions:** Extreme matches in KDPI/EPTS are present in >20% of transplant recipients. Some variables, such as donor and recipient race, are consistently predictive of low-quality organs being matched to recipients with high EPTS or vice versa. Further studies are needed to understand the reasons for these mismatches given that such mismatches do associate with different risks of long-term graft outcomes.

KDPI (%) \ EPTS (%)	0 – 20	20 – 40	40 – 60	60 – 80	80+
0 – 20	Reference group for high KDPI/low EPTS match (n = 20,230)			High KDPI/Low EPTS Match (n = 5,863)	
20 – 40					
40 – 60	Low KDPI/High EPTS Match (n = 6,640)			Reference group for low KDPI/high EPTS match (n = 18,591)	
60 – 80					
80+					
Total study population = 61,227					

**Table 1: Predictors of Each KDPI/EPTS Mismatch**

	High KDPI/Low EPTS Match (unfavorable*)	Low KDPI/High EPTS Match (favorable†)
	Odds Ratio [95% CI]	Odds Ratio [95% CI]
Factors associated with increased likelihood of mismatch	Black (vs. White) donors	On Medicare/Medicaid
	2.21 [2.02 - 2.41]	1.28 [1.17 - 1.39]
	Asian donors	OPTN region 8
	1.59 [1.29 - 1.95]	1.23 [1.00 - 1.51]
	OPTN region 9 (vs. region 1)	
Factors associated with decreased likelihood of mismatch	1.42 [1.15 - 1.76]	
	OPTN region 7	
	1.28 [1.03 - 1.59]	
	Females (vs. males)	
	1.23 [1.14 - 1.32]	
Factors associated with decreased likelihood of mismatch	Asian (vs. non-Hispanic White) recipients	
	1.23 [1.08 - 1.40]	
	OPTN region 6	Asian donors
	0.48 [0.36 - 0.63]	0.51 [0.39 - 0.65]
	On Medicare/Medicaid (vs. private insurance)	Black donors
Factors associated with decreased likelihood of mismatch	0.88 [0.81 - 0.95]	0.57 [0.51 - 0.63]
		OPTN region 9
		0.61 [0.50 - 0.76]
		OPTN region 7
		0.72 [0.58 - 0.89]
Factors associated with decreased likelihood of mismatch		OPTN region 5
		0.73 [0.60 - 0.88]
		Hispanic recipients
Factors associated with decreased likelihood of mismatch		0.77 [0.70 - 0.86]
		Asian recipients
Factors associated with decreased likelihood of mismatch		0.80 [0.68 - 0.93]

\* High KDPI/low EPTS mismatch indicates the candidate received a donor kidney with relatively shorter estimated graft survival compared to the candidate's expected survival after transplant. This is an unfavorable mismatch for the recipients.

† Low KDPI/high EPTS mismatch indicates the candidate received a donor kidney with relatively longer estimated graft survival compared to the candidate's expected survival after transplant. This is a favorable mismatch for the recipients. We expected recipients with favorable mismatch to be associated with longer graft survival.

## SA-PO799

## Should “Marginal Kidneys” Be Offered for Repeat Transplantation? A Mate-Kidney Analysis

Kalathil K. Sureshkumar,<sup>1</sup> Michelle A. Josephson,<sup>2</sup> Bhavna Chopra,<sup>3</sup> Rita L. McGill.<sup>2</sup> <sup>1</sup>Allegheny Health Network, Pittsburgh, PA; <sup>2</sup>University of Chicago Pritzker School of Medicine, Chicago, IL; <sup>3</sup>Beth Israel Deaconess Medical Center, Boston, MA.

**Background:** Initial and subsequent kidney transplantation improves survival compared to continuing dialysis. Higher kidney donor profile index (KDPI) kidneys (“marginal kidneys”) generally provide inferior transplant outcomes compared to lower KDPI kidneys. Repeat kidney transplant recipients (KTRs) are biologically more complex with increasing immunologic risk. We aimed to explore whether transplantation of high-KDPI “marginal kidneys” might result in suboptimal outcomes for repeat KTRs by utilizing a mate-kidney model.

**Methods:** Deceased donors in the OPTN/UNOS database from 2000 to 2019 were extracted if one kidney was transplanted into a first time recipient and the mate-kidney was transplanted into a repeat recipient. Transplant pairs were then stratified by KDPI: 0-20% (best kidneys); 21-85% (average kidneys); 86-100% (“marginal kidneys”). Using marginal models, transplant outcomes were compared between first time and repeat mate-kidney recipients.

**Results:** During the study period, 9502 mate-kidney pairs were identified with KDPI as follows: 0-20%=2387; 21-85%=6800; 86-100%=315. Risks for delayed graft function (DGF), graft failure, death-censored graft failure and patient death are shown for repeat KTRs compared to first time KTRs (table).

**Conclusions:** Elevated risk for DGF in repeat KTRs regardless of KDPI suggests that recipient related factors are responsible. Inferior death-censored graft survival observed when higher KDPI kidneys are received by repeat KTRs suggests that these patients may preferentially benefit from lower KDPI kidneys. Transplant teams should be cautious about accepting “marginal kidney” offers for repeat KTRs. Improved patient survival observed in repeat KTRs could possibly reflect stringent listing criteria for repeat kidney transplantation, or other factors.

Outcomes: Repeat vs. first transplant

	KDPI 0-20%		KDPI 21-85%		KDPI 86-100%	
	OR (95% CI)	P	OR (95% CI)	P	OR (95% CI)	P
Delayed graft function	1.30 (1.10-1.54)	0.002	1.15 (1.06-1.25)	0.001	1.61 (1.11-2.32)	0.01
Graft failure	1.00 (0.89-1.12)	0.90	1.02 (0.96-1.09)	0.50	0.99 (0.89-1.12)	0.90

## SA-PO800

## Geographic Hot Spots of Post-Dialysis Kidney Transplant Waitlisting Are Associated With Socioeconomic Deprivation

Robert B. Buchalter, Anne M. Huml, Emilio D. Poggio, Jesse D. Schold. Cleveland Clinic, Cleveland, OH.

**Background:** Wait-listing of deceased donor kidney transplant candidates before maintenance dialysis improves outcomes. Preemptive listing disparities have not been examined with geospatial methods, so identifying hot spot areas where post-dialysis wait-listing is most prevalent is a first step towards localizing interventions and health policy. Socioeconomic deprivation is linked to post-dialysis wait-listing but has not been studied in the context of geographic hot spots, suggesting an opportunity to examine differences in deprivation between post-dialysis wait-listing hot spots and non-hot spots.

**Methods:** We used 2010-2020 zip code tabulation area-level SRTR deceased donor kidney transplant candidate data and 3 geospatial cluster analysis methods to identify statistically significant post-dialysis wait-listing hot spots. We classified ZCTAs by area deprivation index quartile derived from 2010-2019 ACS 5-year estimates and computed odds ratios and 95% confidence intervals comparing deprivation values in hot spots and non-hot spots.

**Results:** We identified hot spots in southeastern, southwestern, and California ZCTAs, with most hot spots occurring in the southeast (Figure 1). Hot spot ZCTAs were more likely to be in the highest deprivation quartile (OR: 6.76, 95%CI: 6.52-7.02) compared to non-hot spot ZCTAs.

**Conclusions:** Our results reveal novel small area post-dialysis kidney transplant wait-listing disparity patterns where clinical interventions and health policies can be targeted. Our work is the first to identify localized preemptive listing disparities and the first to identify geographic preemptive listing disparities in California. The strong link between post-dialysis wait-listing hot spots and socioeconomic deprivation reflects previous findings but sheds new light by integrating geography.

## Risk Prediction for Early Post-Donation Kidney Dysfunction in Live Kidney Donors Using a Common Data Model

Sehoon Park,<sup>1</sup> Eunjeong Kang,<sup>2</sup> Sejoong Kim,<sup>3</sup> Kwon Wook Joo,<sup>1</sup> Yon Su Kim,<sup>1</sup> Hajeong Lee.<sup>1</sup> <sup>1</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>2</sup>Ewha Womans University Seoul Hospital, Seoul, Republic of Korea; <sup>3</sup>Seoul National University Bundang Hospital, Seongnam, Republic of Korea.

**Background:** Determination of the prognosis of living kidney donors is important. Impairment of early post-donation kidney function is associated with a higher risk of long-term kidney failure. Therefore, a prediction model for early post-donation kidney function in living kidney donors is warranted.

**Methods:** Common Data Model was implemented for inclusion of uniform data from three tertiary hospitals in Korea. The development cohort consisted of living kidney donors at Seoul National University Hospital (N=1074), and the two validation cohorts consisted of 2595 and 189 living kidney donors from other hospitals in Korea. Logistic regression analysis was performed for insufficient kidney function recovery, comprising estimated glomerular filtration rates (eGFRs) <60 and <50 mL/min/1.73 m<sup>2</sup>. Variables that were associated with most of these study outcomes were selected for construction of the final prediction model, a multivariable logistic regression model.

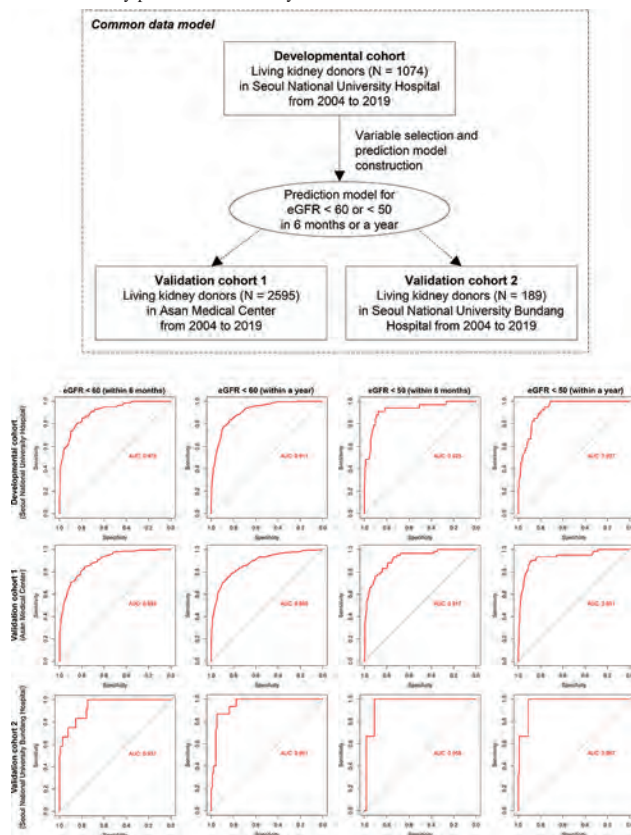

**Results:** Among the study cohorts, 10%-35% of living kidney donors had an eGFR <60 mL/min/1.73 m<sup>2</sup> and 3%-9% had an eGFR <50 mL/min/1.73 m<sup>2</sup> in the outcome-assessment period. Older age, male sex, higher body mass index, lower baseline eGFR, higher serum uric acid concentration, and the occurrence of postoperative acute kidney injury were included in the final prediction model. The model yielded acceptable

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

discriminative power (AUC $\geq$ 0.88) in both the development and validation cohorts. The calibration results were also acceptable (Hosmer-Lemeshow test, all P values but one were  $>0.05$ ). A risk calculator for the four study outcomes was developed and published online (<https://snhnephrology.github.io/>).

**Conclusions:** We constructed an easily accessible and useful risk prediction calculator for early post-donation kidney function.

## SA-PO802

### Death on Kidney Transplant Waitlist: Clues to Better Listing Decision Making

Ninoshka Mendonca, Jaya Mehta, Anil S. Paramesh, Hoonbae Jeon, Mary Killackey, Adarsh Vijay. Tulane Transplant *Tulane University School of Medicine, New Orleans, LA.*

**Background:** Wait-list mortality with risk adjustment is one of the pre-transplant metrics currently used for monitoring transplant program performance. Understanding risk factors and mortality trends in wait-listed kidney transplant candidates are essential to implement better screening protocols and better listing decision making.

**Methods:** We performed a single-center five-year retrospective study of kidney transplant candidates who were accepted to the transplant wait-list between January, 2012 and December, 2016. Characteristics of transplanted recipients [TG] were compared with candidates that expired [EG] on the kidney transplant waitlist.

**Results:** A total of 266 patients on the transplant wait-list were included in our study, of which 185 (70%) were transplanted and 81 (30%) expired. The groups were comparable with respect to gender, ethnicity, BMI, blood type, functional status at listing, history of previous transplants and history of prior malignancy. Our analysis showed median age at listing was lower in TG in comparison to EG (47 vs 51 years;  $p=0.001$ ). Average length of time spent on the transplant waitlist was higher in EG (884 vs 819 days;  $p=0.50$ ). The occurrence of polypharmacy ( $>5$  medications) was higher in EG in comparison to TG (92% vs 81%;  $p=0.017$ ) along with the increased use of blood thinners in the EG group (49% vs 34%;  $p=0.018$ ). We also found that 98% of patients in the EG group had a diagnosis of hypertension at the time of listing in comparison to 88% in the TG group ( $p=0.01$ ). When comparing groups, 61% of the EG patients were diabetic in comparison to only 31% of TG patients. Similarly, the median HbA1c as well as the use of insulin was significantly higher in EG patients (7.1 vs 5.6;  $p=0.0001$ , 41% vs 19%;  $p=0.0002$ ). A higher proportion of patients in TG had EF  $>50\%$  on pre-listing echo than patients in EG (68% vs 56%;  $p=0.09$ ). 51 patients (63%) in EG underwent heart catheterization in comparison to 88 patients (48%) in TG. However, the percentage of positive heart catheterizations were higher in the TG 28% vs 21% in EG.

**Conclusions:** Our study shows greater mortality risk in wait-listed kidney transplant candidates with EF  $<50\%$ , poorly controlled diabetes, poly-pharmacy and use of blood thinners. The discrepancy in positive heart catheterization rates should alert future prospective trials to further streamline cardiac screening protocols in kidney transplant candidates.

## SA-PO803

### Use of Peritoneal Dialysis After Kidney Transplant Failure Is Associated With Survival Advantage in a Contemporary National Cohort of ESKD Patients

Sanjana Kapoor, Molly Fisher, Michele H. Mokrzycki, Luz E. Liriano-Ward, Enver Akalin, Tanya S. Johns. *Albert Einstein College of Medicine, Bronx, NY.*

**Background:** Kidney allograft failure (KAF) is associated with increased mortality. Prior studies suggest that peritoneal dialysis (PD) may offer short-term survival advantage over hemodialysis (HD) after KAF. We compared patient survival by dialysis modality and HD access type with mortality in patients with KAF.

**Methods:** From 2009-2019, adult ( $>18$  years) incident dialysis patients following KAF were identified using the US Renal Data System. We excluded patients who were missing data on dialysis modality or died within 30 days of initiating dialysis. Dialysis modality was analyzed with an intention-to-treat approach in which mortality was attributed to the initial modality. Patients were censored at re-transplantation or study end. Multivariable Cox Proportional hazards models with multiple imputation for missing data were used to determine the association between dialysis modality and access type and mortality.

**Results:** Of 32,649 KAF patients, 3,201 (9.8%) were initially treated with PD and 29,448 (90.2%) with HD. Among those on HD, 11,284 (38.4%) and 18,127 (61.6%) used an arteriovenous access and central venous catheter (CVC), respectively. Compared to the HD group, the PD group was younger (median age 55 vs 51 years,  $p<0.001$ ); more likely to be Caucasian (69.6% vs 63.4%,  $p<0.001$ ) and received a living donor transplant (47.1% vs 33.8%,  $p<0.001$ ); and less likely to have diabetes (28.6% vs 41.2%,  $p<0.001$ ) and coronary artery disease (8% vs 12.2%,  $p<0.001$ ). Over the study follow-up [median 6.6y (6.4-6.8y)], there were 10,534 deaths and 6,455 patients had at least one re-transplantation. Compared to HD, initiating PD after KAF was associated with a 14% lower risk of death (adjusted hazard ratio 0.86 [95% confidence interval 0.78 – 0.94]) after adjusting for demographics, donor type, comorbidities, ESKD etiology, albumin, creatinine, hemoglobin and dialysis vintage. The survival advantage was more pronounced when PD was compared to HD initiation via CVC.

**Conclusions:** Among patients with KAF, PD is associated with improved long-term survival compared to HD. CVC for initial access among incident HD patients after KAF is associated with highest risk of mortality. Future studies should elucidate barriers to timely arteriovenous access placement and PD initiation in patients with KAF.

## SA-PO804

### Impact of Willingness to Accept a Hepatitis C Viremic Donor Kidney on Access to Transplant

Warren T. McKinney,<sup>1,2</sup> David P. Schladt,<sup>3</sup> Ajay K. Israni.<sup>1,2</sup> <sup>1</sup>Hennepin Healthcare Research Institute, Minneapolis, MN; <sup>2</sup>Scientific Registry of Transplant Recipients, Minneapolis, MN; <sup>3</sup>Chronic Disease Research Group, Minneapolis, MN.

**Background:** The approval of effective therapy for Hepatitis C (HCV) for use in transplant patients changed considerations for using organs recovered from HCV viremic donors. We evaluated the impact of kidney transplant candidates' willingness to accept a HCV donor on access to deceased donor kidney transplant (DDKT). We also sought to determine the effect of race when considering willingness to accept a HCV donor.

**Methods:** This study used Scientific Registry of Transplant Recipients data, and included all candidates for DDKT between Jan. 1, 2015 and Mar. 12, 2020 ( $n=233,033$ ). Candidates were classified as African American (AA) or non-African American (non-AA) and categorical differences in clinical factors were evaluated by  $\chi^2$  tests. Cox models with time to transplant were constructed to assess the impact of willingness to accept a HCV donor and the effect combined with race. Sub-analyses evaluated the impact of geography and Latino ethnicity.

**Results:** 76,576 (32.9%) candidates during the study period were AA, and there was significant variation in clinical factors between AA and non-AA candidates. AA candidates were more likely to: be female, blood type B, have 3 or more years of waiting time, and be willing to accept a HCV donor (all  $p<0.001$ ). Willingness to accept a HCV donor was associated with increased access to transplant for all candidates, hazard ratios (HR) for non-AA access to transplant was 2.174 (95% CI, 2.097-2.254) and 2.196 (95% CI, 2.096 – 2.300) for AA (Figure 1). Similar results were seen in Latinos and across geographies.

**Conclusions:** Willingness to accept a HCV donor is associated with increased access to DDKT. There is an opportunity to expand access to DDKT by providing decision support for AA and non-AA candidates on accepting HCV donors. However, further analysis is necessary to disentangle the interaction between candidate selection and candidate-level risk tolerance.

**Funding:** Other NIH Support - This material is based in part upon work supported by the Agency for Healthcare Research and Quality (AHRQ) and the Patient-Centered Outcomes Research Institute (PCORI) grant K12HS026379 (W.T.M.).

Impact of willingness to accept HCV donor kidney on access to DDKT

## SA-PO805

### Racial Differences in Trends and Survival After Simultaneous Heart and Kidney Transplantation in the United States

Alexis K. Okoh,<sup>1</sup> Joseph Ruberwa,<sup>2</sup> *Emory University School of Medicine, Atlanta, GA;* <sup>2</sup>*University of North Carolina System, Chapel Hill, NC.*

**Background:** Among patients with chronic kidney disease listed for Heart Transplantation (HT), survival outcomes are better after simultaneous heart and kidney transplantation (sHKT) than isolated HT. However, racial differences in utilization of sHKT and post sHKT survival are unknown.

**Methods:** The United Network for Organ sharing database was queried for data on all adult patients who underwent sHKT between January 1990 and December 2019. Recipients were classified based on self-reported race and ethnicity, including non-Hispanic White, non-Hispanic Black, Hispanic, and Asian. Trends in sHKT over five eras (1990-1995, 1996-2001, 2002-2007, 2008-2013, 2014-2019) were examined. Kaplan-Meier analysis was used to examine one- and five-year post-transplant survival over the eras and by race-ethnic groups. Median survival rates were estimated from Cox proportional Hazard modelling.

**Results:** During the study period, a total of 1872 patients (non-Hispanic White (n=1082), non-Hispanic Black (n=556), Hispanic (n=157), and Asian (n=77) underwent sHKT in the United States. A significant increase in utilization of sHKT from 3.9% in 1990 to 51.9% in 2019 was seen overall and proportionally by race-ethnic group. Both one- and five-year survival post-sHKT were comparable by race. 1-year [Log rank test; p=0.623], 5-year [Log rank test; p=0.063] with no observed differences. Risk adjusted median survival rates by race were estimated as: [Race; Years] Non-Hispanic White: 11.9 non-Hispanic Black: 12.5, Hispanic: 16.8, Asian: 13.2.

**Conclusions:** There has been an increasing trend in the utilization of sHKT over the past 3 decades. There were no differences in post-transplant survival at both one- and five years by race-ethnic groups. Estimated median survival after sHKT is 12-years and remains comparable by race-ethnic groups.

## SA-PO806

### Variations in Access to Repeat Transplantation by Transplant Center Continuity

Davidson F. Emanuels,<sup>1</sup> Timothy P. Copeland,<sup>2</sup> Kirsten L. Johansen,<sup>3</sup> Charles E. McCulloch,<sup>2</sup> Elaine Ku,<sup>4</sup> *<sup>1</sup>University of California San Francisco School of Medicine, San Francisco, CA; <sup>2</sup>University of California San Francisco, Department of Epidemiology and Biostatistics, San Francisco, CA; <sup>3</sup>Hennepin Healthcare, Minneapolis, MN; <sup>4</sup>University of California San Francisco Medical Center at Parnassus, San Francisco, CA.*

**Background:** In the U.S., there is significant fragmentation in the care of patients with a failing kidney transplant. Our objective was to examine the association between transplant center continuity and access to repeat transplantation.

**Methods:** Using US Renal Data System data, we studied adults relisted for kidney transplantation between 2006-2016. We examined whether transplant center continuity (same versus different transplant center where relisting occurred) was associated with time to a second kidney transplant or odds of preemptive relisting using cause-specific and logistic regression models, respectively. We tested for effect modification by race/ethnicity.

**Results:** Among 21,154 patients, 29% switched transplant centers, 31% were preemptively relisted, and 48% received a second transplant during median follow-up of 2.9 years. Patients who switched centers had a 9% lower hazard of repeat transplantation, particularly from a deceased donor source (Figure 1). Patients who switched centers had 29% lower odds of preemptive relisting compared to those who remained at the same center (OR 0.71; 95% CI 0.66-0.77). This finding was modified by race/ethnicity (interaction p<0.001), with non-Hispanic Black (OR 0.52; 95% CI 0.45-0.61) and Hispanic (OR 0.59; 95% CI 0.47-0.73) patients who switched centers having disproportionately lower odds of preemptive relisting compared with non-Hispanic White patients (OR 0.81; 95% CI 0.74-0.89, Figure 2).

**Conclusions:** Individuals who remained at the same transplant center had better access to preemptive relisting and retransplantation. Black and Hispanic candidates who switched centers were especially disadvantaged. Additional studies on the role of continuity of care are needed to improve outcomes.

**Funding:** NIDDK Support

## SA-PO807

### Outcomes of Commercial Renal Transplantation: A Single Center Experience

Amgad E. El Agroudy. *Arabian Gulf University, Manama, Bahrain.*

**Background:** While the ethical aspects of transplant tourism have received much attention recently, less has been written about the medical safety of this practice. We retrospectively evaluated the outcomes of patients who purchased organs internationally and presented to our center for follow-up care.

**Methods:** We report the outcome parameters of 270 local recipients of unrelated kidney (URT) vendor transplants presenting to our institute between 1986 and 2014. Their outcome was compared with 123 recipients of living-related donor transplants matched for age, gender and transplant duration done in our center as controls (RT).

**Results:** Age of unrelated recipients was  $42.6 \pm 13.4$  years with Male % of 68. The country of transplant was mainly in Philippines (n = 85), Pakistan (n = 56), India (n = 57), Iran (n = 40) and Egypt (n = 25). Comparison of commercial recipients with controls showed high co morbidities (P = 0.01) with hepatitis-C (n=2 vs. 0) and hepatitis-B (n=2 vs. 0) and cytomegalovirus (n=4 vs. 1). Donor age was  $25.9 \pm 3.8$  vs.  $34.6 \pm 8.6$  years (P = 0.0001) and 90.4% were male. Biologic agents induction in 74 (27.4%) vs. 123 (100%) (P = 0.00001), acute rejections in 65 (24.1%) vs. 26 (21.1%) (P = 0.7), while recurrent rejection in 13 (4.8%) vs. 1 (0.8%) (P = 0.04), surgical complications including lymphocele 16 (5.9%) vs. 0 (0%) (P = 0.0001), ureteral obstruction 7 (2.6%) vs. 0 (0%) (P = 0.007), hematoma 4 (1.5%) vs. 1 (1.1%) (P = 0.06) and recurrent urinary tract infection 18 (9.9%) vs. 6 (6.8%) (P = 0.3). Overall 1- and 10-year for graft survival was 91% and 22% vs. 98% and 44% and for patient survival 96% and 70% vs. 98% and 78% in URT and RT, respectively (P = 0.001).

**Conclusions:** Although recent developments increased success in renal transplantation, receiving a kidney from a paid living donor at a commercial transplant center still carries great risks for the recipient.

## SA-PO808

### Concordance of Social Deprivation Among Living Kidney Donor-Recipient Pairs

Yara Bilen, Jesse D. Schold, Susana Arrigain, Robert B. Buchalter, Anne M. Huml. *Cleveland Clinic, Cleveland, OH.*

**Background:** Living kidney transplant is the most effective replacement therapy. Pervasive socioeconomic disparities in access to living kidney transplant exist and little is known about how closely socioeconomic indicators match within living donor-recipient pairs. We aimed to examine concordance of social deprivation indices (SDI) in living donor-recipient pairs.

**Methods:** We conducted a retrospective cohort study of living kidney donor-recipient pairs in the Scientific Registry of Transplant Recipients from 2010-2020. Living donors and kidney recipients were geocoded to link with a ZIP code tabulation area-level SDI and outcomes were stratified by donor type (altruistic, biological, non-biological and paired exchange). The association between donor-recipient SDIs were evaluated using Pearson's correlation.

**Results:** 59,575 living donor-recipient pairs ( $\geq 18$  years old) with documented residential ZIP codes were identified. We characterized the donor type among 58,589 pairs: 2,343 altruistic, 26,363 biological, 22,698 non-biological, and 7,185 paired. The mean donor and recipient SDI were 45, with 26% of both donors and recipients coming from the lowest SDI quintile. The mean SDI for donor and recipient was 47.2 vs. 47.4 for biological, 42.5 vs. 42.7 for non-biological, 42.5 vs. 44.7 for paired, and 43.2 vs. 46.7 for altruistic. Among biological and non-biological donor-recipient pairs, SDI was highly correlated (Pearson Rho 0.51, and 0.56 respectively). In contrast, the SDI of altruistic donor-recipient pairs did not show a clear correlation (Rho = 0.15) except for two clusters in lowest and highest SDI. Paired exchanges were clustered at the lowest SDI (Rho=0.10 Fig.1).

**Conclusions:** Living kidney transplants occur across all SDIs, with different representation by donor types. By understanding these differences, we can leverage community resources to better support living donation in areas of neighborhood disadvantage.

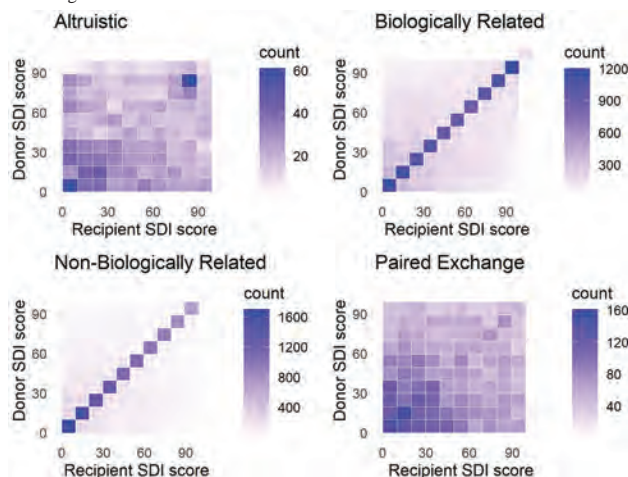

Fig.1 SDI comparison by donor type

#### SA-PO809

##### Opportunities to Leverage Personal Networks to Increase Living Donor Kidney Transplant

Karen-Marie Eaton,<sup>1</sup> Michael H. O'Shea,<sup>2</sup> Steven M. Brunelli,<sup>1</sup> Francesca Tentori.<sup>1</sup> <sup>1</sup>Davita Clinical Research, Minneapolis, MN; <sup>2</sup>DaVita Inc, Denver, CO.

**Background:** Living donor kidney transplant (LDKT) offers patients another treatment option for kidney failure. In this study, we sought to understand dialysis patients' and care partners' knowledge, beliefs, and attitudes toward transplant and living donation.

**Methods:** A total of 38 participants were interviewed by phone between May and August 2021. Interviews ranged in time from 10-45 minutes and included a spectrum of participants including dialysis patients and members of their care team. Interviews were recorded and transcribed verbatim (Figure 1); responses were analyzed separately using inductive thematic analysis.

**Results:** The study found that almost all patients and care partners had discussed transplant with their dialysis care team, and that patients perceived LDKT as superior to both deceased donation and dialysis - leading to longer life and better clinical outcomes. Although LDKT was discussed, the amount of retained/detailed knowledge was inconsistent among patients, often leading to misperceptions of the process. Of the few patients who had a negative perception of transplant, all cited knowing someone who had a poor outcome. When it came to having LDKT discussions with potential donors, 42% of participants had broached the subject; of those, most conversations were with a close relative. Patients and care partners tended to rely heavily on potential donors volunteering to be tested instead of proactively seeking a donor from personal networks.

**Conclusions:** Families are not always skilled in leveraging all resources to identify potential donors and patients/care givers could use assistance crafting their donor pitch as well as a viable strategy to leverage personal and extended networks.

#### SA-PO810

##### Barriers to "The Big Ask" and Opportunities to Increase Living Donor Kidney Transplant Among Dialysis Patients and Care Givers

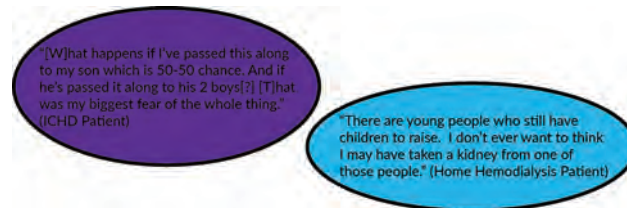

Karen-Marie Eaton,<sup>1</sup> Michael H. O'Shea,<sup>2</sup> Steven M. Brunelli,<sup>1</sup> Francesca Tentori.<sup>1</sup> <sup>1</sup>Davita Clinical Research, Minneapolis, MN; <sup>2</sup>DaVita Inc, Denver, CO.

**Background:** Living donor kidney transplant (LDKT) offers patients another treatment option for kidney failure. Previous studies indicate that while many dialysis patients and care partners are aware of LDKT, they are unable to leverage their personal networks to obtain a living donation. In this study, we sought to understand current barriers to kidney transplant and living donation for dialysis patients and care partners.

**Methods:** A total of 38 participants were interviewed by phone between May and August 2021. Interviews ranged in time from 10-45 minutes and included a spectrum of participants including dialysis patients and their care partners. Interviews were recorded and transcribed verbatim (Figure 1); responses were analyzed separately using the inductive thematic analysis procedure.

**Results:** Results from the study indicated that many participants were reluctant to make the "big ask" for a kidney from people within their networks and instead relied on volunteers. Reasons for this were varied, but it was a key driver of LDKT hesitancy. Interestingly, male participants tend to report more "organic" donor conversations, while females report proactively bringing up the topic of living donation. Some participants stated that they have difficulty getting past the information-sharing stage of the LDKT conversation and the conversation stops before getting to the "big ask". Many participants stated that they have "lived a good life," and do not want to inconvenience anyone. More specifically, older patients felt "less worthy" of receiving a kidney over younger dialysis patients and/or receiving a kidney from a younger donor who has "more life" left to live and may need two functioning kidneys. Additionally, patients are especially averse to the idea of accepting a kidney from their own children - even when they have expressed initial interest in donating. Finally, almost all participants acknowledged future concerns for prospective donors.

**Conclusions:** Significant barriers to LDKT consideration were largely social and psychological, including unwillingness to make the "big ask" of their social network

#### SA-PO811

##### Structured Literature Review of the Economic and Humanistic Burden in Kidney Allograft Loss

Emily Moss,<sup>1</sup> Anita D. Burrell,<sup>2</sup> James C. Lee,<sup>3</sup> Dawn Reichenbach,<sup>3</sup> Sarah E. Mitchell,<sup>1</sup> Songkai Yan,<sup>3</sup> Kris Thiruvillakkat.<sup>3</sup> <sup>1</sup>RTI Health Solutions, Manchester, United Kingdom; <sup>2</sup>Anita Burrell Consulting LLC, Flemington, NJ; <sup>3</sup>CSL Behring LLC, King of Prussia, PA.

**Background:** Kidney allograft loss (KAL) results in both an economic burden to the healthcare system, and an economic and humanistic burden to kidney transplant recipients, with ~30% of patients with antibody-mediated rejection (AMR) experiencing graft loss. The 2017 Banff Criteria includes diagnostic guidelines for AMR, however there are no ICD codes specifically for AMR as a cause of KAL, leading to difficulty in investigating clinical data to understand underlying etiology. The review objective was to systematically gather evidence on the economic burden (costs and healthcare resource use) and humanistic burden (health-related quality-of-life [HRQOL]) in patients with AMR KAL.

**Methods:** A comprehensive review of the literature was conducted from 2011-2021, with a focus on the United States, United Kingdom, France, Germany, Spain, and Italy.

**Results:** The review identified 21 studies reporting on the economic and/or humanistic burden of KAL; nine of these reported AMR-specific outcomes. As the studies were often small and lacking clear case definitions for AMR and the associated costs, comparisons between studies were difficult. However, the studies consistently demonstrated that there was a higher clinical and economic burden associated with AMR-related KAL than non-AMR KAL. A key result of the review was that the total annual cost of AMR-kidney graft loss ranged between \$USD \$116,988 and \$159,705 compared with \$75,909 and \$94,352 for non-AMR KAL, demonstrating a higher cost associated with AMR. One study assessed HRQOL using the Kidney Disease Quality of Life Instrument; HRQOL tended to be lower for AMR patients versus non-AMR patients when compared across different chronic kidney disease (CKD) stages for both the physical composite scores (PCS) and mental composite scores (MCS). The exception to this trend was the PCS in CKD stages 3b and 4 and the MCS in CKD stage 4, where AMR patients had a higher HRQOL than non-AMR; the finding was not discussed in the article.

**Conclusions:** There is a paucity of high-quality studies reporting the burden of AMR-related KAL. The establishment of etiology associated kidney transplant rejection ICD-10 codes including AMR-related KAL would greatly benefit future research activities by enabling the generation of real-world evidence in this population.

## SA-PO812

**Validation of Adjusted Donor Age: A Tool to Support Deceased-Donor Kidney Organ Acceptance at a Eurotransplant Centre**

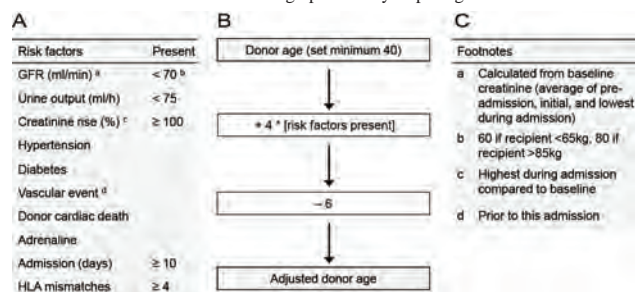

Christoph F. Mahler,<sup>1</sup> Damien Ashby,<sup>2</sup> Christian Nussbag,<sup>1</sup> Claudius Speer,<sup>1</sup> Louise Benning,<sup>1</sup> Daniel Göth,<sup>1</sup> Matthias Schaefer,<sup>1</sup> Arianeb Mehrabi,<sup>3</sup> Martin G. Zeier,<sup>1</sup> Christian Morath,<sup>1</sup> Florian Kälble.<sup>1</sup> <sup>1</sup>Universitätsklinikum Heidelberg Nierenzentrum Heidelberg eV, Heidelberg, Germany; <sup>2</sup>Imperial College London, London, United Kingdom; <sup>3</sup>Universitätsklinikum Heidelberg Chirurgische Klinik, Heidelberg, Germany.

**Background:** In view of the organ donor shortage and growing waiting lists for kidney transplantation an optimal acceptance strategy for deceased-donor kidney offers is paramount. However, acceptance decisions are challenging not the least because current tools for assessment of kidney offers, e.g. KDRI/KDPI (Kidney Donor Risk Index/Kidney Donor Profile Index) are limited and most transplant centres lack clear criteria.

**Methods:** To meet the multi-morbid patient population at a London transplant centre Adjusted donor age (ADA) was developed as a tool to support organ acceptance decision making in deceased-donor kidney transplantation. Thereby offers are divided according to risk into quintiles (A - E). (A - C favourable, D moderate, E unfavourable). These quintiles are associated with the adjusted donor age. Underlying is the real donor age, adjusted for associated risk factors and the immunological constellation.

**Results:** Here, we evaluate whether ADA can be applied at a Eurotransplant Centre in Germany to assess organ quality and guide acceptance decisions. For this monocentre validation study we included 463 deceased-donor kidney organ offers of which 173 were accepted and transplanted. We followed organ recipients for three months after transplantation and measured eGFR as the primary outcome parameter. Statistical analysis revealed that indeed higher ADA quintile was associated with poorer transplant outcome. The three-month eGFR was strongly associated with ADA ( $r=0.56$ ) in patients with functioning graft and decreased with higher ADA quintiles (A: 64, B: 60, C: 49, D: 37 and E: 28 mL/min/1.73m<sup>2</sup>).

**Conclusions:** Taken together our study suggests that ADA can be applied at a Eurotransplant centre as a simple tool to characterise deceased-donor kidney organ offers. ADA may facilitate acceptance decision making and help to distinguish organs with favourable outcomes from ones with high probability of poor graft function.

## SA-PO813

**Evaluation of Measured Glomerular Filtration Rate in Living Related Kidney Donors Before and After Donor Nephrectomy**

Tushar A. Dighe, Abhijit S. Chavan, Charan B. Bale, Pavan Wakhare, Nishar Shinde, Akshay R. Kulkarni, Atul Sajgure. Dr.D.Y.Patil Medical College, Hospital and Research Centre, Pimpri, Pune, Dr DY Patil Vidyapeeth, Pune, India, Pune, India.

**Background:** Understanding the pathophysiologic effects of kidney donation is important for judging donor safety and analysing compensatory changes occurring in remnant kidney after donation. If remnant kidney undergoes inadequate compensatory changes in Glomerular filtration rate (GFR), it can have undesirable effects on long term health of donors.

**Methods:** We performed a prospective observational study of 10 subjects who underwent Nephrectomy for living related kidney transplant over a period of 1 year in tertiary care hospital. It was approved by our Institutional Ethics committee. Baseline evaluation of all subjects was done 10 to 14 weeks prior and at 11 to 13 weeks after nephrectomy, which included Tc-99m DTPA scintigraphy for measured GFR, Spot Urine Albumin Creatinine ratio and laboratory parameters (serum creatinine, urea and electrolytes). Lab parameters, spot urine albumin creatinine ratio and GFR by DTPA scan pre (10-14 weeks) and post (11-13 weeks) nephrectomy were compared and analysed. P values were calculated using paired t test.

**Results:** Mean age of donors was 49.1±15.38 (range 23-73) years. Pre-Nephrectomy, mean total GFR by DTPA scan was 101.7 ml/min (±9.28) which reduced to 61.13 ml/min (±5.87), a 40% decline in total GFR was noticed, 11-13 weeks after Nephrectomy. Mean serum creatinine pre and post donor Nephrectomy was 0.73 mg/dl (±0.94) and 0.96mg/dl(±0.54) respectively, with a significant mean rise of 0.23 mg/dl. Mean GFR of the remnant Kidney increased by + 9.64 ml/min (± 6.36), 11-13 weeks post Donation. Urinary Albumin Creatinine ratio pre and post Nephrectomy was 15.25 (±17.08) and 22.19 (±20.45) ug/mg respectively.

**Conclusions:** The mean total GFR reduced significantly by 40.5% (P<0.0001), however a significant increase in mean GFR of remnant kidney by 9.64 ml/min(±6.36) (P<0.001) 11 to 13 weeks Post Nephrectomy was seen. This average increase in GFR

was not significantly higher in young donors as compared to older donors (P<0.9). There was no significant difference in Urinary Albumin creatinine ratio pre and post nephrectomy (P<0.06). A better understanding of trends and variations observed in post donation GFR over time can aid in analysing effect of compensatory changes in GFR, which can benefit Living related kidney donors, in monitoring and patient care.

## SA-PO814

**A Social Network Analysis of Barriers to Requesting or Accepting an Offer for a Living Donor Kidney Transplant for People With ESKD**

Briana E. Lee,<sup>1</sup> Heather M. Gardiner,<sup>2</sup> Crystal A. Gadegebeku,<sup>3</sup> Peter P. Reese,<sup>4</sup> Zoran Obradovic,<sup>5</sup> Edward L. Fink,<sup>6</sup> Avrum Gillespie.<sup>1</sup> <sup>1</sup>Lewis Katz School of Medicine at Temple University, Philadelphia, PA; <sup>2</sup>Temple University College of Public Health, Philadelphia, PA; <sup>3</sup>Cleveland Clinic, Cleveland, OH; <sup>4</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>5</sup>Temple University, Philadelphia, PA; <sup>6</sup>Temple University, Philadelphia, PA.

**Background:** Living donor kidney transplant (LDKT) is the optimal but underutilized treatment for end-stage kidney disease (ESKD). Most living kidney donations come from a patient's social network through donation offers or requests. Our study aims to identify barriers to living kidney donations by analyzing a patient's social network.

**Methods:** Data were collected via cross-sectional survey of hemodialysis patients at two facilities. We used a multilevel binary logistic regression model to examine from which network member a participant would accept a living donation offer from or make a living donor request to. The independent variables included mean strength of relationships in the network, cohabitation, and emotional support. Confounding variables included patient demographic factors. We performed a qualitative analysis of open-ended responses to assess reasons for declining an offer or non-request.

**Results:** The mean age of 106 patients is 60; 55% are female, 75% self-identify as Black, 16% made a living donor request. The mean network size is 4.6, 70% of the network was eligible for donation, 8% of network members received a donation request, 21% of members offered with 41% of total offers accepted. 73% of members did not offer or receive a request. The odds of accepting an offer or receiving a request is higher for members who lived with the patient (OR: 3.58, 95% CI: 1.07-12.0) and with greater network strength (OR: 3.38, 95% CI: 1.47-7.79). In addition, the odds of accepting an offer or requesting was lower for members that provided the patient with emotional support (OR: 0.15, 95% CI: 0.05-0.44). Feeling guilty/concerned for the donor is the most common reason for declining an offer (48%) or not requesting (28%).

**Conclusions:** Patients with stronger relationships in their network were more likely to accept an offer or request. However, participants were less likely to accept an offer or request from network members that provided emotional support because of guilt/concern for the member. Further network interventions to strengthen relationships, assist in identifying potential donors within the network and alleviate concerns about donation for the patient and their networks may help overcome social barriers to LDKT.

**Funding:** NIDDK Support

## SA-PO815

**Efficacy of Remote Ischemic Preconditioning in Living Donor Renal Transplantation: A Randomized Controlled Trial**

Anurag Gupta, Nikita Pawar, Vaibhav Tiwari, Vinant Bhargava, Manish Malik, Anil Bhalla, Ashwani Gupta, Devinder S. Rana. Sir Ganga Ram Hospital, New Delhi, India.

**Background:** In kidney transplantation, ischemia-reperfusion injury (IRI) is an inevitable complication. However, paradoxically, an additional injury occurs upon reperfusion which limits the amount of tissue that can be salvaged. This is termed 'ischemia-reperfusion injury' (IRI). Different strategies have been tried to reduce ischemic reperfusion injuries. Ischemic preconditioning is one of such strategies. Thus, we have conducted RIPC, a randomized controlled trial in patients undergoing renal transplantation.

**Methods:** A randomized controlled trial was done to assess the efficacy and safety of remote ischemic preconditioning in living donor renal transplantation from June 2020 to September 2021. This study was conducted on a total of 110 ABO compatible live donor kidney transplant recipients. Randomization was done, 58 patients in the RIPC group and 52 patients in the control group were studied. They were followed for 3 months of study. primary objective- the proportion of patients achieving a 50% decline in serum creatinine level at 72 hours after transplantation and oliguria on day 1, 2 and 3. secondary objective- eGFR at 3 months of transplantation, acute rejections, and delayed graft function.

**Results:** The mean age in both groups was comparable (37.09 vs 38.3 years) All patients showed a >50% decline in creatinine level at 72 hours of transplant. The mean serum creatinine on day 7 of transplant level in the RIPC group was 1 mg/dL and 1.1 mg/dL in the control group. There was no oliguria in 1st 3 days. There was no difference in urine output in both groups. The stable graft function was present in 83.6% of cases. It was higher in the RIPC group compared to the control group (p=0.08). Delayed graft function was present in 3.8% of cases in the control group and 1.7% in the RIPC group (p=0.9). Similarly, slow graft function was present in 17.3% in the control group while 10.3% in the RIPC group (p=0.8). The mean serum creatinine level in both groups was the same at 3 months, 1.2 mg/dL. Acute tubular necrosis was the most common finding on biopsy (63.6%). Acute rejections were similar in both the groups (2 vs 3; p=0.9)

**Conclusions:** There was no effect of RIPC on slow graft function, rate of fall of creatinine, graft function and rate of rejection at 3 months.

## SA-PO816

**How Do Kidney Transplant Attitudes and Behaviors Affect Popularity and Influence Within the Hemodialysis Clinic Social Network?**

Hannah Calvelli,<sup>1</sup> Avrum Gillespie,<sup>1</sup> Heather M. Gardiner,<sup>2</sup> Crystal A. Gadegbeku,<sup>3</sup> Peter P. Reese,<sup>4</sup> Zoran Obradovic,<sup>5</sup> Edward L. Fink.<sup>5</sup>  
<sup>1</sup>Lewis Katz School of Medicine at Temple University, Philadelphia, PA; <sup>2</sup>Temple University College of Public Health, Philadelphia, PA; <sup>3</sup>Cleveland Clinic, Cleveland, OH; <sup>4</sup>University of Pennsylvania, Philadelphia, PA; <sup>5</sup>Temple University, Philadelphia, PA.

**Background:** Patient social networks in hemodialysis clinics may facilitate the spread of information, attitudes, and behaviors surrounding kidney transplantation. Identifying influential social network members is an important first step for future transplant interventions among hemodialysis patients. In this study, we mapped the social networks of two different hemodialysis facilities to identify which patients could be the most influential. We used in-degree centrality (identified most frequently by other network members) as a proxy for popularity and influence.

**Methods:** We conducted a cross-sectional social network survey of hemodialysis patients in two geographically and demographically different hemodialysis facilities. We evaluated the demographic and clinical differences between the two facilities using univariate statistics. We used regression models to determine the relationship between in-degree centrality and kidney transplant-related variables.

**Results:** A total of 111 patients were surveyed, with 71 at facility 1 and 40 at facility 2. The mean age was  $60.1 \pm 13.0$  years old. Half (55.0%) identified as male. 73% of participants identified as Black. In-degree centrality was higher in facility 1 ( $1.1 \pm 1.2$ ) compared to facility 2 ( $0.6 \pm 0.9$ ). Facility 1 had a greater percentage of patients who reported being on the kidney transplant waitlist than facility 2 (51% vs. 20%,  $p = 0.02$ ). Patients at facility 1 also knew more people who have had a successful kidney transplant and placed a higher importance on receiving a kidney transplant compared to patients at facility 2 (Median 1 [0-30] vs. 0 [0-4],  $p = 0.002$ ). Participants who knew more successful kidney transplants had higher in-degree centrality ( $\beta 0.11$ , 95% CI [0.05-0.17],  $p = 0.003$ ). Those who had completed more steps in the transplant process also had higher in-degree centrality ( $\beta 0.11$ , 95% CI [0.02-0.20],  $p = 0.02$ ).

**Conclusions:** In-degree centrality is associated with positive attitudes and behaviors towards kidney transplantation and differs between facilities. Patients with high in-degree centrality within the hemodialysis social network have the potential to influence other patients' attitudes and behaviors towards kidney transplant via social network interventions.

**Funding:** NIDDK Support

## SA-PO817

**Detection of Transmissible Severe Acute Respiratory Syndrome Coronavirus-2 (SARS-CoV-2) in Blood and Biopsies From Deceased Kidney Donors**

Ambreen Azhar,<sup>1</sup> Shiba Khorsandi,<sup>1</sup> Irfan A. Moinuddin,<sup>1</sup> Miklos Z. Molnar,<sup>2</sup> Marlon F. Levy,<sup>1</sup> Bekir Tanriover,<sup>3</sup> Gaurav Gupta,<sup>1</sup> <sup>1</sup>Virginia Commonwealth University, Richmond, VA; <sup>2</sup>University of Utah Health, Salt Lake City, UT; <sup>3</sup>Banner University Medical Center Tucson, Tucson, AZ.

**Background:** We recently reported that in United States, 388 organs from SARS-CoV-2 nucleic acid test (NAT) positive 150 donors were procured between Aug 2020 to Sep 2021. Nearly 1 million deaths have been attributed to SARS-CoV-2 pandemic however only selected group of donor organs were assessed for transplantation. Even after procurement, 28% (of 388) organs were discarded. For kidney transplants (KT), commonest reason for relatively high-quality organ discards (35%) was 'exhaustion of wait list', indicating reluctance to accept these organs.

**Methods:** We investigated potential risk of donor transmission of SARS-CoV-2 by a prospective study including 23 KT recipients with prior SARS-CoV-2 vaccination. Donor serum and pre-implantation kidney biopsy tissue were assessed for detection of SARS-CoV-2 via a validated commercially available real-time reverse transcription polymerase chain reaction (RT-PCR) (threshold 73 copies/mL). All recipients had SARS-CoV-2 RT-PCR on plasma and nasopharyngeal swab at Day-7 post-KT.

**Results:** A total of 23 KT were performed from 22 SARS-CoV-2 NAT positive donors between Nov 2021 and Feb 2022. All 22-donor serum samples and 23 procurement biopsies were negative for SARS-CoV-2, including those from 8 donors with symptomatic disease. Six (of 22 donors; 27%) had death attributable to SARS-CoV-2 complications. Three recipients with asymptomatic donors were diagnosed with clinical SARS-CoV-2 disease at 10, 14, and 23 days post-KT during 4<sup>th</sup> pandemic surge. Both graft and patient survival rate was 100% at a median 3 month followup. Collation with national 'Organ Procurement and Transplant Network' registry showed that majority of other organs from these donors were not procured [zero pancreata, zero lungs, 11 (50%) livers, 19 (86%) hearts]. Among 42 KT [55% (23/42) performed at our center], 10 transplanted livers, and 3 hearts; no graft loss or death was reported.

**Conclusions:** In this single-center study we report an absence of detectable SARS-CoV-2 virus in donor kidney tissue and plasma from SARS-CoV-2 positive donors and absence of recipient viremia and nasopharyngeal detectable virus immediately after KT indicating a lack of donor transmission. Our results of excellent graft and patient survival favor utilization of SARS-CoV-2 infected donors.

## SA-PO818

**Transplant or Discard: Pathology From a Single Biopsy Should Not Influence Decision to Discard**

Stephen C. Muzyka,<sup>1</sup> Gavin T. Oxley,<sup>1</sup> Hannah Morrison,<sup>1</sup> Helen P. Cathro,<sup>2</sup> Kimberly Deronde,<sup>3</sup> Aleksandra Cwiek,<sup>1</sup> Kevin M. Bennett,<sup>4</sup> Jennifer R. Charlton.<sup>3</sup> <sup>1</sup>University of Virginia, Charlottesville, VA; <sup>2</sup>UVA Health, Charlottesville, VA; <sup>3</sup>University of Virginia Children's Hospital, Charlottesville, VA; <sup>4</sup>Washington University in St Louis, St Louis, MO.

**Background:** Thousands of patients die awaiting a transplant, while 20% of kidneys are discarded. Glomerulosclerosis (GS) and interstitial fibrosis with tubular atrophy (IFTA) are the main reasons to discard kidneys. Histologic risk scores have been developed, but assume a single biopsy represents the whole kidney. The variance of pathology from high risk kidneys, representing the reproducibility of a decision to transplant based on biopsy, has not been evaluated. Here, we measured the variance of pathology in KPDI $\geq$ 85 kidneys to determine the effect on discard decisions.

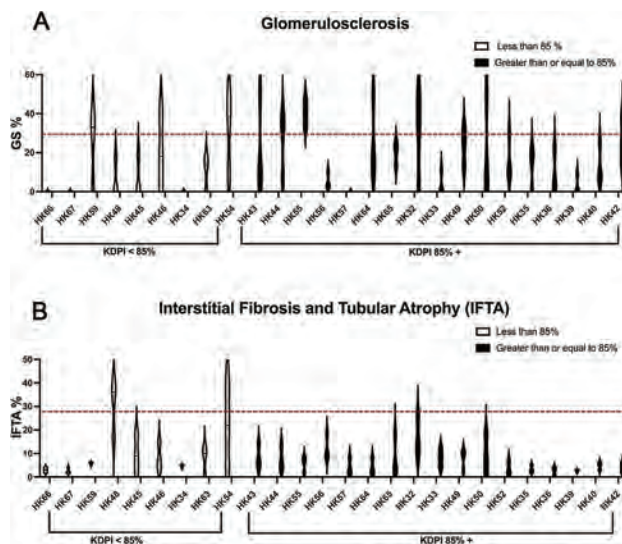

**Methods:** Kidneys unsuitable for transplant (some non-renal reasons) were acquired (n=26, 18 donors). KDPI was calculated. Three needle biopsies were performed. A renal pathologist identified GS. IFTA was measured with Amira software.

**Results:** Table 1 has donor demographics. The intra- and inter-kidney variance of GS was large (Figure). There was no difference in the %GS or variance in those with KDPI<85 vs  $\geq$ 85 ( $p=0.65$ ). Four KDPI $\geq$ 85 kidneys had GS scores of  $\leq$ 20% in all biopsies. IFTA variance was greater in KDPI<85 vs.  $\geq$ 85 ( $p=0.02$ ).

**Conclusions:** A single biopsy does not represent whole kidney pathology. Pathologic findings from a single biopsy should not guide decisions to discard potentially suitable kidneys. These data, and observations that biopsy findings do not predict transplant outcomes, highlight the need for tools to measure whole kidney pathology to identify transplantable kidneys.

**Addressing the Organ Shortage, Increasing Transplant Longevity, and Enabling Minimally Invasive Kidney Transplantation: Ex Vivo Validation of a Kidney Anastomosis Facilitation and Cooling Device**

Keith S. Hansen,<sup>1,2</sup> James M. Gardner.<sup>1</sup> <sup>1</sup>University of California San Francisco, San Francisco, CA; <sup>2</sup>Stanford University, Stanford, CA.

**Background:** Kidneys are particularly susceptible to anoxic damage and ischemia due to their aerobic metabolism. Hypothermia protects against anoxia by reducing the energy dependent metabolic activities. The warming of a donor kidney during the vascular anastomosis of a transplant i.e., second warm-ischemia time (SWIT), is independently associated with higher rates of delayed graft function, premature graft failure, and the discard of high-risk kidneys. SWIT is protracted in patients with complex anatomy, obesity, and in minimally invasive transplantation. Elimination of SWIT via intra-operative thermal regulation can increase the donor pool and proffer significant cost-savings.

**Methods:** ASTS surgeons (n=185) and transplant nephrologists were surveyed to determine the needs-criteria for a device. A prototype applied to the kidney immediately prior to anastomosis was built using stretchable hydrogel and phase-change gel. Adult porcine kidneys were used to test the device in a validated retroperitoneal-model placed

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

within a water bath at 37°C (98.6°F). Core temperatures were monitored using implanted probes at 30 second intervals. Time to reach the maximum ischemic threshold of necrosis (15°C, 59°F) was compared to an ice + gauze control.

**Results:** The needs-criteria for the device were addressed with a retraction handle, no tubing, a low profile, and a flexible material to accommodate variable kidney sizes. The device-covered kidneys (n=3) did not reach the ischemic threshold at the 60-minute cutoff and remained below 6°C compared with the ice + gauze covered control kidneys (17±1.8 minutes, n=3, p<0.001).

**Conclusions:** A breakthrough designated medical device to facilitate the vascular anastomosis and eliminate SWIT was successfully developed. Device-covered kidneys remained well below the ischemic threshold of necrosis for a duration exceeding 95% of vascular anastomoses. Use of this device will enhance the surgical workflow and enable minimally-invasive transplantation and has the potential to significantly impact rates of delayed graft function, organ longevity, and organ acceptance practices.

Cooling Device

### Factors Enabling Transplant Program Participation in the Scientific Registry of Transplant Recipients (SRTR) Living Donor Collective: A National Survey

Krista L. Lentine,<sup>1</sup> Mary amanda Dew,<sup>2</sup> Addie Wisniewski,<sup>1</sup> Macey L. Henderson,<sup>3</sup> Fawaz Al Ammary,<sup>4</sup> Asif A. Sharfuddin,<sup>5</sup> Bertram L. Kasiske.<sup>6</sup>  
<sup>1</sup>Saint Louis University School of Medicine, Saint Louis, MO; <sup>2</sup>University of Pittsburgh, Pittsburgh, PA; <sup>3</sup>New York University, New York, NY; <sup>4</sup>Johns Hopkins University, Baltimore, MD; <sup>5</sup>University of Indiana, Indianapolis, IN; <sup>6</sup>Hennepin Healthcare, Minneapolis, MN.

**Background:** The Scientific Registry of Transplant Recipients (SRTR) Living Donor Collective (LDC), the first effort to create a lifetime registry for living donor candidates in the United States, requires transplant centers to register candidates while the SRTR conducts follow-up.

**Methods:** To better understand facilitators and barriers to program participation, we conducted a brief electronic survey of U.S. transplant program staff (10/26/2021–12/17/2021).

**Results:** We received 132 responses, with at least one response from 87 living donor programs (46 kidney programs, 33 kidney and liver programs, and 8 liver programs alone). We found 86% of program representatives strongly agreed or agreed that funding adequate to cover the cost of data collection would facilitate LDC participation, 92% agreed or strongly agreed with importance of electronic data submission options, and 74% reported that elimination of requirements to submit duplicative pre-operative information to the Organ Procurement and Transplantation Network (OPTN) would be helpful. Other potentially enabling factors include reduction in duration of OPTN follow-up requirements, ease-of-use, protection from data use for regulation, adequate data security, and equity in data access. Responses did not differ significantly when stratified by program type (Figure), role, volume and follow-up success.

**Conclusions:** Collaboration and investment to overcome barriers to program LDC participation are vital to generate long-term data on living donation for donor candidates, donors, and patients in need of transplant.

## SA-PO821

### Long-Term Outcomes for Living Kidney Donors With Early Guideline-Concordant Follow-Up Care

Anisha Dhalla,<sup>1</sup> Anita Lloyd,<sup>4</sup> Krista L. Lentine,<sup>2</sup> Amit X. Garg,<sup>3</sup> Robert R. Quinn,<sup>1</sup> Pietro Ravani,<sup>1</sup> Scott Klarenbach,<sup>4</sup> Brenda Hemmelgarn,<sup>4</sup> Ngan Lam.<sup>1</sup>  
<sup>1</sup>University of Calgary Cumming School of Medicine, Calgary, AB, Canada; <sup>2</sup>Saint Louis University School of Medicine, Saint Louis, MO; <sup>3</sup>Western University Schulich School of Medicine & Dentistry, London, ON, Canada; <sup>4</sup>University of Alberta Department of Medicine, Edmonton, AB, Canada.

**Background:** Current guidelines recommend that living kidney donors receive lifelong annual follow-up care. In the United States, the reporting of complete clinical and laboratory data for kidney donors has been mandated for the first two years post-donation to improve adherence with follow-up; however, the long-term impact of early guideline-concordant care remains unclear.

**Methods:** We conducted a retrospective, population-based cohort study using linked healthcare databases in Alberta, Canada to compare long-term post-donation follow-up care and clinical outcomes of living kidney donors with and without early guideline-concordant care. The primary outcome was receipt of continued follow-up at 5 and 10 years after donation as defined by annual physician visits, serum creatinine, and albuminuria measurements (adjusted odds ratio with lower and upper 95% confidence limits,  $_{LCL}^{aOR}_{UCL}$ ).

**Results:** Of the 460 donors included in the study, 187 (41%) had clinical and laboratory evidence of guideline-concordant follow-up care throughout the first two years post-donation. The odds of receiving annual follow-up for donors without early guideline-concordant care were 76% lower at 5 years ( $aOR_{0.18}^{0.24,0.32}$ ) and 68% lower at 10 years ( $aOR_{0.22}^{0.32,0.40}$ ) compared to donors with early care. The odds of continuing follow-up remained stable over time for both groups. Early guideline-concordant follow-up care did not substantially influence estimated glomerular filtration rate (eGFR) or hospitalization rates over the longer term.

**Conclusions:** Although policies directed towards improving early donor follow-up may encourage continued follow-up, additional strategies may be necessary to mitigate lifetime donor risks.

**Funding:** Government Support - Non-U.S.

Proportion of living kidney donors with 3 markers of follow-up care (physician visit, serum creatinine and albuminuria measurement) during each post-donation year stratified by those with and without early guideline-concordant care (EGCC).

## SA-PO822

### Risk Factors for Developing Low eGFR and Albuminuria in Living Kidney Donors

Anisha Dhalla, Huda Al-Wahsh, Ngan Lam. University of Calgary Cumming School of Medicine, Calgary, AB, Canada.

**Background:** Chronic kidney disease is associated with significant morbidity and mortality in the general population, but little is known about the incidence and risk factors associated with developing kidney dysfunction in living donors following nephrectomy.

**Methods:** We conducted a retrospective, population-based control study using linked healthcare databases in Alberta, Canada to identify 590 donors who underwent nephrectomy between May 2001 and December 2017. The primary outcome was evidence of sustained kidney dysfunction following nephrectomy, defined as either 2 estimated glomerular filtration rate (eGFR) measurements <45 mL/min/1.73 m<sup>2</sup> or 2 measurements of moderate or severe albuminuria that were at least 90 days apart. We used Cox proportional hazard regression analyses to examine the association between potential risk factors and the outcome of post-donation kidney dysfunction.

**Results:** Over a median follow-up period of 8.6 years (interquartile range [IQR]: 4.7-16.9 years), 47 donors (8.0%) developed sustained kidney dysfunction, with an incidence rate of 9.2 per 1,000 person-years (95% confidence interval: 6.6-11.8). The median time for development of kidney dysfunction beyond the first year after nephrectomy was 2.9 years (IQR: 1.4-8.0 years). Donors who developed kidney dysfunction after donation were more likely to be older, male, have lower pre-donation eGFR, have evidence of pre- or post-donation hypertension, and post-donation diabetes.

**Conclusions:** A small proportion of kidney donors will develop post-donation kidney dysfunction. Donors with risk factors associated with sustained kidney dysfunction may benefit from more diligent follow-up care.

**Funding:** Government Support - Non-U.S.

Kaplan-Meier curve with 95% confidence interval of estimated kidney dysfunction free survival in living kidney donors from one-year post-donation onwards.

**Living Kidney Donor Candidates With Nephrolithiasis: Examination of Current Practices**

Matthew Howard,<sup>1</sup> Andrew D. Rule,<sup>5</sup> Nan Zhang,<sup>2</sup> Matthew D’Costa,<sup>5</sup> Hasan Khamash,<sup>3</sup> Hani Wadei,<sup>4</sup> Ivan E. Porter,<sup>4</sup> Caroline Jadowiec,<sup>6</sup> Mira T. Keddiss,<sup>3</sup> <sup>1</sup>Mayo Clinic School of Medicine - Scottsdale Campus, Scottsdale, AZ; <sup>2</sup>Mayo Clinic Department of Quantitative Health Sciences, Scottsdale, AZ; <sup>3</sup>Mayo Clinic Department of Nephrology and Hypertension, Scottsdale, AZ; <sup>4</sup>Mayo Clinic Department of Nephrology and Hypertension, Jacksonville, FL; <sup>5</sup>Mayo Clinic Department of Nephrology and Hypertension, Rochester, MN; <sup>6</sup>Mayo Clinic Department of Transplant Surgery, Phoenix, AZ.

**Background:** There are currently no universal standards regarding acceptance policies for potential kidney donors with nephrolithiasis. The objective of this study was to describe the acceptance practices at a large center and factors associated with being denied to donate.

**Methods:** 446 adult potential living kidney donors evaluated between 2000 and 2016 with either a personal history or radiological evidence of nephrolithiasis were included. We assessed whether various clinical characteristics and risk factors for stone recurrence including stone size, stone number, and history of symptomatic stone events affected the selection committee’s final decision.

**Results:** Mean age was 46.0 years (SD 11.7), 247(55.4%) were female, 391(87.7%) were white. 297 (67%) were approved for donation. Of the 149 who were denied, 75 (50%) were denied specifically due to kidney stones and 74 (50%) were denied for other reasons. When comparing the group that was denied due to kidney stones with the approved group, the number of symptomatic stone events (p=0.01), number of stones present on CT (p<0.001), stone diameter (p<0.001), and bilaterality (p<0.001) were all significantly associated with denial. Donor age, sex, family history of stones, presence of medullary sponge kidney, and history of hematuria were not significant predictors of denial. On multivariate analysis, symptomatic stone event (OR 2.3 (95% CI 1.16, 4.56), p=0.017), bilateral kidney stones (OR 4.39 (95% CI 1.78, 11.7), p=0.002) and diameter of largest stone ≥3mm (OR 5.23 (95% CI 2.86, 9.68), p<0.001) were independent predictors of denial due to kidney stone risk.

**Conclusions:** Most patients seeking to donate a kidney with either a personal history or radiological evidence of nephrolithiasis were approved. Symptomatic stone events, bilateral stones, and stone size ≥3mm negatively influenced donor candidacy. Future studies to assess risk of stone recurrence and related morbidity among those who were approved and those who were denied will better inform selection committee.

Table 1. Risk Factors comparison by Approved vs. Denial due to kidney stone group

Variables of interest	Approved (N=297)	Denial due to kidney stone (N=75)	Total (N=372)	p value:
Symptomatic stone events, n (%)	64 (21.5%)	26 (34.7%)	90 (24.2%)	0.018
Number of symptomatic stone events ≥ 2	16 (5.4%)	10 (13.3%)	26 (7.0%)	0.023
Medullary sponge kidney	16 (5.4%)	8 (10.7%)	24 (6.5%)	0.113
Number of stones present on CT, mean (SD)	1.3 (1.3)	3.3 (3.4)	1.7 (2.0)	< 0.001
Number of stones present on CT ≥ 2	73 (24.6%)	50 (66.7%)	123 (33.1%)	< 0.001
Bilateral kidney stones	35 (12.1%)	41 (54.7%)	77 (20.7%)	< 0.001
Diameter of largest stone on CT, mean (SD) mm	1.6 (1.2)	3.9 (3.6)	2.1 (2.1)	< 0.001

**Distinct Phenotypes of Kidney Retransplantation by Machine Learning Consensus Clustering in the United States**

Michael A. Mao,<sup>1</sup> Shennen Mao,<sup>1</sup> Charat Thongprayoon,<sup>2</sup> Pradeep Vaitla,<sup>3</sup> Caroline Jadowiec,<sup>4</sup> Prakrati C. Acharya,<sup>5</sup> Napat Leeaphorn,<sup>6</sup> Wisit Kaewput,<sup>7</sup> Patharawin Pattharanitima,<sup>8</sup> Wisit Cheungpasitporn,<sup>2</sup> <sup>1</sup>Mayo Clinic, Jacksonville, FL; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN; <sup>3</sup>University of Mississippi Medical Center, Jackson, MS; <sup>4</sup>Mayo Clinic Arizona, Scottsdale, AZ; <sup>5</sup>Texas Tech Health Sciences Center, El Paso, TX; <sup>6</sup>St. Luke’s Health System, Kansas City, MO; <sup>7</sup>Phramongkutklo College of Medicine, Bangkok, Thailand; <sup>8</sup>Thammasat University, Pathum Thani, Thailand.

**Background:** The application of machine learning may provide a novel understanding of unique phenotypes of kidney retransplant recipients that will allow identification of new strategies to improve outcomes. Our study aimed to characterize kidney retransplant recipients using an unsupervised machine learning approach.

**Methods:** We performed consensus cluster analysis using recipient-, donor-, and transplant-related characteristics in 17,443 kidney retransplant recipients from the 2010-2019 OPTN/UNOS database. We identified each cluster’s key characteristics using the standardized mean difference of >0.3. Posttransplant outcomes including acute allograft rejection, death-censored graft failure, and mortality were compared among the assigned clusters.

**Results:** Consensus cluster analysis identified three distinct clusters of kidney retransplant recipients. The key characteristics of cluster 1 were white patients who received pre-emptive kidney retransplant or had dialysis duration less than 1 year before receiving kidney retransplant from living, female, and older donors. Cluster 1 patients had lower PRA, cold ischemia time, use of kidney machine perfusion, and occurrence of delayed graft function, but had more private insurance. In contrast, cluster 2 patients had higher PRA and received kidney retransplant from non-ECD deceased donors with a lower number of HLA mismatches. Cluster 3 patients received kidney retransplant from non-ECD deceased donors with a higher number of HLA mismatches. Cluster 1 had the most favorable patient and graft survival while cluster 3 had the worst patient (HR 2.17) and graft survival (HR 2.64).

**Conclusions:** Unsupervised machine learning approach characterized kidney retransplant recipients based on their pattern of clinical characteristics into three clinically distinct clusters with differing posttransplant outcomes.

Standardized differences across the three clusters for each baseline parameter.

## Using Twitter for Kidney Transplant: A Tweet Analysis for Living Donation

Everly Ramos,<sup>1</sup> Dillon Corrigan,<sup>2</sup> Anne M. Huml,<sup>1</sup> Liza Cholin.<sup>1</sup> <sup>1</sup>Cleveland Clinic, Cleveland, OH; <sup>2</sup>Cleveland Clinic Department of Quantitative Health Sciences, Cleveland, OH.

**Background:** Social media is increasingly utilized by patients, health-care providers, and medical centers to disseminate information. This study aimed to describe Twitter conversations relating to kidney transplant and specifically, living kidney donation.

**Methods:** Using the open-source sncrape tool, we identified twitter posts between February 2021 and February 2022 that contained the hashtags “living donor,” “live donor,” “living kidney donor,” “live kidney donor,” “kidney donor,” or “kidney transplant.” A descriptive analysis was done on the tweets using the R statistical software.

**Results:** A total of 6,773 unique tweets were generated. 70.8% of tweets contained the hashtag “kidney transplant.” The most popular terms used were “kidney,” “transplant,” and “donor.” Peaks in tweet volumes were noted around World Kidney Day and on the event of a pig kidney xenotransplantation (Fig 1). The top Twitter users were private nephrology practices in the US. Sentiment analysis on the tweets in English language showed a general positive sentiment about living kidney organ donation (Fig 2).

**Conclusions:** There is a lot of positive discussion on Twitter relating to living kidney donation. Further research is needed to determine the impact these social media conversations have on actual donation.

Figure 1. (A) Monthly tweet count; and (B) cumulative total tweet count by hashtag.

Figure 2. Distribution of Average Sentiment Score by Hashtag. Vertical line represents median; dot represents mean.

## SA-PO826

## BK Polyomavirus (BKPyV) and Cytomegalovirus (CMV) Infections in Kidney Transplantation (KT) From Hepatitis C Positive (HCV) Viremic Donors to Uninfected Recipients

Viralkumar Amrutiya, Idris Yakubu, Irfan A. Moinuddin, Marlon F. Levy, Gaurav Gupta, Ambreen Azhar. Virginia Commonwealth University, Richmond, VA.

**Background:** KT from HCV viremic donor to uninfected recipients (D+/R-) is becoming more common across United States. Recent 'transmit-and-treat' studies suggest that donor HCV might be associated with an increased risk of BKPyV and CMV infections due to the suppression of host immune response by HCV. We have previously reported HCV transmission rate of only 9% with ultra-short pangenotypic Direct Acting Antiviral prophylaxis (DAA) of 2-7days. Here we report the incidence of BKPyV and CMV infections in this cohort in comparison with a matched cohort (1:1) of HCV D-/R- KT recipients.

**Methods:** All patients received rabbit anti-thymocyte globulin followed by tacrolimus, mycophenolate and prednisone. D-/R- recipients (controls) were matched with cases (D+/R-) in a 1:1 distribution based on; waitlist time, 'kidney-only' transplant with  $\leq 1$  previous organ transplant, pre-transplant diabetes, Expected Post Transplant Survival category in four quantiles, calculated Panel Reactive Antibodies  $< 50\%$ ; negative crossmatch, and Donor Specific Antibodies (DSA) at transplant  $\leq 3000$  MFI.

**Results:** A total of 102 D+/R- transplants were included as; Group 1 (2-4d prophylaxis (ppx); N=52) and Group 2 (7d ppx; N=50). All 9 patients that developed viremia achieved sustained virologic response post-full course DAA. Controls were more likely to be African American (73% vs 59%;  $p=0.04$ ), with pre-formed DSAs (13% vs 3%,  $p=0.02$ ) and higher Kidney Donor Profile Index (66 vs 56,  $p=0.001$ ) compared to the cases. Recipients of HCV D+/R- had equivalent CMV infection (14% vs 14%,  $p=1.0$ ) but less CMV disease vs controls (71% vs 29%,  $p=0.05$ ) amongst those who developed viremia. There was a numerically higher incidence of any BKPyV infection (20% vs 12%,  $p=0.12$ ), and high plasma titer BKPyV  $\geq 10000$  (12% vs 6%,  $p=0.21$ ) in the D+/R- group compared with D-/R- group that did not reach statistical significance.

**Conclusions:** We did not find increased risk of CMV infections however numerical trend for increased BKPyV was seen predominantly in patients without HCV replication in (D+/R-) recipients suggesting either lack of HCV replication may be protective against CMV, or apparent increased risk of opportunistic viral infections due to unmeasured confounders in patient selection.

## SA-PO827

## Survival Differences in Elderly Patients on Renal Replacement Therapy

Erzsi Tegzess,<sup>1</sup> Hessel Peters-Sengers,<sup>2</sup> Robert Pol,<sup>1</sup> Jan-Stephan Sanders,<sup>1</sup> Stefan P. Berger.<sup>1</sup> <sup>1</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>2</sup>Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.

**Background:** Rising numbers of elderly patients ( $\geq 65$  years) are in need of renal replacement therapy (RRT), with a growing proportion being waitlisted for kidney transplantation. To date little is known about the effect of living versus deceased donor kidney transplantation in these recipients. This study investigated the differences in patient survival between elderly kidney transplant recipients with a living donor (LDK), a young ( $< 65$ , YDK) or an old ( $\geq 65$ , ODK) deceased donor kidney and compared it to waitlisted dialysis patients ( $\geq 63$ ).

**Methods:** In this nation-wide retrospective cohort study survival was investigated using a multi-state model with Cox regression analysis in elderly patients waitlisted and transplanted between 2000 and 2019 in the Netherlands.

**Results:** 4138 patients were included in this study (65.5% male, age 68 [65-71]), with 1374 (33.2%) remaining waitlisted. Out of the 2762 (66.7%) patients who received a kidney transplant, 1095 (39.6%) had a LDK, 672 (24.3%) a YDK and 997 (36.1%) an ODK. Median patient survival from start of RRT in was significantly lower in patients remaining waitlisted (4.51 years) compared to those who received a transplant (9.54 years,  $p < 0.001$ ). Waiting time on dialysis was significantly longer for YDK [2.5 years (1.4-3.8)] and ODK [2.6 (1.7-3.7)] compared to LDK [0.0 (0.0-1.4)] recipients. 5 year survival from start of RRT did not differ significantly between donor types (82.4%), but median survival from start of RRT was significantly lower in ODK (8.88 years,  $p < 0.001$ ) patients compared to the LDK (10.06 years) and YDK (10.28 years) recipients. After correction for potential confounders, survival still did not differ significantly between LDK (Ref.) and YDK [HR 1.19 (0.99-1.44),  $p = 0.081$ ] recipients, but was lower in ODK [HR 1.67 (1.39-1.99)] recipients.

**Conclusions:** For elderly recipients starting RRT, there was a limited survival difference between donor categories, with slightly lower survival for ODK recipients. Additionally, deceased donor kidney recipients have a longer waiting time, which carries a significantly increased risk of mortality. However, ultimately, all donor types had satisfactory survival, with any type of transplantation having a clear survival benefit over dialysis.

**Funding:** Government Support - Non-U.S.

## SA-PO828

### Effect of Pretransplant Dialysis Vintage on Clinical Outcomes in Deceased Donor Kidney Transplant

Hee Won Noh, Soojee Jeon, Hee-Yeon Jung, Ji-Young Choi, Sun-Hee Park, Chan-Duck Kim, Yong-Lim Kim, Jeong-Hoon Lim, Jang-Hee Cho. *Kyungpook National University Hospital, Daegu, Republic of Korea.*

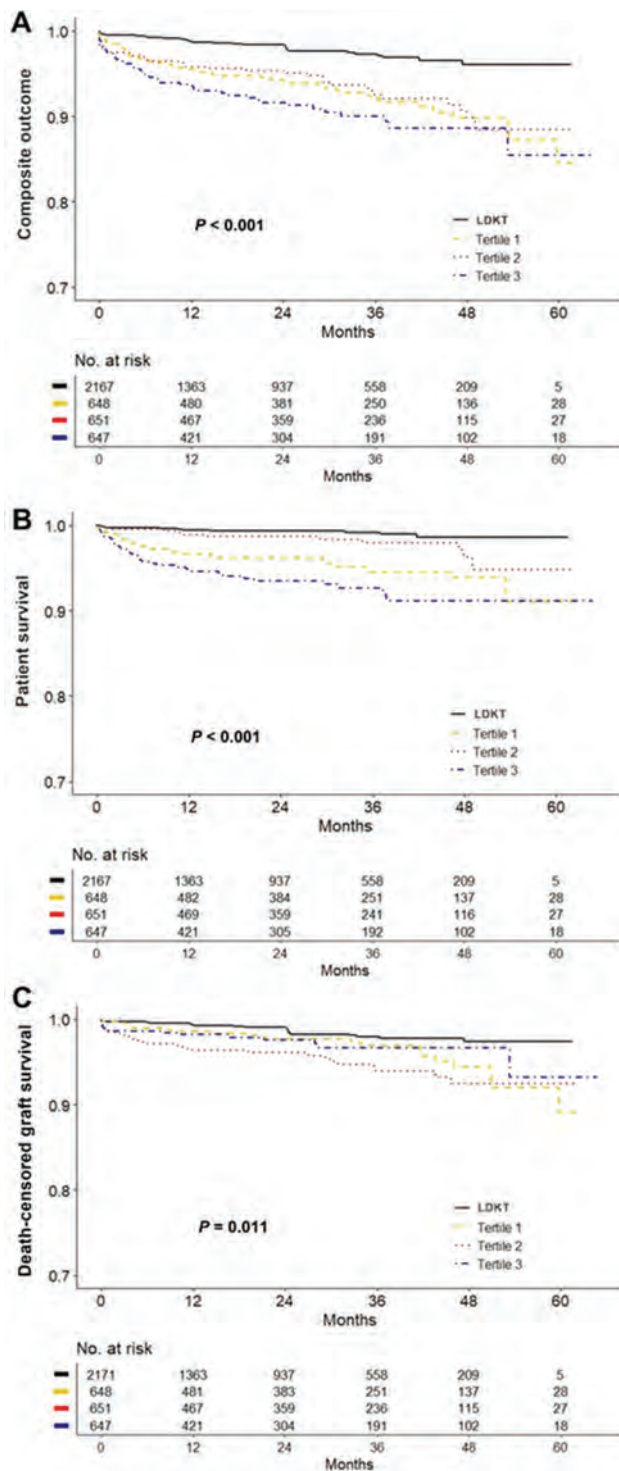

**Background:** The shortage of donor organs and the increase of waiting lists increase the waiting time for deceased donor kidney transplants (DDKT). We evaluated DDKT prognosis according to the pretransplant dialysis vintage.

**Methods:** A total of 4,117 first-time kidney transplant recipients were enrolled from a prospective nationwide cohort. DDKT recipients were divided into tertiles according to pretransplant dialysis duration. Graft failure, mortality, and composite were compared between DDKT and living donor kidney transplant (LDKT) recipients.

**Results:** Pretransplant dialysis vintage was longer annually in DDKT recipients. In the subdistribution of the hazard model for the competing risk (set as patient death), the first tertile did not show an increased risk of graft failure compared with LDKT recipients; however, the second and third tertile groups had an increased risk of graft failure compared to LDKT recipients (adjusted hazard ratio [aHR], 3.59; 95% confidence interval [CI], 1.69–7.63;  $P < 0.001$ ; aHR, 2.37; 95% CI, 1.06–5.33;  $P = 0.037$ ). All DDKT groups showed a significantly higher risk of patient death than LDKT, with the highest risk in the third tertile group (aHR, 11.12; 95% CI, 4.94–25.0;  $P < 0.001$ ). The risk of the composite of mortality and graft loss significantly increased in tertile order compared with LDKT recipients (all  $P < 0.05$ ).

**Conclusions:** A longer pretransplant dialysis period was associated with a higher risk of the composite of patient death and graft failure in DDKT recipients. DDKT after a short period of dialysis had non-inferior results on graft survival compared with LDKT.

**Funding:** Government Support - Non-U.S.

Kaplan–Meier curves for outcomes.

The Effect of Weight, Body Mass Index, and Body-Surface-Area on the Agreement Between Estimated and Measured GFR in Heart Transplant Recipients

Morten B. Jørgensen,<sup>1</sup> Mads Hornum,<sup>1,2</sup> Lærke M. Nelson,<sup>3</sup> Bo Feldt-Rasmussen,<sup>1,2</sup> Kasper Rossing,<sup>3</sup> Esteban Porrini,<sup>4</sup> Finn Gustafsson.<sup>3</sup>  
<sup>1</sup>Department of Nephrology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; <sup>2</sup>Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; <sup>3</sup>Department of Cardiology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; <sup>4</sup>Faculty of Medicine, Instituto de Tecnologías Biomédicas (ITB), University of La Laguna, La Laguna, Spain.

**Background:** Assessing glomerular filtration rate (GFR) in heart transplant (HTx) recipients is paramount to adjust immunosuppressive, anti-bacterial, and anti-viral therapy. Estimated GFR (eGFR) has shown poor agreement with measured GFR (mGFR) in populations with changing body composition yielding HTx recipients at risk of suboptimal treatment as weight gain and weight loss are frequent complications to HTx. We investigated the effect of weight, BMI and body-surface-area (BSA) on the accuracy and precision of eGFR in HTx recipients.

**Methods:** In a longitudinal, observational, retrospective study-design, patients receiving first-time HTx with at least one registered mGFR within 15 months after HTx and a corresponding plasma creatinine were included. GFR was measured by <sup>51</sup>Cr-EDTA. eGFR adjusted for BSA was calculated by creatinine-based CKD-EPI formula and eGFR not adjusted for BSA was calculated using Dubois and DuBois. Longitudinal data were analyzed within a linear mixed model and cross-sectional data were analyzed using Bland Altman analysis and ANOVA.

**Results:** 150 patients with a total of 723 mGFR measurements were included. During the first year after HTx, mean weight increased by 4.2 kg (CI: 3.2 to 5.1) followed by an annual decrease of 0.35 kg/year (CI: -0.05 to 0.74). mGFR increased by 7.5 ml/min (CI: 3.2 to 11.8) the first year but was stable hereafter (0.0 ml/min/year, CI: -1.0 to 1.0). The initial weight gain and increase in mGFR were most pronounced in patients <45 years. Neither eGFR adjusted nor unadjusted for BSA detected the initial increase in mGFR. At one year after HTx, limits of agreement of the Bland Altman plot were -37.2 to 33.1 ml/min with a bias of -2.1 ml/min (CI: -5.0 to 0.9). In patients <45 years, eGFR significantly overestimated mGFR by 7.1 ml/min (CI: 1.0 to 13.2) and showed a significant lower precision than patients >45 years. The overestimation of mGFR was persistent after the first posttransplant year. There was no effect of weight, BMI, BSA or change in BMI class on the difference between eGFR and mGFR.

**Conclusions:** In heart transplant recipients, eGFR was, on average, very accurate and was not affected by body composition. The precision was, however, very low and eGFR performed poorly especially in younger patients.

SA-PO830

Comparing Measures for Evaluating Dialysis Facilities by Their Kidney Transplant Referral Rates

Adam S. Wilk,<sup>1</sup> Mengyu Di,<sup>2</sup> Laura Plantinga,<sup>2</sup> Sudeshna Paul,<sup>3</sup> Stephen O. Pastan,<sup>2</sup> Rachel E. Patzer.<sup>2</sup>  
<sup>1</sup>Emory University School of Public Health, Atlanta, GA; <sup>2</sup>Emory University School of Medicine, Atlanta, GA; <sup>3</sup>Emory University School of Nursing, Atlanta, GA.

**Background:** Among the >560,000 U.S. patients receiving dialysis, many would benefit from transplantation, yet many transplant-eligible dialysis patients are never referred to a transplant center for evaluation. Policymakers are considering including referral rate measures in dialysis facility performance measurement programs. It is unknown to what extent alternative referral rate measures, which are materially different in their sample exclusion criteria and risk adjustment approaches, may be differentially correlated with waitlisting rates downstream.

**Methods:** We compared three measures that can be used to assess dialysis facilities' referral rates: raw referral rate (percent of patients referred), Paul et al.'s (2018) Standardized Transplantation Referral Ratio (STRr), and the Kidney Care Quality Alliance's (KCQA) percent referred measure. Using 2014-2020 registry data for incident dialysis patients referred to all nine established transplant centers across Georgia, North Carolina, and South Carolina (referral dates) linked to United States Renal Data System data (denominators, waitlisting dates), we compared the referral measures' unadjusted distributions and used linear regression to test associations with facility waitlisting rates, overall and among referred patients.

**Results:** Distributions for the raw referral rate (35,627 patients, 815 facilities), STRr (24,241 patients, 718 facilities), and KCQA measure (8,687 patients, 746 facilities), were similarly right-skewed. Pairwise Pearson correlations among the measures were positive but varied (range 0.34-0.57). Each measure was positively associated with overall waitlisting (estimated change in waitlisting [percentage points] per 1 SD increase in measure: raw referral rate  $\beta=5.2$ ; STRr  $\beta=1.3$ ; KCQA  $\beta=2.7$ ; all  $p<0.001$ ). None of these measures was statistically associated with waitlisting among referred patients (all  $p>0.2$ ).

**Conclusions:** The impact of alternative dialysis facility referral rate measures on subsequent waitlisting may be inconsistent, in part because the measures have different facility exclusion criteria—and so represent different patient and facility populations—and risk adjustment approaches. Programs using these measures should be monitored to ensure they are effective in maximizing transplant access for U.S. patients receiving dialysis.

SA-PO831

Indexing Glomerular Filtration Rate by Body Surface Area in Live Kidney Donors: Is It Really Necessary?

Nisarg Gandhi,<sup>1</sup> Sean Hebert,<sup>1</sup> Duc T. Nguyen,<sup>1</sup> Edward A. Graviss,<sup>1</sup> Hassan N. Ibrahim.<sup>2</sup>  
<sup>1</sup>Houston Methodist, Houston, TX; <sup>2</sup>Memorial Hermann Health System, Houston, TX.

**Background:** Glomerular filtration rate (GFR) is proportional to both kidney and body size. It is commonly expressed as estimated (e)GFR as ml/min/1.73m<sup>2</sup>, which represents the adjustment to a standard body surface area (BSA). However, a compelling rationale for this recommendation is lacking. In the case of kidney donor candidates, eGFR adjustment by BSA may result in wider acceptance of those with BSA <1.73 m<sup>2</sup> and restrict access for those with a BSA >1.73 m<sup>2</sup> as adjusted eGFR will be higher in the former and lower in the latter. Long term outcomes of kidney donors who have adjusted eGFR are higher, lower, or equal to their raw eGFR has not been studied.

**Methods:** Using the publicly available data from The Renal and Lung Living Donor Evaluation Study (RELIVE), we compared the development of hypertension, proteinuria, reduced eGFR, and kidney failure in 8578 donors with: 1) raw and adjusted eGFR  $\geq 80$  ml/min/1.73m<sup>2</sup>; 2) only adjusted eGFR  $\geq 80$  ml/min/1.73m<sup>2</sup>; 3) only raw eGFR  $\geq 80$  ml/min; and 4) both raw and adjusted eGFR < 80 ml/min/1.73m<sup>2</sup>.

**Results:** 5504 donors had both adjusted and raw eGFR  $\geq 80$  ml/min, 258 donors had only adjusted eGFR  $\geq 80$  ml/min/1.73m<sup>2</sup>, 1086 donors had only raw eGFR > 80 ml/min, and 1730 had both adjusted and raw eGFR < 80 ml/min. The median age of the entire cohort was 39 years, 43.7% were male, 85.1% were non-Hispanic white, median BMI was 25.8 kg/m<sup>2</sup>, and mean BSA at donation was 1.88  $\pm$  0.22 m<sup>2</sup>. Other than the development of eGFR < 45 ml/min/1.73m<sup>2</sup>, no statistical difference was noted in post-donation mortality, CVD, diabetes, hypertension, proteinuria, eGFR < 30 ml/min/1.73m<sup>2</sup>, and ESKD (Figure 1).

**Conclusions:** Raw and adjusted pre-donation eGFR were highly comparable in predicting long-term outcomes of kidney donors and perhaps the practice of adjusting for BSA should be reconsidered.

Post-donation outcomes	Multivariate		
	Adjusted eGFR	Raw eGFR	p-value
	C-statistic (95% CI)	C-statistic (95% CI)	
Mortality	0.77 (0.74, 0.81)	0.77 (0.74, 0.81)	0.75
Cardiovascular Disease	0.75 (0.73, 0.77)	0.74 (0.72, 0.77)	0.11
Diabetes	0.73 (0.68, 0.77)	0.73 (0.68, 0.77)	0.29
Hypertension	0.70 (0.68, 0.72)	0.70 (0.68, 0.72)	0.40
Proteinuria	0.81 (0.79, 0.84)	0.81 (0.79, 0.84)	0.61
eGFR<45 ml/min/1.73m <sup>2</sup>	0.76 (0.73, 0.79)	0.74 (0.71, 0.77)	<0.001

SA-PO832

Impact of Kidney Volume on Proteinuria 3 Years Post-Transplantation in Living Kidney Donors

Makoto Tsujita, Masuko Kinen Byoin, Nagoya, Japan.

**Background:** In living kidney transplantation, predicting the risk of end-stage kidney disease in the organ donors though crucial remains to be resolved. Thus, any useful biomarker to predict kidney outcome would be highly desirable to safeguard donors.

**Methods:** This retrospective study was conducted at Nagoya Daini Red Cross Hospital to confirm whether an increase in preserved kidney volume (PKV) was a predict marker of proteinuria. The ratio of body surface area (BSA) adjusted PKV before and 1 year after kidney donation was measured, and its association with proteinuria 3 years after the donation was analyzed.

**Results:** A total of 119 kidney donors who met the Japanese donor guideline were enrolled. The mean age of 57.4 years old, 46.2 % were male. The mean values of the variables before kidney donation (baseline) were: BMI levels: 23.4 kg/m<sup>2</sup>, BSA adjusted PKV: 132.9 cm<sup>3</sup>/1.73m<sup>2</sup>, and estimated glomerular filtration rate (eGFRave): 82.9 ml/min/1.73m<sup>2</sup>. A positive correlation was noted between BSA adjusted PKV and eGFRave ( $r = 0.61$ ,  $p < 0.001$ ). The mean ratio increased by 19.5% (143.5 cm<sup>3</sup>/1.73m<sup>2</sup>) 1 year after donation, and the median urine protein was 0.04 g/gCre. Linear regression analyses showed that the ratio and BSA adjusted PKV before the donation were significantly associated with proteinuria 3 years after donation.(Figure 1)

**Conclusions:** The ratio and BSA adjusted PKV before donation is important factors for proteinuria after donation under the Japanese donor guidelines. Further studies would be needed to confirm whether these factors are associated with renal survival after donation.

Understanding Public Perceptions of Deemed Consent Legislation for Organ Donation in Canada

Danielle E. Fox, Maoliosa Donald, Christy Chong, Robert R. Quinn, Paul E. Ronksley, Meghan J. Elliott, Ngan Lam. *The University of Calgary, CALGARY, AB, Canada.*

**Background:** Deemed consent legislation was implemented in Nova Scotia in 2021 and is being considered in other jurisdictions in Canada to increase deceased organ donation and transplantation rates. We have previously described the public perceptions of deemed consent and concerns for lawmakers to consider; however, there are other personal factors that should be understood prior to addressing these public concerns. Our objective was thus to explore the factors underlying public perceptions of deemed consent legislation in Canada.

**Methods:** We searched four major Canadian news outlets for published articles about deemed consent between January 2019 and July 2020. Using a descriptive qualitative method, public comments from relevant articles were extracted and analyzed using an inductive conventional content analysis approach.

**Results:** We extracted and analyzed 4,357 comments from 35 eligible news articles. Four primary themes emerged that helped explain the public's perception of deemed consent. **Entwined beliefs:** Commenters' beliefs included how they defined consent, human rights, and end-of-life practices. **Connected experiences:** Commenters described the impact of life experiences that were connected to deemed consent. These included being an organ donor or recipient but also other experiences such as accessing healthcare and government services (e.g., unable to navigate existing opt-in processes). **Inescapable uncertainty:** Organ donation was a difficult and personal decision. Many commenters were undecided in their decision to be an organ donor yet were being asked to firmly decide. **Guarded trust:** Some commenters described having little trust in healthcare providers, government officials, their family and friends, and others responsible for carrying out their wishes.

**Conclusions:** Public perceptions of deemed consent appeared to be influenced by the collective value commenters ascribed to numerous related elements. Lawmakers should consider these determinants when addressing public concerns.

SA-PO834

Findings From a Cardiovascular Screening Workup of Kidney Transplant Recipients

Ziad Arabi,<sup>1,2</sup> Talha M. Youssouf,<sup>1,2</sup> Mohamad Y. Abdulgadir,<sup>1,2</sup> Nayef Alawadh,<sup>1,2</sup> Dr Junaid Iqbal,<sup>1,2</sup> Mubarak I. Abdalla,<sup>1,2</sup> Ahmad I. Alflaiw,<sup>1,2</sup> <sup>1</sup>*Division of Nephrology, Department of Medicine, King Abdulaziz Medical City, Riyadh, Saudi Arabia;* <sup>2</sup>*King Abdullah International Medical Research Center; College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.*

**Background:** There is limited data about the findings of cardiovascular (CV) workup of kidney transplant recipients (KTR). Our center follows the AHA/ ACC 2013 guidelines of the cardiovascular risk assessment of renal transplant candidates (KTC). Screening echo is performed in all KTC. PET stress nuclear test is done in those who have  $\geq 3$  CV risk factors, limited functional status or abnormal echo findings. Decision of cardiac catheterization is deferred to cardiologist's assessment. Abdominal/ pelvis CT with IV contrast is done to evaluate the extent of pelvic vascular calcifications and atherosclerosis. It is performed in most the KTC unless if they are on PD, undergoing preemptive transplantation or at low surgical risk.

**Methods:** In this single center retrospective study, we reviewed the prevalence of CV risk factors and the results of the CVworkup of KTR who underwent renal transplant from 2017 to 2020.

**Results:** A total of 287 KTR were included. 74% were  $\geq 30$  years, 58% were men and 80% were living-donor KTR. Preemptive transplantation was 10.1%. Pre- KT dialysis modality was PD in 11.5% and HD in 78.4% (AVF: 42% versus Permcath: 58%). Dialysis vintage was  $4.8 \pm 3.3$  years for DDKT versus  $2.4 \pm 2.6$  years for LKT. CV risk factors among KTR were: CAD: 13.2%, CVD: 5.2%, PVD: 2.8%, CVA: 2.4%, HTN: 76%, DM: 34.5%, [DM type I: 25 (25.3%) and DM type II: 74 (74.7%)], HLP (LDL  $> 100$ ): 39.7% and smoking: 10.1%. The prevalence of obesity stage 2 (BMI 35-39.9): 4%, and obesity stage 1 (BMI: 30-34.9) was 20%. LVH was present in 38%. EF was abnormal ( $< 55$ )

in 20.5% [45-55: 43 (15%), 35-45: 15 (5.2%), 25-35: 1 (0.3%)]. Abnormal wall motion (mostly global dyskinesia) was present in 12%. Stress test was indicated in 152 (53.3%) and it showed abnormal perfusion in 26% of cases. Calcium scoring:  $> 400$ : in 17%, zero in 43%, 1-100: in 42 (27%), and 100-400: in 13%. Cardiac catheterization was required in only 46 (16%) and findings were: CAD for intervention in 26%, CAD for med TX in 63% and no CAD in 11% CT abdomen and pelvis was performed in (138) 38.1% and findings were: moderate or severe calcifications/ atherosclerosis in only 6%, normal in 82% or only mild calcifications in 12%.

**Conclusions:** This study outlines the high prevalence of CV risk factors in KTR and the findings of pre-KT CV workup.

SA-PO835

Distinct Characteristics of High Sensitized Kidney Transplant Recipients in the United States by Machine Learning Consensus Clustering

Charat Thongprayoon,<sup>1</sup> Michael A. Mao,<sup>2</sup> Shennen Mao,<sup>2</sup> Caroline Jadowiec,<sup>3</sup> Prakrati C. Acharya,<sup>4</sup> Napat Leeaphorn,<sup>5</sup> Wisit Kaewput,<sup>6</sup> Patharawin Patharanitima,<sup>7</sup> Wisit Cheungpasitporn.<sup>1</sup> <sup>1</sup>*Mayo Clinic Minnesota, Rochester, MN;* <sup>2</sup>*Mayo Clinic in Florida, Jacksonville, FL;* <sup>3</sup>*Mayo Clinic Arizona, Scottsdale, AZ;* <sup>4</sup>*Texas Tech University Health Sciences Center El Paso, El Paso, TX;* <sup>5</sup>*Saint Luke's Health System, Kansas City, MO;* <sup>6</sup>*Phramongkutklao College of Medicine, Bangkok, Thailand;* <sup>7</sup>*Thammasat University Hospital, Khlong Nueng, Thailand.*

**Background:** Our study aimed to characterize highly sensitized kidney transplant patients using unsupervised machine learning approach.

**Methods:** We used the OPTN/UNOS database from 2010 to 2019 to perform consensus cluster analysis based on recipient-, donor-, and transplant-related characteristics in 7,458 kidney transplant patients with pre-transplant panel reactive antibody (PRA)  $\geq 98\%$ . We identified each cluster's key characteristics using the standardized mean difference of  $> 0.3$ . We compared the posttransplant outcomes among the assigned clusters

**Results:** Consensus cluster analysis identified two clinically distinct clusters of highly sensitized kidney transplant patients. Cluster 1 patients were older (mean age 45 vs 54 years), more male (59% vs. 9%), had more kidney retransplant (98 vs. 3%), but less diabetic kidney disease (3% vs 29%), compared to cluster 2. While patient survival was comparable between two clusters, cluster 1 had lower death-censored graft survival but higher acute rejection compared to cluster 2.

**Conclusions:** Unsupervised machine learning approach characterized highly sensitized kidney transplant patients into 2 clinically distinct clusters based on age, sex, kidney retransplant status, and diabetes, with differing posttransplant outcomes.

## SA-PO836

## Should We Discontinue Angiotensin Converting Enzyme Inhibitor and Angiotensin Receptor Blocker Before Kidney Transplantation?

Chung Hee Back, Hyosang Kim, Su-Kil Park. *Asan Medical Center, Songpa-gu, Seoul, Republic of Korea.*

**Background:** Angiotensin converting enzyme inhibitors (ACEi) and Angiotensin receptor blockers (ARB) are usually recommended to stop before surgery to prevent post-operative acute kidney injury. However, it is uncertain that ACEi and ARB should be discontinued before kidney transplantation (KT). Therefore, we investigated the effect of pre-KT administration of ACEi and ARB on the outcomes of KT.

**Methods:** We reviewed patients who received living-donor KT in our tertiary center between 2018 and 2020. Among 923 patients, 291 patients continued ACEi/ARB within 3 days before KT (ACEi/ARB group), and 632 patients did not take ACEi/ARB within 3 days before KT (No ACEi/ARB group). Delayed graft function, hyperkalemia events, slope of creatinine after KT, rejection and graft survival were compared between two groups.

**Results:** Baseline characteristics were not significantly different between two groups except medical history of hypertension (96.2% in ACEi/ARB group vs. 90.2% in no ACEi/ARB group,  $P=0.001$ ) and number of re-transplantation (4.1% in ACEi/ARB group vs. 7.8% in no ACEi/ARB group,  $P=0.039$ ). The numbers of ABO incompatible KT or HLA-sensitized KT, the degree of HLA mismatches and immunosuppressant were not different significantly between two groups. Delayed graft function occurred in 2 patients (0.7% in ACEi/ARB group and 13 patients (2.1%) in no ACEi/ARB group ( $P=0.165$ ). The event of hyperkalemia ( $K \geq 5.5$  mEq/L) did not happen more frequently in ACEi/ARB group (21.3% vs. 22.9%,  $P=0.611$ , the day before KT; 11.3% vs. 10.1%,  $P=0.566$ , the day of surgery; 0.3% vs. 0.3%,  $P=1.000$ , the day after surgery). The slopes of creatinine from post-operative day 0 to day 7 were similar in two groups ( $-0.732 \pm 0.349$  vs.  $-0.751 \pm 0.325$ ,  $P=0.435$ ). Rejection-free survival and graft survival were not significantly different between two groups ( $P=0.890$  and  $0.619$  by Log-Rank test, respectively).

**Conclusions:** Use of ACEi/ARB before KT did not increase the incidence of delayed graft function, hyperkalemia and rejection. Also, renal function improvement after KT was not affected by the use of ACEi/ARB before KT. Therefore, ACEi/ARB might not give significant impact on the outcomes of KT. Further well-designed studies are necessary to confirm the effect of ACEi/ARB on KT.

## SA-PO837

## Organ Discards Rates a Year After Change in Increased Risk Definition for Organ Allocation

Jordan Morrison-Nozik,<sup>1</sup> Marios Prikis,<sup>1</sup> Maricar Malinis,<sup>2</sup> Abhishek Kumar.<sup>2</sup>  
<sup>1</sup>University of Vermont College of Medicine, Burlington, VT; <sup>2</sup>Yale School of Medicine, New Haven, CT.

**Background:** The public health service designation of increased high-risk donor (IRD) was first established in 1994 to identify donors with potential higher risk of transmission of HIV, hepatitis B and hepatitis C infections. The risk criteria were updated recently in 2020 to include only 10 risk categories instead of 14. It also reduced the risk behavior time frame from 12 months to 30 days prior to organ procurement. The new criteria also stipulated that donor specimen should be collected within 96 hours before the procurement.

**Methods:** We analyzed United Network of Organ Sharing data one year prior and one year after the current implementation of new guidelines to see if the new guidelines reduced organ discard rates based on the increased risk criteria. Chi square was used to compare the difference in organ utilization between these two time periods.

**Results:** There were 6111 kidney which were labelled as having increased risk for disease transmission prior to the change in definition and 5970 after the change. The discard rate remained stable at 17%. Discard rates for heart and lungs also did not change, however less pancreas and livers were discarded based on increased risk criteria.

**Conclusions:** Our one year analysis shows that there is increased organ utilization for pancreas and liver but not for heart, lungs and kidney. However we should point out that numbers are small and that this is a very preliminary data. Full impact of the change will likely be observed in few years' time.

		Total organs procured	Organs transplanted	Organs discarded
Kidney	Prior to change	6111	5075	1036 (17%)
	After change	5970	4959	1011 (16.9%)
Lung	Prior to change	1418	1373	105 (7.1%)
	After change	1192	1126	66 (5.5%)
Heart	Prior to change	1150	1134	16 (1.4%)
	After change	1100	1090	10 (0.9%)
Pancreas	Prior to change	323	221	102 (31.6%)
	After change	317	240	77 (24.3%)
Liver	Prior to change	2579	2341	238 (9.2%)
	After change	2384	2209	175 (7.3%)

Total number of organs procured, transplanted and discarded based on increased risk status

## Preemptive Kidney Transplants Lead to Cost Savings in Less Than a Year

Rahul Dhawan, Ashley Crossman, Gregory Wysocky, Jiang Tao, Kevin Plosser. Optum KRS Nurses and Product Team and the OHS Medical Office Team Optum Inc, Eden Prairie, MN.

**Background:** For patients living with chronic kidney disease (CKD), it is theorized that receiving a kidney transplant before they need to start dialysis allows them to stay healthier and live longer than if they were to receive a transplant after initiating dialysis.<sup>1</sup> The current study assessed the cost savings associated with a preemptive kidney transplant, when available.

**Methods:** The study population consisted of patients drawn from a national health plan claims database who were identified as having stage 4–5 CKD and either received a kidney transplant prior to initiating dialysis (N = 249) or initiated dialysis (N = 1,657) between July 2017 and June 2020. To measure the total costs avoided by preemptively transplanting a kidney, the difference between an ESRD per member per month and a post-transplant per member per month was analyzed while adjusting for member retention.

**Results:** For members initiating dialysis, incident ESRD per diseased member per month (PDMPM) was calculated as the mean medical allowed amount for each of the first 6 months following the ESRD start date. The average PDMPM for the first 6 months was \$24,308, and \$18,465 each month after six months. Using the mean cost of a kidney transplant of \$109,513, the costs of the transplant are offset within the first 7 months. If the member is retained on the health plan for at least 1 year, the transplant results in \$211,000 in avoided medical expenditures and a net 1-year savings of \$101,800 after the cost of the transplant.

**Conclusions:** Preemptive kidney transplants for patients with CKD have numerous benefits, including higher patient survival, improved quality of life and significant cost savings. Transitioning a patient to dialysis costs as much as \$211,000 per year. While the cost of transplantation is around \$110,000, those costs are offset after less than seven months due to avoidance of dialysis and other health complications. Preemptive transplants therefore greatly benefit the patient and can also allow for cost savings.

## SA-PO839

## Prediction of Post-Donation Kidney Function for Persons Considering Living Kidney Donation

Fawaz Al Ammary, Abimereki Muzaale, Allan Massie. *Johns Hopkins University, Baltimore, MD.*

**Background:** Healthy adults who donate a kidney lose 50% of their nephron mass following nephrectomy. However, kidney reserve may vary by donor health and demographic characteristics. We aimed to predict 6-month post-donation eGFR (6M-eGFR).

**Methods:** We used the US national registry of 60,584 living kidney donors from 2005-2019 to identify the clinical phenotypes associated with 6M-eGFR. We estimated eGFR for each participant using the CKD-EPI 2009 creatinine equation for eGFR. We built multivariable regression models of 6M-eGFR on baseline donor factors.

**Results:** The median (IQR) pre-donation and post-donation eGFR was 98 (86-110) and 64 (54-75). For 30-year-old female who were biologically related with the recipient and had no hypertension, no history of smoking, BMI=25, and predonation eGFR 100 ml/min/1.73m<sup>2</sup>, the predicted 6M-eGFR was 69 ml/min/1.73m<sup>2</sup> for white, 66 ml/min/1.73m<sup>2</sup> for black, 71 ml/min/1.73m<sup>2</sup> for Asian, and 73 ml/min/1.73m<sup>2</sup> for Hispanic donors.

**Conclusions:** Post-donation six-month compensatory kidney function varies by donor demographic and health characteristics. Our prediction of individualized 6M-eGFR helps inform donor selection and counseling of persons who consider donation.

**Funding:** NIDDK Support, Other NIH Support - NKF

##### A Fatal Case of T-Cell Post-Transplant Lymphoproliferative Disorder After Kidney Transplant Deteriorating to Acute Liver Failure

Jeongmin Cho, Yong Chul Kim, Yon Su Kim, Hajeong Lee. *Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

**Introduction:** Post-transplant lymphoproliferative disorder (PTLD) is a rare and serious complication of kidney transplantation (KT). PTLD, mostly of B-cell lineage, progresses even after reduction of immunosuppression in half of patients. Herein, we report a deteriorating case of T-cell PTLD after KT, that rapidly progressed to liver failure, septic shock, and death despite various therapeutic attempts.

**Case Description:** A 50-year-old woman received HLA-incompatible, ABO-compatible pre-emptive KT for her diabetic end-stage kidney disease under basiliximab induction treatment. In the routine surveillance, Epstein-Barr (EB) viral copies elevated with 318,443 copies/mL at 2 months after KT. EB viremia continued to increase in spite of reducing maintenance immunosuppressive agents or preemptive rituximab treatment. At 8 months after KT, she was admitted due to fever and found multifocal splenic lesions and nonspecific lymph node enlargement in the abdomen-pelvis CT (Figure 1). After then, her liver function test started to elevate without any evidence of hepatitis-viral infection. Considering PTLD, we performed a percutaneous liver biopsy and confirmed EBV-associated T-cell PTLD with CD3 and CD56 expression (Figure 2). Because of the absence of proven treatment for the T-cell lineage PTLD, we just monitored her watchfully. Only 2-month after PTLD diagnosis, she was admitted for acute and severe liver failure. We tried rescue cytotoxic chemotherapy at hospital day 6, although she died at 12 days after hospitalization.

**Discussion:** This is a case of very rare and refractory EB virus-associated T-cell PTLD after KT does not have any specific treatment option until now. Further studies for a preventative and therapeutic method for T-cell lineage PTLD are warranted.

Figure 1. CT findings of hepatic nodules in (A) Arterial and (B) Venous phase indicating liver involvement of PTLD. (C) PTLD with lymph node and (D) splenic involvement.

Figure 2. Pathologic findings of T-cell PTLD of liver. H&E stain (A), lymphoid cells Positive for CD3 (B), Ki67 (C), CD56 (D), and EBV (E).

#### SA-PO841

##### Lenalidomide and Risk of Acute Rejection in the Kidney Allograft

Radames A. Zuquello,<sup>1,2</sup> Shahrzad Zonoozi,<sup>1,2</sup> Suman Chauhan,<sup>2</sup> Ping Li,<sup>2,3</sup> Scott D. Cohen,<sup>2,3</sup> <sup>1</sup>George Washington University Medical Faculty Associates, Washington, DC; <sup>2</sup>Washington DC VA Medical Center, Washington, DC; <sup>3</sup>The George Washington University, Washington, DC.

**Introduction:** Solid Organ Transplant is associated with an increased incidence of malignancy. It is important to understand the complications of chemotherapy and potential interactions with maintenance immunosuppression.

**Case Description:** 72yo male with ESKD secondary to FSGS received a deceased donor kidney transplant in 2008, DM, HTN, prostate CA, and recently diagnosed multiple myeloma (M M) who presented with abdominal pain. He was found to have AKI, Creat 6.9mg/dl from 1.2, with hydronephrosis and partially obstructing ureteral stone. He underwent percutaneous nephrostomy, he did not recover kidney function and required hemodialysis. Patient underwent allograft biopsy which showed grade 2A acute T cell-mediated rejection (TCMR). There was severe tubulointerstitial inflammation, tubulitis, and a focus of endothelialitis. 16/35 sclerosed glomeruli, moderate interstitial fibrosis and tubular atrophy. He was treated with IV methylprednisolone followed by IV thymoglobulin. Patient remained on tacrolimus 5mg BID and mycophenolic acid 360mg BID. It is unusual to see severe TCMR 13 years after his kidney transplant. He had no previous episodes of rejection with stable kidney function. Two months prior to presentation, he was started on chemotherapy for MM with bortezomib, lenalidomide and dexamethasone. The third cycle of chemotherapy was held. The patient had tacrolimus trough levels ranging from < 0.75µg/L to 4.4µg/L during the months leading up to presentation. Despite treatment patient continued to have dialysis dependent AKI without signs of recovery.

**Discussion:** Lenalidomide is associated with acute rejection in solid organ transplantation. A possible mechanism is activation of T-cells with secretion of interferon gamma and interleukin-2 leading to stimulation of CD8 and CD4+ helper T-cells promoting activation of the immune system. It is important to be aware of the potential complications of immunomodulatory chemotherapy which can increase risk of TCMR. Management of post transplant malignancies is challenging and requires a multidisciplinary approach.

#### SA-PO842

##### Refractory Diarrhea Following Kidney Transplantation: A Management Challenge

Mario A. Leone, Reem Daloul, Michael Landau, Khaled Nashar, Kalathil K. Sureshkumar. *AHN Allegheny Health Network, Pittsburgh, PA.*

**Introduction:** Diarrhea in organ transplant recipients can be a management challenge with numerous causes including medications. We present a kidney transplant recipient (KTR) with refractory diarrhea in early post-transplant period. Colon mucosal biopsy showed changes consistent with tacrolimus related colonic injury with complete resolution of diarrhea after tacrolimus was switched to cyclosporine.

**Case Description:** A 65-year female KTR presented with profuse diarrhea in early post-transplant period. Donor and recipient were CMV and EBV IgG positive. Patient received Thymoglobulin induction followed by tacrolimus/mycophenolic acid (MPA) maintenance along with valgancyclovir for CMV and trimethoprim-sulfamethoxazole for Pneumocystis jirovecii prophylaxes. Patient was treated with IV hydration and MPA was held. Stool test returned positive for Clostridium difficile (C diff) toxin for which she received 2-week course of PO vancomycin. Diarrhea continued despite negative follow-up stool C diff toxin. Colonoscopy showed normal mucosa with random biopsies revealing patchy crypt apoptoses (figure) with negative CMV stain and no evidence for lymphocytic or collagenous colitis. Tacrolimus, because of its association with crypt apoptoses was changed to cyclosporine along with azathioprine and prednisone. Diarrhea started improving within a few days with complete resolution in 2 weeks. Currently the patient remains well with stable allograft function.

**Discussion:** There is emerging evidence for tacrolimus related colonic toxicity. Tacrolimus can interfere with mitochondrial oxidative phosphorylation thereby enhancing intestinal mucosa permeability resulting in exposure to luminal antigens that can trigger mucosal injury and diarrhea. In our patient, diarrhea continued despite stopping MPA and clearance of C diff infection. This, along with supporting colon biopsy finding and resolution of diarrhea with tacrolimus discontinuation, strengthened the possible association of tacrolimus use with diarrhea in our patient. High index of suspicion is needed to make early diagnosis.

## SA-PO843

### Meningioma in a Kidney Transplant Recipient a Risk Factor for Primary Central Nervous System Lymphoma

Sami M. Akram,<sup>1,2</sup> Sujay D. Paudel,<sup>1</sup> Rungwasee Rattanavich,<sup>1</sup> Surakshya Regmi,<sup>1</sup> Rafael Villicana,<sup>1</sup> Loma Linda Transplant Institute <sup>1</sup>Loma Linda University, Loma Linda, CA; <sup>2</sup>Masters of Medicine Health Care, Los Angeles, CA.

**Introduction:** Calcineurin inhibitor (CNI) neurotoxicity is common; has a wide array of presentation. Compromised blood brain barrier (BBB) is a risk factor. We studied a case of PCNSL in a kidney transplant recipient (KTR) with meningioma in order to bring to awareness of association between meningioma and PCNSL.

**Case Description:** A 56-year-old female is a deceased donor KTR from 11-years ago by thymoglobulin induction. She develops new left hemiparesis and confusion. She was maintained on Tacrolimus (FK), Mycophenolate (MMF) and Prednisone. FK levels were therapeutic and serum creatinine was 0.9 mg/dL. Epstein Barr Virus (EBV) and SARS-CoV-2 antigen tests were negative. Computed tomography (CT) of the brain showed a 4.2 x 4.5 x 3.9 cm mass centered in the left lentiform nucleus; midline shift of 1.1cm and a calcified meningioma. CT of the abdomen and pelvis was normal. Brain biopsy was consistent with PCNSL lymphoma. EBV encoded RNA staining was positive. Despite cytoreductive surgery and chemotherapy, PCNSL progressed. Her family elected hospice care.

**Discussion:** Meningioma is common primary brain tumor with latency period of up to 30 years. A meningioma makes BBB permeable due to neo-angiogenesis at its margins. PCNSL constitute only 1% of Non-Hodgkin Lymphoma (NHL). Yet, PCNSL is 65 times more common in solid organ transplant recipients (SOTR) than in general population and six times more common than Non-Hodgkin's lymphoma (NHL). Therefore, we posit that PCNSL is a form of neurotoxicity due to persistently high concentration CNI via a permeable BBB. EBV is present in 90% of cases which makes host cell genome vulnerable to neurostructural changes. In our case PCNSL occurred despite therapeutic levels of CNI and despite absence of EBV in the serum. **Conclusion:** Meningioma related BBB permeability, increases severity of neurotoxicity and therefore, risk of PCNSL in a SOTR. Due to long latency of meningioma, risk of PCNSL can be and should be assessed prior to transplantation.

PCNSL

## SA-PO844

### Kidney Transplant In Mentally Challenged Patients: A Single Centre Experience

Jude A. Yagan,<sup>1,2</sup> Tarek S. Mahmoud,<sup>1</sup> Osama Gheith,<sup>1</sup> Mohamed M. Mostafa.<sup>1</sup> <sup>1</sup>Organ transplant centre, Kuwait, Kuwait; <sup>2</sup>Ibn Rushd hospital, Aleppo, Syrian Arab Republic.

**Background:** kidney transplant (KTx) is the best treatment for end-stage kidney disease (ESKD). Some medical conditions, like psychological and neurological status of the recipient, may pose ethical and legal questions on kidney allocation especially if medical improvement is not expected. Conversely, there is an obligation to provide the best care for this vulnerable group.

**Methods:** We retrospectively studied 10 children with a background of mental difficulties with variable severity, most had urological developmental abnormalities as the cause of ESKD. Children had KTx from all types of donors. 7 children were without

a labeled diagnosis (global developmental delay, cerebral palsy), one had Jeune syndrome (received combined deceased donor liver and KTx), 1 had Laurence-moon-Biedl syndrome, 1 with Down syndrome. We interviewed the families during outpatient visits asking questions about improved quality of life, social/emotional well-being, medication adherence.

**Results:** 10 children were followed for up to 23 years, the mean age at transplant time was 7.8 years. 4 had LRKTx, similar number had DDKTx, 2 had LUKTx. Mean serum creatinine of 135umol/l upon the last follow-up. The main benefit was relieving families from the burden of maintaining HD/PD and providing a better quality of life. The general misconception about inability to follow complex medication regimens or nonadherence in this group is highly contested in this cohort. Good caregiver support (family member/housemaid) ensured timely given medications on top of good support/medical education in our center. There were no rejection episodes or prolonged hospitalization except for mild infections (UTIs, chest infections).

**Conclusions:** Mentally challenged patients shouldn't be denied KTx based only on their mental condition. Issues of nonadherence can be overcome with stable family support even in patients with devastating neurological dysfunction. It will solve the ethical issues surrounding depriving this group of the best care while ensuring no waste of precious organs.

## SA-PO845

### BK Virus Nephropathy of Native Kidney After Hematopoietic Stem Cell Transplantation

Ling Hong,<sup>1</sup> Xiaodong Wang,<sup>2</sup> Lin Wang,<sup>3</sup> Ying Wang,<sup>1</sup> Zhihua Zheng,<sup>1</sup> Wenfang Chen,<sup>4</sup> <sup>1</sup>The Seventh Affiliated Hospital Sun Yat-sen University, Shenzhen, China; <sup>2</sup>Shenzhen Children's Hospital, Shenzhen, China; <sup>3</sup>Guangzhou Kingmed Diagnostic Laboratory Ltd, Guangzhou, China; <sup>4</sup>Sun Yat-sen University First Affiliated Hospital, Guangzhou, China.

**Background:** BK virus nephropathy (BKVN) is characterized by a tubulointerstitial injury caused by BK virus infection, which is more common after kidney transplantation. Few cases have been described outside the context of renal allograft. This study aims to elucidate the clinicopathologic features and prognosis of BKVN after hematopoietic stem cell transplantation (HSCT).

**Methods:** A total of 667 patients who received HSCT treatment at 2 centers from January 2020 to April 2022 were reviewed. The clinical characteristics, renal biopsy results, and prognosis of 7 BKVN patients were analyzed.

**Results:** The incidence of BKVN after HSCT was 1.0%, with a median age of 17 years and a median onset time of 12 months post-HSCT. The primary diseases were thalassemia major (5 cases) and acute lymphoblastic leukemia (2 cases). Haploidentical transplantation was performed in 6 patients (85.71%), and cord blood inpatient. Hemorrhagic cystitis occurred in 5 patients (71.43%) after HSCT. Proteinuria was absent or slight and a BK viral load >4 log copies/ml in blood in 7 cases, the median serum creatinine levels were 2.19mg/dl at the time of biopsy. Histologically, all cases showed tubulointerstitial inflammation while glomeruli were spared. Nuclear inclusion was detected in 5 cases (71.43%). There were 4 (57.14%) with severe tubular atrophy and interstitial fibrosis (IFTA), 2 (28.57%) were moderate and 1 (14.29%) mild; with AST stage B1(28.57%), B3(28.57%), C (42.86%). The SV40 T antigen was detected in tubular epithelial cells in 7 cases (100%). 5 (71.43%) were treated with cidofovir against BK infection, while 2 were given intensive immunosuppressive therapy for GVHD. 3 (42.9%) progressed to end-stage renal disease (ESRD) within 6 months after renal biopsy, among which 2 was AST stage C and 1 was stage B1.

**Conclusions:** Patients who undergo HSCT, especially haploidentical transplantation, may develop BK virus infection, initially presenting as high levels of BK viruria or BK viremia and then progressing to BKVN, which will result in ESRD.

**Figure 1.** Pathologic Changes of BKVN after HSCt

#### SA-PO846

### Primary Hyperoxaluria Diagnosed After Second Kidney Transplantation and Treated With Lumasiran: Never Say Never!

Mrinalini Sarkar, Elizabeth A. Kendrick, Erik L. Lum. Connie Frank Kidney Transplant Centre University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

**Introduction:** Primary hyperoxalurias (PHs) are rare autosomal recessive caused by the functional defect of alanine-glyoxylate aminotransferase that causes overproduction of oxalate, increased urinary excretion and end-stage kidney failure via crystal aggregation, and nephrocalcinosis. PH1 is the most common and severe form with rapid progression to kidney dysfunction by young adulthood. We describe a case of a patient who received her second kidney transplant 32 years after her first and developed primary allograft dysfunction from PH1 related oxalate nephropathy.

**Case Description:** 56 y.o. female with end stage kidney disease secondary to unclear etiology underwent deceased donor kidney transplant (DDKT) 32 years after her first transplant for allograft dysfunction. She reported recurrent kidney stones until age 16 but no further renal issues. She developed renal failure a year later and started dialysis. She denied h/o Bowel dysfunction, IBD or bowel surgeries Post transplant she continued to have AKI prompting a renal biopsy that demonstrated extensive ca oxalate crystal deposition. Her serum oxalate was 24.7  $\mu\text{mol/L}$  and urine oxalate was 60mg/d on a 24 hour collection. A genetic test (renasight) confirmed a homozygous pathogenic variant in the AGXT gene. She continued to be dialysis dependent post transplant for 4 months prior to starting lumasiran(RNA-I). She has been weaned off hemodialysis after 2 months of RNA-I use and is being closely monitored for recovery of graft function

**Discussion:** PH1 is a devastating disease especially for kidneys, leading to end-stage renal disease (ESRD) during the first 2 to 3 decades of life. Combined liver and kidney transplantation has become the treatment has been the mainstay of treatment, however newer drugs are on the horizon including lumasiran which has been tested in PH1 patients with severe kidney dysfunction, including chronic dialysis The goal before kidney transplantation is to limit as much as possible the systemic storage of oxalate to prevent oxalate precipitation in the allograft. Early initiation of a treatment (e.g. RNAi drugs) that corrects the metabolic defect should be considered. In PH1 patients not on dialysis and with limited systemic oxalate storage, preemptive kidney transplantation should be proposed as soon as possible after the correction of the metabolic defect

#### SA-PO847

### An Unusual Presentation of Hypercalcemia in a Patient With Kidney Transplant

Thejeswi Pujar, Yasar Caliskan, Fadee Abu Al Rub, Bahar Bastani. Saint Louis University, Saint Louis, MO.

**Introduction:** Hypercalcemia in kidney transplant patients is not uncommon. Persistent hyperparathyroidism is reported to occur in approximately 15 to 50% of patients following transplantation causing hypercalcemia. A rise in calcium level on the background of previously stable calcium levels with stable elevated parathyroid hormone (PTH) should prompt investigating malignant etiology. We present the case of a 67-year-old man who was hospitalized with an unusual case of hypercalcemia.

**Case Description:** A 67-year-old male with history of kidney transplant [YC1] 3.5 years prior presented with progressive weakness and fatigue. On admission he had acute kidney injury (AKI) and hypercalcemia with a corrected calcium of 14.5 mg/dl. He had history of tertiary hyperparathyroidism controlled on cinacalcet, with calcium level in range of (9-10 mg/dl) in the previous year. Workup revealed a mildly elevated PTH 130 pg/ml, normal 25 hydroxy Vit D and normal PTH related protein levels. Serum and urine electrophoresis with immunofixation revealed IgG monoclonal gamma restriction. A bone marrow biopsy ruled out plasma cell dyscrasia. A whole-body PET CT revealed marked splenomegaly with intense Fluorodeoxyglucose (FDG) uptake. Epstein Barr Virus (EBV) PCR was 407,000 IU/ml raising the suspicion for post transplant lymphoproliferative disorder (PTLD). A subsequent splenic biopsy revealed: Diffuse Large B Cell Lymphoma

and EBER ISH (Epstein-Barr Encoding Region in Situ Hybridization) test was positive. Hypercalcemia was treated successfully with intravenous fluids and pamidronate, then the patient was initiated on rituximab. However, due to lack of response, this was changed to rituximab, cyclophosphamide, doxorubicin and prednisone (R-CHOP) therapy. The patient maintained normal calcium Level in the range pf (8-9 mg/dl).

**Discussion:** This is a unique presentation of an EBV induced PTLD involving the spleen in a renal transplant patient. Hypercalcemia by extrarenal overproduction of 1,25-dihydroxyvitamin D3 (1,25(OH)2D3) is seen in < 1% of hypercalcemia of malignancy and is usually found in lymphomas. It is more common in granulomatous disease like Tuberculosis and Sarcoidosis. The extra renal production of calcitriol by these cells results in substantial increase in the absorption of calcium. In this case hyperparathyroidism probably aggravated the condition.

#### SA-PO848

### A Case of Isolated Banff 2b Arteriopathy

Nathan Dang,<sup>1</sup> Alexander Pennekamp,<sup>1</sup> Jonathan Tobias,<sup>2,3</sup> Joseph Kremer.<sup>4,3</sup>  
<sup>1</sup>The Christ Hospital Internal Medicine Residency, Cincinnati, OH; <sup>2</sup>Greater Cincinnati Pathologists, Cincinnati, OH; <sup>3</sup>The Christ Hospital Health Network, Cincinnati, OH; <sup>4</sup>The Kidney and Hypertension Center, Cincinnati, OH.

**Introduction:** Carefully balancing the risk of malignancy with the risk of allograft rejection underscores the importance of treating immunosuppression (IS) as both a science and an art. This case highlight a rare finding of isolated Banff2b TCMR that developed 28 years after initial transplantation.

**Case Description:** This is a 65 y/o male with a past medical history of LDRK transplant 28 yrs ago (ESRD 2/2 IgAN), lymphoma s/p ABVD and invasive skin cancer who presented to the office with progressively worsening creatinine over the past month. The patient has been managed with cyclosporine and low dose prednisone since his initial transplant. He was diagnosed with an invasive microcystic adnexal carcinoma of the skin about 25 years after kidney transplant. He underwent resection of the carcinoma soon after diagnosis. About one year after resection, the invasive carcinoma recurred. He became blind in one eye as a consequence of his worsening malignancy. Ultimately, the decision was made to wean off of cyclosporine and start on sirolimus while low dose prednisone was continued. He was started on carboplatin and paclitaxel shortly after switching his IS medications. One month afterwards, he presented to his Nephrologist's office with a progressive increase in his creatinine and concern for rejection. A kidney biopsy was performed. The biopsy showed minimal interstitial inflammation with one artery showing marked intimal expansion with both fibrosis and an active appearing lymphocytic infiltrate. The chronic inflammatory infiltrate also involved the media and adjacent cortex.

**Discussion:** Isolated Banff 2b arteritis is a rare phenomenon. In this case, acute rejection developed rapidly after years of stable IS therapy once cyclosporine was changed to sirolimus. The findings were favored to represent active endarteritis superimposed on chronic transplant arteriopathy. He was then restarted on sirolimus and higher dose of steroids and completed four treatments of local graft radiation with interval improvement of his creatinine.

Mechanism of Allograft Dysfunction	Test	Value	Units	Interpretation
	creatinine, serum	2.72 (eGFR 42 by CKD-EPI 2009)	g/dL	Acute Allograft Dysfunction
	creatinine, serum, baseline	1.53		
deNovo GN / GN recurrence	Urine protein to creatinine ratio	0.23	g/g	GN Unlikely
	Urinalysis	bland; reflex culture not indicated		
Pre-renal causes	Allograft ultrasound and PVR, doppler	normal, without evidence of allograft renal artery stenosis		Pre-renal contribution unlikely
BK allograft Nephropathy	BK quant	0	copies/mL	BK Ruled Out
TCMR	C4d staining	negative		TCMR ruled out

#### SA-PO849

### Clinical Course of a Kidney Transplant Recipient With BK Polyomavirus Treated With Posoleucel (PSL) Multivirus-Specific T-Cells

Adetokunbo A. Taiwo,<sup>1</sup> Stephan Busque,<sup>1</sup> Francesca Cardarelli,<sup>2</sup> Patrick Ahearn.<sup>1</sup> <sup>1</sup>Stanford University, Stanford, CA; <sup>2</sup>AlloVir, Waltham, MA.

**Introduction:** Treatment of BK viremia and nephropathy primarily involves reducing maintenance immunosuppression. Adjunct therapies such as cidofovir, IVIG, and leflunomide produce mixed results. We present the clinical course of a kidney transplant (KT) recipient with BK polyomavirus treated with posoleucel, a novel therapy using multivirus specific T-cells.

**Case Description:** A 67-year-old man with a history of AL amyloidosis post orthotopic heart transplant developed end stage kidney disease and underwent a living related KT. He received thymoglobulin induction and maintenance immunosuppression with tacrolimus, mycophenolate, and prednisone. His baseline creatinine settled around 1.4 mg/dL. Six months later, he was diagnosed with EBV+ post-transplant lymphoproliferative disease

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

and was treated with rituximab. PET scan showed resolution. Soon after, his creatinine rose to 1.8 -2 mg/dL and a kidney biopsy showed BK polyoma virus nephropathy. Serum BK PCR at diagnosis was 3.5 million copies/mL. Mycophenolate was discontinued, tacrolimus was switched to sirolimus, and he was started on cidofovir q 2 weeks with rise in serum BK to >10 million copies/mL. Cidofovir was discontinued when his kidney function worsened. IVIG was started but was complicated by hemolytic anemia. FDA approved posolecul for compassionate use. He received 4x10<sup>7</sup> PSL cells weekly for 3 doses then every other week for 3 doses. Table 1 summarizes his BK viral load and creatinine.

**Discussion:** PSL treatment was well tolerated with no adverse events. PSL is the only intervention associated with a significant decline of BK viremia in this patient with BK nephritis, with a ½ log decline in BK viral loads during the treatment period and further ½ log decline over follow-up. A phase 2 trial has completed enrollment.

BK viral load and creatinine

Treatment/Follow Up	BK Viral Load (IU/mL)	Creatinine (mg/dL)
Treatment 1	2,530,654	3.35
Treatment 2	2,607,078	3.0
Treatment 3	1,583,579	3.45
Treatment 4	1,920,140	4.06
Treatment 5	1,164,649	3.39
Treatment 6	1,157,669	3.32
Follow-up 1	351,000	3.60
Follow-up 2	346,000	3.63
Follow-up 3	235,000	3.86

SA-PO850

Immune Tolerance in a Kidney Transplant Recipient With Two Related Donors

Aliza Anwar Memon, Krista L. Lentine, Thanh-Mai N. Vo, Fadee Abu Al Rub, Bahar Bastani, John C. Edwards, Yasar Caliskan. Saint Louis University, Saint Louis, MO.

**Introduction:** Immune tolerance is multifaceted and involves the interaction of different cells. Despite major advances, widespread tolerance in solid organ transplantation has not yet been achieved without dependence on immunosuppressive treatment. Compulsory exposure to genetically foreign maternal tissue imprints in offspring sustained tolerance to noninherited maternal antigens (NIMA). Here, we describe a case of successful second transplant with persistence immune tolerance more than 20 years.

**Case Description:** A 53-year-old man with second living donor kidney transplant from his sister was consulted with Transplant Nephrology Unit. Patient had a past medical history of end stage kidney disease due to bilateral vesicoureteral reflux nephropathy, status post failed living donor kidney transplant from his mother in 1981 until 1984, first allograft nephrectomy, status post hemodialysis between 1984-1988 and status post second living donor kidney transplant from his sister in 1988. Patient’s first kidney transplant failed due to rejection after 3 years. The patient received second transplant from his sister in June 1988. Patient discontinued his immunosuppressive treatment in 1999. Since then his serum creatinine level ranged between 1-1.2 mg/dL without any immunosuppressive treatment. Laboratory tests revealed: serum BUN 14 mg/dL, creatinine 1.13 mg/dL, total protein 7 g/dL, albumin 4.2 g/dL. Urine sediment showed 0-2 red blood and 0-5 white blood cells per high power field. Urine analysis showed no proteinuria. The Luminex single antigen bead HLA antibody screening test showed panel reactive antibody level of 0% and 8% for class I and II antibodies. The weak class II antibodies were against HLA-DQ:06:01, DQ:05:01, DQ:05:03, DQ:06:03, DQ:06:04 and DQ:06:02. Previous donors’ HLA DQ typing were not available. Patient continued his posttransplant follow up without any immunosuppressive treatment.

**Discussion:** Although the exact mechanism of tolerance to second kidney transplant in this case is not known, transplantation of a kidney from his mother exposes the patient to the other haplotype carrying the NIMAs and this exposure of the fetus to NIMAs can lead to tolerance because of immaturity of the fetal immune system. This case highlights an important model to study further the NIMA-specific tolerance and the underlying mechanisms.

SA-PO851

Passenger Lymphocyte Syndrome in Post-Transplant Patients

Aliza Anwar Memon, Vidya Fleetwood, Daniela Hermelin, Natalie Malvik, Yasar Caliskan, Bahar Bastani, Fadee Abu Al Rub, Thanh-Mai N. Vo, John C. Edwards, Krista L. Lentine. Saint Louis University, Saint Louis, MO.

**Introduction:** Passenger Lymphocyte Syndrome (PLS) is an immune mediated hemolysis directed against recipient red blood cells as the result of the concurrent transplantation of allograft derived “passenger” lymphocytes. It is an uncommon phenomenon that occurs in the setting of minor ABO mismatched solid organ transplant. We present a unique case of PLS due to Rh-incompatibility.

**Case Description:** A Rh positive 61-year-old man with end stage kidney disease underwent a deceased donor kidney transplant from a Rh-negative donor. Allograft started to function and patient was discharged at postop day 7. He was re admitted after two weeks with a low hemoglobin level. Work up for anemia was significant for elevated lactate dehydrogenase, unconjugated bilirubin, undetectable haptoglobin, and schistocytes on the peripheral smear. Flow cytometry for paroxysmal nocturnal hemoglobinuria and G6PD level were within normal limits. The antibody screen and direct antiglobulin test (DAT) became positive which were previously negative. The DAT showed strong reactivity with

the anti-IgG reagent which was associated with anti-D antibodies in patient’s plasma. Results of RHD genotyping testing showed no associated variants in this patient. However, a premortem donor blood specimen was recovered, which revealed the presence of anti-D and anti-C antibodies in the donor’s plasma. The diagnosis of PLS due to anti-D antibody was made. Patient received supportive treatment with Rh D and C antigen negative blood, steroids and rituximab infusions. Three months from transplant, the patient is stable with a down trending anti-D titer.

**Discussion:** PLS should be suspected in cases of sudden anemia following solid organ transplant. The timing of this occurrence is consistent with an anamnestic immune response. Having an awareness of this potential phenomenon can aid in prompt diagnosis and treatment which can range from transfusion support to immunosuppressive therapy.

Hemoglobin trend in Passenger Lymphocyte Syndrome

SA-PO852

Post-COVID-19 Syndrome Neuropsychiatric Complications Leading to Medication Non-Compliance and Acute Rejection in a Kidney Transplant Patient

Taha M. Shaikh,<sup>1</sup> Thelmo Fidel Ernesto Barrantes Ramirez,<sup>2</sup> Michael B. Kuperman,<sup>3</sup> <sup>1</sup>Burrell College of Osteopathic Medicine, Las Cruces, NM; <sup>2</sup>Renal Medical Associates, Albuquerque, NM; <sup>3</sup>Arkana Labs, Little Rock, AR.

**Introduction:** Depression, anxiety, and fatigue, which can all contribute to medication non-adherence, have been described with different frequencies in post-COVID syndrome patients.

**Case Description:** The patient is a 41-year-old male with a past medical history of hypertension, type 2 diabetes mellitus, and hypothyroidism. He also has a history of end stage renal disease (ESRD) requiring kidney transplantation on 12/24/2017. He initially developed ESRD due to congenital unilateral renal agenesis and hypertension. He presented to the ED on 02/18/22 complaining of fatigue, dizziness, nausea and at least one prior syncopal episode. On 02/22/22, a kidney biopsy was taken showing evidence of acute vascular rejection, acute t-cell mediated rejection and acute antibody mediated rejection. The patient described increased fatigue and depressive symptoms following COVID hospitalization in November 2021, which he had not experienced before. After recovering from COVID in the hospital, he reported sleeping excessively, feeling exhausted throughout the day, decreased interest in activities, difficulty concentrating, and an overall decreased mood without suicidality. This combination of fatigue and depressive symptoms led to his medical non-compliance. He had no prior psychiatric history or issues with non-compliance.

**Discussion:** It is very likely that this patient is one of the first reported cases of post-COVID syndrome phenomena leading to serious downstream consequences such as kidney allograft failure. The goal of this case report is to increase awareness of post-COVID syndrome particularly in patients with chronic conditions that require strict medication regimens. By having adequate surveillance of these patients by both their primary care physicians as well as any specialists involved it is certainly possible to reduce the occurrence of serious downstream consequences. An example of this increased surveillance is prompt follow-up after COVID hospitalization for any patient with chronic health conditions. Another possible intervention is the use of questionnaires or surveys for post-COVID patients that can measure the effects of post-COVID syndrome, similar to how the PHQ-9 is utilized for MDD. Most importantly, it is crucial to provide knowledge of this phenomenon to patients and physicians alike.

SA-PO853

Aliskiren as an Adjunct Treatment for Recurrent C3 Glomerulonephritis (C3GN) in a Transplant Patient

Nouman Akbar, Selvaraj Muthusamy, Layla Kamal, Irfan A. Moinuddin. Virginia Commonwealth University Health System, Richmond, VA.

**Introduction:** C3GN is an immune complex disease mediated by activation of alternative complement pathway. This pathway can be activated by renin resulting in cleavage of C3, thus producing C3 convertase and subsequent membrane attack complex formation. Aliskiren, a direct renin inhibitor, can inhibit the complement and in a recent case report was successfully used for a case of native kidney C3GN.

**Case Description:** 25 years old African-American female with end-stage renal disease due to biopsy proven C3GN had a living unrelated kidney transplant at our center. Her pre-transplant testing showed elevated levels of complement fragments Ba/Bb and soluble C5b-9 but no pathogenic genetic mutations. C3 nephric factor and Factor H autoantibody were negative. She received induction with anti-thymocyte globulin, and maintenance immunosuppression was tacrolimus, mycophenolate mofetil (MMF) and prednisone. A surveillance biopsy at 3 months post-transplant did not show rejection or recurrence of primary disease. She developed 1.5 g/d proteinuria 3 years post-transplant while on losartan. A kidney biopsy showed recurrent C3GN, with immune complex deposits on electron microscopy. Her repeat testing was negative for C3 nephric factor and Factor H autoantibody. The complement fragments Ba/Bb and soluble C5b-9 levels were normal possibly due to her baseline immunosuppression. She was switched from losartan to Aliskiren and her MMF dose was increased by 500mg/d. Her proteinuria improved to 0.2 g/d over the next 8 months. A post-treatment biopsy was performed. Comparison of pre- and post-biopsy data showed a statistical reduction ( $p < 0.01$ ) in the mean (SD, standard deviation) size of deposits [2201 nanometer (SD 1102) vs 884 nm (SD 255)] as well as the density of deposits [3.8 per capillary loop (SD 2.5) vs 2.5 per capillary loop (SD 2.8)].

**Discussion:** Traditionally management of C3GN has included immunosuppressive agents including steroids, MMF and a possible role of complement pathway blocker, eculizumab. There have been case reports of successful treatment of native kidney C3GN in children with Aliskiren and MMF. In this first report we describe achievement of complete remission in a patient with recurrent C3GN after kidney transplant with Aliskiren and MMF intensification. These data support further trials for this relatively cheap therapy in this rare disease space.

## SA-PO854

### Malakoplakia of the Kidney Allograft

Jefferson L. Triozzi, Ramya Krishna Velagapudi, Mohammad Kazem Fallahzadeh Abarghouei, Agnes B. Fogo, Beatrice P. Concepcion. *Vanderbilt University Medical Center, Nashville, TN.*

**Introduction:** Malakoplakia is a rare granulomatous disease associated with infection, usually of the genitourinary tract. Solid organ transplant recipients and other immunocompromised individuals are at increased risk of malakoplakia. This case raises important considerations for the diagnosis and management of malakoplakia in kidney transplant recipients.

**Case Description:** A 40-year-old woman with end-stage kidney disease secondary to atypical hemolytic uremic syndrome, with a first kidney transplant nine years prior, a second kidney transplant four months prior, and a hospitalization for sepsis due to E Coli urinary tract infection one month prior, was hospitalized with worsening acute kidney injury despite resolution of sepsis. On presentation, she had normal vital signs and physical exam findings, and a serologic work-up and hemolysis studies were negative. A kidney biopsy demonstrated diffuse interstitial infiltrate with tubulitis and rare yeast-like forms for which she was empirically treated with fluconazole. Her kidney function continued to worsen, however, requiring hemodialysis. A second kidney biopsy demonstrated findings diagnostic of malakoplakia with foci of Michaelis-Gutmann bodies with targetoid appearance. Her kidney function improved with reduction of immunosuppression and a thirty-day course of ciprofloxacin.

**Discussion:** Malakoplakia is an inflammatory response to infection, often secondary to E coli or gram-negative bacteria in the genitourinary tract. Malakoplakia results from impaired phagolysosomal killing and elimination of bacteria by macrophages, resulting in Michaelis-Gutmann bodies (intracytoplasmic basophilic targetoid lesions of enlarged macrophages). Malakoplakia of the kidney allograft raises considerations for kidney transplant recipients. Firstly, urinary tract infections may herald the development of malakoplakia in predisposed individuals. Secondly, reduction of immunosuppression may improve antimicrobial treatment response. Thirdly, the diagnosis of malakoplakia requires collaboration with renal pathology to evaluate for other fungal or bacterial infectious etiologies that could present similarly. In sum, malakoplakia is a rare finding in the kidney transplant that can be treated with reduction of immunosuppression and appropriate antimicrobial therapy.

## SA-PO855

### Pharmacokinetic-Guided Dosing to Maintain Therapeutic Tacrolimus Levels During Post-Kidney Transplant Erythrocytapheresis in a Patient With Sickle Cell Anemia

John Caldwell, Danielle Lazear, Bradley Miyagawa, Tomoyuki Mizuno, Charles T. Quinn, Hillary Stone, David K. Hooper, Charles D. Varnell. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

**Introduction:** To maximize renal recovery following kidney transplant (KT) in patients with sickle cell nephropathy (SCN) it is important to maintain a lower fraction of sickle hemoglobin (HbS). This can be done with erythrocytapheresis (RBCx). Tacrolimus (TAC), the primary immunosuppressive medication used after KT, is highly localized to red blood cells (RBCs) and is cleared by RBCx. This may result in subtherapeutic TAC levels and increased rejection risk. The impact of RBCx on post-KT TAC levels has not been described.

**Case Description:** A 16-y.o. male with ESKD secondary to SCN received a deceased donor KT. Pre-KT preparation included optimized hydroxyurea therapy and erythropoietin. He received one RBCx to target a HbS of  $< 10\%$  immediately prior to KT and subsequent scheduled RBCx to maintain HbS  $< 20\%$  for the first 3 months post-KT and  $< 30\%$  thereafter. Pre- and post-RBCx TAC levels were measured for pharmacokinetic modeling (PK). The patient received a post-RBCx dose of TAC after each treatment; the

dose was calculated based on estimated fraction of cells remaining (FCR), estimated RBC binding of TAC (85%), and the morning dose (Equation 1). Using PK, the estimated area under the curve (AUC) after RBCx with the extra TAC dose was 289 ng\*h/mL which was comparable to his steady-state AUC (283 ng\*h/mL) (Figure 1).

**Discussion:** Minimizing the risk of injury to a new allograft by minimizing HbS levels is an important aspect of post-KT care in patients with SCN. We show that a PK-guided dose of TAC after RBCx can allow highly effective treatment of SCN post-KT without compromising TAC exposure. This strategy protects the allograft by decreasing both SCN-related damage rejection risk.

$$PostDose = MorningDose * 0.85 * (1 - FCR)$$

Equation 1. Tacrolimus post-dose calculation

Figure 1. PK modeling of tacrolimus level with and without post-RBCx dose. Red dots indicate measured levels.

## SA-PO856

### Kidney Only Transplantation in Primary Hyperoxaluria Type 1: A Novel Approach in the siRNA Therapy Era

Matthew C. Breeggemann, Stephen L. Gluck, Marshall L. Stoller, Marsha May Lee. *University of California San Francisco, San Francisco, CA.*

**Introduction:** Primary hyperoxaluria type 1 (PH1) is a disease of impaired hepatic glyoxylate metabolism due to a deficiency in alanine glyoxylate aminotransferase (AGT) activity. PH1 is a major risk factor for calcium oxalate kidney stones, nephrocalcinosis, and end stage renal disease (ESRD). Following the onset of chronic kidney disease (CKD), plasma oxalate levels rise and oxalate deposition may occur in a variety of tissues. Oxalosis causes significant morbidity and mortality in this patient population and oxalate levels can continue to accumulate even with aggressive dialysis. The current surgical management of PH1 is combined liver-kidney transplantation. With the advent of silent RNA (siRNA) therapies targeting the hepatic overproduction of oxalate, kidney only transplantation is a practical novel approach for managing PH1 patients with severe renal impairment. We present the first known case of kidney only transplantation in a PH1 patient receiving siRNA therapy.

**Case Description:** A 17 year old patient with PH1 developed ESRD and was started on hemodialysis (HD). Three months after HD initiation, they started nedosiran on a compassionate use basis and declined an offer for a combined liver-kidney transplant in favor of waiting for a kidney only transplant. At age 19 years, they received a deceased donor kidney transplant and maintained on hemodialysis post-operatively to decrease oxalate burden (goal pre-HD plasma oxalate  $< 3$  umol/L) while continuing nedosiran. Subsequently, HD frequency decreased significantly and will likely be discontinued altogether at approximately six weeks post-transplantation.

**Discussion:** PH1 is a devastating kidney stone disease. Prior to 2020, there were no FDA approved drugs to treat PH1 and limited medical therapies aimed at delaying the onset of CKD and oxalosis were available. Definitive treatment in those with CKD has been combined liver-kidney transplantation to simultaneously replace the hepatic AGT deficiency and treat the renal impairment. Available novel siRNA therapies not only offer hope to the community of this ultra-rare disease but potentially eliminate the need for liver transplantation. This case is the first known kidney only transplant in a PH1 patient on siRNA therapy and may represent a major shift in the management of this vulnerable patient population.

## SA-PO857

**Relapsing Proliferative Glomerulonephritis With Monoclonal Immunoglobulin Deposits After Renal Transplantation Presenting With AKI and Gross Hematuria**

Sana J. Shaikh, Zoltan G. Laszik, Sandy W. Wong, Allison B. Webber. *University of California San Francisco, San Francisco, CA.*

**Introduction:** Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits (PGNMID) is a subtype of monoclonal gammopathy of renal significance (MGRS), resulting from deposition of intact monoclonal IgG in glomeruli.

**Case Description:** This is a 62-year-old woman with ESRD attributed to HTN who underwent a living-related renal transplant in 2009. She developed MGRS involving her allograft, diagnosed 7 years post-transplant during workup of AKI and nephrotic range proteinuria. Transplant biopsy showed membranoproliferative glomerulonephritis (MPGN) with gamma-3 heavy chain and kappa light chain restriction. Paraproteinemia workup was normal (SPEP, UPEP, serum and urine IFE, bone marrow aspirate and biopsy, PET-CT), aside from a marginal free light chain ratio (2.5). C3, C4, cryoglobulin, HIV, HBV, HCV were normal/negative. She received induction therapy with cyclophosphamide, bortezomib, dexamethasone (CyBorD), then carfilzomib, lenalidomide, dexamethasone. She transitioned to maintenance therapy with daratumumab and remained on tacrolimus monotherapy. Her renal function was stable on this regimen (Cr 1.7 mg/dL, UPCR 0.2) for the next 6 years. She then developed AKI and gross hematuria. Imaging and urologic workup were negative. Transplant biopsy was performed and revealed active MPGN. This was further classified as IgG3-kappa PGNMID, a more recently described entity. For her declining renal function, she required hemodialysis. As prior, there was no detectable paraprotein. She was treated with CyBorD. 3 months later dialysis was discontinued. The inciting event leading to her relapse was not clear.

**Discussion:** PGNMID is a plasma cell disorder associated with a paraprotein causing kidney injury that does not meet criteria for multiple myeloma or lymphoma. The rate of detection of the nephrotoxic monoclonal immunoglobulin in the serum or urine, or of an abnormal bone marrow B cell clone is only 30%. After transplantation, PGNMID has a high recurrence rate and is complicated by frequent relapses and decreased graft survival. Management of this disease requires close collaboration with Hematology and involves targeting the presumed plasma or B cell clone.

Light microscopy (left) - the glomerulus shows prominent endo and extracapillary (arrow) hypercellularity with reduplication of the basement membranes. Immunofluorescence microscopy (middle) - IgG3 is strongly positive in the mesangial area and also along the periphery of the capillary walls. Electron microscopy (right) disclosed subendothelial electron dense immunotype deposits.

## SA-PO858

**Normotensive Scleroderma Renal Crisis 8 Years After Living Donor Renal Transplantation: A Case Report**

Hajime Sanada, Satoshi Hara, Shunsuke Tsuge, Ryo Nishioka, Kiyoaki Ito, Ichiro Mizushima, Mitsuhiro Kawano. *Kanazawa University Hospital Department of Rheumatology, Kanazawa, Japan.*

**Introduction:** Scleroderma renal crisis rarely occurs in transplanted kidneys, and it remains unknown whether prednisolone for transplantation could be the risk factor.

**Case Description:** A 36-year-old man was diagnosed with systemic sclerosis 19 years ago based on skin involvement and positive anti-topoisomerase I antibody. He often had to be hospitalized due to intractable digital ulcers and interstitial lung disease. He developed class 5 lupus nephritis and systemic lupus erythematosus 11 years ago. It was refractory and hemodialysis was started 9 years ago, and he underwent ABO-compatible living donor renal transplantation with his father as the donor 8 years ago. His renal function remained at serum creatinine (sCr) 1.0 mg/dL, but he had suffered from cytomegalovirus (CMV) infections such as esophagitis and enteritis after transplantation. Thus, we switched mycophenolate mofetil to everolimus 2 months ago. One month before, renal function had gradually declined to sCr 1.65 mg/dL, and a renal biopsy was performed. Pathological findings indicated granulomatous interstitial nephritis (GIN), which was diagnosed as idiopathic without any obvious secondary cause. The dose of prednisolone (PSL) was increased from 5 to 30 mg/day after steroid pulse therapy, but his renal function continued to deteriorate to sCr 2.9 mg/dL, and urine protein increased to 4.5 g/day. The second kidney biopsy next month showed the GIN improvement, and microarterial thrombus and glomerular endothelial cell damage were observed, leading to a diagnosis of acute thrombotic microangiopathy (TMA). The patient was considered to have normotensive scleroderma renal crisis (SRC), and an angiotensin-converting enzyme inhibitor was initiated. His renal function stopped falling at the sCr 3 mg/dL.

**Discussion:** SRC rarely develops in transplanted kidneys, and it has been suggested that PSL administration for transplantation may not be a risk factor for the development of SRC. However, we could not identify other causes of TMA except for PSL dose increase which may cause SRC in our case. In conclusion, SRC could emerge in the transplanted kidney and might be induced by PSL dose increase. PSL dose for patients with scleroderma should be taken carefully even after kidney transplantation.

## SA-PO859

**Loin Pain and a New Mechanism: Altruistic Kidney Donation Is a Win-Win!**

Sriram Sriperumbuduri, Pradeep Vaitla, Christopher Anderson, Tariq Shafi. *The University of Mississippi Medical Center, Jackson, MS.*

**Introduction:** Loin pain due to complex reno-vascular anatomy can be debilitating. Refractory cases need auto transplantation and rarely nephrectomy to control the symptoms. Utilizing the nephrectomized kidney for donation is an option that is not commonly explored.

**Case Description:** A 40-year-old-female, non-hypertensive and non-diabetic, with persistent left flank pain for 4 years, sought help at our center for further management. Prior contrast computerized scan of the abdomen showed compression of left renal vein between aorta and vertebra concerning for nutcracker phenomenon. However direct measurement of venous pressures showed no significant pressure gradient across the renal vein, raising concern for loin pain hematuria syndrome. Evaluation showed serum creatinine of 0.6 mg/dl and estimated glomerular filtration rate (eGFR) of 119 ml/min/1.73m<sup>2</sup>. Urine microscopy results over the past 4 years revealed no microscopic hematuria or significant proteinuria. Due to unrelenting and episodic pain despite multiple medications, treatment options were offered including auto transplantation and nephrectomy. She was presented with the option of kidney donation if she chooses to proceed with nephrectomy. She agreed with directed kidney donation to an acquaintance and after appropriate work up, she underwent laparoscopic left kidney nephrectomy. Intraoperatively note made of 2 left renal veins terminating at angles into lumbar veins. The consensus was that it was the lumbar collateral that is retro-aortic and she had venous outflow obstruction from the kidney due to lack of collaterals formed from the lumbar veins. Her most recent serum creatinine was 0.98 mg/dl (eGFR 75 ml/min/1.73m<sup>2</sup>) about 4 months after the surgery and she remains flank-pain free. Recipient of the kidney transplant is a 69-year-old caucasian male. He recovered well from the surgery with no symptoms of pain and hematuria. His nadir post-transplant creatinine was 1.2 mg/dL and eGFR of 55 ml/min/1.73m<sup>2</sup> at 4 months.

**Discussion:** This case demonstrates the treatment options in cases with complex reno-vascular anatomy causing debilitating pain, including the unique possibility of donation of the kidney. Donation of healthy nephrectomized kidney is a unique display of altruism.

## SA-PO860

**Green Donor Kidneys: Transplantable or Not**

Hay Me Me, Pooja Budhiraja, Sumi Sukumaran Nair, Lavanya Kodali. *Mayo Clinic Arizona, Scottsdale, AZ.*

**Introduction:** Hyperbilirubin cause detrimental effects on kidney tubule function. In ongoing organ shortage, utilization of high-risk donor kidneys is needed. The outcomes of transplanting donor kidneys with bile cast nephropathy is uncertain.

**Case Description:** A pair of deceased kidneys were offered from a 34-year-old male with history of cirrhosis of liver with portal hypertension secondary to alcohol dependent disorder. He had acute kidney injury (AKI) requiring continuous renal replacement therapy. His liver function tests were elevated including total bilirubin of 40.5 mg/dl and direct bilirubin of 20 mg/dl. Both kidneys had greenish discoloration in appearance (Fig 2). Renal biopsy on frozen section showed minimal interstitial fibrosis, moderate arterial sclerosis, moderate tubular injury. The right kidney was transplanted into a 67-year-old female with end stage renal disease (ESRD) from renal cell carcinoma and the left kidney was transplanted to a 64-year-old female with ESRD from hypertension. Cold ischemic time were 22 hours 40 minutes and 30 hours and 9 minutes, respectively. Post reperfusion renal pathology was consistent with bile cast nephropathy and acute tubular injury (Fig 1). Both kidneys had delayed graft function and required hemodialysis for 29 days and 22 days respectively. By second month, both creatinine improved to 1.6-1.8 mg/dl.

**Discussion:** Our case report indicates that kidneys from donors with cholemic nephropathy, even with severe AKI can be safely utilized. Although it is associated with delayed graft function in immediate post-transplant period, there is significant improvement by the second month.

Donor Kidneys

Bile Cast Nephropathy

## SA-PO861

### Effectiveness of Lymphatic Lipiodol Embolization for Post Renal Transplant Lymphoceles

Kasumi Konishi, Yugo Ito, Kotaro Shimoyama, Nozomi Kadota, Takuya Fujimaru, Fumika Taki, Masahiko Nagahama, Masaki Shimbo, Masaaki Nakayama. *St. Luke's International Hospital, Tokyo, Japan.*

**Introduction:** Lymphocele is a relatively common complications after kidney transplantation. Although the majority of cases are asymptomatic and self-limiting, interventional treatment is required for cases with worsening kidney function, deep vein thrombosis, lower leg edema or urinary tract obstruction. A wide range of treatment strategies are available, but there is no consensus on the optimal management as far as high recurrence and complication rate is concerned.

**Case Description:** A 75 year-old man with end-stage kidney disease due to diabetic nephropathy underwent ABO-incompatible living kidney transplantation from his wife. His perioperatively course was uneventful. He developed right lower leg edema 1 month after the surgery. Abdominal CT scan revealed the lymphoceles around the transplanted kidney with external iliac vein compression. Percutaneous catheter drainage reduced the size of lymphocele transiently only for 1 day. Since, right intranodal lymphography demonstrated active lymph leakage (Figure), we performed lymphatic embolization with Lipiodol. The lymphocele was diminished and his lower leg edema was improved successfully.

**Discussion:** Regarding treatment of lymphocele after kidney transplantation, high recurrence rate after aspiration and drainage have been important issue. Furthermore, sclerotherapy can cause allergy for sclerosant and spillage of it induces inflammation around the graft. Recently some case reports have indicated that lymphatic lipiodol embolization is effective for lymphoceles. Our case suggested that it is minimally invasive and safe for treatment as well as diagnosis of lymphoceles after kidney transplantation.

## SA-PO862

### A Rare Presentation of Recurrent c-ANCA Glomerulonephritis 10 Years Post-Kidney Transplant

Ahmad A. Masry,<sup>1</sup> Prerna Rastogi,<sup>2</sup> M. Lee Sanders.<sup>1</sup> <sup>1</sup>University of Iowa Hospitals and Clinics, Department of Internal Medicine, Division of Nephrology, Iowa, IA; <sup>2</sup>University of Iowa Hospitals and Clinics, Department of Pathology, Iowa, IA.

**Introduction:** Pauci-immune glomerulonephritis (GN) is the most common type of crescentic rapidly progressive GN. While kidney transplantation remains the optimal treatment for those patients who progress to end stage kidney disease (ESKD), patients remain at risk for disease recurrence even in the modern era of immunosuppression. Most anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis cases reoccur with a median time of 30 months post-transplant. We report a rare case presentation of a first recurrence of crescentic pauci-immune GN ten years following kidney transplantation.

**Case Description:** A 74-year-old female with a history of living related kidney transplant ten years ago was found to have blood and protein on her yearly urinalysis specimen. Her post-transplant course up to that point had been unremarkable with no rejection episodes and a baseline serum creatinine (sCr) range maintained between 0.9-1.1 mg/dL. Her chronic immunosuppression regimen consisted of tacrolimus and mycophenolate. While her sCr was within her baseline range, her urine protein to creatine ratio was 3.0 compared to 0.2 the year prior. No history of diabetes, no rashes were present, and she had no complaints. Additional work-up showed no monoclonal spike on serum protein electrophoresis, no donor specific antibodies, and a donor derived cell free DNA value of 0.16%. Of note, the original cause of her kidney failure was officially listed as lupus nephritis; therefore, an immunologic work-up was performed which revealed a positive ANCA with MPO titer of 1:320. A subsequent renal biopsy revealed pauci-immune necrotizing and crescentic GN. Treatment with rituximab 1000 mg for two doses 14 days apart and high dose oral prednisone was initiated. We were able to obtain the native kidney biopsy for review which showed a crescentic GN with negative immunofluorescence making pauci-immune GN the more likely cause of her original ESKD.

**Discussion:** New onset hematuria and proteinuria in a kidney transplant recipient warrants additional work-up. In this case, we surprisingly discovered a crescentic GN in the setting of stable renal function. This likely recurrence of primary disease ten years post-transplant is also well beyond the typical median time for recurrence. Our next clinical step will be to perform a repeat biopsy after treatment completion to ensure disease resolution.

## SA-PO863

### Kidney Biopsy Proven Thrombotic Microangiopathy in a Heart Transplant Recipient

Syed U. Haider, Kenar D. Jhaveri, Vanesa Bijol, Nupur N. Uppal. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

**Introduction:** Thrombotic Microangiopathy (TMA) after non renal solid organ transplantation is very rare. While few cases of TMA following liver and lung transplants have been published, it has been very rarely reported following orthotopic heart transplant (OHT). We report the first case of kidney biopsy proven De Novo TMA after OHT.

**Case Description:** 58-year-old male with non ischemic cardiomyopathy undergoes OHT in Jan 2021. He had normal renal function pre transplantation. Post-operatively he had pericardial effusion and in that setting developed oliguric AKI from ATN requiring dialysis. His renal function recovered and was discharged without dialysis. He was on tacrolimus, MMF and steroid regimen. Frequent heart biopsies were negative for rejection. In March 2021 the patient was admitted for GI bleed and again noted to have AKI. However, during this episode he developed proteinuria of over 2gm, new compared to previous urine studies. He was discharged with a serum creatinine of 2.6mg/dL. By July 2021 renal function worsened and he underwent a renal biopsy on 7/30/21 which showed acute and chronic TMA, related to calcineurin inhibitor use. Viral causes and other medications were ruled out (CMV, BK, adenovirus, SARS-CoV2). Tacrolimus was held and he was initiated on Everolimus. Genetic and complement testing revealed normal complement levels, an elevated SC5b-9 complex, heterozygous for the APOL1 gene mutation (c.[1024A>G;1152T>G] p.[Ser342Gly;Ile384Met] (G1 allele)), and heterozygous for the CFHR5 gene mutation, suggestive for complement mediated TMA. He was initiated on Eculizumab. After two doses of Eculizumab he was again admitted with acute respiratory failure requiring intubation secondary to mTOR induced pneumonitis. His renal function worsened and he was reinitiated on dialysis. After a multidisciplinary discussion, he was transitioned to cyclosporine for immunosuppression. He continues to be on dialysis and cyclosporine with eculizumab without other non-renal findings of TMA. He is currently being evaluated for kidney transplantation. He has no signs of OHT rejection on heart biopsies.

**Discussion:** The early identification and treatment of TMA in OHT is important in preventing further complications associated with it. Although rare as compared to other solid organ transplants, it is essential to maintain TMA as a differential diagnosis for AKI following OHT.

## SA-PO864

### Severe Hydronephrosis in Kidney Transplant due to Ureteral Malakoplakia and Resolution With Immunosuppression Reduction and Antibiotics

David S. Rustom,<sup>1</sup> Sahar Amin,<sup>1</sup> Barry M. Wall,<sup>1,2</sup> Manish Talwar,<sup>1</sup> Vasanthi Balaraman,<sup>1</sup> Anshul Bhalla.<sup>1</sup> <sup>1</sup>The University of Tennessee Health Science Center, Memphis, TN; <sup>2</sup>VA Memphis Medical Center, Memphis, TN.

**Introduction:** Malakoplakia is chronic granulomatous inflammation that can demonstrate pseudotumor characteristics. It most often affects the genitourinary tract, but ureteral involvement resulting in urinary tract obstruction is rare. In this report, we present a case of extensive malakoplakia surrounding a renal transplant and ureter causing severe hydronephrosis and AKI.

**Case Description:** 55-year-old male with ESRD due to hypertension received a cadaveric kidney transplant in Nov 2020 with postoperative course complicated by recurrent urinary tract infections with *Escherichia coli*. He responded well to courses of antibiotics. However, he developed AKI (creatinine 3.3 mg/dL from baseline 2.0 mg/dL), in Feb 2021 and CT abdomen/pelvis revealed severe hydronephrosis of the transplant kidney and a multifocal hyperdense collection involving the renal transplant and ureter extending into surrounding structures and subcutaneous tissue of the abdominal wall to the skin surface. Due to concern for possible renal abscess, he was treated with IV antibiotics, and nephrostomy tube was placed with subsequent stent. Repeat CT in Mar 2021 showed progression of disease extent. To avoid seeding a potential abscess with invasive biopsy, he underwent superficial left abdominal wall biopsy, which showed foamy epithelioid histiocytes (CD68 positive) with granular eosinophilic cytoplasm and intracytoplasmic Michaelis-Gutmann bodies (Von Kossa positive), consistent with malakoplakia. Long-term antibiotics were continued with ceftriaxone that was transitioned to cefdinir, trimethoprim/sulfamethoxazole, and levofloxacin. Immunosuppression was reduced by discontinuing mycophenolic acid, lowering goal tacrolimus trough level, and maintaining low dose prednisone. Serial CT imaging over several months showed marked improvement in malakoplakia and complete resolution of hydronephrosis and AKI (creatinine 1.4 mg/dL). Ureteral stent was removed with no further hydronephrosis on imaging. Transplant kidney biopsy in June 2021 was negative for acute rejection.

**Discussion:** Malakoplakia can rarely involve a transplant kidney and ureter leading to severe urinary tract obstruction. In this report, we describe a case with gradual but dramatic response to management by treating with long-term antibiotics and reducing immunosuppression.

## SA-PO865

**Recurrence of C3 Deficiency Related Membranoproliferative Glomerulonephritis After Kidney Transplantation**

João F. Bernardo, Sara Gonçalves, Iolanda Godinho, Fernando Abreu, Marta R. Neves, Maria Joao Melo, Joao A. Goncalves, Alice Santana, Jose A. Lopes. *Centro Hospitalar Universitario Lisboa Norte EPE, Lisboa, Portugal.*

**Introduction:** C3 deficiency is hereditary disease leading to ineffective opsonization and defective complement lytic activity, increasing infection susceptibility. Affected patients may develop an immune-complex mediated membranoproliferative glomerulonephritis (MPGN) due to inadequate immune complexes clearance. Theoretically possible, the MPGN disease recurrence in the kidney graft of C3 deficient patients has never been described and its impact on graft survival is unknown.

**Case Description:** 29-year-old caucasian male with complete absence of C3 factor due to a homozygous loss function mutation. He had a history of frequent respiratory infections and one episode of meningitis in childhood. At the age of 20 he presented hematuria, proteinuria (1,3g/24h) and elevated serum creatinine (pCr 2,3mg/dL). Kidney biopsy were compatible with MPGN secondary to IC deposition. He rapidly progressed to end stage kidney disease, starting haemodialysis at the age of 22, and was submitted to a kidney transplant five years later: Maastricht II cardiac death donor with 6 HLA mismatches, no donor specific antibodies (DSA) and induction therapy was thymoglobulin. Despite delayed graft function, one month after discharge the patient had a serum creatinine of 2,1mg/dL. There were no infectious complications but 18 months after transplantation he developed microscopic hematuria, proteinuria (4,1g/24h) and progressive kidney allograft dysfunction without DSA, without cytomegalovirus or polyoma virus infection. Kidney allograft biopsy revealed lobulated glomeruli, thickening of the capillary wall, endocapillary cellularity, mesangial expansion, "full house" pattern (deposition of IgG, IgA, IgM, C1q and C4 in the mesangium and capillary wall) and no C3. Based on this, we assumed a recurrence of IC mediated MPGN secondary to C3 deficiency. Despite initiation of antiproteinuric therapy, graft function deteriorated and nine months after he was started on hemodialysis.

**Discussion:** MPGN recurrence after kidney transplantation of C3 deficient patients seems to occur early and graft survival is considerably shorter. As C3 is mainly synthesized in liver, combined liver-kidney transplantation maybe a better option, in order to restore C3 plasma circulating pool and prevent MPGN recurrence.

## SA-PO866

**A Case of Mutation Negative Transplant Associated Thrombotic Microangiopathy Successfully Treated With Eculizumab**

Ujjwala Murari,<sup>1</sup> Divya Mounisha R. Thimmareddygar, <sup>1</sup> Purna Bindu Nandigam, <sup>2</sup> Umair Khan. <sup>1</sup> *Newark Beth Israel Medical Center, Newark, NJ;* <sup>2</sup> *Cooperman Barnabas Medical Center, Livingston, NJ.*

**Introduction:** Transplant associated Thrombotic Microangiopathy (TA-TMA) is rare and causes graft failure. TMA may occur de-novo, triggered by immunosuppressive medication and antibody mediated rejection (AMR). We present a rare case of TA-TMA due to Atypical HUS (aHUS) successfully treated with Eculizumab.

**Case Description:** A 45-year-old female with history of end-stage renal disease of unclear etiology underwent a renal transplant with Thymoglobulin induction. A pre-transplant work up showed negative CDC cross match, zero percent PRA, and 2A-2B-0DR HLA mismatch. Post-operative course was complicated by persistently high creatinine, hemolytic anemia, thrombocytopenia, elevated LDH, and low haptoglobin by day 3. Given the possibility of Calcineurin inhibitor induced TMA, Tacrolimus was changed to Everolimus and the patient received plasmapheresis/hemodialysis. Allograft biopsy confirmed TMA without concurrent rejection. Disseminated intravascular coagulation was ruled out with a normal prothrombin and partial thromboplastin time. With poor response to Everolimus, a repeat allograft biopsy was done which showed prior findings. A negative workup for infection, ADAMTS13, complement genetic mutation panel, complement levels with above findings pointed towards atypical HUS induced by renal transplant and Tacrolimus. Everolimus was switched to Belatacept and Eculizumab. A significant improvement in her renal function following Eculizumab therapy was noted in the subsequent weeks.

**Discussion:** Incidence of renal transplant associated TMA is around 0.8-1.4%. It's often seen in the first week of post-transplant course when patients receive high doses of immunosuppressive medications. Often mutations in complement regulating or alternate pathway enhancing proteins or the presence of anti-factor H antibodies can predispose a patient to aHUS(I). Complement mutations are not seen in 30% cases. Upon literature review, a few cases with Plasma exchange resistant aHUS were successfully treated with Eculizumab, but had complement mutations, unlike our patient. MAC complex or C5b-9can be used as a marker to monitor complement inhibition. Given the rarity, there are no guidelines regarding the dose and duration of therapy with Eculizumab; relapses and renal complications often direct the duration (2) and is an area of ongoing research.

## SA-PO867

**Hemophagocytic Lymphohistiocytosis Following Simultaneous Liver and Kidney Transplant**

Zeeshan Azeem, Zahir Ali Shaikh, Gitana Bradauskaite, Radi Zaki, Hitesh Kaul, Kamran Khanmoradi, John P. Knorr. *Albert Einstein Medical Center, Philadelphia, PA.*

**Introduction:** Hemophagocytic lymphohistiocytosis (HLH) is a rare disease entity characterized by an inappropriate immune activation syndrome characterized by fever, hepatosplenomegaly, cytopenia and progressive multiple-organ failure. It is broadly classified as either primary or secondary form. Primary HLH is an autosomal recessive usually diagnosed in children less than 2 years of age. Secondary HLH is triggered by immune insults such as vaccinations, viral infections, autoimmune disorders or malignancies. HLH has also been reported after kidney, liver and hematopoietic stem cell transplants. We present a case of HLH secondary to graft vs host disease (GVHD) in a patient who underwent simultaneous liver-kidney transplant (SLKT).

**Case Description:** A 74 year old male received SLKT due to NASH cirrhosis, from a 29 year old female deceased donor. He was re-admitted 4 weeks post-transplant with altered mental status, diarrhea, fever, rash and signs of sepsis. Following initial resuscitation, intubation and mechanical ventilation, the patient was started on broad spectrum antibiotics and anti-fungal medications. His cell counts, kidney function and liver tests were within normal range at admission but he later developed severe pancytopenia and a very high ferritin (15,910 ng/mL). Blood cultures showed *Paeruginosa* and *E. faecium*. Abdominal imaging revealed splenomegaly. Patient's white cell count did not improve despite maximum dose of G-CSF. A bone marrow biopsy revealed hemophagocytes (Fig. 1). A diagnosis of HLH was made and the patient was started on etoposide and dexamethasone. A skin biopsy was suggestive of GVHD. Hemodynamic status continued to deteriorate during hospital course leading to death on 10th day of re-admission.

**Discussion:** HLH is a rare disease and should be suspected in patients with fever, cytopenias and ferritin >500 µg/L. Etoposide and dexamethasone are most commonly used therapies. Secondary HLH has a dismal prognosis and a very high fatality rate. Early diagnosis and treatment can lead to improved outcomes. Keywords: Hemophagocytic lymphohistiocytosis (HLH), graft versus host disease (GVHD).

## SA-PO868

**Granulomatous Interstitial Nephritis due to Histoplasma spp. in a Kidney Transplant**

Alyssa L. Davis,<sup>1</sup> Meghan Kapp,<sup>2</sup> Beatrice P. Concepcion. <sup>1</sup> *Vanderbilt University Medical Center, Nashville, TN;* <sup>2</sup> *University Hospitals, Cleveland, OH.*

**Introduction:** There are numerous causes of acute kidney injury (AKI) in an acutely infected kidney transplant recipient. Here we present an unusual cause of AKI secondary to granulomatous interstitial nephritis.

**Case Description:** A 51/M with a kidney transplant in 2010 (maintained on FK/MMF/Pred), afib and HTN presented in early fall with fever and AKI. He described 1 month of fevers, myalgias, night sweats, shortness of breath and abdominal pain. On presentation, temp was 101.9°F, BP 111/76, HR 130, RR 24, O2 sat 97% RA. Physical exam revealed an ill-appearing man in no acute distress, clear lungs bilaterally and mild epigastric tenderness to palpation. Initial laboratory exam was notable for Na 129 mmol/L, K 6.9 mmol/L, bicarbonate 12 mmol/L, BUN 48 mg/dL and Scr 3.7 mg/dL (baseline 1.6 mg/dL). Urinalysis had no protein, 24 WBC and 19 RBC. Transplant ultrasound was normal. CXR revealed a new 1cm dense nodule in the right lower lobe. CMV, EBV, and BK virus were not detected. Urine bacterial culture had no growth. Urine histoplasma antigen returned strongly positive. His epigastric pain was evaluated with endoscopy and colonoscopy, and he was found to have erosions and friable tissue in the duodenum, colon, and cecum. Due to persistent kidney dysfunction, a kidney biopsy was performed. This revealed two foci of granulomatous inflammation comprised of histiocytes and small lymphocytes. A GMS stain highlighted fungal organisms in these areas consistent with *Histoplasma* spp. There was global granular mesangial staining for C3 (1+) and segmental granular mesangial staining for IgM (trace) suggestive of sequelae of infection. He was treated for disseminated histoplasmosis with liposomal amphotericin B (8 days) with good clinical improvement and was transitioned to maintenance isavuconazole (due to drug interaction of itraconazole with patient's amiodarone). On follow-up eight months later, Scr improved to 2 mg/dL, and the patient remains on isavuconazole.

**Discussion:** Granulomatous interstitial nephritis may occur in the setting of direct infection of the kidney by *Histoplasma* spp. as demonstrated in this patient's kidney biopsy. In this case, prompt and appropriate treatment of the infection led to clinical improvement. Providers should be aware of unusual causes of AKI in an acutely infected kidney transplant recipient which may require a biopsy for diagnosis.

## SA-PO869

**Collapsing Focal Segmental Glomerulosclerosis Complicating BK Allograft Nephropathy in a Heart-Kidney Transplant Recipient**

Zamir A. Zamir,<sup>1</sup> Michelle A. Josephson,<sup>2</sup> Yousuf Kyeso,<sup>2</sup> Sambhavi Krishnamoorthy,<sup>2</sup> Patrick Cunningham.<sup>1</sup> <sup>1</sup> *Chicago State University, Chicago, IL;* <sup>2</sup> *The University of Chicago Medicine, Chicago, IL.*

**Introduction:** Collapsing focal segmental glomerulosclerosis (FSGS) is a variant of FSGS and is associated with severe nephrotic syndrome and acute kidney injury and can occur after kidney transplantation. The exact mechanism of collapsing FSGS after kidney transplantation is unclear, but potential causes include autoimmune diseases, cancers,

medications side effects, and viral infections. We describe a unique presentation of this detrimental diagnosis in kidney transplantation.

**Case Description:** 47-year old South East Asian male with ESRD secondary to DM and ischemic cardiomyopathy underwent HLA compatible simultaneous heart and kidney transplant. Nadir serum Cr was 1.5 mg/dl. Induction with Basiliximab and immunosuppression included Tacrolimus, Prednisone and Mycophenolate Mofetil (MMF). Four months after transplant, serum Cr peaked at 3 mg/dl and BK plasma viral load (VL) found to be 2 million copies per ml. Kidney biopsy confirmed BK nephropathy. MMF replaced with leflunomide, and IVIG 2g/kg were given. Three months later, serum Cr stabilized at 2 mg/dl and BK VL improved to 30,000 copies. Six months later, patient presented with acute onset hypervolemia, proteinuria of 18 grams, and oliguric AKI with Cr of 5.5 mg/dl. Repeat kidney biopsy revealed collapsing FSGS on pathology with diffuse podocytes effacement on electron microscopy. BK VL increased to 900,000 copies, and infectious workup was negative. Patient required hemodialysis for hypervolemia, IVIG 2g/kg, FK goal was lowered to 3-5 ng/ml, and empiric 3 sessions of plasmapheresis were instituted for a concern of de novo FSGS. Six weeks later, patient was able to be weaned off HD, serum Cr stabilized at 3.5 mg/dl, and urine protein improved to 1 mg/dl. Repeat BK VL came down to 35000 copies/ml.

**Discussion:** Here, we present a case of acute nephrotic syndrome secondary to collapsing FSGS 12 months post kidney transplantation. Patient has no known history of FSGS nor any evidence of autoimmune diseases or malignancy. He had no exposure to any new medication and his infectious workup was negative except for BK viremia. We believe that collapsing FSGS was triggered by the significant BK viremia and nephropathy in this case. Early detection of proteinuria and prompt treatment of BK viremia can potentially reverse this catastrophic sequel.

## SA-PO870

### BK Nephropathy in Hematopoietic Stem Cell Transplant Patients: An Upcoming Challenge

Shoaib B. Fareedy,<sup>1</sup> Rana Raheel H. Khan,<sup>1</sup> Amanda Tchakarov,<sup>1</sup> Omar Mamlouk,<sup>2</sup> <sup>1</sup>*The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX;* <sup>2</sup>*The University of Texas MD Anderson Cancer Center, Houston, TX.*

**Introduction:** Nephropathy from BK virus (BKV) infection is a known challenge in the context of kidney transplant patients. Usually, a consequence of potent IS aimed at reducing acute rejection and improving allograft survival. Moreover, it can also be encountered in recipients of HSCT on IS to prevent or treat GVHD and can lead to progressive CKD and poor overall survival. As the number of HSCT patients is increasing worldwide, evidence-based guidelines are required, to combat potential loss of kidney function in these patients. Decreasing IS remains the principal treatment of BKV nephropathy in kidney transplant patients but predisposes to allograft rejection. Antiviral medications including leflunomide, cidofovir, quinolones, and intravenous Ig have been used with variable outcome and with risk for nephrotoxicity. In recipients of SCT there are no established guidelines to help with the diagnosis and treatment of BK nephropathy

**Case Description:** We present a case of a 39-year-old male with a history of AML who underwent cord blood allogeneic stem cell transplant in March 2021. He developed gastrointestinal GVHD and was treated for fungal pneumonia. 8 weeks post-transplant he started to have gradual decline in kidney function with rise in serum creatinine from 3.38 mg/dl to 5.65 mg/dl over 12 weeks. Urine was bland with no microscopic hematuria, pyuria, or proteinuria. US guided biopsy revealed tubulointerstitial injury attributed to BK tubulopathy. BK level in the blood was of 184,000 copies/ml and in the urine of 4.70E+09 copies/ml. Tacrolimus was tapered down and switched to sirolimus. Unfortunately, patient continued to have a steady decline in renal function and is now being prepared to initiate RRT.

**Discussion:** BK virus in HSCT recipient is usually asymptomatic infection, when it manifests clinically, the most common presentation is dysuria and hematuria (hemorrhagic cystitis). BK related nephropathy is a rare complication. Treatment of BK nephropathy in HSCT recipients is challenging and beside decreasing IS, there is still no consensus about effective therapy, and this can lead to progressive CKD. BKV-specific Cytotoxic T cell infusion is currently under investigation for treatment of BK related cystitis. Future studies are needed to evaluate its efficacy and other potential targeted therapies in treating BK nephropathy.

## SA-PO871

### Obinutuzumab Induction in a Kidney Transplant Recipient With Atypical Hemolytic Uremic Syndrome due to CFHR1/CFHR3 Gene Mutation and Anti-Complement Factor H Antibody

Evaldo Favi,<sup>1,2</sup> Paolo Molinari,<sup>2,1</sup> Samuele Iesari,<sup>2</sup> Carlo Alfieri,<sup>2,1</sup> Giuseppe Castellano,<sup>2,1</sup> Mariano Ferraresso,<sup>2,1</sup> Donata C. Cresseri,<sup>2</sup> <sup>1</sup>*Università degli Studi di Milano, Milano, Italy;* <sup>2</sup>*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.*

**Introduction:** For many years, atypical hemolytic uremic syndrome (aHUS) has represented a relative contraindication to kidney transplantation (KT). The wide spread use of the anti-complement component 5 monoclonal antibody eculizumab has reduced post-transplant aHUS relapse and allograft loss rates. However, the optimal management of patients with Deficiency of CFHR plasma proteins and Autoantibody Positive form of Hemolytic Uremic Syndrome (DEAP-HUS) remains debated. In this particular subset of recipients, the benefits of repeated apheresis and/or chronic eculizumab administration should be weighed against the risk of fatal infections, severe adverse events, and exorbitant costs.

**Case Description:** We report the case of a 45-year-old woman with end-stage renal disease due to CFHR1/CFHR3 gene homozygous deletion-associated aHUS who underwent deceased-donor KT despite persistently elevated anti-CFH antibody titers. While on the transplant waiting list, she was not given any aHUS-targeted therapy. At transplant, she received an induction scheme including eculizumab (900 mg before surgery), basiliximab (20 mg on day 0 and day 4), methylprednisolone, and obinutuzumab (1000 mg on day 6). As a maintenance, we used LCP-tacrolimus, mycophenolate mofetil, and prednisone. The post-operative course was uneventful. After 1-year follow-up, she is doing well with excellent allograft function, undetectable anti-CFH antibody, full CD19+ cells depletion, and no signs of aHUS activity. Remarkably, no obinutuzumab infusion-related adverse reactions, severe infectious complications, or hematologic disorders were recorded.

**Discussion:** Although anecdotal, our experience suggests that peri-transplant administration of eculizumab and obinutuzumab safely and effectively inhibits complement activation and block anti-CFH antibody production, thus ensuring long-lasting protection from DEAP-HUS relapse, at a reasonable cost. For the first time, we have also provided evidence in vivo that obinutuzumab-induced B-cell depletion does not necessarily require complement activation. Such preliminary finding could provide the rationale for further studies investigating combined eculizumab and obinutuzumab use for antibody-mediated rejection prophylaxis or treatment.

## SA-PO872

### Parvovirus Red Blood Cell Aplastic Anemia in a Kidney Transplant Patient

Taqui Khaja, Shayan Amini, Angelina Edwards. *Houston Methodist Hospital, Houston, TX.*

**Introduction:** Anemia is common in kidney transplant patients and is linked with increased risk of patient mortality, reduced graft survival, and a decline in allograft function. There are multiples etiologies, and iron deficiency is the main contributor. However, viral infections are often overlooked and can lead to significant anemia post-transplantation. We report a unique case of parvovirus B19 infection leading to pure red blood cell aplasia in a kidney transplant patient.

**Case Description:** This is a 62-year-old Hispanic man with end stage kidney disease and dialysis dependence presumed secondary to diabetes and hypertension. He received a living related kidney transplant in December 2021. He was deemed low-immunologic risk and underwent induction with basiliximab. He was maintained on tacrolimus, mycophenolate, and prednisone. He attained excellent allograft function with nadir creatinine of 1.1 mg/dL. On February 2022, he was admitted to the hospital for symptomatic anemia with hemoglobin of 6.5 g/dL with low reticulocyte index of 0%. Evaluation was negative for GI blood loss, hemolysis, or iron/vitamin B12/folate deficiencies. Supportive blood transfusion was given and he was discharged with outpatient follow-up but remained transfusion dependent. Parvovirus B19 quantitative serum PCR was obtained and his viral load was greater than 5,000,000 copies. Patient was promptly treated 5 doses of IV IgG and his mycophenolate dosage was reduced. Since then, his hemoglobin as continued to improve without blood transfusions and his parvovirus B19 viral load has reduced substantially to 7,249 copies as of April 2022. He is followed closely by his nephrologist and hematologist.

**Discussion:** Parvovirus infection can cause refractory anemia in kidney transplant patients and this problem can progress to transfusion dependence. Incidence rate of anemia from parvovirus can occur up to 23% of renal transplant patients. Diagnosis is confirmed with PCR assay. Treatment consists of IV IgG and reduction in immunosuppression, specifically antiproliferative agents like mycophenolate. Relapse of anemia is common. Effectiveness of therapy is based on improvement in anemia. This disease should be considered when encountering refractory anemia during the post-transplantation period.

## SA-PO873

### A Case of False Elevation in Tacrolimus Levels due to Tacrolimus Line Adsorption

Rutu Shah,<sup>1</sup> Alexander Pennekamp,<sup>1</sup> Joseph Kremer,<sup>2</sup> <sup>1</sup>*The Christ Hospital Internal Medicine Residency, Cincinnati, OH;* <sup>2</sup>*The Christ Hospital Health Network, Cincinnati, OH.*

**Introduction:** Tacrolimus is a cornerstone of immunosuppressive therapy after solid organ transplantation, but post-transplant therapeutic drug level monitoring is crucial. Inappropriately high tacrolimus levels can result in calcineurin inhibitor (CNI) toxicity (and malignancy) while inappropriately low levels will result in acute graft rejection. Central venous catheters (CVC) are routinely used for infusions as well as lab draws, but rarely the CVC can pose challenges by obscuring true drug levels.

**Case Description:** A 60-year-old female with a past medical history of diabetes mellitus, hypertension, COPD, SLE, ESRD on hemodialysis (secondary to lupus nephritis) gastric sleeve procedure underwent deceased donor unrelated kidney transplantation. She was started on high risk immunosuppression with five doses of thymoglobulin, steroid taper and maintained on mycophenolate mofetil (MMF) and tacrolimus. Several days thereafter, she was admitted to the hospital for complications following transplant including development of new Class II antibody mediated rejection (ABMR) with donor specific antibodies (DSA) positive. Due to evidence of kidney biopsy showing antibody mediated rejection, she was treated with PLEX, IV velcade and rituximab. She presented again 1 month later for intractable nausea and vomiting. She underwent GI evaluation which showed gastric ulcerations, negative for CMV and HSV. Unfortunately, her condition progressed to florid septic shock which required ICU admission. CVC was placed through which she received IV tacrolimus. The same port was used to draw tacrolimus levels and surprisingly, levels obtained from that port were extremely elevated on multiple days, which

resulted in dose reduction and multiple instances of held doses. Due to consistently elevated levels, a peripheral draw was obtained which showed a level of <2 ng/mL. The patient's creatinine worsened and eventually she ended up back on renal replacement therapy.

**Discussion:** Blood sampling for tacrolimus should never be performed from lumina previously used for infusing the drug even after prolonged periods of time and extensive rinsing. Physicians should be aware of the phenomenon of drug adsorption as it can lead to dangerous dose reductions putting the patient at risk of life threatening underdosage. Any suspicious tacrolimus lab value should be confirmed by a peripheral draw.

#### SA-PO874

##### Transplant Renal Artery Stenosis: An Overlooked Cause of Acute Kidney Allograft Injury

Rohit Aloor, Ekamol Tantisattamo. *University of California Irvine School of Medicine, Irvine, CA.*

**Introduction:** While recognized as an etiology of kidney dysfunction, transplant renal artery stenosis (TRAS) remains underdiagnosed and can exist with other causes of acute kidney injury (AKI), leading to a delay in diagnosis and treatment. We report a case of kidney transplant recipient that presented with biopsy-proven acute kidney allograft rejection that did not improve despite adequate therapy. Pathology revealed areas of allograft ischemia, leading to treatment for TRAS with balloon angioplasty and subsequent kidney recovery.

**Case Description:** A 74 year old woman with end stage kidney disease secondary to diabetes mellitus status post deceased donor kidney transplant five months prior to admission presented with sepsis from urinary tract infection and pneumonia complicated by oliguric AKI. Serum creatinine (SCr) was 3.7 mg/dL from the baseline creatinine of 2.7-3.1 mg/dL, peaking at 8.8 mg/dL on hospital day 15. Given persistently elevated SCr despite resolved sepsis, transplant allograft biopsy was performed with concerns for acute rejection. Pathology revealed severe tubulitis and acute T-cell mediated rejection (TCMR). Kidney function did not improve with pulse steroids and anti-thymocyte globulin. Further review of the pathology showed multiple areas of ischemia, suspected from compromised renal artery. Blood pressure (BP) was persistently elevated and no bruit noted at the allograft site. Cytomegalovirus PCR was not detected. Transplant ultrasound revealed peak systolic velocity of 310 cm/second at the anastomosis. Carbon dioxide angiography was consistent with severe transplant renal artery stenosis. Balloon angioplasty resulted in allograft recovery and SCr improved to a nadir of 1.0 mg/dL along with blood pressure normalization.

**Discussion:** Although AKI in our patient could be possibly explained by TCMR, persistent allograft dysfunction despite therapy for rejection raised suspicion for other causes. Scattered renal ischemic changes in the setting of ongoing AKI and hypertension within the first 6 months posttransplant led to TRAS evaluation. TRAS is a common complication but rarely occurs concomitantly with acute allograft rejection. Clinical presentation that includes allograft dysfunction and uncontrolled BP, particularly with evidence of allograft ischemia during early post-transplant period, should raise suspicion for this treatable cause of kidney allograft injury.

#### SA-PO875

##### Disseminated Histoplasmosis (DH) Involving the Central Nervous System in a Kidney Transplant Recipient

Antonette Veronica B. Hernandez, Beatrice P. Concepcion. *Vanderbilt University Medical Center, Nashville, TN.*

**Introduction:** Endemic fungal infection is rare but well documented in immunocompromised (IC) hosts where the most common presentation is DH. Of the endemic fungi, infection with *Histoplasma capsulatum* is the most common. Even so, the incidence of disseminated histoplasmosis in IC patients in endemic areas is low at <1%. Here we present a case of DH with CNS involvement in a kidney transplant recipient.

**Case Description:** A 40-year-old man with ESRD from HTN and T2DM received a DDKT in 2018 and was maintained on tacrolimus, mycophenolic acid, and prednisone. He presented with dyspnea and malaise over 3 weeks. Scr on admission was 5.45 mg/dl (baseline of 1.3 mg/dL). On hospital day 2, he became altered. MRI brain revealed 2 left-sided ring-enhancing lesions in the frontal/parietal region, concerning for "septic emboli." A TTE was negative for vegetations. Chest CT showed mild tree-in-bud nodularity and GGO, but no granulomas. Initial blood and urine cultures were negative. Urine and serum histoplasmosis Ag were above the limit of quantification. He was diagnosed with DH with CNS abscesses and started on Liposomal Amphotericin B 5mg/kg daily every 24 hours. CSF analysis showed pleocytosis, elevated protein, and low glucose. CSF histoplasma Ag was positive at 1.93ng/mL and CSF culture was negative. The initial fungal blood culture returned positive for *H. capsulatum* 4 weeks later.

**Discussion:** Only 5 to 10% of DH infections involve the CNS. Routes of infection include donor-derived, reactivation, and de-novo infection, the latter of which is suspected in this patient with no prior evidence of latent disease on chest imaging. Additionally, most cases of donor-derived infection occur within the first few months of transplant. Without obvious neurological symptoms, CNS involvement may be missed. Thus, a high clinical suspicion is necessary for prompt diagnosis and treatment.

MRI T2w-FLAIR ring-enhancing lesions

#### SA-PO876

##### Successful Use of Euro Lupus Regimen in PLA2R-Negative Recurrent Membranous Nephropathy After Kidney Transplant

Sahar Amin,<sup>1</sup> Vasanthi Balaraman,<sup>1</sup> Anshul Bhalla,<sup>1</sup> Manish Talwar,<sup>1</sup> David S. Rustom,<sup>1</sup> Barry M. Wall.<sup>1,2</sup> <sup>1</sup>The University of Tennessee Health Science Center College of Medicine, Memphis, TN; <sup>2</sup>VA Memphis Medical Center, Memphis, TN.

**Introduction:** Membranous nephropathy (MN) may recur after transplant. Recurrent post-transplant MN can occur in approximately 40% of patients, usually within the first year. The antibody most often implicated is M-type phospholipase A2 receptor (PLA2R) found in >70% of primary MN cases.

**Case Description:** 30 year-old male with ESRD secondary to PLA2R negative MN underwent a deceased-donor kidney transplant using induction with ATG. He was discharged with a creatinine of 1.9 mg/dL with UPCR 0.4 and maintained on tacrolimus (goal level 8-10 ng/ml), MMF 750mg twice a day and prednisone 5 mg/day. At two months post-transplant, he developed proteinuria (UPCR of 2.2) and started losartan at 100 mg/day. A graft biopsy revealed recurrent post-transplant MN. Immunohistochemical staining was negative for PLA2R, THSD7A, NELL1, EXT1, EXT2. Despite optimal RAAS blockade proteinuria worsened, Rituximab was given 4 times as 500-mg doses two weeks apart after which proteinuria came down to UPCR of 0.4. He then developed nephrotic range proteinuria UPCR of 4.2 again at 9 months post transplant. He was given another course of Rituximab 500mg weekly x 4 and ACTH gel 40 units SC twice a week after which proteinuria came down to UPCR of 1.8. 15 months post transplant, he presented with AKI (creatinine of 9 mg/dl), UPCR of 9, requiring hemodialysis. Repeat allograft biopsy showed persistent active MN along with Banff borderline TCMR and AMR with positive DSA against DQB1 MFI 4700. He was given pulse dose methylprednisone 500 mg daily x 3 days for ongoing active MN. Since patient had MN refractory to Rituximab, treatment with Cyclophosphamide (CP) was initiated, 500mg every two weeks, total of six doses along with prednisone 70 mg once daily which was slowly tapered. We chose the Euro Lupus regimen to minimize cumulative toxicity of oral CP regimen. For treatment of AMR, he received five sessions of plasmapheresis. His allograft function slowly improved and his creatinine came down to baseline of 1.9 mg/dl and proteinuria stabilized at around 1.2 g/g.

**Discussion:** This is the first report on use of IV low dose CP for treatment of post transplant recurrent MN. Our case describes the management strategy of a very difficult recurrent post-transplant PLA2R negative MN that was highly resistant to standard first line treatment.

#### SA-PO877

##### A Case of BK Virus-Associated Nephropathy in a Heart Transplant Patient

Paul T. Merchant, Kristen Tomaszewski, Saul Nurko. *Cleveland Clinic, Cleveland, OH.*

**Introduction:** BK virus associated nephropathy (BKVAN) causes allograft dysfunction in kidney transplant patients but is rarely reported as a cause of native kidney dysfunction in non-kidney solid organ transplant (NKSOT) patients. Treatment for BKVAN is limited, and reducing immunosuppression is the most common strategy. In NKSOT patients, the prevalence of BKVAN is not known but appears to be rare. We report a case of BKVAN in a heart transplant patient.

**Case Description:** A 26-year-old male with hypoplastic left heart, who underwent orthotopic heart transplant 9 years prior, presented with anemia and AKI. Post-transplant history showed no episodes of rejection requiring treatment and no kidney disease. Immunosuppression was tacrolimus 2mg BID and mycophenolic acid 360mg BID without recent changes. At presentation, patient had a hemoglobin of 7.2g/dL, and an evaluation for gastrointestinal bleeding was negative. The patient also had AKI with

serum creatinine of 4.32mg/dL from 0.88mg/dL five months prior. Workup showed bland urinalysis, unremarkable urine sediment examination, and negative hemolysis studies. The AKI failed to improve with conservative management, so kidney biopsy was performed which showed chronic tubulointerstitial nephritis, severe interstitial fibrosis and tubular atrophy, and negative immunofluorescence. Testing for serum BK virus was positive with 1.21 million copies/mL. The biopsy underwent immunostaining for polyomavirus marker SV40, which was positive in 15% of tubules. A diagnosis of BKVAN was made. The patient's mycophenolate was reduced by half, but serum BK viral load and creatinine remain elevated.

**Discussion:** BKVAN is an important cause of allograft dysfunction in kidney transplant patients, but prevalence in NKSOT patients is less understood and likely underestimated. As this case demonstrates, BKVAN should be part of the differential diagnosis in NKSOT patients with CKD/AKI.

Positive immunostain for polyomavirus marker SV40.

## SA-PO878

### Case Series of Donor-Recipient Renal Transplant Mismatches: Looking Beyond the Size?

Cullen M. Lilley,<sup>1</sup> Maria M. Picken,<sup>2</sup> <sup>1</sup>Loyola University Chicago Stritch School of Medicine, Maywood, IL; <sup>2</sup>Loyola University Health System, Maywood, IL.

**Introduction:** While reports on the long-term pathology in mismatched allografts have been focused on the donor and recipient body surface area, evidence is emerging to support donor-recipient age difference as an additional prognostic factor. Most reports are based on pediatric recipients receiving older/bigger allografts. Here, we describe three cases with age mismatch including two cases of adult patients receiving pediatric allografts and a third case of a younger patient receiving an allograft from an older donor exhibiting findings not described in extant literature (Table 1).

**Case Description:** **Case 1:** a 60-year-old (y) female with history of hypertensive nephrosclerosis (HNS) received bilateral kidneys en block from a 5-day-old donor. Subsequently, stent-related hydronephrosis and hematuria developed. Biopsy showed persistent immature glomeruli. **Case 2:** a 33y male with history of HNS received one kidney from a 14y female donor. He developed perinephric seroma, oliguria and hematuria; biopsy revealed thin glomerular basement membrane disease. **Case 3:** a 21y female with ESRD of an unknown etiology received en block bilateral kidneys from a 74y female donor. Post-surgery one allograft required nephrectomy owing to necrosis. Subsequently, non-nephrotic proteinuria developed and allograft biopsy showed focal & segmental glomerulosclerosis (Fig. 1A) with podocyte effacement and GBM multilayering with Alport-like changes (Fig. 1B). None of these patients exhibited T-cell or antibody-mediated rejection (Table 1).

**Discussion:** Each of these cases exhibit unique changes seen in mismatched donor-recipient size/age post-transplant pathology. These non-rejection changes should be suspected in cases of donor-recipient size/age mismatch. In cases of allograft function decline, a full biopsy workup, including electron microscopy, should be considered.

#### Summary of Cases

Case	Donor Age	Recipient Age	Gender Mismatch	Time to Bx	UA at time of Bx	Diagnosis	T-cell Infiltrate
1	5d	60y	?	96d	Hematuria	Immature Glomeruli	15%
2	14y	33y	Yes	65d	Oliguria with seroma hematuria	Thin GBM Disease	410%
3	74y	21y	No	1057d	Proteinuria	FSGS-Alport-like	<5%

## SA-PO879

### Treatment Dilemma: De Novo Focal Segmental Glomerulosclerosis (FSGS) in the Setting of Kaposi Sarcoma in a Heart-Kidney Transplant Recipient

Joseph Ruberwa, Elizabeth Kotzen, Mark A. Kleman. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

**Introduction:** We present a case of de novo FSGS in the setting of cutaneous kaposi sarcoma in a combined heart-kidney transplant recipient six months after transplant.

**Case Description:** A 48-year-old male status post combined heart and kidney transplant for non-ischemic cardiomyopathy and cardiorenal syndrome respectively; he also has well controlled HIV. Induction immunosuppression was basiliximab and methylprednisolone, and maintenance immunosuppression was tacrolimus, mycophenolate mofetil and prednisone. Post-transplant creatinine was 2.1-2.5. Six months post transplantation, he reported left leg hyper-pigmented macules and nodules that appeared gradually over the prior two months. Skin biopsy showed kaposi sarcoma with immunostain positive for human herpesvirus-8. At the same period, the patient developed nephrotic range proteinuria with urine protein to creatinine ratio (UPCR) of 4.7 g/g. Kidney biopsy demonstrated mild FSGS, and electron microscopy (EM) demonstrated 20% foot process effacement. Multiple UPCR prior to and in the first four months post-transplantation showed no proteinuria. Additionally, kidney biopsy done five weeks prior to this presentation for elevated creatinine had showed only focal interstitial fibrosis with normal glomerular basement membranes on EM. For de novo FSGS, the patient received six sessions of plasmapheresis and valsartan started. The UPCR improved to 1.5 g/g. Management of kaposi sarcoma was mainly modification of immunosuppression due to absence of visceral involvement. Mycophenolate mofetil was stopped, and later after proteinuria improved, sirolimus was initiated. At the last follow-up, the patient had an increase in both creatinine and UPCR. We anticipate reporting longer-term follow-up at the time of the meeting.

**Discussion:** We are not aware of case reports of de novo FSGS in kidney transplant recipients being associated with Kaposi sarcoma. In this case it is difficult to know whether the Kaposi served as an inciting event but the timeline raises this possibility. Sirolimus has become a cornerstone of management of Kaposi sarcoma in solid organ transplant recipients because of its antitumor effects (1,2). However, sirolimus is associated with proteinuria and FSGS (3,4,5). We therefore experienced a treatment dilemma between the potential benefit and risk of sirolimus.

## SA-PO880

### Under the Hood: Nephrosis in Autosomal Polycystic Kidney Disease

Bobak Sharifi, Helen P. Cathro, Angie G. Nishio Lucar, Joseph T. Leeds. *UVA Health, Charlottesville, VA.*

**Introduction:** About 50% of patients with autosomal dominant polycystic kidney disease (APKD) will develop end-stage kidney disease (ESKD). The presence of multiple bilateral cysts is a relative contraindication to percutaneous kidney biopsy. Thus, APKD patients with chronic kidney disease (CKD) rarely undergo a native kidney biopsy. Concomitant proteinuria may appear in advanced CKD but nephrotic syndrome is rare. We report the case of an APKD patient presenting with proteinuria and progressive allograft dysfunction after kidney transplantation (KT) suggesting recurrence of native glomerular disease.

**Case Description:** A 62-year-old female with ESKD secondary to ADPKD underwent an uncomplicated deceased-donor KT in 2020. During her third month post-transplant, her serum creatinine increased to 1.9mg/dL (post-transplant nadir of 1.2 mg/dL) and developed progressive proteinuria (urine protein quantification 2.5g/g). Serologic tests (ANA, ANCA, C3/C4, anti-GBM, SPEP/UPEP/SFLC) were unremarkable. An allograft biopsy revealed no rejection or glomerular abnormalities on light microscopy. No C4d staining seen on immunofluorescence (IF). Capillary loops stained for IgG (3+), kappa (2+), and lambda (3+). Electron microscopy noted moderately effaced foot processes with sub-epithelial immune complex deposits. Serum phospholipase A2 receptor antibody (PLA2Rab) was high at 544 RU/ml. IF was positive (1+) for PLA2Rab granular capillary staining confirming the diagnosis of recurrent membranous nephropathy (MN). She received Rituximab therapy with improvement in her creatinine and proteinuria. Creatinine returned to nadir. Repeat PLA2Rab reduced to 11 RU/ml and proteinuria to 0.06 g/g. interestingly, the patient's pre transplant serum revealed a PLA2Rab of 1247 RU/ml.

**Discussion:** There are few reports of MN associated with APKD and none in the context of KT. MN can present as de novo or recurrent disease after KT in 10-45% of cases. Although rare, limited literature suggest that 15-20% of APKD patients may have concomitant glomerular disease. This case emphasizes the importance of avoiding anchoring cognitive bias and remembering that primary causes of CKD may not be mutually exclusive.

## SA-PO881

**Case Reports of Trimethoprim/Sulfamethoxazole-Induced Pancreatitis Confirmed With a Lymphocyte Transformation Test**

Jin Chul Kim, Hanbi Lee, Byung ha Chung. *Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea.*

**Introduction:** Kidney transplant recipients (KTRs) received trimethoprim/sulfamethoxazole (TMP/SMX) in early days of transplantation and during and after anti-rejection treatment for *Pneumocystis jiroveci* pneumonia (PJP) prophylaxis. TMP/SMX is one of the possible drugs that induce acute pancreatitis. The lymphocyte transformation test (LTT) is a safe diagnostic procedure for drug allergy but is reported to be rarely performed to find association between TMP/SMX and drug-induced acute pancreatitis (DIAP). Here we report two cases of TMP/SMX induced pancreatitis confirmed by rechallenging and LTT in KTRs.

**Case Description:** A 64-year-old man complained with epigastric pain during desensitization for ABO and human leukocyte antigen incompatible living donor kidney transplantation (KT). DIAP was suspected, based on his medical history including 8 days exposure of TMP/SMX without obvious cause. The LTT for TMP/SMX was performed and the result was positive. After quitting TMP/SMX, pancreatitis was resolved. Then he underwent KT without prevention of PJP. Since he developed PJP 2 months post-transplant, TMP/SMX was started. Three days after exposure acute pancreatitis was developed. A 58-year-old man developed acute pancreatitis 6 days after exposure of TMP/SMX, during anti-thymocyte globulin (ATG) infusion for treatment of acute T-cell mediated rejection (TCMR). After discontinuing suspected drugs including TMP/SMX, acute pancreatitis improved. Three months later, he readmitted with acute TCMR and infused ATG with TMP/SMX for prevention of PJP. 1 day after exposure, amylase level elevated. At that time, LTT for TMP/SMX was performed and the result was positive.

**Discussion:** Acute pancreatitis is a rare but life-threatening complication in patients with transplanted kidney if not properly managed. DIAP accounts for 0.1~2% of acute pancreatitis and more than 120 drugs are known to cause DIAP. Although previously TMP/SMX reported as a causative drug of DIAP, it was just suspected with cause-and-effect relationship and repeated episodes of adverse events. Above 2 patients were diagnosed with TMP/SMX induced pancreatitis by rechallenging and the results of LTT, which is known as an adjunctive diagnostic tool for hypersensitivity reactions, confirmed the diagnosis. These cases suggest TMP/SMX should be considered as a causative drug in case of acute pancreatitis in KTRs.

## SA-PO882

**Heartland Virus-Induced Hemophagocytic Lymphohistiocytosis in a Kidney Transplant Recipient**

Zoey Levine, Gaurav Rajashekar. *Washington University in St Louis, St Louis, MO.*

**Introduction:** Heartland virus (HRTV) is a tick-borne phlebovirus first discovered in 2009 in Missouri. Field studies identified *Amblyomma americanum* or the Lone Star tick as the most likely vector for HRTV. Since then, more than 50 cases of Heartland disease have been reported from 11 states in Central and Southeastern United States during the months of April to September, corresponding strongly with the geographical and seasonal distribution of *A. americanum*. Kidney transplant recipients are particularly susceptible to opportunistic infection due their degree of immunosuppression.

**Case Description:** Here we present a case of a 58-year-old male with a past medical history of end stage renal disease secondary to IgA nephropathy, post kidney transplant in 2006 from a living unrelated donor, on a prednisone and tacrolimus, deep vein thrombosis on warfarin, parotidectomy due to squamous cell carcinoma of the parotid gland presented to the hospital with fever, fatigue, and diarrhea for six days. Labs showed acute kidney injury with a serum creatinine 2.7 mg/dL (baseline of 1.2-1.3 mg/dL), thrombocytopenia (platelet 88 k/mm3), and anemia (hemoglobin 7.4 g/dL). Additional labs showed elevated ferritin > 190 000 ng/mL, Lactate dehydrogenase > 2000 units/L, triglycerides > 240 mg/dL, and low fibrinogen < 120 mg/dL. On further inquiry, he reported recent turkey hunting, handling dead mice and exposure to ticks. Based on lab analysis, a bone marrow biopsy was performed which showed normocellular marrow with hemophagocytic macrophages and no evidence of lymphoproliferative process confirming our initial suspicion of Hemophagocytic Lymphohistiocytosis (HLH). Given his recent social history and exposures, an extensive infectious workup was performed and was positive for Heartland Virus infection, a known tick-borne cause of HLH, prevalent in the state of Missouri. Treatment was initiated with high-dose dexamethasone and decreased level of chronic immunosuppression. Kidney function improved and laboratory parameters normalized.

**Discussion:** The case emphasizes the importance of prompt evaluation for HLH in severe heartland virus infection. However, there are many diagnostic challenges that can delay management and worsen survival outcomes. Social history is crucial in establishing a framework to diagnose a case. HLH presents with non-specific and variable findings that can be caused by Heartland virus disease.

## SA-PO883

**Genetically Identical Kidneys With Different Rates of Cyst Formation**

Roma N. Ahuja, Harshit Garg, Deepak K. Pruthi, Ronald Rodriguez. *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

**Introduction:** Renal damage due to end stage renal disease (ESRD) and chronic hypertension may result in the development of acquired cystic kidney disease (ACKD). Additionally, renal transplantation may cause ACKD, however it occurs at a less frequent rate than ESRD patients on dialysis.

**Case Description:** A 54-year-old male underwent voluntary left nephrectomy 18 years ago. Over the 18 year follow up period, he developed minimal cyst progression and retained optimal renal function. His serum creatinine (Cr) was 1.3mg/dL with estimated glomerular filtration rate (eGFR) of 56 mL/min/1.73m<sup>2</sup>. Magnetic resonance imaging (MRI) of the abdomen revealed right solitary kidney with 3 cysts, the largest being 1.1x1.0 cm in the interpolar region. The total cyst volume was 4.2cc and the total kidney volume was 252cc. His wife, a 52-year-old female with diabetes, hypertension, and ESRD underwent renal transplant 18 years ago with donor nephrectomy from her husband. Over the 18 years follow up period, the patient retained optimal renal function but had significant cyst progression. Her renal function was stable with a serum Cr of 1.2mg/dL and eGFR of 47 mL/min/1.73m<sup>2</sup>. MRI of the abdomen and pelvis revealed bilateral atrophic native kidneys with simple cyst of 1.5cm in left atrophic kidney. The right lower quadrant transplant kidney measured 12 cm in maximum dimension with numerous cysts of varying sizes with largest cyst measuring 7.7cm. The total kidney volume was 350cc and the total cyst volume was 185cc.

**Discussion:** Rarely has there been a situation in which the health of both the retained and transplanted kidney were able to be concurrently studied at regular intervals. This case provides a unique opportunity to study the impact of transplantation on the kidney as well as long-standing hypertension and immunomodulation on renal cyst development. A previous study demonstrated that environmental factors such as ischemic reperfusion injury causes acute kidney injury and promotes cystogenesis. In addition, immunomodulation has been reported to impact cyst development through activation of the mTOR pathway. Our findings support current literature and offer insight on the capacity environmental factors have on cyst development and progression in an otherwise healthy kidney.

## SA-PO884

**Citrate Therapy Outcomes in Patients With Renal Allograft Stones**

Holly Thomson, Nan Zhang, Mira T. Keddis. *Mayo Foundation for Medical Education and Research, Phoenix, AZ.*

**Background:** Renal allograft stones occur in 1% of patients, often causing morbidity. Hypocitraturia is the most significant urinary metabolic risk factor. We previously found that only 34 of 56 patients (61%) with allograft stones at our institution had urine supersaturation analysis. Here, we aim to describe treatment effectiveness of patients with stones in their allograft kidney.

**Methods:** Patients with kidney transplant and stones were identified by ICD-10 codes. Those with imaging-confirmed allograft stones and 2 urine supersaturation studies collected after diagnosis at least 3 months apart were included. Chart review yielded demographics, renal disease course, urine supersaturation results, stone therapies, and patient outcomes. Descriptive statistics were used to evaluate response to therapy.

**Results:** Urine supersaturation data were available at multiple time points in 11 patients (55% men; mean transplant age 58 years). In this group, 4 patients had ESRD due to stone related complications and 7 had a history of native stones. All developed de novo allograft stones at mean 4.9 years after transplant. Stones tended to be in the lower pole and nonocclusive at diagnosis. In all cases of known composition, stones were calcium. Mean urine citrate at first supersaturation analysis was 104 mg/24 hr (reference range >500 mg/24 hr). Potassium or sodium citrate was prescribed in 5 of 11 patients; the remaining 6 patients increased dietary citrate. Post-treatment supersaturation analysis occurred at a mean interval of 250 days. Urine citrate increased by mean 80 mg/24 hr and urine volume increased by mean 500 mL/24 hr. Despite improvement in these risk factors, 7 patients required surgical intervention. Radiologic clearance was achieved in 5 patients, in 2 of these without surgery. In both of those cases, urine citrate increased substantially over time. Graft failure occurred in 1 patient due to stone complications.

**Conclusions:** Clinicians should anticipate the possibility of allograft stone formation even years after kidney transplant, in patients with or without prior history of nephrolithiasis. Urine citrate is likely a key modifiable risk factor. In some cases, increasing urine citrate eliminates stone burden independently of surgical intervention.

## SA-PO885

**Effects of Dapagliflozin in Patients Without Diabetes and Microalbuminuria: An Exploratory Analysis From the DAPA-CKD Trial**

Hiddo J. L. Heerspink,<sup>1,2</sup> Glenn Chertow,<sup>3</sup> Niels Jongs,<sup>1</sup> Ricardo Correa-Rotter,<sup>4</sup> Peter Rossing,<sup>5,6</sup> David Sjostrom,<sup>7</sup> Anna Maria Langkilde,<sup>7</sup> David C. Wheeler,<sup>8</sup> DAPA-CKD Trial Committee and Investigators <sup>1</sup>Universitair Medisch Centrum Groningen, Groningen, Netherlands; <sup>2</sup>The George Institute for Global Health, Newtown, NSW, Australia; <sup>3</sup>Stanford University School of Medicine, Stanford, CA; <sup>4</sup>The National Medical Science and Nutrition Institute Salvador Zubiran, Mexico City, Mexico; <sup>5</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>6</sup>Kobenhavns Universitet, Kobenhavn, Denmark; <sup>7</sup>AstraZeneca, Gothenburg, Sweden; <sup>8</sup>University College London, London, United Kingdom.

**Background:** The DAPA-CKD trial demonstrated that the sodium glucose co-transporter 2 inhibitor dapagliflozin slows progressive kidney function loss in patients with CKD without type 2 diabetes. The majority of these participants had macroalbuminuria. Whether this effect persists in participants without type 2 diabetes and with microalbuminuria is unknown. We therefore assessed the effects of dapagliflozin on the rate of kidney function decline, albuminuria, and blood pressure in this subgroup.

**Methods:** DAPA-CKD randomized participants with or with type 2 diabetes and an urinary albumin-to-creatinine ratio (UACR) 200–5000 mg/g and eGFR 25–75 mL/min/1.73m<sup>2</sup> to dapagliflozin 10 mg or placebo once daily, added to standard care. The

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

kidney endpoint was a composite of sustained  $\geq 50\%$  eGFR decline, end-stage kidney disease or renal death. We analyzed, in participants without type 2 diabetes and with microalbuminuria (UACR  $< 300$  mg/g), eGFR slope using mixed effect models with slopes from baseline to Week 2 (acute change) and Week 2 to end-of-treatment (chronic eGFR slope). UACR change was an additional pre-specified exploratory outcome.

**Results:** Of 4304 randomized participants, 136 (72 randomized to dapagliflozin and 64 to placebo) did not have type 2 diabetes and had a UACR  $< 300$  mg/g. Their mean age was 61 years, 49 (36%) were female, mean eGFR was 42 mL/min/1.73m<sup>2</sup> and median UACR was 245 mg/g. In the dapagliflozin group UACR changed from baseline by -24.2% (95%CI -41.2, -2.3) versus -9.8% (-30.8, 17.7) in the placebo group (between group difference -16.0% [95%CI, -41.8, 21.3]). Compared to placebo, dapagliflozin caused an acute eGFR reduction of 2.4 mL/min/1.73m<sup>2</sup> (95%CI 0.4, 4.5). Thereafter, dapagliflozin reduced the mean rate of eGFR decline by 1.8 mL/min/1.73m<sup>2</sup> (95%CI 0.4, 3.1) compared to placebo. Few kidney endpoints occurred during follow-up (1 in the dapagliflozin group and 3 in the placebo group).

**Conclusions:** In patients without type 2 diabetes and with microalbuminuria, dapagliflozin slowed eGFR decline during chronic treatment suggesting that its kidney protective effects may extend to this subgroup of patients.

### Consistent Benefits of Dapagliflozin on Kidney End Points Defined by Different eGFR Thresholds: A Prespecified Analysis From DAPA-CKD

Niels Jongs,<sup>1</sup> Glenn Chertow,<sup>3</sup> John McMurray,<sup>4</sup> Ricardo Correa-Rotter,<sup>5</sup> Peter Rossing,<sup>6</sup> Anna Maria Langkilde,<sup>7</sup> David Sjöström,<sup>7</sup> Robert D. Toto,<sup>8</sup> David C. Wheeler,<sup>9</sup> Hiddo J. L. Heerspink.<sup>1,2</sup> <sup>1</sup>Universiteit Groningen Faculteit Medische Wetenschappen, Groningen, Netherlands; <sup>2</sup>The George Institute for Global Health, Newtown, NSW, Australia; <sup>3</sup>Stanford University School of Medicine, Stanford, CA; <sup>4</sup>University of Glasgow, Glasgow, United Kingdom; <sup>5</sup>National Medical Science and Nutrition Institute Salvador Zubiran, Mexico City, Mexico; <sup>6</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>7</sup>AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden; <sup>8</sup>UT Southwestern Medical Center, Department of Internal Medicine, Dallas, TX; <sup>9</sup>University College London Faculty of Medical Sciences, London, United Kingdom.

**Background:** Doubling of serum creatinine (equivalent to 57% eGFR decline) is an accepted component of composite kidney endpoints. Recently, lesser eGFR declines (40%, 50%) have been used as alternative endpoint components. We assessed the effect of dapagliflozin on kidney endpoints using different eGFR decline to explore whether alternative eGFR thresholds are useful.

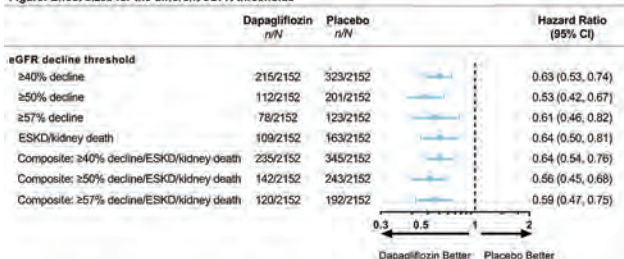

**Methods:** This post hoc analysis of DAPA-CKD (N=4304) compared the effect of dapagliflozin vs placebo on kidney outcomes, including different eGFR thresholds ( $\geq 57\%$ ,  $\geq 50\%$ ,  $\geq 40\%$  eGFR decline from baseline), and a composite with end-stage kidney disease (ESKD) and kidney death. We used Cox-proportional hazards model adjusted for baseline eGFR and stratified according to randomization factors (type 2 diabetes; UACR  $\leq 1000$ / $>1000$  mg/g).

**Results:** Over 2.4 years' median follow-up, there were 201 (4.7%), 313 (7.3%) and 538 (12.5%) events of eGFR decline based on  $\geq 57\%$ ,  $\geq 50\%$ , or  $\geq 40\%$  eGFR decline, respectively. Compared to the effect of dapagliflozin in reducing risk of ESKD and kidney death, effect sizes for dapagliflozin on eGFR endpoints, defined by  $\geq 57\%$ ,  $\geq 50\%$ , or  $\geq 40\%$  decline, were comparable (Figure). Results were also similar when using eGFR endpoints or a composite with ESKD and kidney death (Figure) and in patients with or without type 2 diabetes.

**Conclusions:** Smaller declines in eGFR ( $\geq 40\%$  and  $\geq 50\%$ ) occurred more frequently than 57% decline and provided similar estimates of the efficacy of dapagliflozin on kidney outcomes. Use of smaller eGFR declines as endpoints may facilitate trials assessing CKD progression when sample size is limited.

## SA-PO887

### Translating the Findings of DAPA-CKD to Reductions in Healthcare Resource Utilization and Costs

Philip McEwan,<sup>1</sup> Ryan Miller,<sup>1</sup> Juan Jose Garcia Sanchez,<sup>2</sup> Salvatore Barone,<sup>3</sup> Stephen Nolan,<sup>2</sup> Vivekanand Jha,<sup>4</sup> Ricardo Correa-Rotter,<sup>5</sup> Gil Chermn,<sup>6</sup> Luca De Nicola.<sup>7</sup> <sup>1</sup>Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom; <sup>2</sup>AstraZeneca PLC, Cambridge, United Kingdom; <sup>3</sup>AstraZeneca R&D, Gaithersburg, MD; <sup>4</sup>The George Institute for Global Health, Newtown, NSW, Australia; <sup>5</sup>Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; <sup>6</sup>Kaplan Medical Center, Rehovot, Israel; <sup>7</sup>Universita degli Studi della Campania Luigi Vanvitelli Scuola di Medicina e Chirurgia, Napoli, Italy.

**Background:** Dapagliflozin reduced the risk of kidney failure and all cause, including cardiovascular, mortality in CKD patients with and without type 2 diabetes in the Study to Evaluate the Effect of Dapagliflozin and Prevention of Adverse Outcomes in Chronic Kidney Disease (DAPA-CKD). The trial was stopped early due to overwhelming efficacy, with a 39% reduction in the incidence of the primary composite endpoint ( $\geq 50\%$  eGFR decline, end-stage kidney disease (ESKD) and renal/cardiovascular death). This project aimed to estimate the impact on healthcare resource use and costs.

**Methods:** Event rates in dapagliflozin and placebo arms of the DAPA-CKD trial were used to predict the incidence of components of trial endpoints over a three-year period. Cost-offsets versus standard of care without dapagliflozin (SOC) were estimated by applying published US costs to the incidence of events. Those attributed to a  $\geq 50\%$  decline in eGFR were based on the resulting CKD stage compared with baseline CKD stage. Dapagliflozin costs were excluded. Results were estimated in a treated population of 10,000 people. Analysis of 10,000 people aged  $< 65$  years and 10,000 people  $\geq 65$  years was also conducted. Results for the USA will be supplemented with further analysis for a total of 32 countries.

**Results:** Over a three-year period, the estimation predicted 750 cases of  $\geq 50\%$  decline in eGFR with dapagliflozin versus 1,340 with SOC (590 fewer events, number needed to treat [NNT]: 17). 355 ESKD events would be avoided with dapagliflozin (722 vs 1,077, NNT: 28) as would 231 hospitalisations for heart failure (HHF) compared with SOC (237 vs 468, NNT: 43) and 249 deaths (638 vs 887, NNT: 40). Reduced incidences of adverse clinical outcomes were estimated to give cumulative medical care cost-offsets of \$126.9M per 10,000 treated patients, \$223.0M per 10,000 treated patients aged  $< 65$  years and \$61.9M per 10,000 treated patients aged  $\geq 65$  years, or 34%, 38%, and 25% reductions compared with SOC, respectively.

**Conclusions:** Dapagliflozin treatment in CKD has the potential to significantly reduce healthcare resource use through delayed CKD progression and reduced incidence of cardio-renal events and mortality.

**Funding:** Commercial Support - AstraZeneca

## SA-PO888

### Extrapolation of DAPA-CKD Trial End Points in a Broad Urine Albumin Creatinine Ratio Population

Jason Davis,<sup>1</sup> Peter D. Gabb,<sup>1</sup> Juan Jose Garcia Sanchez,<sup>2</sup> Salvatore Barone,<sup>3</sup> Johannes Nicolaas Martinus Ouwens,<sup>4</sup> David C. Wheeler,<sup>5</sup> Hiddo J. L. Heerspink.<sup>6</sup> <sup>1</sup>Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom; <sup>2</sup>AstraZeneca PLC, Cambridge, United Kingdom; <sup>3</sup>AstraZeneca R&D, Gaithersburg, MD; <sup>4</sup>AstraZeneca, Goteborg, Sweden; <sup>5</sup>University College London School of Life and Medical Sciences, London, United Kingdom; <sup>6</sup>The George Institute for Global Health, Newtown, NSW, Australia.

**Background:** The prevalence of chronic kidney disease (CKD) is estimated to be 8-16% worldwide. Patients with CKD have an increased risk of morbidity and mortality. The DAPA-CKD trial (NCT03036150) demonstrated that dapagliflozin, a sodium-glucose co-transporter-2 inhibitor, reduces kidney and cardiovascular (CV) events and mortality in CKD patients with levels of albuminuria in the range 200 to 5000 mg/g. This study aims to extrapolate the dapagliflozin treatment effect in a CKD population with a UACR  $< 200$  mg/g.

**Methods:** The analysis utilised data from the intention-to-treat DAPA-CKD trial population. The primary endpoint and the composite components, sustained estimate glomerular filtration rate (eGFR) decline and end-stage kidney disease (ESKD), were extrapolated as a function of UACR (continuous variable). Annualised estimated event rates spanning a UACR range (0-2,500 mg/g) were generated using poisson models fitted to each endpoint. Event counts were modelled as a function of baseline UACR using the DAPA-CKD data and extended to lower UACR levels. The results were expressed as the ratio of the event rate with dapagliflozin to that with placebo.

**Results:** The event rate ratios for dapagliflozin versus placebo for the primary composite endpoint (0.67 [95% confidence interval (CI): 0.56-0.80]) and sustained eGFR decline (0.59 [95%CI: 0.48-0.73]) indicated a preserved treatment effect when modelling was applied to those with low UACR ( $< 200$  mg/g). There was no evidence to suggest that efficacy would be different in patients with type 2 diabetes mellitus (T2DM) or without T2DM for the primary composite [95% CI: 0.56-0.86 (T2DM) versus 0.39-0.79 (no T2DM)], sustained eGFR decline [95% CI: 0.45-0.73 versus 0.36-0.86] or ESKD [95% CI: 0.55-1.11 versus 0.39-1.26] endpoints.

**Conclusions:** The analysis suggests that the treatment effect of dapagliflozin might be maintained in relation to the primary endpoint in DAPA-CKD and sustained eGFR decline in patients with low UACR ( $< 200$  mg/g). Furthermore, treatment efficacy could be similar between patients with or without T2DM. Validation in a prospective trial is required.

SA-PO889

Efficacy and Safety of Dapagliflozin in Black vs. White Patients With CKD

Priya Vart,<sup>1</sup> Glenn Chertow,<sup>2</sup> Niels Jongs,<sup>1</sup> Ricardo Correa-Rotter,<sup>3</sup> Peter Rossing,<sup>4,5</sup> Robert D. Toto,<sup>6</sup> David C. Wheeler,<sup>7</sup> John McMurray,<sup>8</sup> Anna Maria Langkilde,<sup>9</sup> Hiddo J. L. Heerspink.<sup>1</sup> <sup>1</sup>Universiteit Groningen Faculteit Medische Wetenschappen, Groningen, Netherlands; <sup>2</sup>Stanford University School of Medicine, Stanford, CA; <sup>3</sup>National Medical Science and Nutrition Institute Salvador Zubiran, Mexico City, Mexico; <sup>4</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>5</sup>Kobenhavns Universitet Sundhedsvidenskabelige Fakultet, Kobenhavn, Denmark; <sup>6</sup>UT Southwestern Medical Center, Department of Internal Medicine, Dallas, TX; <sup>7</sup>University College London Faculty of Medical Sciences, London, United Kingdom; <sup>8</sup>University of Glasgow, Glasgow, United Kingdom; <sup>9</sup>AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden.

**Background:** Previous reports suggest that Black and White patients may respond differently to certain treatments for chronic kidney disease (CKD). We investigated the efficacy and safety of dapagliflozin in Black and White patients in the DAPA-CKD trial.

**Methods:** Adults with CKD, with or without type 2 diabetes, with eGFR 25-75 mL/min/1.73m<sup>2</sup> and UACR 200-5000 mg/g were randomized to dapagliflozin (10mg/day) or placebo. The majority of Black patients (>96%) were randomized in North and South America, so this post-hoc analysis only included patients enrolled in the Americas. Patients self-identified as Black or White. The primary outcome was a composite of ≥50% sustained eGFR decline, end-stage kidney disease, or death from kidney or cardiovascular causes.

**Results:** Overall, 1271 (29.5%) were enrolled in the Americas. Of these, 185 (14.6%) were Black and 1086 (85.4%) White. Over 2.2-years' median follow-up, 20 (10.8%) Black and 139 (12.8%) White patients developed the primary composite outcome (event rate, 5.3 and 6.2/100 patient years, respectively). Compared with placebo, dapagliflozin reduced the risk of the primary outcome in Black (HR: 0.35; 95%CI: 0.14-0.88) and White patients (HR: 0.64; 95%CI: 0.45-0.89; p-interaction=0.31). Consistent benefits were observed for other prespecified outcomes (Table). Occurrence of serious adverse events was similar with dapagliflozin vs placebo in Black (30.4% vs 39.8%) and White patients (34.9% vs 39.0%).

**Conclusions:** Black and White patients experienced similar clinical benefits with dapagliflozin including fewer kidney and cardiovascular events and prolonged survival, with a similar safety profile.

**Funding:** Commercial Support - AstraZeneca

Table: Efficacy of dapagliflozin regarding primary and secondary outcomes in Black and White patients.							
	Dapagliflozin (N=422)		Placebo (N=499)		Absolute Risk Difference (95% CI)	Hazard Ratio (95% CI)	P-Interaction

SA-PO890

Renal Outcome With Empagliflozin in Non-Diabetic CKD Patients: A Randomized Control Trial

Zara Nisar,<sup>1</sup> Hassan Sajjad,<sup>2</sup> Akash Kumar,<sup>2</sup> Saima Afaq,<sup>1</sup> Nisar Anwar:<sup>2,3</sup> <sup>1</sup>Khyber Medical University, Peshawar, Pakistan; <sup>2</sup>Rehman Medical Institute, Peshawar, Pakistan; <sup>3</sup>Khyber Teaching Hospital, Peshawar, Pakistan.

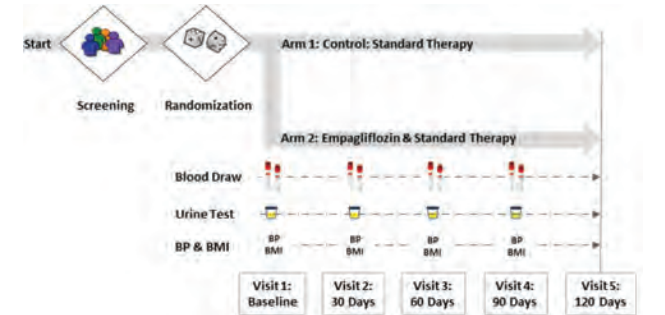

**Background:** As CKD is a rapidly growing disease, it needs rigorous treatment to control its progression. New treatment options for diabetic and non-diabetic CKD are needed

**Methods:** This was a single centre trial(Trial registration: ACTRN12622000265774p). Study schema is in the figure. STUDY SETTING: Khyber Teaching Hospital. SAMPLE SIZE AND POWER: 70 per arm in 1:1 ratio. Statistical Analysis: Microsoft Excel was used to collect the raw data. SAS was used to manage the data and conduct the statistical analyses. This data was summarized to calculate the mean, median, interquartile range (IQR) and standard deviation for continuous variables. Categorical variables were summarized by means of counts and percentages per category. Pairwise correlation coefficient was calculated among the variables to explore between-participant variation. We used multivariate analysis of covariance (MANCOVA) main effect model which is the most efficient approach with smallest variance estimator.

**Results:** The mean age of the participants was 57.9 ±4.51, with 51% being male. The treatment's impact on the five variables of TotalCholesterol60, TotalCholesterol90, LDL60, LDL90, and Proteinuria60; were found to be statistically significant. On average, the treatment decreased a patient's total cholesterol by 20 units after 60 days. It decreased a patient's total cholesterol by 70 units after 90 days. LDL is decreased by 30 units after 60 days, and by 37 units after 90 days. As for proteinuria, the treatment decreased it by 350 units after 60 days. Up to the 60 days, UTI events for the treatment group were more than those for the control group. At the 90-day stage, males had more UTI events in the treatment group than their control counterparts whereas females in the treatment group had fewer events than their control counterparts

**Conclusions:** We conclude that Empagliflozin along with standard therapy has beneficial effect for the symptoms of the patients. Follow-up duration should be increased to see its effect on e-GFR.

**Funding:** Private Foundation Support

Relationship Between Initial eGFR Dip and Changes in Laboratory Parameters With Dapagliflozin Treatment in Non-Diabetic CKD Patients

Maiko Kokubu, Masatomo Yamane, Shunsuke Kitamura, Kosuke Tansho, Masaru Matsui. Department of Nephrology, Nara prefecture General Medical Center, NARA, Japan.

**Background:** Treatment with sodium-glucose co-transporter-2 inhibitors (SGLT2i) induces an initial decline in estimated glomerular filtration rate, also termed the 'eGFR dip' and remains beneficial effects for cardiovascular and kidney outcomes, even after modified by eGFR dip in diabetic CKD. However, the difference of eGFR dip after SGLT2i between diabetic and non-diabetic CKD patients and the effects of eGFR dip on changes of laboratory parameters is not fully understood. In this study, we aimed to investigate the eGFR dip after Dapagliflozin and its relationship with clinical and laboratory data in non-diabetic CKD patients.

**Methods:** We conducted a cohort study on 127 non-diabetic CKD patients receiving Dapagliflozin in whom at least two measurements of eGFR levels at three months were confirmed. eGFR dip was defined by percent eGFR change from baseline. eGFR was calculated using Japanese equation. Correlation analyses between initial eGFR dip and clinical value were conducted using the Pearson correlation coefficient.

**Results:** The mean age of study participants was 60±13 years and 69 (54%) were male. The underlying kidney diseases included glomerulonephritis in 59 (46%) patients and hypertensive nephrosclerosis in 57 (45%). The mean levels of baseline eGFR were 43±13 mL/min/1.73m<sup>2</sup> and the mean proteinuria was 0.58±0.83 g/gCre. The mean eGFR change from baseline was -0.33±4.3 mL/min/1.73m<sup>2</sup> with eGFR dip of 0.8±9.4%. Factors including age, sex, body mass index, baseline eGFR and urinary protein were not significantly associated with the eGFR dip. Dapagliflozin increased hemoglobin levels by 0.5g/dL and decreased uric acid levels by 0.9 mg/dL. We found indirect and direct correlation of the eGFR dip with changes in proteinuria (r=0.30, p=0.001) and uric acid levels (r=0.21, p=0.015) after Dapagliflozin, respectively.

**Conclusions:** Our results suggest that the eGFR dip following SGLT2i initiation may be associated with the changes of proteinuria and uric acid levels in non-diabetic CKD patients.

SA-PO892

Semaglutide as an Aid to Weight Reduction in Adults With Obesity and Advanced CKD

Sarah Bukhari,<sup>1</sup> Sarah Cooney,<sup>1</sup> John Holland,<sup>1</sup> Husam Alzayer,<sup>2</sup> Michael Clarkson,<sup>2</sup> Peter J. Conlon.<sup>1</sup> <sup>1</sup>Beaumont Hospital, Dublin, Ireland; <sup>2</sup>Cork University Hospital, Cork, Ireland.

**Background:** Obesity is becoming more challenging in patients with chronic kidney disease. The efficacy and safety of the GLP-1 analogue semaglutide for weight loss in patients with and without diabetes has been demonstrated. However, there had been limited studies on the use of semaglutide in patients with advanced CKD.

**Methods:** In this retrospective study using electronic healthcare records, we evaluated the efficacy and safety of semaglutide for weight reduction in addition to lifestyle intervention in patients with eGFR of <30 mL/min/1.73 m<sup>2</sup> and a body mass index of >32 kg/m<sup>2</sup>. Paired t-test was performed and a p-value of <0.05 was considered statistically significant.

**Results:** Among the 14 patients included in this study, the mean percentage change in weight loss after three, six and nine months were 5.5%, 8.5% and 9.7%, respectively. After nine months, 7 patients (50%) achieved ≥5% weight loss. The most common

reported adverse events were gastrointestinal, including nausea, vomiting and diarrhoea. Two patients discontinued semaglutide because of intolerable gastrointestinal effects. No serious adverse events were noted.

**Conclusions:** In this set of patients with obesity and advanced CKD, semaglutide was safe, effective and led to significant reduction in weight.

Comparison of weight at baseline and post-treatment at three, six and nine months

Time point (months)	Sample size (N)	Mean weight (kg)	Mean percentage change in body weight (%)	p-value	95% confidence interval
3	13	6.1 kg	5.5%	< 0.001	3.68–8.61
6	10	9.3 kg	8.2%	< 0.001	5.04–13.58
9	7	10.4 kg	9.7%	< 0.001	7.34–13.50

SA-PO893

**The Effect of Semaglutide on Kidney Function: Post Hoc Analysis of Three Randomized Controlled Trials in Non-Alcoholic Fatty Liver Disease**  
Katherine R. Tuttle,<sup>1</sup> Thomas Idorn,<sup>2</sup> Maximilian K. Jara,<sup>2</sup> Mads S. Palle,<sup>2</sup> Anne-Sophie Sejling,<sup>2</sup> Henning Groenbaek.<sup>3</sup> <sup>1</sup>Providence Medical Research Center, Spokane, WA; <sup>2</sup>Novo Nordisk A/S, Søborg, Denmark; <sup>3</sup>Aarhus Universitetshospital Lever- Mave- og Tarmsygdomme, Aarhus, Denmark.

**Background:** Chronic kidney disease is a common comorbidity in non-alcoholic fatty liver disease (NAFLD). Semaglutide is being investigated in non-alcoholic steatohepatitis (NASH), a severe form of NAFLD. This post-hoc analysis pooled data from three randomized, placebo-controlled, phase 1 or 2 NAFLD trials to investigate the effects of semaglutide on kidney function.

**Methods:** Data from NCT03357380 (semaglutide 0.4 mg once daily [OD] for 72 weeks in NAFLD), NCT02970942 (semaglutide 0.1, 0.2, or 0.4 mg OD for 72 weeks in NASH with fibrosis stage 1–3), and NCT03987451 (semaglutide 2.4 mg once weekly [OW] for 48 weeks in compensated NASH cirrhosis) were included. Placebo arms were pooled, as were the semaglutide 0.4 mg OD arms in NCT03357380 and NCT02970942, and the semaglutide 2.4 mg OW arm in NCT03987451 (NCT02970942 semaglutide 0.1 and 0.2 mg OD arms were excluded). Annual slope of change in estimated glomerular filtration rate (eGFR) was analyzed for semaglutide vs placebo. Results were analyzed by baseline eGFR: <75 and ≥75 mL/min/1.73 m<sup>2</sup>.

**Results:** Baseline characteristics were comparable for semaglutide (n=163) and placebo (n=137). In eGFR <75 mL/min/1.73 m<sup>2</sup>, semaglutide appeared to have a beneficial effect on eGFR (annual slope semaglutide 5.91 mL/min/1.73 m<sup>2</sup> [n=19], placebo -1.53 mL/min/1.73 m<sup>2</sup> [n=19]; difference 7.45 mL/min/1.73 m<sup>2</sup> 95% confidence interval [CI] 3.12, 11.74). In eGFR ≥75 mL/min/1.73 m<sup>2</sup> there was no treatment difference (semaglutide n=144, placebo n=118; difference 0.40 mL/min/1.73 m<sup>2</sup> 95% CI -1.12, 1.92). The test for interaction between the <75 and ≥75 mL/min/1.73 m<sup>2</sup> groups was significant (p=0.0026). Semaglutide did not affect annual change in eGFR vs placebo in the overall population (difference 1.19 mL/min/1.73 m<sup>2</sup> 95% CI -0.24, 2.62). The difference in slopes was primarily driven by the positive slope in the eGFR <75 mL/min/1.73m<sup>2</sup> group.

**Conclusions:** A potential protective effect of semaglutide on eGFR was seen in patients with NAFLD and eGFR <75 mL/min/1.73 m<sup>2</sup>. Although this post-hoc analysis had a small sample size, the results support further studies of semaglutide in NAFLD with low eGFR, irrespective of diabetes status.

SA-PO894

**Effects of Colchicine on Renal Fibrosis Marker in Patients With CKD**  
Thunyatorn Wuttiputhanun, Jeerath Phannajit, Paweena Susantitaphong, Somchai Eiam-Ong, Pisut Katavetin. Chulalongkorn University Faculty of Medicine, Bangkok, Thailand.

**Background:** Renal fibrosis and chronic inflammation are key contributors to CKD. Colchicine which has both anti-fibrotic and anti-inflammatory properties might be an attractive drug to retard CKD progression.

**Methods:** In this randomized, double-blind, placebo-controlled trial, we randomly assigned patients with CKD stage 3 and 4 to receive either colchicine 0.6 mg on alternate day or placebo in 1:1 ratio. The primary outcome was the change in urine transforming

growth factor beta-1 (TGF-β1) from baseline to 12 weeks. Secondary outcomes were changes in urine monocyte chemotactic protein-1 (MCP-1), kidney function, chronic inflammatory indicators and safety outcomes.

**Results:** A total of 40 patients underwent randomization. The change in urine TGF-β1 from baseline to 12 weeks did not differ among the two groups. The colchicine group showed significantly lower values of WBC counts, neutrophil counts, neutrophil-to-lymphocyte ratio and platelet count compared with the placebo group. On the contrary, the change in urine MCP-1 in colchicine group was significantly higher than placebo group. No significant differences of the change of kidney function and C-reactive protein were found. Adverse events between groups were comparable.

**Conclusions:** Colchicine failed to show improvement of renal function indicators and renal fibrosis marker. Effects on inflammation was inconclusive. Colchicine decreased systemic neutrophil-related inflammation in patients with CKD stage 3 and 4 but increased urine MCP-1. Further investigation of the role of colchicine in slowing CKD progression is required.

	Colchicine (n=20)	Placebo (n=20)	P-value
Primary outcome (change in)			
- Urine TGF-β1 (pg/gCr)	-1.238 (-3.382 to -0.065)	-0.463 (-1.803 to 0.624)	.414
Secondary outcomes (change in)			
- Urine MCP-1 (pg/gCr)	20.044 (4.628 to 77.618)	-5.273 (-25.068 to 14.551)	.038
- Urine albumin-to-creatinine ratio (mg/gCr)	-24.71 (-117.72 to 16.53)	-11.57 (-71.52 to 77.95)	.547
- eGFR (mL/min/1.73m <sup>2</sup> )	-1.59 ± 4.25	-1.33 ± 4.02	.841
- C-reactive protein (mg/L)	-0.25 (-0.70 to 0.08)	-0.02 (-0.76 to 0.675)	.565
- WBC count (x10 <sup>9</sup> /L)	-598.5 ± 731.4	122.1 ± 640.1	.002
- Absolute neutrophil count (x10 <sup>9</sup> /L)	-626.3 ± 644.7	240.5 ± 541.9	0.001
- Neutrophil-to-lymphocyte ratio	-0.380 ± 0.692	0.215 ± 0.582	.006
- Hemoglobin level (g/dL)	0.09 ± 0.63	-0.14 ± 0.68	.284
- Platelet count (x10 <sup>9</sup> /L)	-5,600 ± 28,577	13,000 ± 26,608	.04
- Platelet-to-lymphocyte ratio	-1,092 ± 2,054	1,203 ± 2301	.002

**Efficacy and Safety of Urate Lowering Therapy (ULT) in CKD Patients With Gout**

Lindsay N. Helget,<sup>1,2</sup> Anne Davis-Karim,<sup>3</sup> James R. O’Dell,<sup>1,2</sup> Ted R. Mikuls,<sup>1,2</sup> Jeff A. Newcomb,<sup>1</sup> Maria Androsenko,<sup>4</sup> Mary T. Brophy,<sup>4</sup> Bryant England,<sup>1,2</sup> Ryan Ferguson,<sup>4</sup> Michael Pillinger,<sup>5,6</sup> Tuhina Neogi,<sup>7</sup> Hongsheng Wu,<sup>4</sup> Paul M. Palevsky.<sup>8,9</sup> <sup>1</sup>VA Nebraska-Western Iowa Health Care System, Omaha, NE; <sup>2</sup>University of Nebraska Medical Center, Omaha, NE; <sup>3</sup>VA Cooperative Studies Program Clinical Research Pharmacy Coordinating Center, Albuquerque, NM; <sup>4</sup>VA Boston Cooperative Studies Program Coordinating Center, Boston, MA; <sup>5</sup>VA New York Harbor Health Care System, New York, NY; <sup>6</sup>NYU Langone Health, New York, NY; <sup>7</sup>Boston University School of Medicine, Boston, MA; <sup>8</sup>VA Pittsburgh Healthcare System, Pittsburgh, PA; <sup>9</sup>University of Pittsburgh School of Medicine, Pittsburgh, PA.

**Background:** Limited data exist on the comparative effectiveness of allopurinol (ALL) and febuxostat (FEB) for the management of gout in patients with CKD. Using data from STOP-Gout, a recently completed multicenter RCT, we examined the efficacy and safety of ALL and FEB in the subgroup of patients with CKD.

**Methods:** Patients with gout and serum urate (SU) concentration ≥6.8 mg/dL were randomized 1:1 to receive ALL or FEB. ULT was titrated during weeks 0-24 (Phase 1) and maintained during weeks 25-48 (Phase 2), with escalation, to reach goal SU of <6.0 mg/dL. Participants were observed on stable ULT dose during weeks 49-72 (Phase 3). CKD was defined as an eGFR 30-59 mL/min/1.73 m<sup>2</sup> at baseline. Primary outcome was presence of ≥ 1 gout flare during Phase 3. Secondary outcomes were achievement of SU <6mg/dL at end of Phase 2, gout flare rates, and serious adverse events (SAEs).

**Results:** 351 of 940 trial participants had CKD;277 were assessed for the primary outcome. Fewer patients randomized to ALL had ≥1 gout flare during phase 3 (32% v 45%; p=0.02) despite similar attainment of SU <6.0 mg/dL by the end of Phase 2 (Table). CKD participants did not require higher doses of either ULT to reach goal SU as compared to non-CKD but had more SAEs. There were no differences in overall SAEs between ALL and FEB.

**Conclusions:** This prespecified sub-analysis from a large, RCT demonstrates that ALL and FEB are equally efficacious and well-tolerated in the treatment of gout in CKD when used in a treat-to-target regimen.

**Funding:** Veterans Affairs Support

## Primary and secondary end points

	Allopurinol (n=181)	Febuxostat (n=170)	Total	P Value
<b>Primary Endpoint</b>				
≥1 Gout flare in Phase 3, %	31.9 (44/138)	45.3 (63/139)	38.6 (107/277)	0.02
<b>Secondary Endpoints</b>				
Serum Urate <6.0 mg/dL in Phase 2, %	78.8 (119/151)	81.3 (117/144)	80.0 (236/295)	0.59
Rate of gout flares (events/patient years)				
during Phase 3	1.54	2.36	1.85	<0.001
during Phase 1 and 2	1.47	2.04	1.75	<0.001
Serious Adverse Event, %	38.1 (69/181)	35.9 (60/170)	37.0 (130/351)	0.66
Cardiovascular event, %	13.8 (25/181)	10.6 (18/170)	12.3 (43/351)	0.35

## Urate Lowering Drugs for CKD Patients With Asymptomatic Hyperuricemia and Hypertension: A Randomized Trial

Kentaro Kohagura,<sup>1</sup> Atsushi Satoh,<sup>2</sup> Masako Kochi,<sup>3</sup> Kazushi Kinjo,<sup>5</sup> Masanobu Yamazato,<sup>4</sup> Akio Ishida,<sup>4</sup> Atsushi Sakima,<sup>4</sup> Kunitoshi Iseki,<sup>6</sup> Hisatomi Arima,<sup>2</sup> Yusuke Ohya,<sup>4</sup> URIC CKD study group <sup>1</sup>Ryukyu Daigaku Igakubu Fuzoku Byoin, Nakagami-gun, Japan; <sup>2</sup>Fukuoka Daigaku Igakubu Daigakuin Igaku Kenkyuka, Fukuoka, Japan; <sup>3</sup>Tomishiro Chuo Byoin, Tomishiro, Japan; <sup>4</sup>Ryukyu Daigaku Igakubu Daigakuin Igaku Kenkyuka, Nakagami-gun, Japan; <sup>5</sup>Nakagami Byoin, Okinawa, Japan; <sup>6</sup>Nakamura clinic, Urasoe, Japan.

**Background:** Xanthine oxidase (XO) inhibitors may retard the progression of chronic kidney disease (CKD). It is unknown whether a different type of urate-lowering therapy is comparably effective for it. To determine urate-lowering therapy with XO inhibitor and urate transporter 1 inhibitor are comparable for slowing the decline in renal function among CKD patients with hypertension and hyperuricemia.

**Methods:** Open-label, randomized, parallel-group clinical trial in 96 patients with stage 3 CKD from 9 facilities in Okinawa, Japan. Eligible patients had hyperuricemia without a history of gout, and hypertension. Patients were randomized to receive either febuxostat (n = 47) or benzbromarone (n = 48) and titrated to achieve serum urate levels less than 6.0mg/dL. The primary endpoint was change in the estimated glomerular filtration rate (eGFR) from baseline to 52 weeks. Secondary endpoints included percent change in uric acid, blood pressure, urinary albumin to creatinine ratio, and XO activity from the baseline to 8 and 52 weeks.

**Results:** Among 95 randomized patients, 88 (92.6%) completed the trial. There was no significant difference in change in eGFR (mL/min/1.73 m<sup>2</sup>) between the febuxostat (-0.23, 95% CI, -2.00 to 1.55) and benzbromarone (-2.18, 95% CI, -3.84 to -0.52) groups (difference, 1.95; 95% CI, -0.48 to 4.38; P = 0.1), and in secondary endpoints except for XO activity. Febuxostat significantly reduced XO activity. There were no significant differences in the effects of febuxostat compared with benzbromarone on primary outcomes in the whole analysis, although subgroup analysis demonstrated a significant benefit from febuxostat in patients with stage 3a CKD. There were no adverse effects specific to either drug.

**Conclusions:** There was no clear difference between febuxostat and benzbromarone in inhibiting the decline in renal function among stage 3 CKD patients with hyperuricemia and hypertension.

**Funding:** Commercial Support - Teijin Pharma

## SA-PO897

## eGFR Changes in Uncontrolled Gout Patients Undergoing Pegloticase Plus Methotrexate Co-Therapy

Brad A. Marder,<sup>1</sup> John A. Albert,<sup>2</sup> Aaron Broadwell,<sup>3</sup> Lissa Padnick-Silver,<sup>1</sup> Brian LaMoreaux,<sup>1</sup> <sup>1</sup>Horizon Therapeutics plc, Deerfield, IL; <sup>2</sup>Rheumatic Disease Center, Milwaukee, WI; <sup>3</sup>Rheumatology and Osteoporosis Specialists, Shreveport, LA.

**Background:** Renal function decline is associated with hyperuricemia and gout. Pegloticase can lower serum uric acid (sUA) in uncontrolled gout (UG) patients (pts), independent of CKD status. Recent trial/case data support immunomodulator (IMM) use with pegloticase to limit anti-drug antibody formation, increasing urate-lowering response rate and decreasing infusion reaction (IR) risk. CKD can limit IMM use, particularly methotrexate (MTX), and pegloticase+IMM clinical trials excluded pts with eGFR <40. However, CKD is common in gout pts and pegloticase+IMM use in CKD pts has been reported. Here we analyse case data to examine eGFR changes during pegloticase+MTX co-therapy in CKD and non-CKD pts.

**Methods:** Deidentified case data of pegloticase+MTX co-therapy were pooled and retrospectively analyzed. Pts were labeled as CKD (baseline [BL] eGFR <60 mL/min/1.73m<sup>2</sup>) or non-CKD (BL eGFR ≥60 mL/min/1.73m<sup>2</sup>). sUA, eGFR, blood cell counts, and liver function tests were monitored. Pt characteristics, treatment parameters, response rate (≥12 infusions [inf], pre-inf 12 sUA <6 mg/dL), eGFR, and AEs were examined. Pts on therapy at data collection with <12 inf were excluded from response analyses.

**Results:** 42 UG pts were included; 15 CKD (13 stage3, 2 stage4; eGFR=43±11 mL/min/1.73m<sup>2</sup>; sUA=9±2 mg/dL), 27 non-CKD (eGFR=83±19 mL/min/1.73m<sup>2</sup>; sUA=10±2 mg/dL). Comorbidity profiles were similar, but more CKD pts were female (33% vs 7%) and ≥65 yrs (60% vs 19%). MTX was started ~4 wks before pegloticase in both groups,

but CKD pts had lower dose (15±6 vs 19±5 mg/wk). Pegloticase response rate (CKD: 92% vs non-CKD: 86%) and treatment (14.7±8.1 vs 14.1±7.1 inf) were similar. In non-CKD pts, 44% had an eGFR increase (mean[±SD]: +4.2±15.0 mL/min/1.73m<sup>2</sup>). In CKD pts, 60% had an eGFR increase (+11.5±20.9 mL/min/1.73m<sup>2</sup>), with CKD stage stability/improvement in 13 (87%, both stage4→3a; 2 stage3a→3b). No new safety signals were identified. 7 (47%) CKD and 13 (48%) non-CKD pts had ≥1 AE; most-commonly gout flare (47%, 41%). Pancytopenia (n=1) and mild IR (n=1) were reported (both non-CKD pts).

**Conclusions:** These limited data show similar pegloticase+MTX urate-lowering efficacy in CKD and non-CKD pts. Most CKD pts had renal stability/improvement during therapy, but further study is needed.

**Funding:** Commercial Support - Horizon Therapeutics plc

## SA-PO898

## eGFR Changes in Uncontrolled Gout Patients Randomized to Receive Methotrexate or Placebo as Co-Therapy to Pegloticase: MIRROR RCT Findings

Abdul A. Abdellatif,<sup>1</sup> John K. Botson,<sup>2</sup> Katie L. Obermeyer,<sup>3</sup> Brian LaMoreaux,<sup>3</sup> Brad A. Marder,<sup>3</sup> <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>Orthopedic Physicians Alaska, Anchorage, AK; <sup>3</sup>Horizon Therapeutics plc, Deerfield, IL.

**Background:** The MIRROR RCT trial (methotrexate [MTX] or placebo [PBO] co-therapy to pegloticase) showed increased urate-lowering response rate (71.0% vs 38.5% during Month 6) and lower infusion reaction rate (4% vs 31%) in patients (pts) co-administered MTX. Because CKD is prevalent in gout pts and MTX is used cautiously in CKD pts, pegloticase+MTX co-therapy impact on renal function is of interest. Here we report eGFR changes in MIRROR RCT pts.

**Methods:** Uncontrolled gout pts (serum uric acid [sUA] ≥7mg/dL, ULT failure/intolerance, ≥1 gout symptom) received pegloticase (biweekly 8mg infusion) and blinded oral MTX (15mg/wk) or PBO (2:1 randomization) following a 2-wk MTX tolerance test and 4-wk blinded MTX/PBO Run-in (eGFR <40mL/min/1.73m<sup>2</sup> excluded). Baseline eGFR was measured before MTX exposure (Wk -6). Mean (SE) change from baseline (CFB) in eGFR was examined by treatment and baseline eGFR status (<60 and ≥60mL/min/1.73m<sup>2</sup>). Analyses were performed on all randomized pts (ITT).

**Results:** 100pts were randomized to pegloticase+MTX (56±13 yrs, 91% men, eGFR=68.9±18.0mL/min/1.73m<sup>2</sup>) and 52pts to pegloticase+PBO (53±12yrs, 85% men, eGFR=71.1±17.6mL/min/1.73m<sup>2</sup>). eGFR was stable during MTX/PBO Run-in and after pegloticase initiation (Day1) in both treatment groups (Figure). At Wk24, eGFR CFB was +5.3±1.3 and +4.3±2.3mL/min/1.73m<sup>2</sup> in the MTX (N=70; 69responders) and PBO (N=19, 19responders) groups, respectively. eGFR CFB at Wk24 did not differ between eGFR <60 and ≥60 groups in MTX (+4.1±2.4 [N=27], +6.3±1.7 [N=43] mL/min/1.73m<sup>2</sup> respectively) or PBO (+2.5±5.6 [N=7], +7.8±4.1 [N=12] mL/min/1.73m<sup>2</sup> respectively) pts (both p≥0.48).

**Conclusions:** eGFR did not appear to decrease after oral MTX initiation when administered as co-therapy with pegloticase. This was true for pts with and without pre-therapy eGFR <60mL/min/1.73m<sup>2</sup>. These findings suggest MTX co-therapy did not negatively impact renal function in MIRROR RCT trial participants.

**Funding:** Commercial Support - Horizon Therapeutics plc

Abstract Withdrawn

SA-PO901

**Amelioration of Uremic Toxin Indoxyl Sulfate by Oral Chito-Oligosaccharide in Predialysis Patients: A Randomized Controlled Trial**  
Chumphon Sirisuksakun, Paramat Thimachai, Pamila Tasanavipas, Narongrit Siriwattanasit, Pitchamon Inkong, Narittaya Varothai, Amnart Chaiprasert, Naowanit Nata, Theerasak Tangwonglert, Wisit Kaewput, Bancha Satirapoj, Ouppatham Supasyndh. *Phramongkutklao College of Medicine, Bangkok, Thailand.*

**Background:** Chito-oligosaccharide (COS) can bind indoxyl sulfate (IS) from protein-based foods. However, sparse data of COS on serum IS was studied. The study aimed to determine the efficacy of COS on serum IS reduction and delay of chronic kidney disease (CKD) progression.

**Methods:** A randomized, double-blind, placebo-controlled trial was conducted in CKD patients with eGFR < 20 ml/min/1.73 m<sup>2</sup> during September 2021 to February 2022. Treatment group received oral COS 500 mg once daily for 12-week. The other group received a placebo, which was identical to COS capsule. Patient's baseline characteristics and serum IS were collected at baseline, week-4 and week-12.

**Results:** Forty-seven out of fifty participants were enrolled and completed the study. The mean (SD) of IS level at baseline in the treatment (N=26) and placebo (N=21) group were 585.1 (402.2) and 466.8 (421.5) ng/ml (p=0.4). There was significant decrease in IS level at week-4 and week-12 in the treatment group (p=0.006 and p=0.007) but not in the placebo group, in which the IS level was increased significantly at week-12 (p=0.002). The mean of IS level at the end of the trial was significantly lower in the treatment group with the mean difference (95% CI) -960.1 (-1384.6 to -535.5) ng/ml (p<0.001). The eGFR declined significantly in the placebo at week-4 and week-12 (p =0.022 and p=0.004) but not in the treatment group (p=0.497 and p=0.113). No serious adverse event was found.

**Conclusions:** Oral 12-weeks of COS demonstrates the reduction of serum IS level and stabilizes eGFR without significant adverse event.

Kovesdy,<sup>1,2</sup> Prabin Shrestha,<sup>1</sup> Yamini Mallisetty,<sup>1</sup> Abu Mohd Naser,<sup>4</sup> Satya Surbhi,<sup>1</sup> Fridtjof Thomas,<sup>1</sup> Elani Streja,<sup>3</sup> Connie Rhee,<sup>3</sup> Kamyar Kalantar-Zadeh,<sup>3</sup> Keiichi Sumida.<sup>1</sup> *<sup>1</sup>The University of Tennessee Health Science Center, Memphis, TN; <sup>2</sup>VA Memphis Medical Center, Memphis, TN; <sup>3</sup>University of California Irvine, Irvine, CA; <sup>4</sup>The University of Memphis, Memphis, TN.*

**Background:** Thiazide diuretics are widely used for the treatment of hypertension and to improve outcomes in hypertensive patients without kidney disease. It is unclear whether the use of thiazides improves outcomes in patients with mild-to-moderate CKD.

**Methods:** In a nationwide cohort of >3.5 million US veterans, we identified 2,494 patients with an eGFR ≥45 mL/min/1.73m<sup>2</sup> who were incident new users of thiazides. Within the same 180-day calendar period, we identified 104,277 comparators who never used thiazides during the entire follow-up. After 1:1 propensity-score (PS) matching for socio-demographics, comorbidities, vital signs, eGFR, UACR, serum sodium and calcium, and relevant medications, the associations of thiazide use with incident ESKD and all-cause mortality were examined using competing risk regression and Cox regression models, respectively, overall and by subgroups of loop diuretic use status.

**Results:** Baseline characteristics were similar in patients with and without thiazide use (n=1,593 each) after PS matching. There were 53 and 823 cases of incident ESKD and all-cause death (event rates [95%CI], 3.1 [2.4-4.1] and 41.2 [38.5-44.2]/1000 PY) over a median follow-up of 5.4 and 6.1 years, respectively. Thiazide use was significantly associated with lower risk of all-cause mortality (HR [95%CI], 0.83 [0.73-0.93]) but not with incident ESKD (sub-HR [95%CI], 1.40 [0.81-2.40]). There was a significant interaction between loop and thiazide diuretic use, with the significantly lower thiazide-associated mortality risk only seen in patients without loop diuretic use (Table).

**Conclusions:** In patients with CKD stages G1-G3a, thiazide use was associated with significantly lower all-cause mortality but not with higher or lower incident ESKD. The lack of significant thiazide-mortality association among loop diuretic users may suggest the need for prudent use of combination diuretic therapy in patients with mild-to-moderate CKD.

**Funding:** Veterans Affairs Support

Associations of incident thiazide use (vs. no use) with outcomes in PS-matched cohort

**Incident Thiazide Use and Outcomes in Advanced CKD: A Large Nationwide Observational Study of US Veterans**  
Keiichi Sumida,<sup>1</sup> Prabin Shrestha,<sup>1</sup> Yamini Mallisetty,<sup>1</sup> Abu Mohd Naser,<sup>2</sup> Satya Surbhi,<sup>1</sup> Fridtjof Thomas,<sup>1</sup> Elani Streja,<sup>3</sup> Connie Rhee,<sup>3</sup> Kamyar Kalantar-Zadeh,<sup>3</sup> Csaba P. Kovesdy.<sup>1,4</sup> *<sup>1</sup>The University of Tennessee Health Science Center, Memphis, TN; <sup>2</sup>The University of Memphis, Memphis, TN; <sup>3</sup>University of California Irvine, Irvine, CA; <sup>4</sup>VA Memphis Medical Center, Memphis, TN.*

**Background:** A recent randomized controlled trial showed that chlorthalidone therapy improved blood-pressure control in patients with advanced CKD and poorly controlled hypertension. It remains unclear if the use of thiazide diuretics improves clinical outcomes in patients with advanced CKD.

**Methods:** In a nationwide cohort of >3.5 million US veterans, we identified 266 patients with an eGFR <45 mL/min/1.73m<sup>2</sup> who were incident new users of thiazides. Within the same 180-day calendar period, we identified 14,077 comparators who never used thiazides during the entire follow-up. After 1:1 propensity-score (PS) matching for socio-demographics, comorbidities, vital signs, eGFR, serum sodium and calcium, and relevant medications, the associations of thiazide use with incident ESKD and all-cause mortality were examined using competing risk regression and Cox regression models, respectively, overall and by subgroups of loop diuretic use status.

**Results:** Baseline characteristics were similar in patients with and without thiazide use (n=212 each) after PS matching. There were 54 and 184 cases of incident ESKD and all-cause death (event rates [95%CI], 35.3 [27.0-46.1] and 93.0 [80.5-107.5]/1000 PY) over a median follow-up of 3.0 and 4.2 years, respectively. Thiazide use was not associated with incident ESKD (sub-HR [95%CI], 0.94 [0.55-1.60]) nor with all-cause mortality (HR [95%CI], 0.99 [0.74-1.32]). There was a significant interaction between loop and thiazide diuretic use, with significantly higher thiazide-associated mortality risk observed in patients with loop diuretic use (1.67 [1.02-2.76]) (Table).

**Conclusions:** In patients with CKD stages G3b-G5, thiazide use was not significantly associated with incident ESKD or with all-cause mortality. The higher mortality risk associated with thiazide use in loop diuretic users may reflect an elevated risk of drug adverse effects and suggests the need for careful risk-benefit assessment for combination diuretic therapy in advanced CKD.

**Funding:** Veterans Affairs Support

**Angiotensin Receptor-Neprilysin Inhibitor vs. Renin-Angiotensin-Aldosterone System Inhibitors in Patients With Advanced CKD**  
Jin hyuk Paek, Yaerim Kim, Woo Yeong Park, Seungyeup Han, Kyubok Jin. *Keimyung University School of Medicine, Daegu, Republic of Korea.*

**Background:** Patients with chronic kidney disease are at increased risk of cardiovascular events. Recently, angiotensin receptor-neprilysin inhibitor (ARNi) led to a reduced risk of heart failure hospitalization and cardiovascular mortality among patients with heart failure with reduced ejection fraction. However, there are few studies regarding ARNi in patients with advanced chronic kidney disease.

**Methods:** Among patients with estimated glomerular filtration rate (eGFR) < 30 ml/min/1.73m<sup>2</sup> and left ventricular ejection fraction (LVEF) < 40%, 31 patients who received ARNi were enrolled from August 2018 to April 2020. As a control group, 31 age- and sex-matched cohort who received renin-angiotensin-aldosterone system inhibitor (RAASi) with eGFR < 30 ml/min/1.73m<sup>2</sup> and LVEF < 40% were selected. We compared efficacy and safety of ARNi at 12 months. The primary outcome was four-point major adverse cardiovascular events (MACE), composite of death from cardiovascular disease, hospitalization for heart failure, nonfatal myocardial infarction, and nonfatal stroke.

**Results:** In total of 62 patients, the mean eGFR was 15.8 ± 9.7 mL/min/1.73m<sup>2</sup> and the mean LVEF was 29.8 ± 7.5%. There were 26 dialysis patients (41.9%) in the study cohort. At 12 months, there was no significant difference in LVEF between two groups, but MACE was significantly lower in ARNi group than RAASi group (12.9% vs. 35.5%, respectively, *p* = 0.038). The Kaplan-Meier curves showed that cumulative incidence of MACE was lower in the ARNi group than in the RAASi group (*p* = 0.043). The incidence of hyperkalemia was comparable between two groups. In non-dialysis cohort, there were no significant differences in the decrease of eGFR and development of hyperkalemia between two groups.

**Conclusions:** This study showed that ARNi might improve cardiovascular outcomes in patients with advanced chronic kidney disease. Further clinical trials are warranted.

Figure 1, Kaplan-Meier Curves of MACE according to the type of medication

Outcomes Differences in User vs. Non-User of Renin-Angiotensin Blockers in Early CKD

Narayan Prasad<sup>1</sup>, Monica Kundu,<sup>2</sup> Ashok K. Yadav,<sup>3</sup> Vivek Kumar,<sup>3</sup> Vivekanand Jha.<sup>2</sup> Indian Chronic Kidney Disease Study Group <sup>1</sup>Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India; <sup>2</sup>The George Institute for Global Health India, New Delhi, India; <sup>3</sup>Post Graduate Institute of Medical Education and Research, Chandigarh, India.

**Background:** Renin-angiotensin-aldosterone-system blockers (RASB) are the antihypertensive drug class of choice in patients with CKD. There are few head-to-head comparisons of the renal or nonrenal outcomes between RASB users and non-users. We aimed to compare the renal and cardiovascular outcomes between the two in patients enrolled in the Indian Chronic Kidney Disease (ICKD) Study.

**Methods:** A total of 4050 patients with mild-moderate CKD recruited in the ICKD cohort were studied. Patients were categorized as ARB users or nonusers. The renal outcomes [50% decline in eGFR and end stage kidney disease (ESKD)], all-cause mortality, and cardiovascular mortality was analysed over a median follow up period of 2.65 (1.40, 3.89) years between RASB users and nonusers.

**Results:** Out of a total of 4056 patients, 3487 (86%) were hypertensive. A total of 82 (89%) out of 92 in stage 1, 192 (70%) out of 275 in stage 2, 1677 (61%) out of 2742 in stage 3 and 154 (41%) out of 378 in stage 4 hypertensive patients received RASBs. The rate of decline of eGFR in RASB user was numerically low as compared to non-users (Figure 1). The adjusted hazard ratio (HR) for RASB user for a 50% decline in eGFR, ESKD, all-cause mortality and cardiovascular mortality was 0.72, 0.72, 0.59, and 0.48 respectively (Figure 2).

**Conclusions:** The use of RASBs decreased with advancing CKD stages from stage 1 to 4. RASB use is associated with slower rate of decline in eGFR in those with CKD stage 1-3. RASB users had a significantly lower risk of all-cause mortality and cardiovascular mortality

**Funding:** Government Support - Non-U.S.

Mean eGFR decline in ACE/ARB users and non-users in stage 1-4 CKD patients at last follow up

Use of Renin-angiotensin-aldosterone-system blockers (RASBs) and diuretics and outcome of Chronic kidney disease

	Unadjusted hazards ratio (95% CI)	P value	Adjusted hazards ratio (95% CI)	P value

The Association of Statins on Mortality of Patients With CKD Based on Two Large-Scale Databases

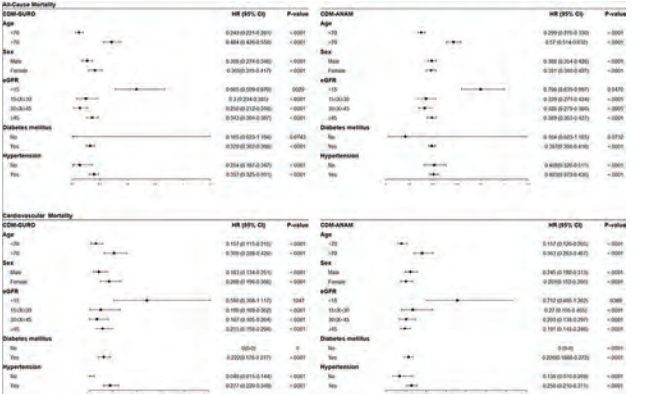

Gang Jee Ko. Korea University College of Medicine and School of Medicine, Seoul, Republic of Korea.

**Background:** The role of statins in CKD has been extensively evaluated, but it remains controversial in specific population such as dialysis-dependent CKD. This study examined the effect of statins on mortality in CKD patients using two large-scaled databases.

**Methods:** Database for the Observational Medical Outcomes Partnership Common Data Model (OMOP-CDM) were formed from two hospitals. Medical records of patients admitted from 2002-2020 were extracted, which scored more than 2,000,000 cases from each hospital. As a sensitivity analysis, the results were validated with another large-scaled database, the Korea-National-Health-Insurance (KNHI) claims database constructed between 2003-2015. Multivariable Cox regression analyses were performed using adjustment with age, sex, and comorbidities.

**Results:** Among 44,431 and 64,165 CKD patients of two hospitals, the numbers of statin users were 7,467 (16.80%) and 13,212 (20.59%). During the follow-up period for 8.9±5.8 and 9.5±5.6 years of each hospitals, statin users were associated with 67% and 61% lower all-cause mortality (Hazard ratios [95% confident interval], 0.33[0.30-0.36] and 0.39[0.33-0.42] respectively). Risk for Cardiovascular mortality were 78% lower in both hospital. In both centers, the risk of all-cause mortality was consistently reduced in statin users regardless of age, sex, renal function, and the presence of diabetes or hypertension (Fig 1). Risk difference was also analyzed in low-risk young patients (currently statins are not recommended), and the risks for all-cause and cardiovascular mortality were significantly lower among statin users even in low-risk patients aged under 50. When confirmatory analysis were performed in 4,114 CKD patients of KNHI data, statin in non-dialysis patients were associated with 59% lower risk of all-cause mortality. Dialysis patients showed similar results as 36% lower risks.

**Conclusions:** Statins were associated with lower mortality in CKD patients, regardless of dialysis status or other risk factors.

SA-PO907

Sevelamer vs. Cardiopulmonary Bypass on Renal Replacement Treatments, Cardiovascular Events, and Mortality in Non-Dialysis Dependent (NDD)-CKD Patients

Ping Li, Xuefeng Sun, Xiangmei Chen, Guangyan Cai. Chinese PLA General Hospital, State Key Laboratory of Kidney Disease, Beijing, China.

**Background:** Hyperphosphatemia is a key uremic toxin associated with adverse outcomes in patients with CKD. Sevelamer, a widely used non-calcium-based phosphate binder, has been proven to provide extra benefits. However, there is limited evidence on the long-term benefit of Sevelamer on renal and cardiovascular outcomes in NDD-CKD patients.

**Methods:** We used Optum Clinformatics® administrative claims database (May 1, 2000-November 30, 2021) as the data source in this study. We used 1:1 Propensity score matching (PSM) techniques to improve the comparability between Sevelamer group and CPB group. The primary endpoint is renal replacement therapy (RRT). The secondary endpoints include major adverse cardiovascular events (MACE, defined as a composite of non-fatal MI, non-fatal stroke, or all-cause mortality), MACE plus (defined as a composite of MACE, unstable angina pectoris, and congenital heart failure), and all-cause mortality. We also examined the incidence of hemorrhage stroke and fracture as safety endpoints.

**Results:** In total, 9,047 patients were included (Sevelamer group: n=6,644; CPB group: n=2,403). After PSM, 2399 patients remained in each group. During 3 years follow-up, patients in Sevelamer group experienced significantly lower incidence of RRT compared with patients in CPB group [1,560 (65.0%) in Sevelamer group vs. 1,687 (70.3%) in CPB group, HR, 0.84 (95%CI: 0.79-0.91), P<0.0001], MACE [1,077(44.9%) in Sevelamer group vs. 1,217 (50.7%) in CPB group, HR: 0.91 (95%CI: 0.84-0.99), P=0.0249] and MACE plus [1,244 (51.9%) in Sevelamer group vs. 1,419 (59.1%) in CPB group, HR: 0.88 (95%CI: 0.81-0.95), P=0.0009]. Patients in both groups experienced similar incidence of all-cause death, hemorrhage stroke and bone fracture.

**Conclusions:** In this PSM cohort study, Sevelamer showed a lower incidence of RRT, MACE, and MACE plus compared with CPB in NDD-CKD patients with

hyperphosphatemia. **Acknowledgement:** The access to Optum Clinformatics® administrative claims database and data analysis were supported by Sanofi Pharmaceuticals, In according to Good Publication Practice guidelines. ### Association of Pharmacotherapy for Nausea and Vomiting Symptoms With Incident CKD and the Role of Confounding by Indication

Diana S. Kalantar,<sup>1</sup> Csaba P. Kovessy,<sup>2</sup> Fridtjof Thomas,<sup>2</sup> Keiichi Sumida,<sup>2</sup> Jun Ling Lu,<sup>2</sup> Kamyar Kalantar-Zadeh,<sup>1</sup> Elani Streja.<sup>1</sup> <sup>1</sup>University of California Irvine Medical Center, Orange, CA; <sup>2</sup>The University of Tennessee Health Science Center, Memphis, TN.

**Background:** Nausea and vomiting are effectively treated with pharmacotherapy. Potential associations of anti-emetic therapy with adverse kidney outcomes may reflect confounding by indication (CBI). We aimed to examine the association of anti-emetic therapies with the incidence of new onset CKD across Propensity Score (PS) methods that account for CBI.

**Methods:** In a historical cohort of 323,970 US Veterans with normal baseline eGFR ( $\geq 60$  ml/min/1.73m<sup>2</sup>) during 2004-2006, we identified 13,154 Veterans who were incident new anti-emetic therapy users. We used clinical trial emulation methods to model the associations of anti-emetic use with incident CKD (defined as eGFR  $< 60$  ml/min/1.73m<sup>2</sup> on two separate occasions with at least 90 days in-between) including PS matching and PS weighing.

**Results:** Non-users and users of anti-emetics were 64.1 $\pm$ 14.2 and 62.1 $\pm$ 12.9 (mean $\pm$ SD) years old, respectively and anti-emetic users were more likely to be female, smokers, and had higher frequencies of comorbidities. Anti-emetic use (vs. non-use) was associated with a higher risk of incident CKD in unadjusted analyses (hazard ratio and 95%CI: 1.26, 1.22-1.31), and in PS matched (1.22, 1.17-1.28) and PS weighed analyses (1.28, 1.18-1.46) respectively [figure].

**Conclusions:** Anti-emetic medication use was associated with 22% to 28% higher risk of incident CKD in patients with no preexisting kidney disease. This association appears robust across different PS implementation models suggesting less likely involvement of confounding by indication as the explanation. The potential causality of this association still needs to be tested in additional studies, including clinical trials.

## SA-PO909

### Association of Long-Term Aspirin Use With Kidney Disease Progression

Jun Ling Lu,<sup>1</sup> Prabin Shrestha,<sup>1</sup> Elani Streja,<sup>2</sup> Kamyar Kalantar-Zadeh,<sup>2</sup> Csaba P. Kovessy.<sup>1,3</sup> <sup>1</sup>The University of Tennessee Health Science Center, Memphis, TN; <sup>2</sup>University of California Irvine, Irvine, CA; <sup>3</sup>VA Memphis Medical Center, Memphis, TN.

**Background:** Chronic microinflammation contributes to the progression of CKD. Aspirin (ASA) has been used to treat inflammation for centuries. Currently ASA is used for anti-platelet and analgesic functions, but the effects of ASA on CKD progression is unclear.

**Methods:** We examined the association of chronic use of newly initiated low-dose ASA (50-200mg) with ESKD and with eGFR decrease of  $\geq 40\%$  (eGFR40) in a nationwide cohort of US Veterans with incident CKD. Among 806,058 patients, we identified 21,161 who initiated ASA within one year of CKD diagnosis. We used propensity score matching to account for differences in key characteristics between ASA users and non-users, yielding 32,528 patients (16,264 in each group). We examined the association between ASA use and outcomes in competing risk regressions.

**Results:** In the matched cohort, the mean age (SD) was 67.1(11.0), 95.8% were male, baseline eGFR was 61.0 (20.7) and 38.1% had albuminuria. The characteristics were balanced between the two groups. Over a 4.8-year median follow-up, 857 (2.6%) patients reached ESKD (event rate: 5.2/1000 patient-years (95%CI: 4.9-5.6)) and 5,187 (16.5%) developed eGFR40 (34.9/1000PY (34.0-35.9)). ASA use was associated with a trend toward lower risk of ESKD (Subhazard ratio and 95%CI: 0.88 [0.77, 1.01], p=0.07), and with a higher risk of eGFR40 (1.24 [1.17, 1.31], p<0.001).

**Conclusions:** Long term use of ASA was associated with a trend towards lower ESKD risk, but higher risk of eGFR40 in patients with CKD. The higher risk of eGFR40 may be due to an acute glomerular hemodynamic effect of ASA. The long-term renoprotective benefits of ASA therapy will need to be examined in clinical trials.

### The Effect of Randomized Beta-Carotene Supplementation on CKD in Men

Api Chewcharat,<sup>1</sup> Julie E. Buring,<sup>2</sup> Howard D. Sesso,<sup>2</sup> Kathryn Rexrode,<sup>2</sup> J. Michael Gaziano,<sup>2</sup> Robert J. Glynn,<sup>2</sup> Pol Chewcharat.<sup>3</sup> <sup>1</sup>Mount Auburn Hospital, Cambridge, MA; <sup>2</sup>Brigham and Women's Hospital, Boston, MA; <sup>3</sup>Harvard University T H Chan School of Public Health, Boston, MA.

**Background:** Beta-carotene may protect the body against free radicals that may damage the kidney and lead to the development of acute kidney injury and chronic kidney disease (CKD). Previous studies in animal models have demonstrated a potential protective effect of 30 mg/kg beta-carotene supplementation on renal ischemia/reperfusion injury and subsequently improved kidney function. The extension of these findings to humans, however, remains unclear.

**Methods:** Our study leverages previously collected data from the Physicians' Health Study I (PHS I), a large-scale, long-term, randomized trial of middle-aged and older U.S. male physicians testing 50 mg beta-carotene (BC) every other day for the primary prevention of cardiovascular disease and cancer. We examined the impact of BC supplementation on incident CKD identified by self-reports stating "yes" to kidney disease from annual follow-up questionnaires and ICD-9 codes, including 585.3-585.6 from randomization in 1982 through the end of the randomized BC intervention at the end of 1995. Analyses compared incident CKD between BC supplementation and placebo using Cox proportional hazards regression models. We also examined whether smoking status (current vs former/never smoker) modified the effect of randomized beta-carotene supplementation on CKD.

**Results:** A total of 10,947 participants were randomized to BC, and 10,965 participants were randomized to a placebo group. Baseline characteristics between randomized BC groups were similar. There was no significant association between BC supplementation and self-reported incident CKD after adjusting for age and randomized aspirin assignment (HR = 1.11, 95% CI [0.70, 1.76], p-value = 0.66). Stratified by smoking status, there was no significant association between BC supplementation and self-reported incident CKD either among former/never smoker (HR = 0.88, 95%CI [0.53, 1.47], p-value = 0.62) or current smoker (HR = 1.81, 95% CI [0.44, 7.71], p-value = 0.41). Smoking status did not modify the association between BC supplementation and incident CKD (p-interaction = 0.37).

**Conclusions:** Long-term randomized BC supplementation did not affect the risk of incident CKD in middle-aged and older male physicians.

## SA-PO911

## Associations Between Risperidone Use and Kidney Function Decline in Patients With Schizophrenia

Megumi Oshima, Tadashi Toyama, Hisayuki Ogura, Shiori Nakagawa, Taro Miyagawa, Shinji Kitajima, Akinori Hara, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada. *Kanazawa Daigaku Daigakuin Iyaku Hokengaku Sogo Kenkyuka Iyaku Hoken Gakuiki Igakurui, Kanazawa, Japan.*

**Background:** We have previously reported that the gut microbiota produces D-amino acids, and some acids have protective effects against acute kidney injury in mice. Risperidone is used as an atypical antipsychotic agent for schizophrenia and also known to inhibit the activity of D-amino acid oxidase. We thus hypothesized that risperidone may prevent kidney disease progression by enhancing the effects of D-amino acids and assessed the associations of risperidone use with kidney function decline in patients with schizophrenia.

**Methods:** This is a retrospective case-control study which included patients who were diagnosed with schizophrenia and had more than two measurements of serum creatinine at Kanazawa University Hospital between April 2010 and March 2020. Among them, 212 patients used risperidone for 30 days or more (risperidone group), while 1479 patients had no record of risperidone use (control group). The study outcome was a 40% decline in eGFR. Cox regression model was used to estimate the risk of kidney function decline.

**Results:** The mean( $\pm$ SD) age was 55 $\pm$ 19 years, 759 (45%) were men, and mean eGFR was 88 $\pm$ 35 mL/min/1.73 m<sup>2</sup> at baseline. Both groups had similar baseline characteristics except for age: the risperidone group was younger than the control group (52 vs 56 years,  $p=0.006$ ). During a mean follow-up of 1.6 years, 267 patients (16%) had a 40% eGFR decline. The incidence rate of a 40% eGFR decline was lower in the risperidone group than the control group (60 vs 104 per 1000 person-years). Compared with control, risperidone use was associated with a reduced risk of a 40% eGFR decline (HR 0.54, 95% CI 0.34 to 0.85,  $p=0.008$ ). Similar association was observed after adjustment for baseline age, sex, and eGFR (0.54, 0.33 to 0.87,  $p=0.01$ ).

**Conclusions:** Risperidone use was associated with a reduced risk of kidney function decline in patients with schizophrenia.

## SA-PO912

## High-Density Lipoprotein Lipidomics Across the Spectrum of Kidney Dysfunction

Benjamin Lidgard,<sup>1</sup> Andrew N. Hoofnagle,<sup>1</sup> Leila R. Zelnick,<sup>1</sup> Bryan R. Kestenbaum,<sup>1</sup> Ian H. de Boer,<sup>1</sup> Cassianne Robinson-Cohen,<sup>2</sup> Amanda M. Fretts,<sup>1</sup> Rozenn Lemaitre,<sup>1</sup> Nisha Bansal.<sup>1</sup> <sup>1</sup>University of Washington, Seattle, WA; <sup>2</sup>Vanderbilt University, Nashville, TN.

**Background:** Patients with CKD are known to have dysfunctional high-density lipoprotein (HDL), with impaired cholesterol efflux and anti-inflammatory properties. Differences in the lipid composition of HDL particles in these patients may in part be responsible for these impaired functions.

**Methods:** We studied 499 CKD participants from the Seattle Kidney Study. In each participant, HDL was isolated from serum, and targeted lipidomics were used to quantify amounts of ceramides, sphingomyelins, and phosphatidylcholines composing HDL. We evaluated the cross-sectional associations of estimated GFR (modeled continuously, per 15-point decrement) and natural log-adjusted albuminuria with individual lipids and lipid classes using multiple linear regression, adjusting for confounding characteristics and accounting for multiple comparisons at a false discovery rate of 5%.

**Results:** After adjustment, eGFR was not significantly associated with classes of lipids or individual lipids present in HDL. In contrast, natural log-transformed albuminuria was significantly associated with higher HDL levels of ceramides, short-chain sphingomyelins, glucosylceramide 16:0, and sphingomyelin 16:0, and phosphatidylcholine 30:1 (Figures).

**Conclusions:** Albuminuria, but not eGFR, was significantly associated with specific alterations in the lipid composition of HDL in participants with HDL. Further studies investigating the functional consequences of these differences are warranted.

**Funding:** NIDDK Support

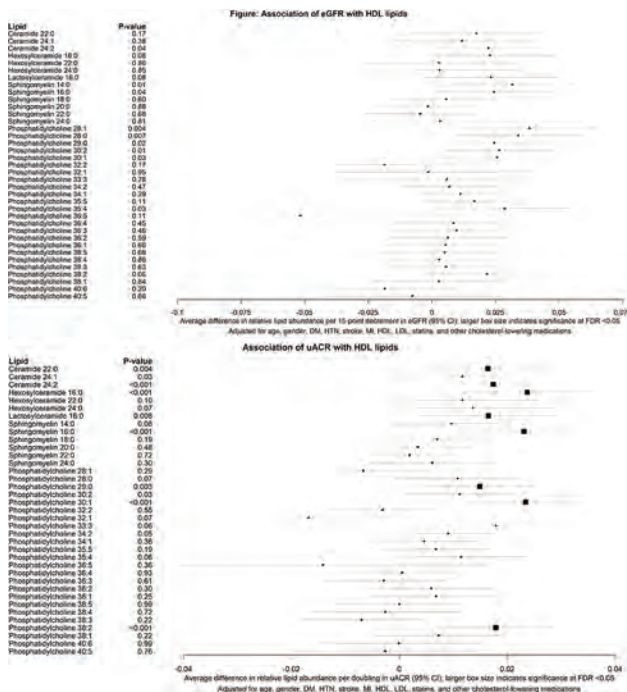

Table: Association between eGFR, albuminuria and levels of various classes of lipids

	eGFR (per 15-point decrement)		Natural log-adjusted albuminuria (per SD-increase)	
	Beta (95% CI)	p-value	Beta (95% CI)	p-value
Ceramides	0.05 (-0.10, 0.21)	0.50	<b>0.32 (0.07, 0.56)</b>	<b>0.01</b>

## Impact of Using the 2021 CKD-EPI Creatinine Equation on Clinical and Surrogate End Points in Trials

Juhi Chaudhari,<sup>1</sup> Shiyuan Miao,<sup>1</sup> Hocine Tighiouart,<sup>2</sup> Lesley A. Inker.<sup>1</sup> Chronic Kidney Disease-Epidemiology Collaboration: Clinical Trials <sup>1</sup>Tufts Medical Center, Boston, MA; <sup>2</sup>Tufts Clinical and Translational Science Institute, Boston, MA.

**Background:** The new 2021 CKD-EPI creatinine GFR estimating equation that does not include a term for Black race is now recommended to replace the 2009 CKD-EPI creatinine equation in the US. We evaluated the impact of using the 2021 vs 2009 equation on treatment effects of GFR slope and on time-to-confirmed 40% decline in GFR in three past randomized trials.

**Methods:** In the SPRINT (low vs usual blood pressure control), IDNT (RAS blocker vs calcium channel blocker), and EMPA-REG Outcomes (SGLT2 inhibitor vs placebo) trials, we estimated GFR using the CKD-EPI 2009 and 2021 creatinine equations and computed total GFR slope (randomization to 3 years) as well as chronic slope (excluding the initial 3 months post-randomization) in the whole study as well as in Black and non-Black race groups. We estimated treatment effects on GFR slope as the mean difference in GFR slope between the randomized groups and treatment effects on a composite of time-to-confirmed 40% decline in GFR, GFR<15 mL/min per 1.73 m<sup>2</sup> and end-stage kidney disease using Cox proportional hazard regressions.

**Results:** The mean baseline GFR using the 2009 and 2021 equations are shown in Figure 1, along with the treatment effects on GFR slopes and on the time-to-event outcome. As expected, GFRs were lower for Black individuals using the 2021 equation compared to 2009. The treatment effects on the three outcomes did not meaningfully differ when using the two equations for each study and for Black and non-Black race groups.

**Conclusions:** Substituting the 2021 CKD-EPI equation for the 2009 equation had minimal numerical impact on the estimated treatment effects on GFR slope and on time-to-confirmed 40% decline in GFR in three past studies as a whole or in the Black race subgroup. It is reasonable to apply the new GFR equation in the design of future trials.

**Funding:** Private Foundation Support

### Cannabis Use and CKD: Epidemiological Associations and Mendelian Randomization

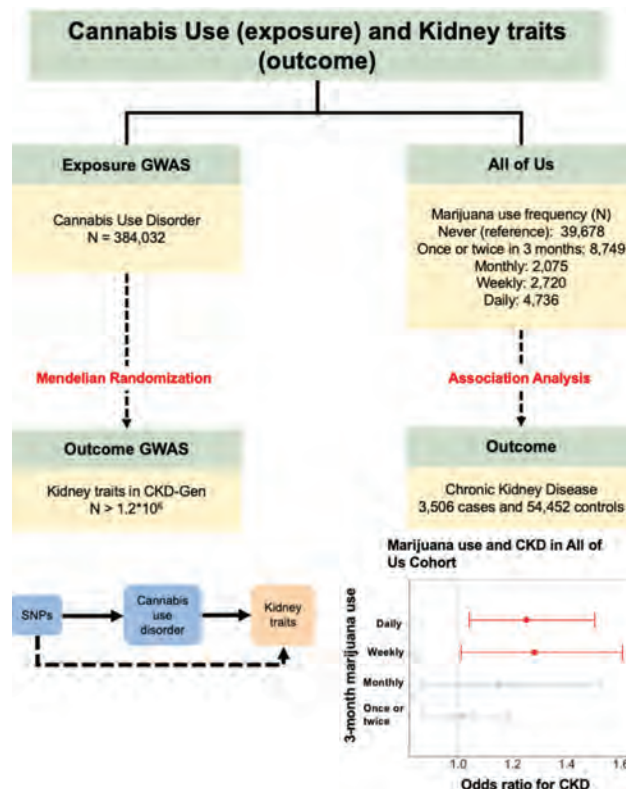

Sergio Dellepiane, Faris F. Gulamali, Lili Chan, Joshua L. Rein, Ron Do, Steven G. Coca, Benjamin S. Glicksberg, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY.*

**Background:** The association between cannabis use and chronic kidney disease (CKD) is controversial. We aimed to assess association of kidney traits with cannabis use in one of the largest cohort studies in the United States and then assess causality using Mendelian Randomization (MR) with genome wide association study (GWAS) summary statistics

**Methods:** In the retrospective study (n=315,297) we conducted an association analysis to test for frequency of cannabis use and CKD. To evaluate causal associations, we performed a two sample MR from a GWAS of cannabis use disorder (n=384,032 – exposure GWAS) and an outcome GWAS of CKD (n=1.2 million).

**Results:** In the observational study, compared to never users, less than monthly (OR 1.01, 95% CI 0.87 – 1.18 p = 0.867) and monthly cannabis users (OR 1.15, 95% CI 0.86 – 1.15, p = 0.327) did not have higher CKD odds. Conversely, weekly (OR 1.28, 95% CI 1.01 – 1.60, p = 0.0355) and daily use (OR 1.25, 95% CI 1.04 – 1.50, p = 0.018) were significantly associated to CKD, adjusted for multiple confounders. In MR, genetic liability to cannabis use disorder was not associated with increased odds for CKD (OR=1.00, 95% CI: 0.99 – 1.01, P=0.96). These results were robust across different MR techniques and considering multiple kidney related traits (cystatin-C and creatinine-based kidney function, proteinuria, and blood urea nitrogen).

**Conclusions:** We conducted the largest observational study to date and the first MR about the association between cannabis and CKD. Although there was an epidemiological association between frequent cannabis use and CKD, there was no evidence of a causal association indicating confounding in observational studies.

## SA-PO915

### CT-Based Radiomic Feature Analysis for Identifying Baseline Kidney Function in Patients With Underlying CKD

Seongho Jo,<sup>1</sup> Kipyoo Kim.<sup>2,1</sup> <sup>1</sup>Department of Internal Medicine, Inha University Hospital, Incheon, Republic of Korea; <sup>2</sup>Department of Internal Medicine, Inha University College of Medicine, Incheon, Republic of Korea.

**Background:** Decreased kidney size and cortical thickness were known as indicators for chronic changes in kidney, but the diagnostic accuracy was relatively low. Radiomics is a promising approach for quantitative analysis of various medical images. In this study, we investigated CT-based radiomic feature analysis for identifying baseline kidney function in patients with underlying chronic kidney disease (CKD).

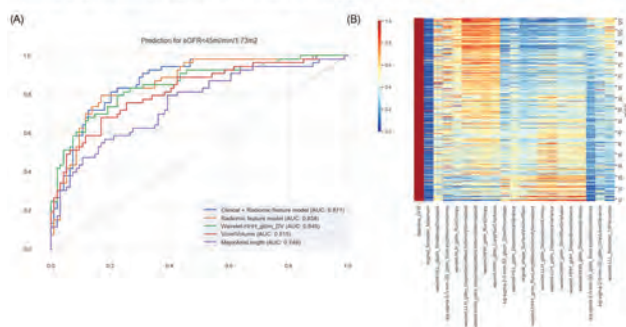

**Methods:** A total of 487 patients who underwent a non-enhanced CT scan of the abdomen were included in the main analysis. Three-dimensional kidney segmentation was performed using semi-automated tools. A total of 1218 radiomic features were extracted using the PyRadiomics package, including shape features (n=14), original first order features (n=108), texture features (n=408), and wavelet features (n=688). We perform feature selection (n=20) using maximum-relevance minimum-redundancy methods. A prediction model for baseline kidney function was developed and validated using the XGBoost algorithm. For kidney biopsy findings within 3 months before and after CT scan, the association between selected radiomic features and chronic pathological findings was also examined.

**Results:** Conventional markers of CKD showed relatively low diagnostic accuracy (major axis length, AUC 0.75; kidney volume, AUC 0.82). The wavelet-HHH glcm dependence variance was the most predictive radiomic feature for eGFR <45ml/min/1.73m<sup>2</sup> (AUC 0.85). A multivariable predictive model only with radiomic features revealed an improved performance (AUC 0.86). Finally, a model combined with clinical and radiomic features showed the best performance (AUC 0.87). Most selected radiomic features were highly correlated with baseline kidney function, and several wavelet transform features for texture showed a high AUC value for the presence of severe interstitial fibrosis and tubular atrophy.

**Conclusions:** Our findings indicate that CT-based radiomics feature analysis can provide a more accurate predictive model for CKD than traditional morphological markers.

**Figure 1.** The performance of predictive model for eGFR <45 ml/min/1.73m<sup>2</sup> and the characteristics of the selected radiomic features. (A) The receiver operating characteristic curves of predictive models with different types of features. (B) The heatmap of selected radiomic features ordered vertically according to the baseline kidney function.

### Sixteen Weeks of High Amylose-Resistant Starch Supplementation Leads to a Reduction in p-Cresyl-Sulphate in Predialysis Patients

Sam A. Headley,<sup>1</sup> Donna J. Chapman,<sup>1</sup> Karen Madsen,<sup>4</sup> Elizabeth E. Evans,<sup>1</sup> Allen Cornelius,<sup>5</sup> Emily Miele,<sup>1</sup> Kristyn Kirton,<sup>1</sup> Joshua D. Loseke,<sup>1</sup> Brian J. Martin,<sup>6</sup> Talat Alp Ikizler,<sup>3</sup> Michael J. Germain.<sup>2</sup> <sup>1</sup>Springfield College, Springfield, MA; <sup>2</sup>Baystate Medical Center, Springfield, MA; <sup>3</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>4</sup>University of Alberta, Edmonton, AB, Canada; <sup>5</sup>Fielding Graduate University, Santa Barbara, CA; <sup>6</sup>University of Pittsburgh, Pittsburgh, PA.

**Background:** Patients with chronic kidney disease (CKD) have high levels of systemic inflammation and oxidative stress. The current study was designed to determine the effect of 16 weeks of supplementation with high amylose resistant starch (HAM-RS2) on the microbiota and biomarkers indicative of inflammation, oxidative stress, and uremic toxins in stage 3-4 patients with CKD.

**Methods:** This was a double-blind, placebo controlled, parallel arm, randomized controlled trial. Sixty-eight participants were randomized to one of two groups: HAM-RS2 & usual care (RS2) or placebo (cornstarch) & usual care (Con). RS2 was provided as Hi-Maize® 260 RS. For week 1, the dose of supplements was 15 grams/day. The dose was then increased to 33 grams/day for weeks 2-16. Participants attended two baseline (BL) sessions with follow up visits 8 (wk8) and 16 weeks (wk16) later. Fasting blood samples were collected at BL, wk8 and wk16. A stool sample was collected for analysis of microbial composition using 16s RNA sequencing at BL and wk16. The blood samples were analysed for interleukin 6, interleukin 10, tumor necrosis factor alpha, c reactive protein, monocyte chemoattractant protein-1, malondialdehyde, 8-isoprostanes F2a, indoxyl sulphate (IS), and p-cresyl sulphate (PCS).

**Results:** Sixty-five patients completed the study (RS2 = 33, Con = 32). RS2 led to a significant increase in the levels of butyrate producing bacteria. RS2 also led to a significant reduction in PCS (mg/dl): (BL, 3.75 ± 2.88, wk8 3.34 ± 2.65, wk16 2.88 ± 1.78)  $\chi^2(2) = 8.74$ ,  $p = .02$ , while the control group did not change (BL 3.01 ± 2.18, wk8 2.62 ± 1.71, wk16 3.13 ± 2.52)  $\chi^2(2) = 1.13$ ,  $p = .57$ . Post hoc analysis indicated that the change from baseline to 16 weeks for PCS in the RS2 group was significant ( $p = .02$ ). IS followed a similar pattern but did not reach statistical significance. In addition, RS2 did not lead to any significant changes in inflammatory or oxidative stress markers.

**Conclusions:** Supplementation with RS2 led to a reduction in PCS in our sample of patients with CKD. Since high levels of PCS are associated with increased mortality and progression of CKD, our finding has important clinical implications.

**Funding:** Commercial Support - Ingredion donated the resistant starch and the placebo that was used in this study

### Ticagrelor Is Superior to Clopidogrel in Inhibiting Platelet Aggregation in Patients With Stages 4-5 CKD

Otis Davis,<sup>1</sup> Junqiang Dai,<sup>2</sup> Nishank Jain.<sup>1</sup> <sup>1</sup>University of Arkansas for Medical Sciences, Little Rock, AR; <sup>2</sup>University of Kansas School of Medicine, Kansas City, KS.

**Background:** Although the more potent ticagrelor was shown to be superior to clopidogrel in reducing thrombotic events and mortality in a subgroup of PLATO trial non-dialysis participants with stage 4-5 CKD, post-marketing studies failed to demonstrate similar benefits among CKD population. Studies exploring the antiplatelet effects of ticagrelor in CKD have been limited by the lack of a control arm, high drop-out rates and lack of randomization. There are no RCT to dissect antiplatelet effects of ticagrelor vs. clopidogrel in CKD.

**Methods:** We conducted a mechanistic, double-blind, RCT to compare ADP-induced platelet aggregation on treatment with ticagrelor vs. clopidogrel in 48 people with CKD. In a parallel arm, we investigated the pharmacokinetics and the antiplatelet effects of ticagrelor among CKD and non-CKD controls (n=26).

**Results:** The population of our study was diverse- mean age 53.7 years, 62% women, 54% African American, mean GFR 16 ml/min/1.73m<sup>2</sup>. Ticagrelor was found to be

statistically superior to clopidogrel at inhibiting ADP-induced WBPA ( $87 \pm 22\%$  vs.  $63 \pm 50\%$  inhibition of platelet aggregation;  $P=0.04$ ), while the difference in post-treatment values remained significant when adjusting for diabetes (ANCOVA  $P=0.002$ ). There were no differences in the percent inhibition of ADP-induced platelet aggregation between CKD ( $87 \pm 22\%$ ) and controls ( $77 \pm 29\%$ ),  $P=0.14$ . This coincided with no difference in the pharmacokinetics of ticagrelor and its metabolite between CKD and controls.

**Conclusions:** Our findings provide mechanistic evidence for the greater efficacy of ticagrelor over clopidogrel in patients with stage 4-5 CKD.

**Funding:** Private Foundation Support

### Treatment With Nicotinamide Riboside Alters Systemic Mitochondrial Metabolism Without Impacting Exercise Capacity in Patients With CKD

Armin Ahmadi,<sup>1</sup> Gwenaëlle Begue,<sup>2</sup> Ana P. Valencia,<sup>3</sup> Jennifer E. Norman,<sup>1</sup> David J. Marcinek,<sup>3</sup> Matthew P. Van Doren,<sup>4</sup> David K. Prince,<sup>3</sup> Bryan R. Kestenbaum,<sup>3</sup> Baback Roshanravan.<sup>1</sup> <sup>1</sup>University of California Davis, Davis, CA; <sup>2</sup>California State University Sacramento, Sacramento, CA; <sup>3</sup>University of Washington, Seattle, WA; <sup>4</sup>Fred Hutchinson Cancer Research Center, Seattle, WA.

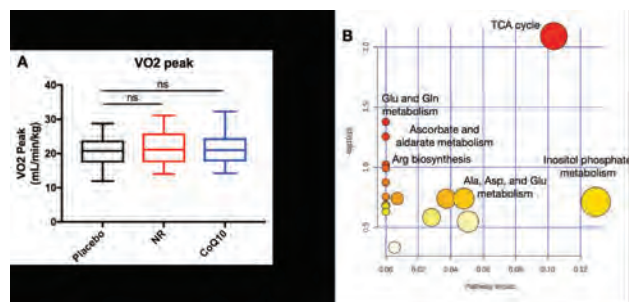

**Background:** The impact of therapies that target mitochondrial function in CKD is still unknown. We conducted a clinical trial of coenzyme Q10 (CoQ10) and nicotinamide riboside (NR) to determine their impact on endurance exercise capacity and metabolic profile in CKD patients.

**Methods:** We conducted a placebo-controlled, double blind, cross-over trial with 3 arms: placebo, CoQ10, and NR. Adults aged between 30-79 with moderate-severe CKD (N=25), eGFR of <60ml/min/1.73m<sup>2</sup>, were recruited. Subjects received NR (1000 mg/day) or CoQ10 (1200 mg/day) for 6 weeks. Maximal aerobic capacity (VO<sub>2</sub> peak) was assessed using a graded cycle exercise test. Plasma samples underwent semi-targeted metabolomics profiling using gas chromatography. Impact of treatment on VO<sub>2</sub> peak was assessed statistically using ANOVA. Linear mixed effects modeling was used to estimate differences in plasma metabolites

**Results:** Participants mean age was 61.0±11.6 with a mean eGFR of 36.9±9.2. Females comprised 40% of the cohort with a 16% prevalence of diabetes. CoQ10 and NR treatment had no impact on VO<sub>2</sub> peak ( $p=0.37$ ,  $p=0.38$  respectively) (Figure 1A). A total of 13 out of the 98 detected metabolites were significantly altered in response to NR treatment. These metabolites were predominantly involved in TCA cycle and amino acid metabolism (Figure 1B). All noted metabolites significantly increased compared to placebo except for two TCA cycle intermediates ( $\alpha$ -KG and malate). Only 2 metabolites were significantly altered post CoQ10 treatment compared to placebo.

**Conclusions:** NR treatment alters systemic mitochondrial metabolism but had no meaningful impact on aerobic capacity in CKD. Future studies will focus on treatment associated changes in the mitochondrial transcriptome and other performance-based outcomes.

**Funding:** NIDDK Support

**Figure 1.** Impact of CoQ10 and NR on VO<sub>2</sub> peak compared to placebo (A). Pathway analysis of changes with NR treatment compared to placebo (B).

### Results of Phase 2 MERLIN: An Evaluation of Safety, Tolerability, and Efficacy of Bardoxolone Methyl in Patients With Rapidly Progressing CKD

Pablo E. Pergola,<sup>1</sup> Laura Kooienga,<sup>2</sup> Angie Goldsberry,<sup>3</sup> Colin J. Meyer,<sup>3</sup> Arnold L. Silva,<sup>4</sup> Samina Khan.<sup>3</sup> <sup>1</sup>Renal Associates PA, San Antonio, TX; <sup>2</sup>Colorado Kidney Care, Denver, CO; <sup>3</sup>Reata Pharmaceuticals Inc, Irving, TX; <sup>4</sup>Boise Kidney and Hypertension Institute, Meridian, ID.

**Background:** Bardoxolone methyl (Bard) is an investigational drug that activates Nrf2. Improvements in eGFR, creatinine clearance, and inulin clearance have been observed with Bard treatment in multiple clinical trials in patients with CKD of various etiologies like Alport syndrome, ADPKD, IgA nephropathy and DKD.

**Methods:** MERLIN (NCT04702997) was a multi-center, randomized, double-blind, placebo-controlled, phase 2 trial that enrolled patients with CKD of multiple etiologies at risk of rapid kidney disease progression (rate of eGFR decline  $\geq 4$  mL/min/1.73 m<sup>2</sup> in prior year or urine albumin-to-creatinine ratio  $\geq 300$  mg/g or persistent hematuria). Patients 18-75 years of age with eGFR  $\geq 20$  to  $< 60$  mL/min/1.73m<sup>2</sup> were randomized 1:1 to receive Bard or placebo. Patients with BNP  $> 200$  pg/mL at screening visit were excluded. The primary efficacy endpoint was the change from baseline (CFB) in eGFR at Week 12. To assess the exploratory objective of characterizing change in eGFR during the off-treatment (OT) period, serial eGFR was assessed at 3, 7, 14, 21, 28, and 35 days after last dose of Bard. Safety endpoints included lab results, vital signs, ECG, weight, and AEs.

**Results:** Eighty-one patients were treated with Bard (n=39) or placebo (n=42). Baseline eGFR was 35.7 $\pm$ 9.9 mL/min/1.73m<sup>2</sup> (mean $\pm$ SD), with 68 patients (84%) having eGFR  $< 45$  mL/min/1.73 m<sup>2</sup>. The CFB in eGFR after 12 weeks of treatment was 6.79 $\pm$ 0.93 (mean $\pm$ SE) in patients treated with Bard as compared to -0.92 $\pm$ 0.87 (mean $\pm$ SE) mL/min/1.73m<sup>2</sup> in patients treated with placebo (p<0.0001). Mean eGFR CFB for patients on Bard declined once it was discontinued and stabilized at 1.58 $\pm$ 0.83 (mean $\pm$ SE) mL/min/1.73m<sup>2</sup> by Day 21 OT, with no further decline after that. Most TEAEs were mild to moderate in severity. Those reported in  $> 5\%$  of patients in either treatment group were muscle spasms, nausea and decrease in weight.

**Conclusions:** Consistent with previous studies of patients treated with Bard, the 12-week treatment in the MERLIN study resulted in significant increases in eGFR in patients taking Bard when compared with placebo. The acute eGFR increase associated with Bard was resolved by Day 21 OT. Bard was found to be safe and well tolerated. Overall, no new safety signals emerged during the study.

**Funding:** Commercial Support - Reata Pharmaceuticals, Inc

### Evaluating GFR Slope as a Surrogate End Point Across Diseases

Willem H. Collier,<sup>1</sup> Benjamin Haaland,<sup>1</sup> Lesley A. Inker,<sup>2</sup> Hiddo J. L. Heerspink,<sup>3</sup> Tom Greene.<sup>1</sup> Chronic Kidney Disease Epidemiology Collaboration <sup>1</sup>University of Utah Health, Salt Lake City, UT; <sup>2</sup>Tufts Medical Center, Boston, MA; <sup>3</sup>Universitair Medisch Centrum Groningen Afdeling Cardiologie, Groningen, Netherlands.

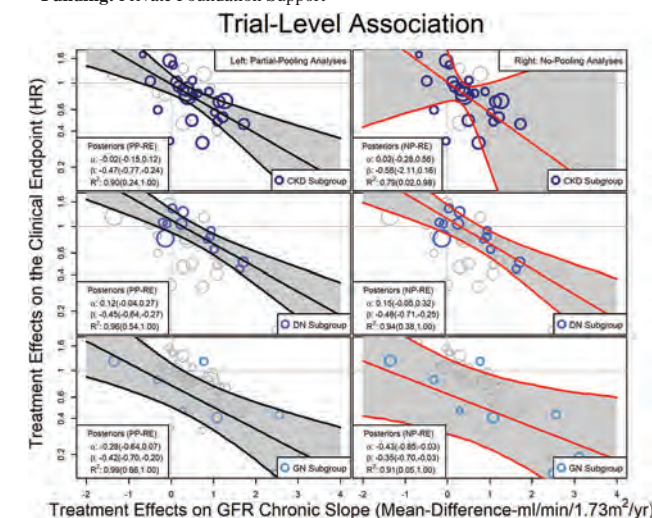

**Background:** We have previously demonstrated that treatment effects on GFR slope can be used to accurately predict treatment effects on time-to-kidney failure (KFRT) in randomized CKD trials. It has been hypothesized that accuracy can vary by sub-categories of disease. Yet, low statistical power in subgroups can challenge the interpretation of subgroup-to-subgroup variability in GFR slope as a surrogate.

**Methods:** We performed analyses on N=47 previously conducted CKD trials. For each trial, we estimated treatment effects on time-to-KFRT using proportional hazards models and treatment effects on GFR chronic slope using mixed-effects models. Meta-regression methods were used to assess the strength of the association between treatment effects on the separate endpoints within three disease-defined subgroups: Diabetes (DN), glomerular diseases (GN), and CKD without diabetes (CKD). We used a novel Bayesian modeling approach (partial-pooling) to facilitate improved precision in our estimation of model parameters. The results were contrasted with those obtained using an earlier no-pooling approach.

**Results:** Relative to no-pooling, the partial-pooling model improved precision in parameter estimates key to the interpretation of the surrogate (see the 95% credible intervals in Figure 1 legends). The partial-pooling model also improved prediction of treatment effects on time-to-KFRT (see narrower confidence bands on the left of Figure 1).

**Conclusions:** On a collection of CKD trials, use of a novel meta-regression approach for surrogate evaluation indicated homogeneity in the quality of GFR chronic slope across subgroups of trials defined by disease.

**Funding:** Private Foundation Support

$\alpha$ : Meta-regression intercept  $\beta$ : Meta-regression slope. We display meta-regression lines as well as the upper and lower confidence bands in grey (partial-pooling) and red (no-pooling). Grey circles are trials not in the featured disease-defined subgroup.

## SA-PO921

### Accuracy of CKD-EPI GFR Estimating Equations According to the Difference in eGFR Using Cystatin C vs. Creatinine

Yeli Wang, Chronic Kidney Disease-Epidemiology Collaboration Harvard University T H Chan School of Public Health, Boston, MA.

**Background:** Estimated glomerular filtration rate (eGFR) using cystatin C is recommended as a confirmatory test, with eGFRcr-cys more accurate than eGFRcys. A large difference between eGFRcys and eGFRcr (eGFRdiff) likely indicates a substantial divergence from usual in the non-GFR determinants of cystatin C, creatinine or both and a potential large error in either eGFR compared to measured GFR (mGFR). However, it is not known whether eGFRcys or eGFRcr-cys is more correct. We aimed to evaluate the performance of eGFRcr, eGFRcys, and eGFRcr-cys compared to mGFR according to the magnitude of eGFRdiff.

**Methods:** We assessed the CKD-EPI 2021 eGFRcr and eGFRcr-cys, and 2012 eGFRcys among 4,050 participants from 12 studies included in the CKD-EPI 2021 external validation dataset. eGFRdiff was defined as eGFRcys minus eGFRcr. The negative, reference, and positive eGFRdiff categories were defined as  $< -15$ ,  $-15$  to  $< 15$ , and  $\geq 15$  mL/min per 1.73 m<sup>2</sup>, respectively. We compared bias (median difference in mGFR minus eGFR), P<sub>30</sub> (percentage of eGFR within 30% of mGFR), and concordance between eGFR and mGFR categories ( $< 30$ , 30-59, 60-89,  $\geq 90$  mL/min/1.73m<sup>2</sup>) according to eGFRdiff categories.

**Results:** In the overall cohort, mean (SD) GFR, age and BMI were 76.4 (29.6) mL/min/1.73m<sup>2</sup>, 57.0 (17.4) years and 26.9 (5.00) kg/m<sup>2</sup>, respectively. As reported before, eGFRcr-cys in the overall dataset had greater accuracy (higher P<sub>30</sub> and greater concordance) than eGFRcr or eGFRcys. In the reference eGFRdiff category, all equations displayed similar performance (small differences in bias, similar P<sub>30</sub> and concordance). In both negative and positive eGFRdiff categories, eGFRcr-cys generally had better performance (lesser bias, higher P<sub>30</sub> and higher concordance) than eGFRcr and eGFRcys (Table). These results were consistent across subgroups of age, sex, and BMI.

**Conclusions:** In ambulatory clinical settings eGFRcr-cys is more likely to be correct than either eGFRcr or eGFRcys across sex, age, and BMI groups. Future work should evaluate whether clinician knowledge of non-GFR determinants provides more informative decision making.

**Funding:** NIDDK Support

	Total population	eGFRdiff group (eGFRcys-eGFRcr) category		
		Negative ( $< -15$ ) (eGFRcr higher)	Reference (-15 to $< 15$ )	Positive ( $\geq 15$ ) (eGFRcys higher)
Sample size	4,050 (100%)	851 (21.9%)	2,811 (69.2%)	388 (9.8%)
Age, y	57.0 $\pm$ 17.3	60.4 $\pm$ 17.3	57.1 $\pm$ 17.5	48.7 $\pm$ 13.8
Female, %	1,557 (38.4%)	314 (36.8%)	1,111 (39.7%)	132 (33.1%)
Body mass index, kg/m <sup>2</sup>	26.9 $\pm$ 5.00	27.6 $\pm$ 5.64	26.8 $\pm$ 4.74	28.6 $\pm$ 4.49
eGFRcr				
Bias, median difference (mL/min/1.73 m <sup>2</sup> )	-3.05 (-1.46, -2.63)	-13.3 (-14.5, -12.2)	-1.96 (-2.45, -1.49)	8.60 (7.20, 10.7)
Accuracy, P <sub>30</sub>	87 (86.88)	70 (86.73)	91 (90.92)	88 (85.91)
Agreement with mGFR	70 (69.72)	58 (54.61)	76 (74.77)	58 (55.83)
eGFRcys				
Bias, median difference (mL/min/1.73 m <sup>2</sup> )	0.60 (0.09, 1.03)	9.91 (9.138, 11.15)	-0.54 (-0.98, -0.11)	-13.4 (-15.5, -11.8)
Accuracy, P <sub>30</sub>	88 (87.89)	83 (80.55)	91 (90.92)	77 (73.81)
Agreement with mGFR	71 (70.72)	58 (55.62)	76 (74.77)	64 (59.88)
eGFRcr-cys				
Bias, median difference (mL/min/1.73 m <sup>2</sup> )	-2.51 (-2.89, -2.14)	-0.77 (-1.74, 0.126)	-2.67 (-3.09, -2.24)	-5.07 (-6.84, -3.70)
Accuracy, P <sub>30</sub>	91 (90.92)	74 (73.76)	91 (90.92)	82 (89.94)
Agreement with mGFR	74 (73.76)	71 (68.78)	76 (74.77)	69 (64.74)

\*Bias was expressed as the median difference in measured GFR minus estimated GFR (95% confidence interval). A negative bias indicates overestimation of the measured GFR, and a positive bias indicates underestimation of the measured GFR.  
\*Accuracy (P<sub>30</sub>) was defined as the percentage of individuals with estimated GFR within 30% of measured GFR (95% confidence interval).  
\*Abbreviations: eGFRcr, creatinine-based estimated GFR; eGFRcys, cystatin C-based estimated GFR; eGFRcr-cys, estimated GFR based on creatinine and cystatin C; GFR, glomerular filtration rate.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

## Using the Difference in Estimated Glomerular Filtration Rate by Cystatin C vs. Creatinine to Improve the Ability to Predict the Competing Risk of Death or ESKD

O. Alison Potok,<sup>1,4</sup> Stein I. Hallan,<sup>2</sup> Joachim H. Ix,<sup>1,4</sup> Ronit Katz,<sup>3</sup> Nisha Bansal,<sup>3</sup> Dena E. Rifkin,<sup>1,4</sup> <sup>1</sup>University of California San Diego, La Jolla, CA; <sup>2</sup>Norges teknisk-naturvitenskapelige universitet, Trondheim, Norway; <sup>3</sup>University of Washington, Seattle, WA; <sup>4</sup>VA San Diego Healthcare System, San Diego, CA.

**Background:** Glomerular filtration rate (GFR) can be estimated using serum creatinine or cystatin C. Prior research shows that a greater negative difference in estimated GFR by cystatin C vs. creatinine (eGFRDiff = eGFRcys - eGFRcr) associates with frailty, hospitalizations, and mortality. We aimed to determine whether including eGFRDiff into existing predicting tools for kidney failure (KFRE) and mortality risk (MREK) would increase their accuracy in older persons with chronic kidney disease (CKD). We hypothesized that the MREK with eGFRDiff would perform better than the current equation, while the KFRE with eGFRDiff would perform as well as the current equation.

**Methods:** 1146 community-living participants of the Norwegian HUNT study (age >65, eGFRcr < 45 mL/min/1.73m<sup>2</sup>) were evaluated. eGFRDiff was calculated as eGFRcys - eGFRcr using the CKD-EPI 2012 and 2009 equations respectively. Standard KFRE and MREK scores were computed for each participant. Outcomes were end stage kidney disease (ESKD) and death at 5 years. C-statistics were computed for each predictor (KFRE and MREK) with and without the addition of eGFRDiff.

**Results:** Mean  $\pm$ SD age was 80 $\pm$ 7 years, eGFRcr was 36 $\pm$ 8, eGFRcys was 37 $\pm$ 15, and eGFRDiff was 1.04 $\pm$ 12 mL/min/1.73m<sup>2</sup>. Over the 5 year observation period, 60 participants (5%) reached ESKD and 444 died (39%), corresponding to KFRE and MREK predictions of 5 (10) % and 30 (19) %, respectively. Diagnostic accuracy measured as C-statistics [95% confidence interval] were 92.7% [88.9; 96.5] for KFRE alone, 93.5% [90.4; 96.6] for KFRE and eGFRDiff (Figure 1a, p=0.31), 70.6% [67.2; 74.0] for MREK alone, 73.4% [70.1; 76.5] for MREK and eGFRDiff (Figure 1b, p<0.01).

**Conclusions:** The eGFRdiff improves the accuracy of the mortality risk but not the kidney failure risk equation in older patients with advanced CKD. Thus, incorporation of eGFRDiff may improve estimation of the competing risk of death vs. ESKD in older adults.

## Clinical Significance of Serum Creatinine-to-Cystatin C Ratio on Renal Outcomes in Non-Dialysis-Dependent CKD Patients: Results From the KNOW CKD Study

Donghyuk Kang,<sup>1,2</sup> Yaeni Kim,<sup>3,4</sup> <sup>1</sup>Korea University College of Medicine and School of Medicine, Seoul, Republic of Korea; <sup>2</sup>Korea University Guro Hospital, Seoul, Republic of Korea; <sup>3</sup>Catholic University of Korea School of Medicine, Seoul, Republic of Korea; <sup>4</sup>Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea.

**Background:** Sarcopenia is prevalent in CKD patients and is associated with poor clinical outcomes. The assessment of skeletal muscle mass and strength may help in decision-making in patient care, but it is difficult to perform. Recently, the serum creatinine-to-cystatin C ratio has been proposed as a surrogate marker for detecting muscle wasting. We aimed to evaluate the impact of the creatinine-to-cystatin C ratio on renal outcomes in non-dialysis-dependent CKD patients.

**Methods:** In this observational Korean Cohort Study for Outcome in Patients with CKD (KNOW-CKD), 1,452 patients with CKD stages 1-3 were analyzed. Men and women were separately categorized into quartile groups according to their creatinine-to-cystatin C ratio. The primary outcome was a composite of renal outcome consisting of a 50% reduction in estimated glomerular filtration rate (eGFR) or initiation of renal replacement therapy, whichever occurred first. Using Cox regression analysis, the association between the creatinine-to-cystatin C ratio and the primary outcome was analyzed.

**Results:** During a median follow-up of 6.0 (4.3-7.8) years, the primary composite renal outcome occurred in 325 (22%) patients within a median of 4.0 (2.8-5.8) years. After sequential adjustment with 15 variables in the fully adjusted Cox regression model, lower creatinine-to-cystatin C ratio groups (quartiles 1 and 2) had a poor primary outcome compared to the highest group (quartile 4); the hazard ratios for quartiles 1, 2, and 3 compared with quartile 4 were 2.41 (95% confidence interval [CI], 1.61-3.60), 1.93 (95% CI, 1.37-2.72), and 1.40 (95% CI, 0.98-2.01), respectively.

**Conclusions:** Serum creatinine-to-cystatin C ratio is an independent predictor of renal outcomes. A low creatinine-to-cystatin C ratio is associated with poor renal outcome.

## SA-PO924

## Age-Specific Racial Differences in Kidney Failure and Death Following Incident CKD Using the 2021 CKD-EPI Creatinine Equation

Guofen Yan,<sup>1</sup> Robert Nee,<sup>2</sup> Julia J. Scialla,<sup>1</sup> Wei Yu,<sup>1</sup> Tom Greene,<sup>3</sup> Alfred K. Cheung,<sup>3,4</sup> Keith C. Norris,<sup>5</sup> <sup>1</sup>University of Virginia, Charlottesville, VA; <sup>2</sup>Walter Reed National Military Medical Center, Bethesda, MD; <sup>3</sup>University of Utah Health, Salt Lake City, UT; <sup>4</sup>VA Salt Lake City Health Care System, Salt Lake City, UT; <sup>5</sup>University of California Los Angeles, Los Angeles, CA.

**Background:** Recent research suggests that the 2021 CKD-EPI creatinine equation led to smaller estimated disparities in CKD outcomes (kidney failure [KF] and death) between Black and White veterans, but a greater disparity in age of CKD onset. Because the new equation changes estimated GFR (eGFR) for all adult individuals, we examined whether the recently reported racial differences in CKD outcomes based on the new equation also persisted across age groups.

**Methods:** The cohort included 180,881 non-Hispanic White and 32,187 non-Hispanic Black veterans, aged 18-90 years, with incident CKD from 2003-2008 in the US Veterans Health Administration, followed through 2018. Incident CKD was defined by the first time when two eGFR values at >3 months apart were both <60 mL/min/1.73 m<sup>2</sup> using the 2021 CKD-EPI equation. For each age group, we calculated cause-specific hazard ratios (HR) of KF, censoring on death, as well as HRs of death (including death after KF) over 10 years of follow-up for Blacks versus Whites, adjusting for covariates.

**Results:** Upon study entry, Black and White veterans had similar mean eGFRs (50-51 mL/min/1.73 m<sup>2</sup>). However, age distribution at incident CKD differed, with 4% of White veterans being aged 18-55 years, 17% aged 56-65, 29% aged 66-75, and 50% aged 76-90, in contrast to 20%, 32%, 24% and 24% respectively in Black veterans. In the overall cohort, the adjusted risk of KF was 30% greater in Black than White veterans (Table), consistent with a recent report. This greater risk of KF was consistently seen in the younger age groups  $\leq$ 75 years (31%, 36% and 26% greater risk, respectively). In the overall cohort, after adjusting for major confounding of age, along with sex, clinical factors, and comorbidities, Blacks had similar risk of death as White peers; however, this depended on age (Table).

**Conclusions:** The relative risk of KF and death comparing Black and White patients depends on age, which warrants greater understanding of the underlying mechanisms.

**Funding:** NIDDK Support

Adjusted hazard ratios (95% CIs) of CKD outcomes for Black versus White veterans by age group

	Adjusted hazard ratio (95% CI and p value) of kidney failure		Adjusted hazard ratio (95% CI and p value) of death	
Whole cohort	1.30 (1.24-1.37)	<0.0001	1.01 (0.99-1.03)	0.28
Age 18-55	1.31 (1.20-1.44)	<0.0001	0.82 (0.77-0.87)	<0.0001
Age 56-65	1.36 (1.27-1.46)	<0.0001	0.90 (0.87-0.94)	<0.0001
Age 66-75	1.26 (1.13-1.40)	<0.0001	1.01 (0.97-1.04)	0.74
Age 76-90	0.97 (0.81-1.15)	0.71	1.04 (1.01-1.07)	0.008

## Gender-Specific Risk of Atheromatous and Non-Atheromatous Cardiovascular Events in CKD

Anne-Laure Faucon,<sup>1,2</sup> Oriane Lambert,<sup>1</sup> Natalia Alencar de Pinho,<sup>1</sup> Carole Ayav,<sup>10</sup> Christian Combe,<sup>8</sup> Denis Fouque,<sup>4,5</sup> Christian Jacquelinet,<sup>9,1</sup> Maurice Laville,<sup>4,5</sup> Sophie Liabeuf,<sup>6</sup> Roberto Pecoits-Filho,<sup>7</sup> Ziad Massy,<sup>11,1</sup> Nicolas Mansencal,<sup>3,1</sup> Benedicte Stengel.<sup>1,2</sup> CKD-REIN study group <sup>1</sup>Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; <sup>2</sup>Universite Paris-Saclay, Villejuif, France; <sup>3</sup>Department of Cardiology, Hopital Ambroise Pare, Boulogne Billancourt, France; <sup>4</sup>Department of Nephrology, CHU Lyon Sud, Lyon, France; <sup>5</sup>Universite Claude Bernard Lyon 1, Lyon, France; <sup>6</sup>Centre Hospitalier Universitaire Amiens-Picardie, Amiens, France; <sup>7</sup>Arbor Research Collaborative for Health, Ann Arbor, MI; <sup>8</sup>Centre Hospitalier Universitaire de Bordeaux Groupe hospitalier Pellegrin, Bordeaux, France; <sup>9</sup>Agence de la biomedecine, La Plaine Saint-Denis, France; <sup>10</sup>Centre hospitalier regional universitaire de Nancy, Nancy, France; <sup>11</sup>Department of Nephrology, Hopital Ambroise Pare, Boulogne-Billancourt, France.

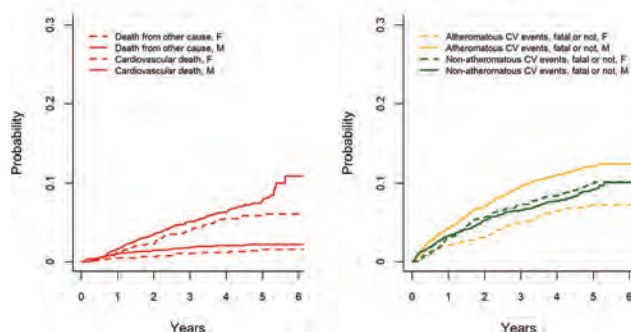

**Background:** The excess risk of atheromatous cardiovascular disease (CVD) in men vs women is well-known in the general population. CKD increases the risks of both atheromatous and non-atheromatous CVD (ACVD, N-ACVD), but gender-related differences in risk by CVD type are poorly documented.

**Methods:** Among 3033 non-dialysis CKD patients included in the CKD-REIN Cohort (65% men; 67 years; eGFR 33 mL/min/1.73m<sup>2</sup>), we reviewed all hospitalization and death reports for CV events. Using criteria from the *Cardiovascular and Stroke Endpoint Definitions for Clinical Trials*, these were classified into fatal and non-fatal ACVD (coronary, cerebral, lower limb artery diseases) and N-ACVD (heart failure, atrial fibrillation). Cause-specific Cox models were used to estimate adjusted hazard ratios for CV death, ACVD and N-ACVD according to gender.

**Results:** At baseline, the prevalence of ACVD was higher in men (46%) than in women (28%), and slightly higher for N-ACVD (33% vs 27%). During a median follow-up of 4.6 [IQR 2.8;5.0] years, 98 (5.0%) men and 43 (4.1%) women died from CVD. The crude risk for ACVD was significantly higher in men than in women, but not that for N-ACVD events and CV death (Figure). Kidney function was more strongly associated with N-ACVD than with ACVD, similarly in both genders. After adjusting for age, CV risk factors, and kidney function, the excess risk of ACVD associated with men was on the borderline of significance, HR: 1.33[1.00;1.77]; there was none for CV death, 0.93[0.58;1.50] and N-ACVD, 0.92[0.71;1.20].

**Conclusions:** In CKD patients, the burden of ACVD is higher in men than in women, and largely explained by their higher prevalence of CV risk factors. In contrast, the risk of N-ACVD appears to be similar in both genders and closely associated with kidney function, suggesting a more prominent role of CKD specific risk factors including volume disorders and uremic toxins.

Cumulative incidence of cardiovascular events, according to gender

## SA-PO926

### Association of suPAR, Galectin-3, and ST2 With CKD Progression in Heart Failure With Reduced Ejection Fraction

Bethany A. Roehm, Jonathan Gordon, Meredith C. McAdams, Pin Xu, Justin Grodin, Susan Hedayati. *The University of Texas Southwestern Medical Center, Dallas, TX.*

**Background:** Patients with heart failure with reduced ejection fraction (HFrEF) are at risk for CKD. Elevated levels of the circulating biomarkers soluble urokinase plasminogen activator receptor (suPAR), Galectin-3, and soluble suppression of tumorigenicity 2 (ST2) have been associated with a greater risk of CKD progression and mortality. However, little is known about the predictive value of these biomarkers in a population with HFrEF and kidney disease.

**Methods:** We aimed to determine whether these biomarkers could be used to predict decline in eGFR in HFrEF and whether they are associated with mortality using a joint longitudinal and cox regression model to account for competing risks of ventricular assist device (VAD) implantation and heart transplantation (OHT). We included 310 participants from the Registry Evaluation of Vital Information for Ventricular Assist Devices in Ambulatory Life with baseline biomarkers and repeated eGFR measures, followed for 2 years. The primary outcome was change in creatinine-based eGFR, adjusted for age, sex, race, diabetes mellitus, and NYHA class. Secondary outcome was mortality, adjusted for the same covariates and change in eGFR.

**Results:** Mean age was 59 years. Median eGFR was 60 mL/min/1.73m<sup>2</sup>. Forty-five participants died, 33 received VAD, and 25 received OHT. Higher baseline plasma suPAR ( $\beta$  coefficient, -0.22 mL/min/1.73m<sup>2</sup>;  $P < 0.001$ ), Galectin-3 (-0.02 mL/min/1.73m<sup>2</sup>;  $P = 0.012$ ), and ST2 (-0.01 mL/min/1.73m<sup>2</sup>;  $P < 0.001$ ) were associated with a decline in eGFR. Only ST2 (HR 1.02 per ng/mL increase;  $P < 0.001$ ) was associated with mortality (Figure).

**Conclusions:** Higher baseline suPAR, Galectin-3, and ST2 were associated with a decrease in eGFR in patients with HFrEF. Only ST2 was associated with increased mortality. These biomarkers may provide prognostic value with regards to kidney disease in HFrEF and may help guide candidacy for potential advanced heart failure therapies.

### Influence of Urine Creatinine Concentration on the Prognostic Value of Proteinuria for Major Adverse Cardiovascular Events in Patients With CKD: Findings From the KNOW-CKD Study

Yun Jung Oh,<sup>1</sup> Kook-Hwan Oh,<sup>2</sup> Ji Yong Jung,<sup>3</sup> H Plus Yangji Hospital, Seoul, Republic of Korea; <sup>2</sup>Seoul National University College of Medicine, Seoul, Republic of Korea; <sup>3</sup>Gachon University Gil Medical Center, Incheon, Incheon, Republic of Korea.

**Background:** Proteinuria is typically quantified according to the spot urine protein-creatinine ratio (UPCR) and an association with cardiovascular events has not been thoroughly investigated in chronic kidney disease (CKD) patients. We investigated whether the severity of proteinuria assessed by spot UPCR is associated with an increased risk for cardiovascular outcomes in the CKD population, and whether the relationship is influenced by urine creatinine concentration.

**Methods:** We analyzed 1,746 patients enrolled as part of The KoreaN cohort study for Outcome in patients With Chronic Kidney Disease (KNOW-CKD). Multivariable Cox proportional hazard analysis was performed to evaluate models with proteinuria as a predictor of renal events and extended major adverse cardiovascular events (eMACEs).

**Results:** Risk for renal events was significantly associated with proteinuria across all eGFR and UPCR categories. By contrast, risk for eMACEs increased significantly with UPCR in patients with eGFR  $\geq 60$  mL/min/1.73 m<sup>2</sup> (hazard ratio [HR] = 2.051; 95% confidence interval [CI] = 1.359–3.096;  $P = 0.001$ ), but not in patients with eGFR  $< 60$  mL/min/1.73 m<sup>2</sup> (HR = 1.083; 95% CI = 0.914–1.283;  $P = 0.358$ ). However, in those with the lower eGFR, risk for eMACEs increased significantly with UPCR in participants with urine creatinine concentration  $\geq 95$  mg/dL (HR = 1.480; 95% CI = 1.045–2.097;  $P = 0.027$ ).

**Conclusions:** In non-dialysis CKD patients, the prognostic value of UPCR for eMACEs is weakened in patients with reduced eGFR levels, for whom it has prognostic significance only in patients with high urine creatinine concentration.

## SA-PO928

### Non-Alcoholic Fatty Liver Disease (NAFLD) Diagnosed by Bioimpedance (BIA) and Heart Failure With Preserved Ejection Fraction (HFpEF) in CKD Stages 1-5 ND

Secundino Cigarrán Guldres,<sup>1</sup> Jose Lomban,<sup>2</sup> Luis E. Pérez Casares,<sup>2</sup> Ana maria Sanjurjo amado,<sup>1</sup> Eva P. Varela,<sup>1</sup> Lucía Grela,<sup>3</sup> Juan Latorre,<sup>3</sup> Jesus Calvino.<sup>4</sup> <sup>1</sup>Nephrology Hospital Publico Da Mariña, Burela, Spain; <sup>2</sup>Cardiology Hospital Publico Da Mariña, Burela, Spain; <sup>3</sup>Renal Research Unit. Hospital Publico Da Mariña, Burela, Spain; <sup>4</sup>Nephrology Hospital Lucas Augusti, Lugo, Spain.

**Background:** NAFLD, the hepatic outcome of metabolic abnormalities such as obesity, insulin resistance or T2DM and dyslipidemia, affects about 25% of the general population worldwide and is associated with an increased incidence of CVD, including impaired cardiac structure and function, endothelial dysfunction and early carotid atherosclerosis. A new tool derived from bioimpedance has emerged to identify NAFLD in the four stages based on the ratio of fat/muscle. The aim of this cross-sectional study is to assess the influence of NAFLD diagnosed by BIA compared to ultrasound in CKD pts with HFpEF.

**Methods:** 219 pts were included with GFR  $44.22 \pm 12.9$  mL/min, UACR  $4419.19 \pm 941.25$  mg/gr crea. 26% women, Age mean  $73.14 \pm 12.2$  yo, 90.4% obese and 50.2% diabetic. BIA (Maltron, London) was performed using the manufacturer software based on the fat/muscle ratio, and echocardiographic HF was performed to determine subclinical left ventricular (LV) systolic dysfunction was defined using values of absolute peak global longitudinal strain (GLS). Analytical tests performed to assess liver function, GFR-EPI and UACR. AGEs by autofluorescence were read by (DiagnOtics, Groningen, Netherlands), and vascular Age was obtained from the Koetsier equation. The concordance between BIA & Liver echography was established in 195 pts with correlation of 96% for healthy and 98% for NAFLD. Data were processed with SPSS 27. A "p value  $< 0.05$  was considered statistically significant.

**Results:** Prevalence of NAFLD was: healthy 9.6%, Grade 1 10.5%, Grade 2 11%, Grade 3 18.7%, Grade 4 50.2%. NAFLD had higher LV filling pressure (E/e' ratio:  $11.37 \pm 7.01$  vs  $10.8 \pm 3.9$ ,  $p < 0.001$ ) and worse absolute GLS ( $-13.69 \pm 4.0\%$  vs  $-14.85 \pm 5.4\%$ ,  $p < 0.001$ ) than non-NAFLD. When adjusted for HF risk factors, diabetes, carotid atherosclerosis or body mass index, NAFLD remained associated with subclinical myocardial remodelling and dysfunction ( $P < 0.01$ ).

**Conclusions:** NAFLD prevalence in CKD pts is 50% and is independently associated with subclinical myocardial remodelling and dysfunction. It provides further insight into a link between NAFLD and HF in CKD pts. BIA is a noninvasive, economic, non-observer tool and of easy use.

**Funding:** Government Support - Non-U.S.

**High-Density Lipoprotein Lipidomics and Risk of Mortality in CKD**  
Benjamin Lidgard,<sup>1</sup> Andrew N. Hoofnagle,<sup>1</sup> Leila R. Zelnick,<sup>1</sup> Bryan R. Kestenbaum,<sup>1</sup> Ian H. de Boer,<sup>1</sup> Cassianne Robinson-Cohen,<sup>2</sup> Amanda M. Fretts,<sup>1</sup> Rozenn Lemaître,<sup>1</sup> Nisha Bansal.<sup>1</sup> <sup>1</sup>University of Washington, Seattle, WA; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN.

**Background:** Patients with CKD are at higher risk for mortality compared to the general population. Abnormalities in the structure and function of high-density lipoprotein (HDL) may contribute to this increased risk. We isolated HDL and utilized targeted lipidomics to identify its ceramide, sphingomyelin, and phosphatidylcholine components in participants with CKD and examined adjusted associations between these lipids and mortality.

**Methods:** We studied 498 participants with CKD from the Seattle Kidney Study. In each participant, HDL was isolated from serum, and targeted lipidomics were used to identify levels of various ceramides, sphingomyelins, and phosphatidylcholines composing HDL. We evaluated the associations between each lipid and mortality using Cox regression adjusted for potential confounders, accounting for multiple comparisons at a false discovery rate of 5%.

**Results:** Over a median (IQR) follow-up time of 5.9 (3.4, 8.9) years, there were 168 deaths. After adjustment, higher HDL composition of ceramide 24:2, glucosylceramide 16:0, and sphingomyelin 16:0 were significantly associated with death (HR per standard deviation greater lipid concentration, 95% CI; 1.31, 1.14-1.51; 1.25, 1.08-1.46; and 1.22, 1.07-1.40; respectively) (Figure).

**Conclusions:** After adjustment, higher HDL concentrations of ceramide 24:2, glucosylceramide 16:0, and sphingomyelin 16:0 were significantly associated with risk of death in patients with CKD. Further studies investigating functional significance for these findings may direct development of future therapies.

**Metabolomics Identifies New Markers of Tubular Secretory Clearance**  
Michael L. Granda,<sup>1,2</sup> David K. Prince,<sup>1,2</sup> Oliver Fiehn,<sup>4</sup> Yan Chen,<sup>3</sup> Andrew N. Hoofnagle,<sup>1</sup> Bryan R. Kestenbaum.<sup>1,2</sup> <sup>1</sup>University of Washington, Seattle, WA; <sup>2</sup>Kidney Research Institute, Seattle, WA; <sup>3</sup>Analysis Group Inc, Los Angeles, CA; <sup>4</sup>University of California Davis, Davis, CA.

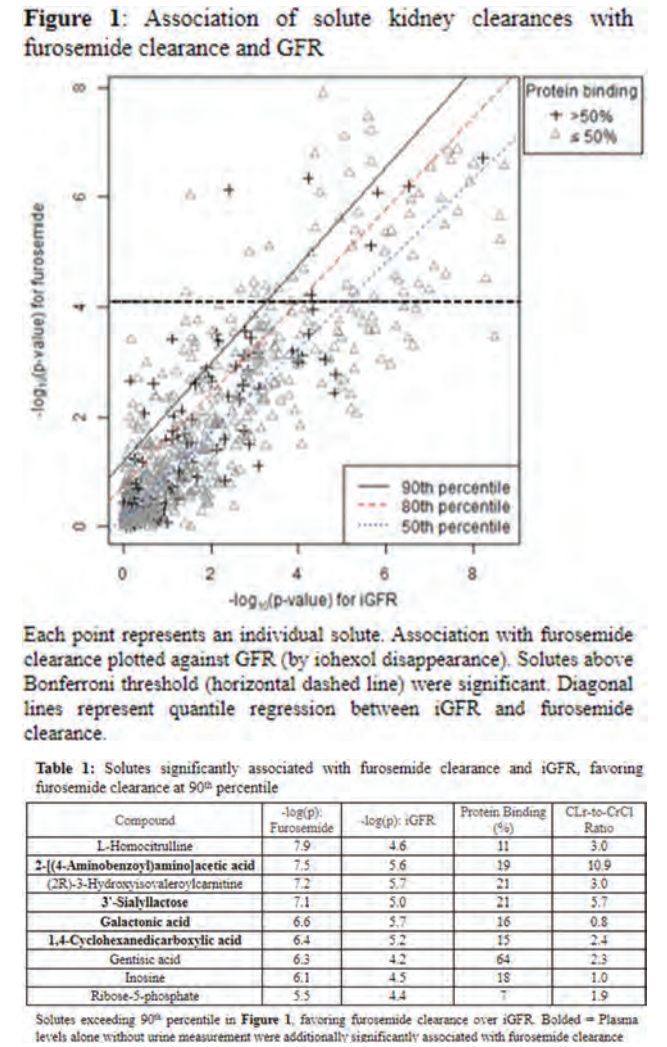

**Background:** The proximal tubules eliminate protein-bound solutes and drugs via secretion, an energy dependent process that differs from glomerular filtration. Estimation of secretory clearance remains limited to research settings. We used metabolomic profiling to identify potential solutes that could serve as reliable markers of secretory clearance.

**Methods:** We quantified 528 small molecular solutes in plasma and timed urine from 50 people in a kidney pharmacokinetic study. We compared the kidney clearance of candidate solutes with the clearance of administered IV furosemide, an avidly secreted minimally filtered drug. We identified solutes favoring secretory clearance over GFR based on regressions of  $-\log_{10}(p\text{-values})$  for joint associations with furosemide and iohexol clearance. We further explored the prediction of secretory clearance by transformed plasma measurements alone.

**Results:** Mean age was 56  $\pm$  13 years; 32% were women. A total of 63 solutes met Bonferroni corrected significance for the association with furosemide clearance (Fig.1). Several solutes demonstrated preferential associations ( $>90^{\text{th}}$  percentile) with furosemide clearance over GFR. Transformed plasma measurements of 4 solutes were also associated with kidney furosemide clearance in the absence of concomitant urine measurements: 2-[(4-aminobenzoyl) amino]acetic acid, 3'-sialyllactose, galactonic acid, 1,4-cyclohexanedicarboxylic acid.

**Conclusions:** We identified endogenous solutes that demonstrate properties for potential use as markers of tubular secretory clearance.

Metabolomics of Uremic Symptoms in CKD

Kendra E. Wulczyn,<sup>1</sup> Anand Srivastava,<sup>2</sup> Jiang He,<sup>3</sup> Tanika Kelly,<sup>4</sup> Ana C. Ricardo,<sup>5</sup> Vallabh O. Shah,<sup>6</sup> Robert G. Nelson,<sup>7</sup> Chi-yuan Hsu,<sup>8</sup> Amanda H. Anderson,<sup>4</sup> Michelle Denburg,<sup>9</sup> Vasan S. Ramachandran,<sup>10</sup> Harold I. Feldman,<sup>11</sup> Clary B. Clish,<sup>12</sup> Tianqi Ouyang,<sup>1</sup> Paul L. Kimmel,<sup>14</sup> Hernan Rincon-Choles,<sup>15</sup> Rupal Mehta,<sup>2</sup> Tariq Shafi,<sup>13</sup> Eugene P. Rhee,<sup>1</sup> Sahir Kalim.<sup>1</sup> CKD Biomarkers Consortium <sup>1</sup>Massachusetts General Hospital, Boston, MA; <sup>2</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>3</sup>Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; <sup>4</sup>Tulane University, New Orleans, LA; <sup>5</sup>University of Illinois Chicago, Chicago, IL; <sup>6</sup>University of New Mexico Health Sciences Center, Albuquerque, NM; <sup>7</sup>National Institutes of Health, Bethesda, MD; <sup>8</sup>University of California San Francisco, San Francisco, CA; <sup>9</sup>The Children's Hospital of Philadelphia, Philadelphia, PA; <sup>10</sup>Boston University School of Medicine, Boston, MA; <sup>11</sup>University of Pennsylvania, Philadelphia, PA; <sup>12</sup>Broad Institute, Cambridge, MA; <sup>13</sup>The University of Mississippi Medical Center, Jackson, MS; <sup>14</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>15</sup>Cleveland Clinic, Cleveland, OH.

**Background:** The disrupted metabolic pathways causing uremic symptoms are not known. We utilized untargeted metabolomics to identify potential metabolite markers of uremic symptoms in patients with CKD.

**Methods:** We measured 540 plasma metabolites in 1,766 randomly selected CRIC Study participants at the Year-1 visit and examined their association with uremic symptoms, assessed concurrently using the KDQOL-36 instrument. Metabolites significantly associated with symptoms were identified in cross-sectional analyses using multivariable adjusted linear regression with Bonferroni correction. Then, a parsimonious metabolite profile for each symptom was investigated using LASSO regression.

**Results:** The mean eGFR of participants was 42 mL/min/1.73 m<sup>2</sup>. The most prevalent symptoms were pain (56%), fatigue (54%), paresthesia (46%), and pruritus (45%); nausea (29%) and anorexia (22%) were less common. Regression models identified several metabolites significantly associated with uremic symptoms (Table). Only xenobiotic metabolites were significantly associated with fatigue and paresthesia in both regression models. Notably, higher levels of dimethylguanidino valerate, a metabolite associated with cardiovascular risk, was associated with increased pruritus and nausea severity, and higher levels of N4-acetylcytidine, a potential uremic toxin, was associated with increased anorexia and pain.

**Conclusions:** Metabolomics may advance our understanding of the biologic pathways contributing to uremic symptoms. Results from this hypothesis-generating study identify metabolites that may contribute to symptoms and warrant further investigation.

**Funding:** NIDDK Support

Metabolites significantly associated with uremic symptoms among 1,766 participants in the CRIC Study, as identified by two statistical models						
Symptom	Linear regression*		Linear regression and LASSO		Least absolute shrinkage and selection operator (LASSO)†	
	Metabolite	β (+/-)	Metabolite	β (+/-)	Metabolite	β (+/-)

The Association Between TMAO, CMPF, and Clinical Outcomes in Advanced CKD: Results From the EQUAL Study

Lu Dai,<sup>1</sup> Ziad Massy,<sup>2</sup> Peter Stenvinkel,<sup>1</sup> Nicholas C. Chesnaye,<sup>3</sup> Islam A. Larabi,<sup>4</sup> Jean-claude Alvarez,<sup>4</sup> Fergus Caskey,<sup>5</sup> Claudia Torino,<sup>6</sup> Gaetana Porto,<sup>7</sup> Maciej Szymczak,<sup>8</sup> Magdalena Krajewska,<sup>8</sup> Christiane Drechsler,<sup>9</sup> Christoph Wanner,<sup>9</sup> Kitty J. Jager,<sup>3</sup> Friedo M. Dekker,<sup>3</sup> Pieter Evenepoel,<sup>10</sup> Marie Evans.<sup>1</sup> <sup>1</sup>Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Centre Hospitalier Universitaire Ambroise Pare, Boulogne-Billancourt, France; <sup>3</sup>Universiteit van Amsterdam, Amsterdam, Netherlands; <sup>4</sup>Universite de Versailles Saint-Quentin-en-Yvelines, Versailles, France; <sup>5</sup>University of Bristol, Bristol, United Kingdom; <sup>6</sup>Universita degli Studi Mediterranea di Reggio Calabria, Reggio Calabria, Italy; <sup>7</sup>Azienda Ospedaliera Bianchi-Melacrino-Morelli, Reggio Calabria, Italy; <sup>8</sup>Uniwersytet Medyczny im Piasow Slaskich we Wroclawiu, Wroclaw, Poland; <sup>9</sup>Universitätsklinikum Würzburg Medizinische Klinik und Poliklinik II Abteilung für Molekulare Innere Medizin, Würzburg, Germany; <sup>10</sup>Katholieke Universiteit Leuven, Leuven, Belgium.

**Background:** Trimethylamine N-oxide (TMAO), a metabolite from red meat and fish consumption, plays a role in promoting cardiovascular events. However, data regarding TMAO and its impact on clinical outcomes are inconclusive, possibly due to its undetermined dietary source. We hypothesized circulating TMAO derived from fish intake might cause less harm compared to red meat by examining the concomitant level of 3-carboxy-4-methyl-5-propyl-2-furanpropionate (CMPF), a known biomarker of fish intake, and investigated the association between TMAO, CMPF and outcomes in CKD.

**Methods:** Patients were recruited from the European QUALITY study on treatment in CKD (EQUAL) among patients (≥65 years) whose eGFR had dropped for the first time to ≤20mL/min/1.73m<sup>2</sup> during last 6 months. The association between TMAO, CMPF and outcomes including all-cause mortality and kidney replacement therapy (KRT) was assessed among 824 patients. Patients were further stratified by median cut-offs of TMAO and CMPF, suggesting high/low red meat and fish intake.

**Results:** Higher TMAO was independently associated with an increased risk of all-cause mortality (multivariable-hazard ratio (HR) 1.41, 95% CI) 1.15-1.74). Higher CMPF was associated with a reduced risk of both all-cause mortality (HR 0.80, 95%CI 0.71-0.89) and KRT (HR 0.83, 95%CI 0.74-0.93), independent of TMAO and other confounders. In comparison to patients with low TMAO and CMPF, patients with low TMAO and high CMPF had reduced risk of all-cause mortality (adjusted HR 0.50, 95% CI 0.33-0.75), and those with high TMAO and high CMPF had a non-significant association with mortality risk (Figure1).

**Conclusions:** High CMPF conferred an independent role in health benefits and might even counteract the unfavorable effect of TMAO on outcomes. Whether higher circulating CMPF are due to fish consumption, and/or CMPF is a protective marker remain to be demonstrated by further studies.

Figure 1. Kaplan-Meier estimates for all-cause mortality and cause-specific cox regression models according to TMAO and CMPF median groups. Model1, adjusted for age, sex, country; Model2, model1 + diabetes, pre-existing CVD, Charlson comorbidity index, diastolic blood pressure, systolic blood pressure, malnutrition (SGA<5); Model3, model2 + albumin, phosphate, hemoglobin; Model4, model3 + eGFR.

SA-PO933

Indoxyl Sulfate Levels Are a Predictor for Sarcopenia but Myostatin Levels Are an Indicator for Muscle Mass in Patients With CKD

Su mi Lee, Won Suk An. Dong-A University, Busan, Republic of Korea.

**Background:** Serum myostatin and indoxyl sulfate (IS) levels are increased according to renal function decline and are the main mediators of chronic kidney disease (CKD)-related sarcopenia. However, a recent report showed that myostatin levels were increased in balance-trained CKD patients associated with increased lean mass. The aim of this study was to assess the association between serum myostatin and IS levels and sarcopenia in CKD patients. We performed a post-hoc analysis of data extracted from a RECOVERY study (clinicaltrials.gov: NCT03788252).

**Methods:** Baseline data from the RECOVERY study were analyzed in 150 CKD patients (mean CKD-EPI eGFR: 33.8±12.5). A Six-meter gait speed test and handgrip strength (HGS) were assessed. Skeletal muscle index (SMI) was measured by an InBody S10 based on bioelectrical impedance analysis. Low muscle mass was defined as an SMI <7.0 kg/m<sup>2</sup> in men and <5.7 kg/m<sup>2</sup> in women. Sarcopenia was assessed using the Asian Working Group for Sarcopenia 2019. Serum myostatin and IS levels were measured. We classified patients into two groups according to the median value of myostatin: patients with high myostatin levels (≥4.5 ng/mL) and those with low myostatin levels (<4.5 ng/mL). In addition, IS levels were divided into high (≥0.365 pg/mL) and low (<0.365 pg/mL) groups.

**Results:** The proportion of patients with sarcopenia was higher in patients with high IS levels but was lower in patients with high myostatin levels. SMI and HGS were significantly lower in patients with high IS levels but were significantly higher in patients with high myostatin levels. IS levels showed a negative correlation with eGFR, SMI, and HGS but myostatin levels showed a positive correlation with SMI, and HGS. Myostatin/SMI ratio reflected muscle mass was negatively associated with eGFR and was not associated with SMI and HGS. The ROC curve of IS levels for presarcopenia was 0.67 (95% CI, 0.51–0.84;  $P=0.022$ ). The sensitivity and specificity for predicting presarcopenia were 64.7% and 64.4%. Sarcopenia and presarcopenia were independently associated with age and IS levels after adjustment for gender, diabetes mellitus, creatinine, and myostatin/SMI.

**Conclusions:** Serum IS levels are an important predictor for sarcopenia but serum myostatin levels are indicator muscle mass in CKD patients with lower eGFR.

## SA-PO934

### Predicting Renal Function Decline From Readily Available Clinical Variables in Electronic Health Records Using Machine Learning

Roy O. Mathew,<sup>1,2</sup> Brendan E. Odigwe,<sup>4</sup> Sujay D. Paudel,<sup>2</sup> Celestine I. Odigwe,<sup>5</sup> Enrica Fung,<sup>1,2</sup> Sayna Norouzi,<sup>2,6</sup> Sergio Infante,<sup>2,6</sup> Amir Abdi Pour,<sup>2,6</sup> Janani Rangaswami,<sup>3</sup> Homayoun Valafar.<sup>4</sup> <sup>1</sup>Loma Linda VA Health Care System, Loma Linda, CA; <sup>2</sup>Loma Linda University School of Medicine, Loma Linda, CA; <sup>3</sup>The George Washington University School of Medicine and Health Sciences, Washington, DC; <sup>4</sup>University of South Carolina School of Engineering, Columbia, SC; <sup>5</sup>Thomas Hospital, Fairhope, AL; <sup>6</sup>Loma Linda University Health, Loma Linda, CA.

**Background:** This analysis sought to implement machine learning (ML) algorithms to incorporate readily available clinical variables from a nationally representative administrative dataset to predict future renal function decline.

**Methods:** All data retrieved from the Veterans Affairs (VA) corporate data warehouse. The outcome was the rate of estimated glomerular filtration rate (eGFR) decline over 3 years. An Artificial Neural Network (ANN) was developed as our machine learning technique of choice and was implemented utilizing the *neuralnet* package in R. A total of 183,054 unique veterans with baseline eGFR between 15 and 60 mL/min/1.73m<sup>2</sup> with follow up serum creatinine annually for 3 years following the index creatinine value were included. Training cohort consisted of 75% of the total population, leaving 25% for ML model testing. A total of 101 variables were initially available. For the final training cohort, 74 variables were included (after excluding outcomes, dates, and identifiers). Loma Linda VA IRB provided expedited review approval. For experimentation, we created a feed-forward Neural network with 2 hidden layers, having 32 and 16 neurons in the first and second hidden layers, respectively.

**Results:** Of the included patients, 81% had CKD G3a, 15% G3b, and 4% with G4. The optimal neural network architecture produced the prediction of the 3-year decline in eGFR in the testing cohort with mean square error of 0.04, and correlation coefficient of 0.998 (Figure).

**Conclusions:** ANNs accurately predicted the rate of progression. Such ML techniques can accurately identify high-risk patients for intensive risk reduction and/or targeted research efforts for novel interventions.

Predicted vs actual rate of eGFR decline using feed forward neural network from administrative health data.

## SA-PO935

### Development and Validation of Deep Learning Algorithm for Evaluating Kidney Function Based on Electrocardiogram

Dong Hee Lee, Jung Nam An, Sungmin Kim, Jwa-kyung Kim, Sung Gyun Kim. *Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.*

**Background:** Chronic kidney disease (CKD) is a chronic progressive disease; however, there are no symptoms accompanying deterioration of kidney function, so evaluation of kidney function is possible only through periodic blood tests. Therefore, we aimed to detect kidney function through a deep learning-based model using an electrocardiogram (ECG) that is non-invasive and can be quickly measured.

**Methods:** Among patients who underwent an ECG at least once from 2006 to 2020, patients with blood test results within 24 hours were included. All ECGs were acquired using a GE ECG machine and the raw data (XML datatype) were stored using the MUSE data management system. For model training and evaluation, the ECG-CKD-EPI eGFR pair was separated into train, validation, and test set. We trained two binary classification model using a Convolutional Neural Network. The model input was a standard 10-second, 12-lead ECG and the output being the likelihood of the ECG being from a patient with CKD.

**Results:** In a total of 299,431 patients, 324,875 ECG-eGFR pairs were analyzed, of which 285,031 cases were in the train set, 13,805 cases in the validation set, and 26,039 cases in the test set. For the detection of eGFR below the 60 mL/min, the sensitivity and specificity of deep learning model were 85.2% and 72.9%; and for eGFR below the 30 mL/min, they were 87.6% and 75.8% in test set. These performances were calculated by using the operating point at Youden J statistics of validation set.

**Conclusions:** The deep learning model using the 12-lead ECG waveform detected CKD based on CKD-EPI eGFR with high accuracy. In the case of advanced CKD, the diagnostic predictive power is more increased. These results suggest the clinical applicability of AI software for diagnosing kidney function using ECG.

## SA-PO936

### Charlson Comorbidity Index as a Predictor of Mortality in ESRD Inpatients in Rural America: Evidence From a Nationally Representative Sample

Emmanuel O. Adeyemi. *Saint Peter's University Hospital, New Brunswick, NJ.*

**Background:** End Stage Renal Disease (ESRD) has been associated with an increase in all-cause mortality among patients. The accumulation of comorbidities appears to be a contributing factor. This study set out to identify the effect of comorbidity severity among ESRD inpatients in rural America.

**Methods:** This is a cross-sectional study that used the 2016-2018 Nationwide Inpatient Survey (NIS) from the Healthcare Cost and Utilization Project (HCUP). The study included patients aged 18yrs or more with ESRD hospitalized in rural hospitals in America. Independent variables used from the survey include age, gender, race, type of admission (elective vs non-elective), type of hospital control, expected primary payer, and severity of comorbidities. The dependent variable was death during hospitalization. All analyses were weighted. Univariate (frequencies), bivariate (Chi-square) and logistic regression (stepwise selection with P-value for entry of a variable and stay of a variable put at  $\leq 0.05$ ) analyses were done using SAS studio.

**Results:** There were 144,575 weighted ESRD hospitalizations. 5.0% of hospitalizations died. Gender was the only non-significant variable on bivariate analysis ( $P=0.6577$ ), hence, gender was not considered in our regression model. On multivariable logistic regression analysis that adjusted for age, race, type of admission, type of hospital control, and expected primary payer; ESRD patients with severe comorbidities had 40% (AOR: 1.40, 95% CI: 1.26-1.54) more odds of mortality compared to those with mild comorbidities and those with moderate comorbidities had 22% (AOR: 1.22 95% CI: 1.10-1.36) more odds of mortality compared to those with mild comorbidities. The area under the curve (AUC) for the model was 62%.

**Conclusions:** Severity of comorbidities is a modifiable predictor of ESRD inpatient mortality from this study. This suggests that strategies aimed at preventing accumulation of comorbidities might help reduce ESRD inpatient mortality in rural America.

## SA-PO937

### Higher Number of Kidney Cysts Predicts Progressive CKD After Radical Nephrectomy Independent of Kidney Function

Moldovan Sabov, Aleksandar Denic, Aidan F. Mullan, Timothy L. Kline, Andrew D. Rule. *Mayo Clinic Minnesota, Rochester, MN.*

**Background:** Simple kidney cysts are common and usually considered of limited clinical relevance. They are associated with older age and lower glomerular filtration rate (GFR), but little is known of their prognostic utility for progressive chronic kidney disease (CKD) or end-stage kidney disease (ESKD).

**Methods:** We studied patients with a pre-surgical CT or MRI imaging who underwent a radical nephrectomy for a tumor between 2000 and 2019 and who had no cancer recurrence at least 4 months after nephrectomy. We reviewed the retained kidney images to characterize the number, size, and location of any parenchymal cysts. Cox models to assess the risk of ESKD defined as dialysis, kidney transplantation, or eGFR <10 mL/min/1.73 m<sup>2</sup> or CKD progression (ESKD or a 40% decline from postnephrectomy baseline eGFR). Models were adjusted for baseline age, sex, body mass index, hypertension, diabetes, eGFR, proteinuria, and tumor volume.

**Results:** There were 1237 patients (mean age 64 years; postnephrectomy baseline eGFR 48.4 mL/min/1.73 m<sup>2</sup> with 128 progressive CKD events and 26 ESKD events over a median 4.3 years of follow-up. In the cohort, 42% had any kidney cyst and the mean  $\pm$  SD number of cysts was  $0.9 \pm 1.7$  and diameter of largest cyst was  $1.9 \pm 1.8$ cm. Higher number of cysts (but not diameter of largest cyst) predicted both CKD progression and ESKD. The risk of both progressive CKD and ESKD was strongest with presence and number of medullary cysts.

**Conclusions:** Detection and number of cysts in the kidney, and in particular the medulla, may be useful imaging biomarker beyond current clinical evaluations for predicting risk of progressive CKD and ESKD.

Table. Kidney cysts measures as predictor of CKD progression or ESKD.

	CKD Progression		ESKD	
	HR (95% CI)	P value	HR (95% CI)	P value
Number of any cysts	1.09 (1.00-1.19)	0.04	1.22 (1.06-1.42)	0.007
Number of cortical cysts	1.10 (0.98-1.23)	0.11	1.33 (1.11-1.60)	0.002
Number of medullary cysts	1.44 (1.13-1.83)	0.003	1.82 (1.23-2.70)	0.003
Number of indeterminate cysts	0.99 (0.75-1.32)	0.96	0.20 (0.03-1.40)	0.11
Presence of any cyst	1.04 (0.72-1.50)	0.83	0.84 (0.36-1.93)	0.67
Presence of any cortical cysts	1.11 (0.76-1.63)	0.59	1.25 (0.53-2.93)	0.61
Presence of any medullary cysts	2.03 (1.29-3.20)	0.002	2.76 (1.08-7.06)	0.03
Presence of any indeterminate cysts	0.80 (0.49-1.29)	0.35	0.17 (0.02-1.30)	0.09
Largest cyst diameter	1.02 (0.90-1.15)	0.75	1.00 (0.74-1.31)	0.97

SA-PO938

Outcomes for Patients With Renal AA Amyloidosis Associated With Injection Heroin Use

Rachel R. Johnson,<sup>1</sup> Anatoly Urisman,<sup>4</sup> Kerry C. Cho,<sup>6</sup> Ramin Sam,<sup>2,5</sup> Sandy W. Wong,<sup>3</sup> <sup>1</sup>American University of the Caribbean School of Medicine BV, Cupecoy, Sint Maarten (Dutch part); <sup>2</sup>Zuckerberg San Francisco General Hospital and Trauma Center Department of Medicine, San Francisco, CA; <sup>3</sup>University of California San Francisco Department of Medicine, Division of Hematology and Oncology, San Francisco, CA; <sup>4</sup>University of California San Francisco Department of Pathology, San Francisco, CA; <sup>5</sup>University of California San Francisco School of Medicine, San Francisco, CA; <sup>6</sup>University of California San Francisco Department of Medicine, San Francisco, CA.

**Background:** AA amyloidosis is a rare but serious complication of chronic inflammation. Skin popping is a common practice among heroin users in the western United States and an under-studied cause of renal AA amyloidosis (R-AA). We performed a multicenter retrospective analysis of R-AA due to injection heroin use (IHU) in San Francisco (SF).

**Methods:** Patients with biopsy-proven R-AA were identified at UCSF and SF General Hospital between 1/1/2000 and 6/30/2021 under an IRB-approved study. Only patients with R-AA from IHU were included. Data for these patients including baseline characteristics, renal survival, and overall survival were abstracted from the medical records. Overall survival (OS), renal survival (RS) and time-to-dialysis (TTD) were summarized using Kaplan-Meier methods via GraphPad Prism 9.3.1.

**Results:** Sixty-seven subjects with biopsy-proven R-AA were identified, of which 55 had adequate medical records available to determine the underlying etiology. All R-AA biopsies must have had Congo Red positivity and amyloid typing by SAA positivity or mass spectrometry to be included. Of these 55 cases, 45 (82%) were attributable to IHU. For patients with R-AA due IHS, the median age was 50 (range 24-70), 9 (20%) were female, 31 (69%) were Caucasian, 40 (89%) were non-Hispanic. At diagnosis, 82% had a history of skin abscess or skin ulceration related to IHU. Eighty-nine percent also had hepatitis C, 24% hepatitis B and 20% HIV. Twelve (27%) patients with R-AA from IHU were dialysis-dependent at the time of diagnosis. Thirty-three patients (73%) were dialysis-independent at diagnosis with a median eGFR of 13 ml/min/1.73m<sup>2</sup> (range 3 - >60) and a median protein/creatinine ratio of 8440 mg/g creat (range 380-48,280). Of these patients, 17 eventually required dialysis. Median RS and TTD for this cohort was 1.9 years and 6.7 weeks respectively. None of the patients who required dialysis came off dialysis. After cessation of IHU, 1 patient received a renal allograft with a renal allograft survival of 6 years. The median OS for patients with R-AA was 2.8 years. Median follow-up was 5.0 years.

**Conclusions:** The leading cause of R-AA in SF is IHS. R-AA patients often have concomitant infections such as hepatitis and HIV. R-AA is associated with high rates of dialysis-dependence and mortality.

SA-PO939

Kappa-Restricted Light Chain Proximal Tubulopathy (LCPT) in Waldenström Macroglobulinemia (WM)

Yani Zhang,<sup>1</sup> Donghyang Kwon,<sup>2</sup> Michael J. Choi,<sup>2</sup> <sup>1</sup>MedStar Union Memorial Hospital, Baltimore, MD; <sup>2</sup>MedStar Georgetown University Hospital, Washington, DC.

**Introduction:** WM is a lymphoproliferative disorder with possible renal involvement from high tumor burden of IgM monoclonal protein or monoclonal gammopathy of renal significance (low tumor burden). LCPT is a rare cause for progressive kidney dysfunction in WM.

**Case Description:** A 62-yo man with CKD 3a from unknown cause and WM diagnosed 2 years ago presented with a serum creatinine of 1.71 mg/dL (1.38 mg/dL 15 months prior). Work up revealed serum albumin 4.8 g/dL, IgM 4,596 mg/dl, free K:L ratio 31, M-spike: 2.5 mg/dL, uric acid 1.7 mg/dL, phosphorus 3.3 mg/dL, LDH 153 u/L, viscosity 2.8, C3 81 mg/dL, UA: 1+ protein, trace glucose (serum glucose 87 mg/dl), pH 7, 0 RBCs or WBCs/HPF. 24-hr urine protein 2,139 mg, urine protein electrophoresis showed albumin 22.6%, and M spike 26.6%. Renal ultrasound unremarkable. Kidney biopsy revealed k-LCPT [Figure]. Serum parameters improved with stable proteinuria after therapy for WM with bortezomib, rituximab and dexamethasone.

**Discussion:** Crystalline k-LCPT is a rare renal presentation of WM in which monoclonal light chain can accumulate in proximal tubular cells when light chain production exceeds proximal tubule reabsorption capacity and lysosomal degradation. Clinicians should consider this disease in WM patients with CKD, sub-nephrotic proteinuria, and evidence of proximal tubulopathy with or without complete Fanconi syndrome.

Proximal tubules show eosinophilic amorphous granular material in the cytoplasm and lumen.

PTC shows intracytoplasmic and membrane-bound crystalline structures with rhomboid shapes.

SA-PO940

Not So Familiar: A Case on Familial Mediterranean Fever

Ram Sinha, Neha Siddiqui, Robert J. Mathews, Magdalena Szulc. *AtlantiCare Regional Medical Center, Atlantic City, NJ.*

**Introduction:** Familial Mediterranean Fever (FMF) is an autoinflammatory disorder that was thought to be autosomal recessive, however, there is increasing evidence of possible dominant penetrance. FMF is caused by mutations of the MEFV gene and the expression of pyrin. Pyrin is an intracellular pattern recognition receptor that leads to the formation of inflammasome complexes. Pyrin is expressed in several cells including granulocytes, monocytes, and fibroblasts of the synovium and peritoneum. The threshold to activate pyrin inflammasomes is reduced in patients with FMF. Up to ninety percent of patients have their first febrile attack with symptoms including pleural or abdominal pain, arthritis, and skin lesions by the age of 20. Systemic amyloidosis, caused by the deposition of serum amyloid A, was a common complication that affected the kidneys prior to the use of colchicine prophylaxis. This report presents a case of amyloidosis in the setting of FMF.

**Case Description:** We report a case of a 57-year-old white male with known PMHx of hypertension, arthritis on NSAIDs, and medication non-compliance who presented with hypertensive emergency. Patient endorsed no known family history. Patient was deemed to have acute kidney injury versus progression of chronic kidney disease. Urinalysis noted macroscopic hematuria and proteinuria. Renal ultrasound was read as unremarkable. Urine indices were consistent with an intrinsic etiology. The patient continued to have reduced kidney function, hematuria, and proteinuria. The patient was found to be positive for p-ANCA. A renal biopsy was performed and noted A.A. type amyloidosis and significant interstitial fibrosis. The patient denied fevers, abdominal and pleural pain. Upon learning his diagnosis, the patient endorsed a family history of arthritis and what was likely FMF. Patient was subsequently started on colchicine for suppressive therapy.

**Discussion:** Familial Mediterranean Fever is an autoinflammatory disorder that presents in ninety percent of patient by the age of 20. Recognition of the constellation of non-specific symptoms is crucial to the initiation of suppressive therapy to prevent systemic amyloidosis. In our case, the patient presented with renal amyloidosis at a later age and likely lacked febrile attacks due to his chronic NSAID use. The biopsy proved to be instrumental in the diagnosis and initiation of suppressive management.

## SA-PO941

### Major Adverse Kidney Events in Multidisciplinary CKD Care Compared With Usual Outpatient Care: A Propensity Score Matched Analysis

Palita Chittinandana, Pongsathorn Gojaseeni, Anan Chuasuwan, Worawon Chailimpamontree, Anutra Chittinandana. *Bhumibol Adulyadej Hospital, Bangkok, Thailand.*

**Background:** Chronic kidney disease (CKD) causes a public health problem worldwide. Multidisciplinary CKD care (MDC) has been recommended in clinical practice guideline to delay disease progression and minimize complications. However, effectiveness of MDC on major adverse kidney events (MAKE) in CKD patients is still inconclusive.

**Methods:** We conducted a cohort study in patients with CKD stage G3b and 4 who were followed up at Bhumibol Adulyadej Hospital since 2014 to 2020. Propensity score matching by age, sex, CKD staging, diabetes, blood pressure and rate of estimated glomerular filtration rate (eGFR) decline before inclusion between patients in MDC and usual outpatient care (UOC) was done. The primary outcome was MAKE, a composite of cardiovascular or renal mortality, 40% eGFR decline and initiation of long-term kidney replacement therapy.

**Results:** After 1:1 propensity score matching, 822 patients were included. The mean age was 70.9 years, 64% have diabetes. During the mean follow up of 3.3 years, rate of the primary endpoint was lower in MDC group than UOC group (24.1% vs. 38.9%; hazard ratio [HR], 0.66; 95% confidence interval [CI], 0.52 to 0.86;  $P=0.002$ ). The results showed benefit of MDC over UOC in 40% eGFR declined (21.7% vs. 35.0%; HR, 0.67; 95%CI 0.52 to 0.88;  $P=0.004$ ), all-cause mortality (8.5% vs. 19.5%; HR, 0.60; 95%CI 0.40 to 0.90;  $P=0.014$ ), non-cardiovascular death (6.1% vs. 15.1%; HR, 0.56; 95%CI 0.35 to 0.90;  $P=0.015$ ) and hospitalization per year ( $1.0 \pm 1.5$  vs.  $1.6 \pm 2.0$ ;  $P<0.005$ ). According to subgroup analysis, diabetic patients benefit the most from MDC.

**Conclusions:** In a tertiary care hospital, MDC showed benefits over UOC on kidney outcomes in patients with CKD stage G3b and 4. The benefit will be enhanced in diabetes group.

**Funding:** Government Support - Non-U.S.

Clinical outcomes	UOC (n = 411)	MDC (n = 411)	MDC better UOC better	Hazard ratio (95% CI)
Primary outcome	160 (38.92%)	99 (24.09%)	→●←	0.66 (0.52-0.86)

## SA-PO942

### Acceptance of Recommendations for SGLT2 Inhibitors and GLP1 Receptor Agonists in a High-Risk CKD Population

Melanie R. Weltman,<sup>1</sup> Manisha Jhamb,<sup>1,2</sup> Jonathan Yabes,<sup>3</sup> Manqi Cai,<sup>4</sup> Thomas D. Nolin,<sup>2,5</sup> Khaled Abdel-Kader.<sup>5,1</sup> *UPMC, Pittsburgh, PA; <sup>2</sup>University of Pittsburgh Renal-Electrolyte Division, Pittsburgh, PA; <sup>3</sup>University of Pittsburgh Department of Medicine, Pittsburgh, PA; <sup>4</sup>University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; <sup>5</sup>University of Pittsburgh School of Pharmacy, Pittsburgh, PA; <sup>6</sup>Vanderbilt University Medical Center, Nashville, TN.*

**Background:** Delaying or preventing CKD progression and reducing risk of cardiovascular events are priorities in the treatment of patients with CKD. SGLT2 inhibitors and GLP1 receptor agonists have shown kidney and cardiovascular benefit in those with CKD but prescribing of these medications remains low. We evaluated acceptance of recommendations for SGLT2 inhibitors and GLP1 receptor agonists and barriers to prescribing in a group of patients with high-risk CKD from the Kidney CHAMP trial.

**Methods:** The Kidney CHAMP trial is testing whether an electronic health record-based population health management approach improves CKD care. Eligible patients are 18-85 years with CKD, high risk of progression to ESKD, and are not followed

by a nephrologist. Enrolled patients receive nephrologist-led electronic consults and pharmacist-led medication therapy management encounters with recommendations (including use of SGLT2 inhibitors and GLP1 receptor agonists) provided to the primary care provider (PCP) for review at the upcoming office visit, with follow-up encounters every 6 months.

**Results:** Between October 1, 2019 and March 31, 2022, 697 baseline encounters and 709 follow-up encounters were completed. At baseline, 4% and 6% of patients were prescribed an SGLT2 inhibitor or a GLP1 receptor agonist, respectively. 284 recommendations were made for initiation or dose adjustment of an SGLT2 inhibitor in 206 unique patients, and 206 recommendations were made for initiation or dose adjustment of a GLP1 receptor agonist in 141 unique patients. PCPs accepted 26% of recommendations for SGLT2 inhibitors and 30% of recommendations for GLP1 receptor agonists. Commonly documented reasons for not accepting the recommendations were patient refusal, deferring to endocrinology, and cost/insurance coverage limitations.

**Conclusions:** Baseline use and acceptance of recommendations for SGLT2 inhibitors and GLP1 receptor agonists remains poor in our patient population. Reasons for nonacceptance suggest a need for patient and provider-level education related to their benefits, as well as system-level efforts to address medication cost and siloed care.

**Funding:** NIDDK Support

## SA-PO943

### Patient Perceptions of a CKD Population Health Management Program to Improve Kidney Care

Susan M. Devaraj,<sup>1</sup> Megan E. Hamm,<sup>1</sup> Balchandre N. Kenkre,<sup>1</sup> Flor Cameron,<sup>1</sup> Khaled Abdel-Kader,<sup>2</sup> Manisha Jhamb.<sup>1</sup> *<sup>1</sup>University of Pittsburgh Department of Medicine, Pittsburgh, PA; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN.*

**Background:** The majority of chronic kidney disease (CKD) patients are managed by primary care providers (PCPs), and novel approaches are needed to improve care and outcomes in these patients. We sought to ascertain patient perceptions of a population health management (PHM) approach to improving CKD care in high-risk patients managed by their PCP.

**Methods:** Patients with high-risk CKD who were receiving PHM intervention in an ongoing randomized control trial involving remote co-management of CKD by a nephrologist, pharmacist led medication reconciliation, and CKD education who had at least one CKD education session were recruited from May 2021-Feb 2022 for this study. Using purposive sampling, patients from three pre-defined strata (racial/ethnic minorities, low socio-economic status, multi-morbidities) were enrolled until thematic saturation was reached. A one-time 30-min phone interview was conducted, and data was analyzed using MAXQDA software.

**Results:** In this preliminary analysis of 30 of 45 patient interviews (mean age 74 years, 47% females, 17% racial/ethnic minorities, 47% low SES, 43% high comorbidity burden), several themes have emerged. First, patients expressed support for a collaborative relationship between their PCP and the nephrologist for co-management of CKD. Secondly, patients expressed poor understanding of the cause or health risks associated with CKD. In fact, some did not even recall receiving education although they had all met with the nurse educator. Thirdly, patients reported receiving diet/fluid education tips and had interest in implementing them, with many reporting a greater understanding of how diet/fluid recommendations related to their kidney health and could be implemented in the context of their personal habits. Finally, most patients affirmed they would recommend the education sessions to other CKD patients.

**Conclusions:** CKD patients who are managed by their PCP have high acceptance of remote co-management by a nephrologist. Patients perceive some aspects of CKD health education to be beneficial, however more effective approaches to communicating risk for CKD development and progression may be needed.

**Funding:** NIDDK Support

## SA-PO944

### Patient Navigators for CKD and Kidney Failure: A Systematic Review

David T. Collister,<sup>1</sup> Yasmin A. Iman,<sup>2</sup> Clara Bohm,<sup>2</sup> Paul Komenda,<sup>2</sup> Navdeep Tangri.<sup>2,1</sup> *<sup>1</sup>University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; <sup>2</sup>University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada.*

**Background:** To what degree and how patient navigators improve clinical outcomes for patients with chronic kidney disease (CKD) and kidney failure is uncertain. We performed a systematic to summarize patient navigator program design, evidence, and implementation in kidney disease.

**Methods:** A search strategy was developed for randomized controlled trials and observational studies that evaluated the impact of navigators on outcomes in the setting of CKD and kidney failure. Articles were identified from various databases. Two reviewers independently screened the articles and identified those which met the inclusion criteria. Data was abstracted from full texts and risk of bias was assessed.

**Results:** After screening a total of 3371 citations, 17 articles met the inclusion criteria including 14 original studies. Navigators came from various healthcare backgrounds including nursing (n=6), social worker (n=2), medical interpreter (n=1), research (n=1) and also included kidney transplant recipients (n=2) and non-medical individuals (n=2). Navigators focused mostly on education (n=9) and support (n=6). Navigators were used for patients with CKD (n=5), peritoneal dialysis (n=2), in-center hemodialysis (n=4), kidney transplantation (n=2) but not home hemodialysis. Navigators improved transplant workup and listing, adherence, peritoneal dialysis utilization and patient knowledge.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

However, many studies did not show benefits across other outcomes, were at a high risk of bias, and none reported cost effectiveness or patient reported experience measures.

**Conclusions:** Navigators improve some health outcomes for CKD but there is heterogeneity in their structure and function. High-quality randomized controlled trials are needed to evaluate patient navigator program efficacy and cost effectiveness.

## SA-PO945

### Where Do Primary Care Physicians Fit in CKD Patient Care?

Meghan Staudt, Denise Foy. *Spherix Global Insights, Exton, PA.*

**Background:** This research examines the management of patients with chronic kidney disease (CKD) who are not on dialysis by primary care physicians (PCPs) and evolving best care practices given the emergence of new treatment options to delay CKD progression.

**Methods:** Patient level data was collected via an online, HIPAA-compliant form during June 2020 as part of an independent, retrospective chart audit. A total of 1,009 CKD non-dialysis patient records were submitted by 207 PCPs.

**Results:** While 87% of PCPs express that they are comfortable treating patients with mild kidney disease (CKD Stages 1-2), the majority are not comfortable managing patients who have progressed to more severe kidney disease (CKD Stages 4-5). Comorbidities and complications that patients have as CKD progresses contribute to this sentiment. Nearly two-thirds of PCPs agree early referral to nephrology results in better outcomes for patients with progressive renal disease; however, the referral often does not occur until patients reach CKD Stage 3, highlighting contradiction in PCP perceptions versus their actions. 75% of PCPs report they are comfortable initiating patients on an SGLT2 inhibitor, a therapy among several others proven to slow the progression of CKD, indicating there is potential to delay referral to nephrology even further. Several factors contribute to the delayed referrals, including 28% of PCPs who believe nephrologists cannot do more than a PCP to manage a patient until their CKD is severe enough to require dialysis, and 32% who believe many patients consider nephrologists as "dialysis doctors" and are reluctant to be referred. Additionally, one-quarter of PCPs say nephrologists have a financial incentive to place patients on dialysis, which further delays referrals. Conversely, 69% of PCPs report they have an excellent relationship with nephrologists when co-managing CKD patients. However, 24% report the wait time for a newly referred patient to see a nephrologist (when not an emergency) is very long. This compares well against rheumatology and dermatology where more than one-half of PCPs report the wait time is very long.

**Conclusions:** Although PCPs recognize the benefit of co-managing CKD patients with nephrologists, barriers to optimal care between physicians do exist. As PCPs adopt new therapies that delay CKD progression, there is potential for their CKD patient pool to expand and further delay referrals to nephrology.

## SA-PO946

### Feasibility of a Remotely Delivered Trial Testing an Online Self-Management Programme for People Living With CKD

Courtney J. Lightfoot,<sup>1,2</sup> Thomas J. Wilkinson,<sup>1,3</sup> Noemi Vadasz,<sup>1,2</sup> Alice C. Smith,<sup>1,2</sup> <sup>1</sup>University of Leicester, Leicester, United Kingdom; <sup>2</sup>Leicester NIHR Biomedical Research Centre, Leicester Diabetes Centre, Leicester, United Kingdom; <sup>3</sup>NIHR Applied Research Collaboration East Midlands, Leicester Diabetes Centre, Leicester, United Kingdom.

**Background:** Self-management of a long-term health condition, like CKD, requires appropriate knowledge, skills, and confidence (termed patient activation). However, resources to support and improve self-management behaviours in CKD are lacking. We developed a 10-week online self-management programme for people with non-dialysis CKD, called My Kidneys & Me (MK&M). This programme is being evaluated in an ongoing multi-centre randomised control trial (called SMILE-K). To ensure that the full-scale trial protocol is feasible, we conducted a mixed-methods nested feasibility pilot involving the first 60 participants.

**Methods:** The SMILE-K trial is conducted entirely using remote recruitment and outcome assessment methods. It has a 2:1 (intervention:control) randomisation. Assessment surveys, including the Patient Activation Measure, are collected at baseline and at 10 weeks. Based on recruitment rates, acceptability of recruitment and randomisation methods, feasibility and acceptability of outcome assessments, and engagement with and usage of MK&M, *a-priori* progression criteria were set using a 'red' (stop), 'amber' (make changes) and 'green' (go) system. Semi-structured interviews explored participant views of the trial design.

**Results:** 128 people expressed initial interest in the study, of which 77 (60%) consented to participate. 60/77 (78%) completed the baseline survey and were randomised and included in the pilot. Mean age was 63 (range: 20-88) years and 63% were male. All the pre-specified 'stop' progression criteria thresholds were exceeded, suggesting the full trial is feasible. Access to and engagement with MK&M were high with 36/41 (88%) participants in the intervention group activating their account. On average participants logged in 35 times during the 10 weeks spending a mean of 18 minutes per login. Participants described their views and experiences of taking part in this remote trial, including email communication, engaging in online assessments, online education and suggestions for improvements to full study protocol.

**Conclusions:** This nested pilot study provides evidence for the feasibility of the full-scale trial. Consequent refinements to the protocol have been made through the identified areas for improvement. These results are relevant to inform the design of other remotely delivered trials in CKD.

## SA-PO947

### Participant Experience in the Kidney Precision Medicine Project

Angela M. Victoria Castro,<sup>1</sup> Celia P. Corona Villalobos,<sup>2</sup> Natalya Sarkisova,<sup>4</sup> Kristina N. Blank,<sup>4</sup> Ashveena Dighe,<sup>4</sup> Glenda V. Roberts,<sup>4,3</sup> Alan Y. Xu,<sup>2</sup> Victoria Blanc,<sup>3</sup> Michael P. Rose,<sup>5</sup> Ian H. de Boer,<sup>4</sup> Jonathan Himmelfarb,<sup>4</sup> Katherine R. Tuttle,<sup>4</sup> KPMP <sup>1</sup>*Yale University School of Medicine, Department of Internal Medicine, New Haven, CT;* <sup>2</sup>*Johns Hopkins University, School of Medicine, Division of Nephrology, Baltimore, MD;* <sup>3</sup>*Kidney Precision Medicine Project Patient Partner, Seattle, WA;* <sup>4</sup>*Kidney Research Institute and Division of Nephrology, University of Washington, Seattle, WA;* <sup>5</sup>*University of Michigan, Ann Arbor, MI.*

**Background:** Optimal participant experience is a foundation of the Kidney Precision Medicine Project (KPMP). This study aimed to identify participants' motivation to participate in research, comprehension of informed consent, satisfaction with processes, and perception of personal impact.

**Methods:** Participants with acute kidney injury (AKI) or chronic kidney disease (CKD) enrolled at nine recruitment sites in the United States during 2019-2022 attended a visit 28 days after their KPMP protocol kidney biopsy. At that time, participants were asked to complete a survey about their experience with 48 questions developed in collaboration with an evaluation expert from the Institute of Translational Health Sciences at University of Washington.

**Results:** A 28-day survey was completed by 70% of 129 participants, 17 enrolled for AKI and 73 for CKD. Median age was 60 (IQR 46-66) years, 46% were women, and 27% identified as Black race. Individuals most commonly joined the KPMP to help future patients (56%), and 97-99% understood the informed consent process and their role in the study. They were asked to rate their anxiety during the biopsy on a graded scale; 4% of participants reported a scale of 10 (maximum) anxiety compared to 29% who reported no anxiety. They also rated the pain of the biopsy on a graded scale with 2% reporting 10 (maximum) while 46% chose a rating of 0 (none). Difficult aspects of their KPMP experience were reported by 8%, mostly related to biosample collection. They also commonly reported positive changes in taking medication, diet, physical activity, and views of kidney disease after receiving their biopsy results.

**Conclusions:** KPMP participants are motivated to participate primarily by altruism and report positive experiences with informed consent and the impact of the study on their daily lives, despite some anxiety and pain related to the biopsy. The KPMP will improve methodology based on participant feedback and will provide guidance for better clinical research processes more broadly.

## SA-PO948

### Assessing Cognition and Sex Differences in CKD Using the NIH Toolbox

Luis M. Perez, Seth B. Furgeson, Zhiying You, Jessica B. Kendrick. *University of Colorado Denver School of Medicine, Aurora, CO.*

**Background:** Chronic kidney disease (CKD) is largely an age-related clinical disorder with accelerated cognitive and cardiovascular aging. Cognitive impairment is a well-documented occurrence in midlife and older adults with CKD and affects multiple domains. In the general population, there is a higher prevalence of cognitive impairment in women. We examined whether cognition differed by sex in adults with CKD.

**Methods:** We included 109 individuals (51% women) with CKD stage 3b-4 (eGFR 15-44 ml/min) from the Bicarbonate Administration in CKD Trial. We measured cognitive function using the National Institute of Health (NIH) Toolbox® (TB) cognitive battery, which assesses cognitive and motor measures such as executive function, attention, memory, and dexterity. All study measures were collected and analyzed at the study baseline.

**Results:** The mean age and eGFR were 61 ± 12 years and 34.9 ± 9.8 ml/min/1.73m<sup>2</sup>. Overall, both men and women scored below the 50<sup>th</sup> percentile on all fluid cognition measures, dexterity and total fluid and total cognition scores (Table). Notably, men scored higher than women on the flanker test (11±21 pts, p<0.01). However, women scored higher on both the dominant/non-dominant pegboard test (12±16 pts, p<0.01, 10±15, p=0.01 respectively). There were no other sex differences among other cognitive measures (all p>0.05). EGFR was associated only with crystallized cognition (r=-0.26, p<0.01).

**Conclusions:** Individuals with CKD had cognitive function below the median NIH-TB reference population values. These results establish baseline cognitive impairment levels in individuals with CKD as well as sex differences in cognitive measures.

**Funding:** NIDDK Support

NIH-TB Cognitive Battery Scores

Measure	Uncorrected score (mean ± SD)	Corrected score (mean ± SD)	Percentile (mean ± SD)
Fluid Cognition Measures			
Flanker Test	92.9 ± 10.1	42.5 ± 7.7	28.4 ± 21.2
List Sort	95.5 ± 12.7	48.8 ± 10.2	46.1 ± 29.9
Pattern Comparison	87.7 ± 14.8	44.4 ± 11.9	35.9 ± 30.9
Picture Sequence	94.5 ± 13.0	48.4 ± 9.4	43.3 ± 28.5
Card Sort Test	97.1 ± 12.2	50.5 ± 10.9	48.4 ± 31.8
Dexterity			
Peg board (dominant)	80.5 ± 17.3	42.2 ± 10.1	27.6 ± 24.0
Peg board (non-dominant)	93.1 ± 16.6	43.7 ± 8.7	31.8 ± 24.2
Total Cognition Measures			
Fluid cognition	89.7 ± 13.1	45.2 ± 10.4	38.1 ± 30.4
Crystallized cognition	107.4 ± 10.0	51.7 ± 8.7	54.1 ± 27.6

SA-PO949

Preliminary Self-Report Findings From the NIH Emotional Toolbox Among Youth With CKD

Rebecca J. Johnson,<sup>1</sup> Lyndsay Harshman,<sup>2</sup> Marc Lande,<sup>3</sup> Joann M. Carlson,<sup>4</sup> Camille Wilson,<sup>5</sup> Anne E. Dawson,<sup>5</sup> Matthew Matheson,<sup>6</sup> Susan L. Furth,<sup>7</sup> Bradley A. Warady,<sup>1</sup> Stephen R. Hooper.<sup>8</sup> <sup>1</sup>Children’s Mercy Kansas City, Kansas City, MO; <sup>2</sup>The University of Iowa Stead Family Children’s Hospital, Iowa City, IA; <sup>3</sup>University of Rochester Medical Center, Rochester, NY; <sup>4</sup>Robert Wood Johnson University Hospital, New Brunswick, NJ; <sup>5</sup>Nationwide Children’s Hospital, Columbus, OH; <sup>6</sup>Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; <sup>7</sup>The Children’s Hospital of Philadelphia, Philadelphia, PA; <sup>8</sup>University of North Carolina School of Medicine, Chapel Hill, NC.

**Background:** On measures of psychopathology, children with chronic kidney disease (CKD) are known to be at risk for inattention and internalizing symptoms such as sadness and anxiety. Less is known about their self-report of overall emotional health. The NIH Emotional Toolbox assesses negative emotions as well as psychological well-being, social relationships, stress, and self-efficacy.

**Methods:** The Chronic Kidney Disease in Children (CKiD) study is a multi-site, prospective cohort of children with eGFR 30-90ml/min/1.73m<sup>2</sup> at entry. In the past 3 years, 57 participants aged 8-17 have completed the NIH Emotional Toolbox. Linear regression models examined associations between emotional constructs and disease-related variables known to be associated with emotional health (glomerular diagnosis, urine Pr/Cr, blood pressure). These variables were hypothesized to be associated with poorer emotional and social health. Models were adjusted for U25eGFR, age, sex, and maternal education. Significance was set as p <= .01.

**Results:** 16 participants aged 8-12 and 41 aged 13-17 completed assessment of 11 NIH Emotional Toolbox constructs in 4 domains (Psychological Well-Being, Social Relationships, Stress and Self-Efficacy, and Negative Emotions). Median age was 14.7 [IQR=12.8,16.4], 58% were male, 16% had glomerular diagnosis, 78% of mothers had completed education beyond high school, median urine Pr/Cr was 0.23 [IQR=0.12,0.76], 75% were normotensive, and median eGFR was 52 [IQR 40, 70]. Emotional Toolbox T scores placed in the average range across constructs (median scores 43-55). Glomerular diagnosis was significantly associated with the construct positive affect in that participants with glomerular disease reported less positive affect (β=-13.54, 99% CI=-23.58, -3.50; p=.0007); this finding reflected a large effect size.

**Conclusions:** Preliminary findings suggest average self-reported emotional health for a subset of children enrolled in the CKiD study who completed the NIH Emotional Toolbox. Glomerular diagnosis was associated with less positive affect. A larger, more diverse sample of children with CKD is needed to determine if other disease-related variables are associated with emotional health. Future analyses will examine parent proxy report of emotional health for this cohort.

**Funding:** NIDDK Support, Other NIH Support - Eunice Kennedy Shriver National Institute of Child Health and Human Development, and the National Heart, Lung, and Blood Institute

SA-PO950

Cystatin C-Based Equations Underestimate Glomerular Filtration Rate in Men With or at Risk for Mesoamerican Nephropathy

Nathan H. Raines,<sup>1,2</sup> Lesley A. Inker,<sup>3</sup> Jesse C. Seegmiller,<sup>4</sup> Daniel R. Brooks,<sup>6</sup> Marvin A. Gonzalez,<sup>5</sup> David Friedman.<sup>1,2</sup> <sup>1</sup>Beth Israel Deaconess Medical Center, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA; <sup>3</sup>Tufts Medical Center, Boston, MA; <sup>4</sup>University of Minnesota Academic Health Center, Minneapolis, MN; <sup>5</sup>Research Center on Health, Work, and Environment, National Autonomous University of Nicaragua, León, Leon, Nicaragua; <sup>6</sup>Boston University School of Public Health, Boston, MA.

**Background:** Estimated glomerular filtration rate (eGFR) equations using serum creatinine or cystatin C may introduce bias when applied to populations other than those in which the equation was derived. The accuracy of eGFR equations has not been evaluated in populations with high rates of Mesoamerican nephropathy (MeN), a syndrome of chronic kidney disease of unknown cause (CKDu) usually affecting young men from agricultural areas who are of mixed ancestry, perform strenuous labor, and live in poverty.

**Methods:** We compared eGFR from three modern and three historically-used equations against measured GFR (mGFR) by serum iohexol disappearance in 50 men aged 19-45 from a population with high risk for MeN in Nicaragua.

**Results:** mGFR ranged from 24 to 137ml/min/1.73m<sup>2</sup>. Among modern equations, the CKD Epidemiology Collaboration (CKD-EPI) creatinine equation (2021) had minimal bias and good accuracy, while equations that incorporated cystatin C led to a systematic underestimation of GFR and poorer overall performance (Fig. 1), potentially resulting in misdiagnosis (Fig. 2).

**Conclusions:** CKD-EPI creatinine (2021) accurately estimates GFR in men with or at risk for MeN, whereas Cystatin C-based equations do not. More studies are needed to extend these results to other populations affected by CKDu.

**Funding:** Private Foundation Support

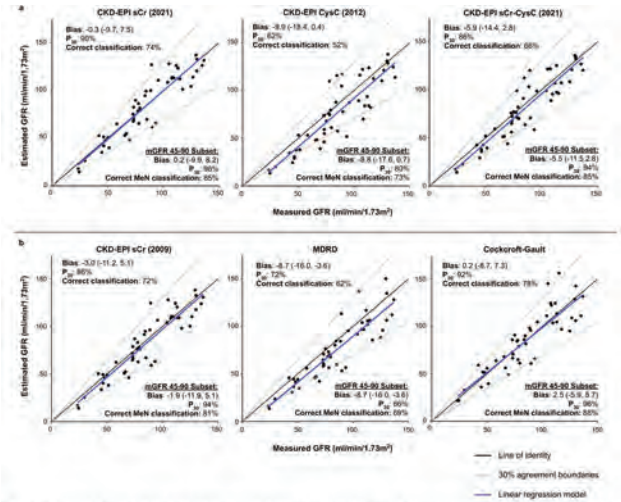

Figure 1. Performance of estimating equations against measured glomerular filtration rate (GFR) by iohexol disappearance in a Nicaraguan Mesoamerican Nephropathy (MeN) population. (a) Equations currently recommended by the National Kidney Foundation–American Society of Nephrology Task Force on Reassessing the Use of Creatinine in Diagnosing Kidney Disease. (b) GFR estimating equations historically used in MeN populations. Bias is defined as the median difference between measured GFR (mGFR) and estimated GFR (eGFR), with interquartile range in parentheses. P<sub>30</sub> is defined as the percentage of eGFR values with 30% of the mGFR. Correct classification is defined as the percent agreement between mGFR and eGFR when categorized as <15, 15 to <30, 30 to <45, 45 to <60, 60 to <90, and 90 or greater ml/min/1.73m<sup>2</sup>. Correct MeN classification is defined as the percent agreement between mGFR and eGFR when classifying individuals as having a GFR above or below 60 ml/min/1.73m<sup>2</sup>, the threshold frequently used for diagnosing MeN. CKD-EPI, Chronic Kidney Disease Epidemiology Collaboration; sCr, serum creatinine; CysC, serum cystatin C; MDRD, Modification of Diet in Renal Disease.

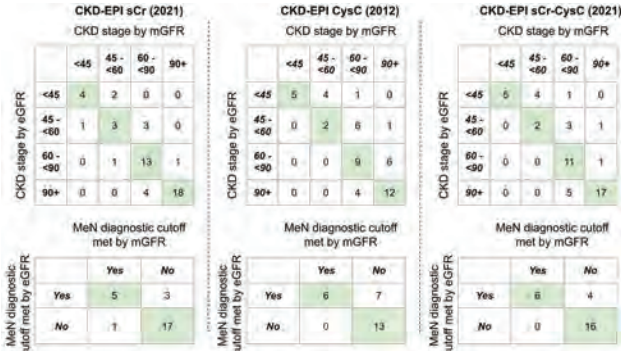

Figure 2. Agreement in staging of chronic kidney disease (CKD) and Mesoamerican Nephropathy (MeN) diagnostic criteria by estimated glomerular filtration rate (eGFR) compared with measured GFR (mGFR). Data presented as counts of participants meeting criteria by mGFR versus eGFR. MeN diagnostic criteria are defined by a GFR cutoff of 60ml/min/1.73m<sup>2</sup> and are evaluated only in the subset of individuals with measured GFR falling between 45 and 90 ml/min/1.73m<sup>2</sup>. Green shading indicates staging agreement between mGFR and eGFR. CKD-EPI, Chronic Kidney Disease Epidemiology Collaboration; sCr, serum creatinine; CysC, cystatin C.

SA-PO951

Enhanced Telemedicine With Trained Medical Assistants Using Augmented Reality Glasses for Inpatient Nephrology Visits

Thelmo Fidel Ernesto Barrantes Ramirez,<sup>1,2</sup> Chudi Adi,<sup>3,1</sup> Jayant Kumar.<sup>1</sup> <sup>1</sup>Renal Medicine Associates, Albuquerque, NM; <sup>2</sup>Burrell College of Osteopathic Medicine, Albuquerque, NM; <sup>3</sup>CADIS Healthcare Inc, Albuquerque, NM.

**Background:** Tele-nephrology utilizes communication technologies to provide care to patients with kidney diseases. Inpatient non-nephrology telemedicine services have shown positive outcomes such as decreased mortality and length of hospital stay. Despite its advantages, “conventional” telemedicine is limited by inadequate clinical examination, and reduced provider/patient emotional connection. Here, we report the use of a novel inpatient telemedicine delivery model with trained medical assistants (MAs) wearing augmented reality (AR) glasses and using a digital stethoscope (DS) capable of maintaining real-time audio-visual telecommunication with the nephrologist.

**Methods:** Six MAs underwent a customized 6-week long training on history taking, physical examination (PE), and use of the AR telehealth platform with two nephrologists. Training involved hands-on interaction with patients. Inpatient telemedicine privileges

were provided by the hospital. Inpatient visits were performed by the MA equipped with AR glasses capable of hands-free operation, and a live-transmitting DS. The consulting nephrologist was located remotely, and could synchronously see and hear what the MA was experiencing in patients' rooms. Direct communication with the patient if needed, and real-time guidance to the MA including AR telestration capabilities, were provided by nephrologist. Auscultation sounds were live streamed to the nephrologist located remotely within or outside the hospital facility.

**Results:** Between January and April 2022, 89 patients consented to participate. The average patient age was 62.3 years, and 65.5% were male. From the total, 14.6% were new consults and 85.3% were follow-ups. Average encounter time was 21.2 minutes. PE was completed in all patients, 17.9% were seen on dialysis. After, each encounter, the MA surveyed the patient on usefulness, technology interface quality and interaction quality. Of the total, 16.8% requested a post encounter doctor visit (in person/video), 55% declined the additional encounter and 28.1% did not respond. Written feedback from patients was positive. Hearing impaired patients showed some difficulty with this technology.

**Conclusions:** Inpatient telemedicine nephrology evaluation using MAs, AR glasses and a DS platform was found to be effective, with excellent clinical utility, patient satisfaction and acceptance.

**Funding:** Private Foundation Support

## SA-PO952

### Mayo Clinic Experience With Endovascular Renal Denervation for Kidney Pain

Vartika Singh, Seif Bugazia, Rajiv Gulati, Abhishek Deshmukh, Stephen B. Erickson, Marie C. Hogan. *Mayo Clinic Minnesota, Rochester, MN.*

**Background:** The objective of this study was to evaluate outcomes following endovascular renal denervation (ERD) for intractable kidney pain performed in patients from 1/2017-5/2022. ERD has been used in few medical centers to manage kidney pain and only reported in small case series.

**Methods:** Retrospective & prospective analysis of 18 patients (with 23 ERDs). Data included patient demographics, etiology, response to ERD, time to recurrence of pain (visual analog scale) following first&/or second ERD. After renal artery angiogram in the electrophysiology lab under general anesthesia, 8 Fr sheath was placed in the femoral artery & renal artery cannulated using a destination sheath. Using Smarttouch DF(TM) catheters, serial, sequential ablation lesions were delivered in a spiral manner from distal to the ostium of renal arteries (power15-20W seeking impedance drop). Repeat renal angiogram was performed to ensure patency of the renal artery.

**Results:** Eighteen (13 F; 5M; median 42yo, range 23-71) had 23 RDNs (2 bilateral; 5 ipsilateral redos; median follow-up 33mo). Etiologies were loin pain hematuria (LPHS) (n=5; 28%), nephrolithiasis (n=5;28%), PKD (n=5; 28%), reflux (n=1; 5%), NOS (n=2; 11%). Five cases (28%) had recurrent ipsilateral pain at a median 21 mo(range 6-28 mo) after ERD. Six cases (33%; 2M; 4F) had abrogation of their pain (median follow-up 33 mo). Using the 'Was it Worth It' questionnaire, 9 pts reported ERD was worthwhile. A total of 13 (72%) reported improvement or resolution (n=7) of pain. One who underwent bilateral ERD had abrogation of right kidney pain while pain continued on the left kidney. Procedural complications included post-operative pain (n=8), dissection (n=2), retroperitoneal bleed (n=2), stenosis (n=1), where 1 patient experienced renal artery dissection after a repeat procedure. Five (all females) had no benefit from ERD.

**Conclusions:** ERD reduced or abrogated pain in 13 (72%) cases but had no impact on pain in 5 cases. LPHS cases had the highest likelihood of success. ERD may be used for palliation of pain within an interdisciplinary chronic pain management & rehabilitation program at specialty centers & only when patients have exhausted other conservative measures.

**Funding:** Private Foundation Support

## SA-PO953

### Biomarker-Enriched Risk Scores and Prognostication of Kidney Outcomes Among African Americans With High-Risk APOL1 Variants

Kinsuk Chauhan,<sup>1</sup> George Vasquez-Rios,<sup>1</sup> Nidhi Naik,<sup>1</sup> Pattharawin Pattharanitima,<sup>2</sup> Lili Chan,<sup>1</sup> Girish N. Nadkarni,<sup>1</sup> Steven G. Coca,<sup>1</sup> <sup>1</sup>Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; <sup>2</sup>Thammasat University Faculty of Medicine, Khlong Nueng, Thailand.

**Background:** Apolipoprotein L1 (APOL1) variants confer a high-risk for chronic kidney disease (CKD) among African American (AA) individuals. Adequate measures to understand abnormal pathophysiologic domains associated with this condition and risk-stratify those with high-risk APOL1 variants are lacking.

**Methods:** Participants with APOL1 high-risk (G1/G2 variants) genotype were selected from the Mount Sinai BioMe Biobank. Plasma TNFR1, TNFR2, KIM-1, MCP-1, YKL-40, IL-18, and suPAR were measured on banked specimens. The association between biomarkers and the composite kidney outcome (sustained  $\geq 40\%$  eGFR decline or ESKD during follow-up) was determined. A biomarker risk score was derived for each patient by summing the integer assigned to each biomarker tertile based on the coefficient in the hazard ratio (HR) model. The total score was divided into 8 categories and then further into low, moderate, and high-risk groups.

**Results:** Among 498 participants, the median age was 56 years, 67.6% were females, median eGFR was 83.3 ml/min/1.73m<sup>2</sup>, and 16.1% reached the outcome. Biomarkers were independently associated with a higher risk of the composite kidney outcome: adjusted HR per doubling for suPAR 1.7 (95% CI: 1.1-2.7), TNFR1: 2.2 (1.5-3.3), TNFR2: 1.6 (1.3-2.1), KIM-1: 1.5 (1.2-1.8), and IL-18: 1.4 (1.1-1.8). The incidence of the composite kidney outcome significantly increased with escalating risk scores. Overall, only 7% of participants in the low-risk group experienced the outcome compared with 15% in the moderate-risk group, and 33% in the high-risk group (Figure).

**Conclusions:** Inflammation and injury pathways may be differentially and independently associated with kidney events among patients with APOL1 high-risk variants. Measuring biomarkers may assist in risk stratification to inform during patient care and potentially serve to enrich clinical trials.

Higher biomarker risk scores show the increased risk of the composite kidney outcome

## SA-PO954

### Radiomic Features of Kidney Magnetic Resonance Imaging (MRI) to Characterize CKD and Progressive CKD

Alexander S. Leidner,<sup>1</sup> Luping Li,<sup>2</sup> Emily Wilt,<sup>2</sup> Stuart M. Sprague,<sup>2</sup> Henry Rusinek,<sup>3</sup> Anand Srivastava,<sup>1</sup> Pottumarthi V. Prasad,<sup>2</sup> <sup>1</sup>Northwestern University Feinberg School of Medicine, Chicago, IL; <sup>2</sup>NorthShore University HealthSystem, Evanston, IL; <sup>3</sup>NYU Langone Health, New York, NY.

**Background:** CKD represents a wide-spectrum of conditions with varying etiologies, manifestations and rates of progression. Application of radiomics, objective numerical representations of image texture, on MRI has potential to non-invasively identify disease features through evaluation of spatial heterogeneity. However, there is limited data on the application of kidney MRI-based radiomics in individuals with CKD.

**Methods:** We generated radiomic features from arterial spin labeling (ASL)-derived cortical blood flow (BF), blood oxygenation level dependent (BOLD)-derived relaxation rate (R2\*), and diffusion-weighted (DW)-derived apparent diffusion coefficient (ADC) maps on 9 healthy and 24 individuals with diabetic CKD (eGFR <60 ml/min/1.73m<sup>2</sup>). FireVoxel was used to calculate 54 radiomic features of the kidney cortex. Spearman correlations were calculated between features. Logistic regression models of radiomics and clinical variables were used to classify (1) CKD and (2) rapidly progressive CKD (eGFR decline >3 ml/min/1.73m<sup>2</sup>/year). Forward stepwise regression was based on area under the receiver operating characteristic curve (AUC) changes.

**Results:** The best model in predicting CKD used the ASL-derived mean BF value had an AUC of 1.0. The best model to predict rapidly progressive CKD included ASL-derived BF and BOLD-derived R2\* parameters with an AUC of 1.0 (Figure 1a). Model parameters were significantly correlated with the presence of CKD, eGFR, eGFR slope, and urine protein excretion (Figure 1b).

**Conclusions:** These preliminary results show the potential of MRI radiomics as a non-invasive diagnostic tool in phenotyping CKD. These results require validation in future larger studies with heterogeneous CKD etiologies.

**Differential Expression of Renal and Hepatic PCSK9 During Development of Hypercholesterolemia in the Puromycin Aminonucleoside Nephrosis Rat Model of Nephrotic Syndrome**  
Eduardo Molina-Jijon,<sup>1</sup> Camille E. Mace,<sup>1</sup> Carmen Avila-Casado,<sup>2</sup> Lionel C. Clement.<sup>1</sup> <sup>1</sup>Rush University Medical Center, Chicago, IL; <sup>2</sup>University Health Network, Toronto, ON, Canada.

**Background:** In the US, 85% of patients with nephrotic syndrome (NS) have hypercholesterolemia, compared to 31.5% of the general population. Proprotein convertase subtilisin/kexin type 9 (PCSK9) plays a main role in the regulation of LDL-cholesterol in the liver. In the kidney, PCSK9 is expressed in the cortical collecting duct (CCD) where acts as a chaperone for the epithelial sodium channel. We showed that PCSK9 is increased in kidney biopsies of patients with NS and that it is implicated in the initiation of hypercholesterolemia in two animal models, Buffalo-Mna rats (model of focal and segmental glomerulosclerosis) and Rm2b<sup>-/-</sup> mice (model of collapsing glomerulopathy) (Molina-Jijon et al, 2020). In this study, we investigate the expression of PCSK9 in puromycin aminonucleoside (PAN) nephrosis in rats, a model of human Minimal Change Disease (MCD)

**Methods:** Sprague-Dawley rats were injected with saline 0.9% (control) or PAN (15 mg/100 g). Rats were euthanized daily from day 1 to 7 after PAN injection. Proteinuria, PCSK9 and serum cholesterol were assessed. PCSK9 gene and protein expression in liver and kidney were studied by RealTime PCR and Western blot

**Results:** Control rats did not develop proteinuria, hypercholesterolemia or high serum PCSK9. PAN rats developed proteinuria (mg/18h) from day 4 after injection (0.82±0.1 day 0; 4.4±1 day 4; 63±17 day 5; 145±7 day 6 and 128±13 day 7). Serum PCSK9 (ng/mL) significantly increased from day 5 (144±26 day 0; 404±81 day 5; 1635±263 day 6; 1816 ± 191 day 7), and hypercholesterolemia (mg/dL) significantly developed from day 6 to 7 (93±6 day 0; 326.80±37 day 6; 352±10 day 7). In the kidney, PCSK9 expression increased from day 3 after injection, and was not modified in the liver. Similarly, PCSK9 mRNA increased in the kidney from day 5 with no significant modification in the liver (fold change mRNA expression=18.9 for renal cortex vs 2.4 for liver day 5; 11.4 vs 2.6 day 6; 20.5 vs 1.6 day 7)

**Conclusions:** As rats develop NS, PCSK9 protein level increase in the kidney and serum and did not change in the liver. PCSK9 from CCD may play a role in the initiation of hypercholesterolemia in MCD-related nephrotic syndrome and could become a new therapeutic target to prevent development of hypercholesterolemia in nephrotic syndrome patients

SA-PO956

**The Cell-Type and Region-Specific Chromatin Landscape of the Kidney**  
Debora L. Gisch,<sup>1</sup> Blue Lake,<sup>3</sup> Jeannine M. Basta,<sup>4</sup> Lynn Robbins,<sup>4</sup> Michelle Pherson,<sup>5</sup> Daria Barwinska,<sup>1</sup> Samir V. Parikh,<sup>2</sup> Brad H. Rovin,<sup>3</sup> Ying-Hua Cheng,<sup>1</sup> Kun Zhang,<sup>3</sup> Tarek M. El-Achkar,<sup>1</sup> Shamim Mollah,<sup>4</sup> Pierre C. Dagher,<sup>1</sup> Sanjay Jain,<sup>4</sup> Michael I. Rauchman,<sup>4</sup> Michael T. Eadon.<sup>1</sup> KPMP <sup>1</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>2</sup>The Ohio State University Wexner Medical Center, Columbus, OH; <sup>3</sup>University of California San Diego, La Jolla, CA; <sup>4</sup>Washington University in St Louis, St Louis, MO; <sup>5</sup>Saint Louis University, Saint Louis, MO.

**Background:** Activation or repression of gene transcription is regulated by changes in the chromatin landscape, including post-translational modifications of histones and DNA methylation. In an integrated multi-omic approach, we characterized the regulation of reference transcript expression for the podocyte, proximal tubule (PT), and thick ascending loop of Henle (TAL) cells.

**Methods:** Using human nephrectomy and biopsy tissue, we developed quality (QC) standards for whole genome bisulfite sequencing (WGBS, N=30) of dissected glomeruli (GLOM) and tubulointerstitium (TI), Cleavage Under Targets & Release Using Nuclease (CUT&RUN) in bulk (N=12) with H3K27ac and H3K27me3 antibodies and single cell Multiome (combined snRNAseq and scATACseq, N=12) to comprehensively define epigenomic features of accessible chromatin regions in the kidney. Peak alignment in genomic regions (promoter, exon, CpG island, etc) was determined by Fisher's exact test. In identical specimens, proteomic, transcriptomic, and KPMP/HubMAP snRNAseq atlas (>200,000 nuclei) phenotypes were compared.

**Results:** QC measures for batch correction, controls, and reproducibility are optimized for human kidney. We describe the methylome for 22,156,845 CpGs. After genomic feature modeling (promoter, etc), WGBS inversely correlated with mRNA

(R=0.61) and protein (R=0.55). Peaks of WGBS, CUT&RUN, and the Multiome were aligned for cell-specific expressed genes, comparing podocytes to GLOM, and TAL/PT to TI or Bulk. Glom/TI WGBS valleys aligned with scATACseq peaks (p<9x10<sup>-11</sup>). CUT&RUN H3K27ac peaks aligned with TI WGBS valleys (p<0.03). CUT&RUN H3K27ac and scATAC-seq peaks coincided in TAL and PT (both p<0.001). A tensor factorization network analysis identified consistent regulation of ESRRG, a gene associated with TAL injury in a snRNAseq atlas, showing consistent WGBS, H3K27ac, H3kme3, and scATACseq regulation in its promoter and introns 1 and 3.

**Conclusions:** These studies integrate histone modification and DNA methylation, which contribute to chromatin accessibility in the kidney. This epigenomic reference atlas is a first step to assess downstream expression changes in multiple kidney cell types and will be valuable to characterize CKD GWAS variants that map to distal enhancers.

**Gene Ontology Reveals Potentially Unique Mechanism of Action Underlying Selected Renal Cells Bioactivity**  
Prakash Narayan, Joseph Stavas, Tim A. Bertram, Deepak Jain. *ProKidney, Winston-Salem, NC.*

**Background:** Selected renal cells (SRC), a renal epithelial cell-enriched platform, is being advanced as autologous cell-based therapy for treatment of chronic kidney disease (CKD). In this study, we coupled empirical data with gene ontology to test the hypothesis that SRC stabilizes or improves renal function at least in part by co-expressing proteins involved in early kidney development.

**Methods:** Genes coding for 8 proteins viz. Rack1 (Gnb2l1), Six2, Osr1, Lhx1, Ret, Fgf8, nephrin (nphs1) and podocin (nphs2) expressed by human SRC (doi.org/10.1016/j.ekir.2022.04.014) were seeded into STRING and Genemania. The knowledge bases were queried for co-expression of these empirically identified nodes in human tissue, and other nodes comprising this interactome.

**Results:** Use of either database suggested that these 8 nodes are not known to be co-expressed in human tissue (Figures 1a and b). Indeed, both search engines returned co-expression interactomes less Rack1 and Ret. The resulting network nevertheless included additional nodes (Figure 1b) involved in urogenital development, metanephric nephron development, renal polarity, glomerular development, and other aspects of neo-nephrogenesis.

**Conclusions:** To the best of our knowledge, human SRC is unique, co-expressing Rack1, Six2, Osr1, Lhx1, Ret, Fgf8, nephrin and podocin. These data also suggest that SRC bioactivity is driven by co-expression of proteins critical to several elements of neo-nephrogenesis and their spatiotemporal coordination, and support the mechanism of action of its clinical effects. SRC-based Renal Autologous Cell Therapy (REACT™) is in clinical trials for CKD caused by type 2 diabetes and congenital anomalies of kidney and urinary tract and has been granted Regenerative Medicine Advanced Therapy designation by Food and Drug Administration.

**Funding:** Commercial Support - ProKidney

Figure 1. STRING (a) and Genemania (b) queries in human tissue for co-expression networks of 8 nodes expressed on SRC returned interactomes less *rack1* and *ret* (red underbars); additional nodes were identified as part of this interactome.

**Characterization of the Effects of HIV Vpr on Renal Distal Tubules by Single-Nucleus RNA-Sequencing**  
Khun Zaw Latt,<sup>1</sup> Teruhiko Yoshida,<sup>1</sup> Shashi Shrivastav,<sup>1</sup> Amin Abedini,<sup>2</sup> Hewang Lee,<sup>6</sup> Yongmei Zhao,<sup>3</sup> Joon-Yong Chung,<sup>4</sup> Avi Z. Rosenberg,<sup>5</sup> Pedro A. Jose,<sup>6</sup> Cheryl A. Winkler,<sup>4</sup> Mark A. Knepper,<sup>7</sup> Tomoshige Kino,<sup>8</sup> Katalin Susztak,<sup>2</sup> Jeffrey B. Kopp.<sup>1</sup> <sup>1</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>2</sup>University of Pennsylvania, Philadelphia, PA; <sup>3</sup>Frederick National Laboratory for Cancer Research, Frederick, MD; <sup>4</sup>National Cancer Institute, Bethesda, MD; <sup>5</sup>Johns Hopkins University, Baltimore, MD; <sup>6</sup>The George Washington University School of Medicine and Health Sciences, Washington, DC; <sup>7</sup>National Heart, Lung and Blood Institute, Bethesda, MD; <sup>8</sup>Sidra Medicine, Doha, Qatar.

**Background:** HIV retroviral protein R (Vpr) contributes to the pathogenesis of HIV-associated nephropathy (HIVAN). Vpr induces cell cycle arrest and apoptosis, and regulates expression of glucocorticoid- and mineralocorticoid-responsive genes.

**Methods:** To investigate the effects of Vpr on aldosterone-mediated regulation of *Slc12a3* expression and sodium reabsorption in distal nephron segments, we performed single-nucleus RNA sequencing of wild-type and Vpr transgenic mouse kidney cortex after 4 days of low (0.045%) sodium diet.

**Results:** In Vpr transgenic mouse, *Slc12a3* downregulation was observed in late distal convoluted tubule and connecting tubule cluster (DCT2/CNT) but not in early distal convoluted tubules (DCT1). Expression levels of the mineralocorticoid receptor (*Nr3c2*) and the enzyme 11- $\beta$ -hydroxysteroid dehydrogenase 2 (*Hsd11b2*) genes were higher in the DCT2/CNT compared to the DCT1 cluster. The percentage of DCT cells in Vpr mouse was lower (1.8% of total cells) compared to that observed in salt-depleted WT (3.7%) and salt-replete WT (3.6%). Sub-clustering of distal tubular cell clusters identified *Pvalb*<sup>+</sup> DCT1 and *Slc8a1*<sup>+</sup> DCT2 subclusters. The DCT1 cluster showed fewer cells in Vpr mouse (0.95%) compared to salt-depleted WT (2.9%) and salt-replete WT (3.1%). Pathway analysis of differentially expressed genes in DCT1 cluster showed that genes involved in autophagy and protein ubiquitination were upregulated in Vpr mouse compared to WT. There is an open chromatin mark over a 50 kb region spanning the *Slc12a3* gene exclusively in DCT cells, suggesting a DCT-specific super-enhancer state. RNAScope imaging revealed fewer *Slc12a3*<sup>+</sup> DCT segments in Vpr mouse cortex compared to WT.

**Conclusions:** The downregulation of *Slc12a3* and the higher expression levels of *Nr3c2* and *Hsd11b2* in the DCT2/CNT cluster suggest that the aldosterone-mediated upregulation of *Slc12a3* in the context of salt depletion was inhibited by Vpr mostly in late distal convoluted tubules. The major effect of Vpr on the DCT was the loss of DCT1 cells, likely due to autophagy. These observations suggest the salt-wasting effect of Vpr in transgenic mice was associated with loss of *Slc12a3*<sup>+</sup> DCT1 segments and not with the lower abundance in individual DCT1 cells.

## SA-PO959

### SHROOM3 Expression and CKD: A Mendelian Randomization Analysis

Pukhraj S. Gaheer,<sup>1</sup> Nikhil Uppal,<sup>2</sup> Darren Bridgewater,<sup>2</sup> Matthew B. Lanktree,<sup>2,3</sup>  
<sup>1</sup>McMaster University Faculty of Arts and Science, Hamilton, ON, Canada;  
<sup>2</sup>McMaster University Faculty of Health Sciences, Hamilton, ON, Canada; <sup>3</sup>St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada.

**Background:** Genome-wide association studies (GWAS) identified common genetic variants within 100 kilobases of the transcription start site of *SHROOM3* individually associated with chronic kidney disease (CKD), estimated glomerular filtration rate (eGFR), and urinary albumin-to-creatinine ratio (uACR). This upstream region contains regulatory elements, and the location of these variants suggests that altered *SHROOM3* expression could be the mechanism underlying the observed associations. We sought to evaluate if a genetically predicted decrease in *SHROOM3* expression was associated with an increased risk of CKD.

**Methods:** First, we found genetic variants associated with *SHROOM3* expression, known as expression quantitative trait loci (eQTL), by conducting a meta-analysis of 7408 genetic variants from 51 tissue datasets from the public Human Kidney eQTL Atlas, GTEx, and NephQTL resources. Independent eQTL variants were then selected to be used in a two-sample Mendelian randomization analysis. Using European ancestry summary-level GWAS results from the CKDGen Consortium, UK Biobank, and the Finnish Genetics Consortium, we compared the effect of each variant on *SHROOM3* expression to its effect on risk of CKD (n = 480,698), baseline cross-sectional eGFR (n = 1,201,929), previously defined decline in eGFR phenotypes “Rapid3” or “CKD125” (n = 141,964), and uACR (n = 547,361).

**Results:** We identified 50 independent genetic variants associated with *SHROOM3* expression ( $P < 0.05$ ,  $r^2 < 0.01$ ). These variants cumulatively explained 2% of the variability in *SHROOM3* expression. A 34% reduction in genetically predicted *SHROOM3* expression was associated with a 0.3% (95% CI: 0.1% - 0.5%) reduction in cross-sectional eGFR ( $P = 0.002$ ). There was no association between genetically predicted *SHROOM3* expression and CKD, longitudinal rapid decline in eGFR, or uACR ( $P > 0.05$ ).

**Conclusions:** Mendelian randomization analysis suggests a small reduction in genetically predicted *SHROOM3* expression throughout life is associated with a slightly lower baseline eGFR. In a seeming contradiction, we did not find that lower genetically predicted *SHROOM3* expression was associated with the presence of CKD, rapid decline in eGFR, nor uACR. These results are consistent with recent reports that genetic association with cross-sectional eGFR, maximum attained eGFR, longitudinal decline in eGFR, and risk of CKD may differ.

### Single Nucleus Multiomic Sequencing of Human Kidney Identifies Potential Regulators of Fibrosis and Injury in CKD

Nicolas Ledru,<sup>1</sup> Yoshiharu Muto,<sup>1</sup> Parker C. Wilson,<sup>1</sup> Haojia Wu,<sup>1</sup> Giuseppe Orlando,<sup>2</sup> Sushrut S. Waikar,<sup>3</sup> Benjamin D. Humphreys,<sup>1</sup> <sup>1</sup>Washington University in St Louis School of Medicine, St Louis, MO; <sup>2</sup>Wake Forest Baptist Medical Center, Winston-Salem, NC; <sup>3</sup>Boston Medical Center, Boston, MA.

**Background:** Chronic kidney disease (CKD) is a progressive and prevalent disease with disproportionate impact on BIPOC patients, representing a large source of both disease burden and disparities in health outcomes in the US. CKD is characterized by declining renal function and fibrosis. We have identified a proximal tubule subpopulation that fails to repair following acute kidney injury (AKI) and takes on pro-inflammatory and pro-fibrotic characteristics, implicating its potential role in transition to CKD. This failed repair state also increases in prevalence with both aging and disease, indicating that accumulation of this cell population may contribute to fibrosis and declining kidney

repair capacity in CKD as well. Identification of regulatory elements associated with this proximal tubule state may lead to putative therapeutic targets in the treatment of CKD.

**Methods:** We performed single nucleus multiomic (simultaneous snRNA-seq and snATAC-seq) sequencing of eight healthy adult human kidneys in order to characterize the proximal tubule gene regulatory networks and the *cis*- and *trans*-regulatory elements underpinning the transition to the failed repair cell state. After quality control, we had 50,768 single cell transcriptomes and epigenomes. The latter identified 193,787 peaks.

**Results:** We applied a regularized regression analysis to generate a list of prioritized transcription factors and enhancer regions that regulate genes that changed in expression along the healthy to failed repair trajectory. The findings were also integrated with CKD risk variants to provide putative mechanistic annotations. We used Cut&Run and siRNA knockdown in primary proximal tubule cell culture to validate our model's predicted *cis*- and *trans*-regulatory elements of interest.

**Conclusions:** Our integrated single nucleus multiomic sequencing atlas allowed us to construct predictive parametric gene regulatory networks for genes that changed in expression along the healthy-failed repair proximal tubule trajectory. This identified several regulatory elements that, when therapeutically targeted, may allow for targeting of the failed repair population to reduce fibrotic and inflammatory signaling, while promoting repair mechanisms and return to a healthy proximal tubule state.

## SA-PO961

### Early Signaling Events in Renal Compensatory Hypertrophy Revealed via Multi-Omics

Hiroaki Kikuchi,<sup>1</sup> Chin-Rang Yang,<sup>1</sup> Lihe Chen,<sup>1</sup> Hyun Jun Jung,<sup>2</sup> Euijung Park,<sup>1</sup> Mark A. Knepper,<sup>1</sup> Epithelial Systems Biology Laboratory, Systems Biology Center <sup>1</sup>National Institutes of Health, Bethesda, MD; <sup>2</sup>Johns Hopkins University, Baltimore, MD.

**Background:** Mechanisms involved in compensatory hypertrophy of the kidney remain incompletely understood. New “-omic” methodologies have been recently introduced that have the potential of identifying complex mechanisms. Here we seek to identify the earliest signaling changes in the contralateral kidney after unilateral nephrectomy (UNx) in mice using next-generation sequencing and proteomics techniques.”

**Methods:** Experiments were done in mice undergoing UNx and sham nephrectomy. At specific time points (24 hours and 72 hours) after surgery, the earliest first portion of the kidney proximal tubule (PT-S1) was manually micro-dissected and utilized for transcriptomic analysis by single-tubule small sample RNA-Seq and single-tubule ATAC seq. Furthermore, quantitative proteomic analysis was carried out using protein mass spectrometry.

**Results:** Kidney volume was already increased 24 hours after UNx, reaching a plateau at 72 hours. Quantitative morphometry in microdissected proximal tubules showed that significant increases in outer diameter and mean cell volume in proximal tubules, but no clear increase in the cell count per unit length. RNA-Seq in microdissected PT-S1 at 24 hours showed that peroxisome proliferator-activated receptor alpha (PPARA) target genes such as *Angptl4*, *Acot1*, *Cyp4a14*, *Fabp1*, *Hmgcs2* and *Mgl1* were strongly upregulated in PT (confirmed statistically). Motif analysis (HOMER) of sequences corresponding to significantly upregulated single tubule ATAC-seq peaks revealed upregulation of binding site motifs corresponding to PPARA and HNF4A, both lipid-regulated transcription factors. Quantitative protein mass spectrometry revealed increased abundances of PPAR regulated proteins such as HMGCS2, CYP4A14 and ANGPTL4 at 24 hours, consistent with RNA-Seq results.

**Conclusions:** Compensatory growth of the kidney is associated with increased proximal tubule cell size, but not cell number. Early stages of compensatory hypertrophy are associated with altered fatty acid and cholesterol metabolism including anabolic pathways required for synthesis of new membranes needed for cell growth.

## SA-PO962

### Pathophysiology and Molecular Characterization of a Novel Model of CKD and Left Ventricular Diastolic Dysfunction (CKD-LVDD Model)

Alejandro R. Chade,<sup>1</sup> Alfonso Eirin,<sup>2</sup> <sup>1</sup>The University of Mississippi Medical Center, Jackson, MS; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN.

**Background:** Chronic kidney disease (CKD) is an independent risk factor for the development of heart failure, but the underlying mechanisms remain unknown. We developed a translational swine model of CKD and left ventricular diastolic dysfunction (CKD-LVDD) that replicates human disease and showed that cardiac abnormalities associate with a marked renal release of inflammatory cytokines to the systemic circulation, suggesting a potential pathophysiological connection. We examined whether the cardiac transcriptomic landscape is altered in CKD-LVDD pigs compared to normal controls.

**Methods:** CKD-LVDD and normal pigs (n=6 each) were studied for 14 weeks. Cardiac morphology and function (echocardiography) and renal hemodynamics (multi-detector CT) were quantified *in vivo*. mRNA-sequencing studies were performed (n=3 each) and expression profiles for dysregulated (fold change >1.4 or <0.7 and p<0.05) mRNAs in CKD-LVDD pigs were functionally interpreted by gene ontology analysis. Cardiac remodeling, inflammation, calcium cycling, and mitochondrial morphology.

**Results:** Cardiac abnormalities in CKD-LVDD were associated to differentially expressed calcium signaling, mitochondrial, and inflammatory genes, accompanied by cardiac fibrosis, mitochondrial damage, M1 macrophage infiltration, and altered calcium cycling vs. normal controls.

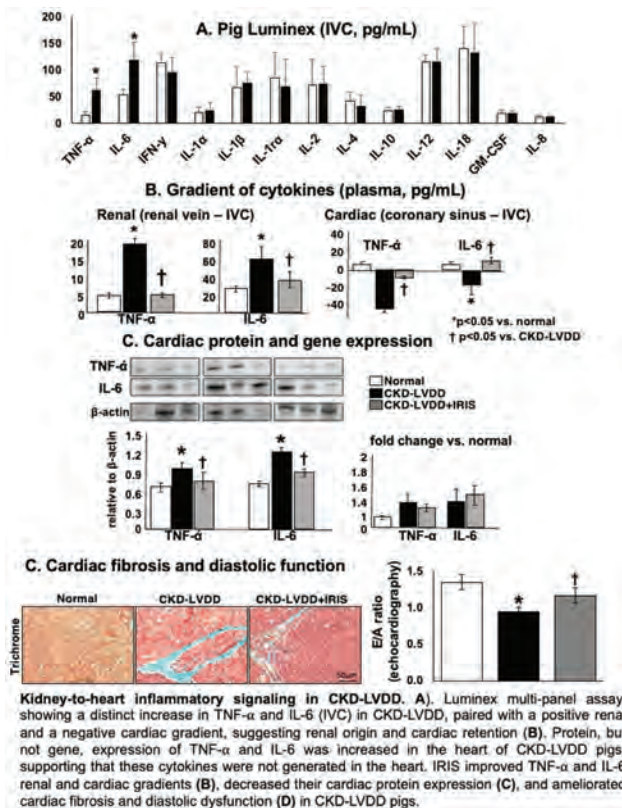

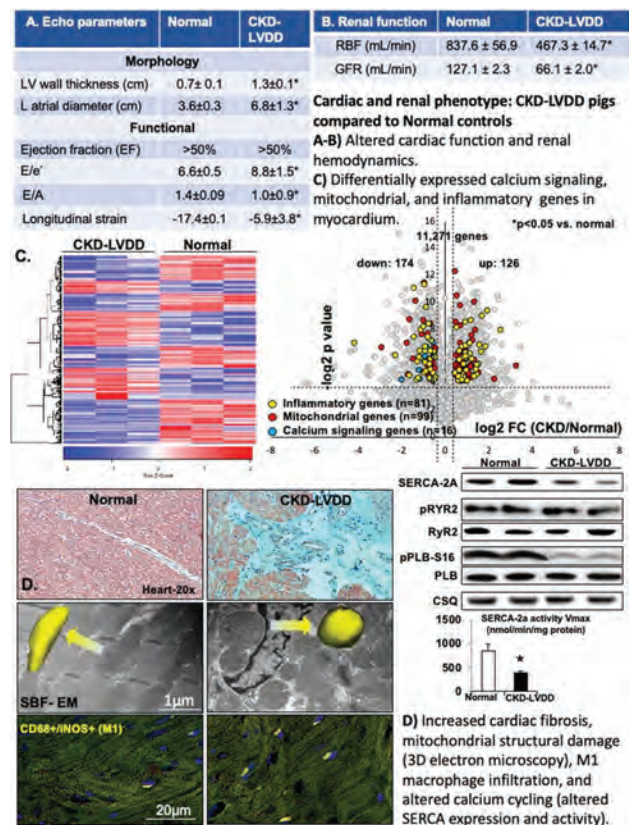

**Conclusions:** Our integrated pathophysiology and molecular data from a translational model of disease may set the stage for future specific interventions to ameliorate the development of LVDD in CKD.

## SA-PO963

### Pathophysiology of CKD-Left Ventricular Diastolic Dysfunction: Role of Renal TNF- $\alpha$ and IL-6 Inflammatory Signaling

Alejandro R. Chade,<sup>1</sup> Alfonso Eirin,<sup>2</sup> <sup>1</sup>The University of Mississippi Medical Center, Jackson, MS; <sup>2</sup>Mayo Clinic Minnesota, Rochester, MN.

**Background:** Chronic kidney disease (CKD) is an independent risk factor for the development of heart failure, but their actual pathophysiological connection remains to be fully elucidated. We developed a translational swine model that recapitulates human CKD and left ventricular diastolic dysfunction (CKD-LVDD). We hypothesized that increased pro-inflammatory cytokine signaling of renal origin imposes cardiac structural and functional abnormalities in swine CKD-LVDD.

**Methods:** CKD-LVDD pigs (n=6 each) were studied for 14 weeks, after inhibition of renal inflammatory signaling (IRIS) achieved by a single intra-renal administration of a biopolymer fused peptide inhibitor of NF- $\kappa$ B (SynB1-ELP-p50i) 8 weeks earlier. Untreated CKD-LVDD and Normal pigs served as controls (n=6 each). Using a specific pig Luminex, circulating levels (inferior vena cava blood, IVC) of inflammatory cytokines were measured. Tumor necrosis factor (TNF)- $\alpha$  and interleukin (IL)-6 levels were distinctly elevated, confirmed by (ELISA), also measured in renal vein (RV) and coronary sinus (CS) blood, and their renal (RV-IVC) and cardiac (CS-IVC) gradients quantified. Cardiac morphology, function (echocardiography), and fibrosis were also quantified.

**Results:** TNF- $\alpha$  and IL-6 levels were higher in CKD-LVDD (A), paired with a positive renal and a negative cardiac gradient (B), and increased cardiac protein, but not gene, expression levels (C). IRIS improved TNF- $\alpha$  and IL-6 renal and cardiac gradients (B), decreased their cardiac protein expression (C), and ameliorated cardiac fibrosis and diastolic dysfunction (D).

**Conclusions:** Our study supports a crosstalk between the kidney and the heart in CKD, suggesting that inflammatory signaling of renal origin (partly led by TNF- $\alpha$  and IL-6) may impose cardiac abnormalities towards development of LVDD in CKD.

**Funding:** NIDDK Support, Other NIH Support - HL095638

## SA-PO964

### Circulating SIRP $\alpha$ Stimulates CKD-Induced Cardiomyopathy

Jiao Wu, William E. Mitch, Sandhya S. Thomas. Baylor College of Medicine, Houston, TX.

**Background:** A major etiology of chronic kidney disease (CKD) is insulin resistance in CKD-induced cardiomyopathy. We have discovered a potential driver of insulin resistance, signal regulatory protein alpha (SIRP $\alpha$ ) that circulates in response to CKD which adversely influences myocardial muscle.

**Methods:** Myotubes and cardiomyocytes, but not adipocytes treated with high glucose, or cardiomyocytes treated with uremic toxins stimulated secretion of SIRP $\alpha$  in culture media. Next, to determine myocardial-specific effects of suppressing SIRP $\alpha$  in CKD, csSIRP $\alpha$  mice were created and subjected to subtotal nephrectomy and compared to flox mice with CKD. *In vivo* M-mode echocardiography imaging was utilized to determine myocardial function. csSIRP $\alpha$  mice with CKD displayed improved ejection fraction %, fractional shortening %, and cardiac output when compared to flox littermate control mice with CKD.

**Results:** Myotubes and cardiomyocytes, but not adipocytes treated with high glucose, or cardiomyocytes treated with uremic toxins stimulated secretion of SIRP $\alpha$  in culture media. Next, to determine myocardial-specific effects of suppressing SIRP $\alpha$  in CKD, csSIRP $\alpha$  mice were created and subjected to subtotal nephrectomy and compared to flox mice with CKD. *In vivo* M-mode echocardiography imaging was utilized to determine myocardial function. csSIRP $\alpha$  mice with CKD displayed improved ejection fraction %, fractional shortening %, and cardiac output when compared to flox littermate control mice with CKD.

**Conclusions:** These results suggest that skeletal or cardiac muscle are the origin of circulating SIRP $\alpha$  in response to uremia or hyperglycemia which stimulates its release. Importantly, cardioprotection from CKD was observed with myocardial suppression of SIRP $\alpha$ .

**Funding:** Private Foundation Support

## SA-PO965

### The Gut Microbiome Regulates Glomerular Filtration Rate

Jiaojiao Xu, Kunal Gupta, Jason Sanchez, Sepideh Gharraie, Hamid Rabb, Jennifer L. Pluznick. Johns Hopkins University School of Medicine, Baltimore, MD.

**Background:** Gut microbes influence physiology and pathophysiology. We hypothesized that gut microbes alter glomerular filtration rate (GFR).

**Methods:** Gut microbes were depleted using antibiotics in drinking water (ABX: 1g/L ampicillin, 1g/L neomycin, 0.5 g/L vancomycin). C57BL/6J male and female mice (6-weeks-old) were treated with ABX for 5 weeks, and GFR was measured by transcutaneous detection of FITC-sinistrin. Another cohort of mice were randomly assigned to four different groups (n=8/sex/group): control diet (CD), high fat diet (HFD),

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

CD + ABX, HFD + ABX. After 9 weeks, we analyzed body weight (BW), non-fasting glucose, insulin, GFR, glucose tolerance test (GTT), and insulin tolerance test (ITT).

**Results:** Bacteria reduction with ABX treatment was confirmed by qPCR of fecal samples using pan-bacterial primers (Ct for Females, F: Ctrl 13±0.2 vs ABX 21±0.4; Males, M: 13±0.1 vs ABX 20±0.4, n=8). GFR increased with ABX (F: 172±11 vs ABX 229±8,  $p=0.03$ ; M: 167±7 vs ABX 266±15  $\mu\text{L}/\text{min}$ ,  $p=0.02$ , n=8). Next, we measured GFR in germ-free (GF) mice (born and raised without gut microbes), conventional mice (Ctrl, born with gut microbes), and conventionalized GF mice (CGF, born without gut microbes but given oral gavage of a fecal slurry with gut microbes). GFR increased in GF mice (F: 286±23,  $p<0.001$ ; M: 248±17,  $p=0.002$ ) versus both conventional (F: 163±6; M: 186±5) and CGF (F: 185±21,  $p=0.003$ ; M: 186±7,  $p=0.002$ , n=7-8). GFR also increases in high-fat diet (HFD) induced diabetic renal disease. To elucidate if mechanisms are similar, we measured GFR in mice on CD and HFD and/or with ABX. GFR was increased by HFD in both sexes. GFR in females was increased by ABX on CD (F: 182±13 vs. F+ ABX: 282±13;  $p=0.0005$ ) and HFD (F: 290±20 vs. F+ ABX: 373±20;  $p=0.01$ ). GFR in males increased with ABX on CD (M: 191±10 vs. M+ ABX: 263±10;  $p=0.04$ ) but not HFD (M: 385±20 vs. M+ ABX: 390±33; NS). In both sexes, BW, GTT, and fasting glucose were affected by diet but not ABX. In females, ITT was affected by diet but not ABX. For males on a CD (but not HFD), ABX improved insulin responsiveness.

**Conclusions:** The absence (GF) and suppression (ABX) of gut microbes increase GFR. In females, the increased GFR from ABX and HFD are additive. The mechanisms of this microbe-GFR interaction merit further study.

## SA-PO966

### Gut Microbiota Modulates Gene Expression in the Kidney

Brittini Moore, Jiaojiao Xu, Jennifer L. Pluznick. Pluznick Lab Johns Hopkins University School of Medicine, Baltimore, MD.

**Background:** Gut microbes impact host gene expression in peripheral tissues; however, it is unknown whether gut microbes influence renal gene expression.

**Methods:** Germ-free (GF; lacking gut microbes) and conventionalized (Conv; GF mice given gut microbes by oral gavage at 4 wks of age) C57Bl/6J mice were compared by bulk RNA sequencing (RNA-Seq) of kidney, liver, and large intestine. At 8 wks of age, GF and Conv mice were sacrificed, tissues processed, and fecal pellets from Conv mice collected for 16S rRNA sequencing. Differentially expressed genes (DEGs) were defined as log<sub>2</sub> foldchange(log<sub>2</sub>fc)≥±0.5,  $p<0.05$ , and baseline≥15 TPM. For antibiotic-treated mice (ABX), conventional C57Bl/6 mice were given ampicillin (1g/L), neomycin (1g/L), and vancomycin (0.5g/L) in drinking water for 9 wks and kidneys were collected for real-time quantitative PCR (qPCR).

**Results:** Comparing Conv and GF mice (both sexes analyzed together, n=3-4/sex/condition) revealed 918 DEGs in kidney, 1701 in liver, and 1324 in large intestine. In males, 85% of kidney DEGs did not change in liver or large intestine. In females, 80% of DEGs were kidney-specific. 4 genes were changed in all 3 tissues in males (*Per1*, *Foxo3*, *Mt1*, *Mt2*), and 6 genes in females (*Per2*, *Mt1*, *Mt2*, *Jchain*, *Extl1*, *Lpl*). *Mt1* and *Mt2* were the only genes increased in GF mice in both sexes and in all 3 tissues. In kidney, *Mt1* expression was upregulated by log<sub>2</sub>fc 1.10±0.22 ( $p<0.001$ ) in GF vs Conv males (n=4,4), and by log<sub>2</sub>fc = 0.57±0.22 ( $p=0.01$ ) in GF vs Conv females (n=4,4). *Mt2* was also increased in GF males (log<sub>2</sub>fc = 1.44±0.29,  $p<0.001$ ) and GF females (log<sub>2</sub>fc = 0.80±0.29,  $p=0.006$ ) vs Conv. To determine if changes in *Mt1* and *Mt2* are due to the absence of gut microbes, we performed qPCR using kidneys from ABX vs conventional mice (n=3 sex/condition). Although the trends in *Mt1* and *Mt2* were replicated in ABX samples, this only reached significance for *Mt2* in males (*Mt1* males: log<sub>2</sub>fc = 1.15±0.6,  $p=0.35$ ; *Mt1* females: log<sub>2</sub>fc = 1.31±0.4,  $p=0.28$ ; *Mt2* males: log<sub>2</sub>fc = 1.87±0.7,  $p=0.03$ ; *Mt2* females: log<sub>2</sub>fc = 1.54±0.69,  $p=0.31$ ). Finally, 16S rRNA sequencing showed *Verrucomicrobia* was more abundant in males (11.17% of gut microbes) compared to females (1.68%,  $p=0.005$ ); no differences were observed in other phyla.

**Conclusions:** Renal gene expression is altered in GF mice. Genes regulated across tissues play roles in circadian entrainment (*Per1* and *Per2*) and zinc-binding (*Mt1* and *Mt2*).

### Immune-Mediated Tubule Atrophy Promotes AKI to CKD Transition

Leyuan Xu, Jiankan Guo, Dennis G. Moledina, Lloyd G. Cantley. Yale School of Medicine, New Haven, CT.

**Background:** Incomplete repair after acute kidney injury (AKI) is associated with progressive loss of tubular cell function and development of chronic kidney disease (CKD).

**Methods:** We compared the kidney response to identical times of ischemic injury between mice subjected to unilateral ischemia-reperfusion kidney injury with contralateral nephrectomy (IRI/CL-NX, in which tubule repair predominates) or unilateral IRI with contralateral kidney intact (U-IRI, in which fibrosis and atrophy predominates). We performed single cell RNA-sequencing analysis on day 7, 14, and 30 after injury to identify major cell types in the kidney and the differential transcriptional response between the models in each cell type.

**Results:** The initial injury and early recruitment and activation of macrophages, dendritic cells (DCs), neutrophils, and T cells were similar through day 7 but markedly diverged afterwards between the two models. By day 14, kidneys subjected to U-IRI had greater numbers of macrophages with higher expression of *Ccl2*, *Ccl7*, *Ccl8*, *Ccl12*, and *Cxcl16*. These chemokines correlated with a second wave of *Ccr1*-positive neutrophils and *Cxcr6*-positive T cells, resulting in a proinflammatory milieu, accompanied by

increased expression of tubular cell injury, oxidative stress and major histocompatibility complex genes. This second wave of immune dysfunction led to a distinct profile of tubule injury with morphologic kidney atrophy and a decreased proportion of differentiated tubule cells. Combined depletion of neutrophils and T cells beginning on day 5 after U-IRI was found to reduce tubular cell loss and the associated kidney atrophy. In kidney biopsy samples from patients with AKI, the number of interstitial T cells and neutrophils negatively correlated with 6-month recovery of GFR.

**Conclusions:** Macrophage persistence after AKI promotes a T cell- and neutrophil-mediated proinflammatory milieu that leads to progressive tubule damage.

## SA-PO968

### Role of Proximal Tubule DPP4 in the Development and Progression of Obesity-Related Kidney Disease

Manoj K. Datta, Trupti Joshi, Sidharth Sen, Pallav Singh, Ricardo J. Restrepo, Jing Ren, Ravi Nistala. University of Missouri System, Columbia, MO.

**Background:** Western diet (WD) rich in refined sugars and fat, is associated with overnutrition and obesity that can lead to obesity related kidney disease (ORKD). We developed a mouse model of ORKD that mimics human ORKD in its pattern of initial glomerular hyperfiltration followed by decline in GFR, histopathological lesions in the form of proximal tubule brush border vacuolization and injury, basement membrane thickening, glomerular accumulation of fat globules and proteinuria. This model manifested increased proximal tubular (PT) expression and activity of Dipeptidyl Peptidase 4 (DPP4) causing activation of inflammatory pathways and fibrosis. The activation of pro-inflammatory cells and cytokines was suppressed by DPP4 inhibitors, global deletion of DPP4 & PT specific deletion of DPP4 which led to improvement in histopathological lesions and GFR. Therefore we hypothesized that PT DPP4 activation contributes to pathophysiological changes in ORKD.

**Methods:** PTWT and PTKO (Proximal Tubule specific DPP4 KO) mice were fed a WD and control chow (CD) till they were 6, 16 and 18-27 mths old. Unbiased gene expression analysis was performed on kidney tissue using Bulk RNAseq and mass spec.

**Results:** WD-feeding increased expression of DPP4 at all time-points and in comparison to CD-fed mice. WD-feeding increased gene expression of many pathways including pro-inflammatory cytokines/chemokines, growth pathways such as mTOR, MAPK, PI3K-Akt and NF-Kb and pathways such as Wnt, NAFLD and insulin resistance. Further analysis of differentially expressed genes revealed cell death/apoptosis gene (*trib3*, *fos*) expression was increased in the WD-fed WT animals. WD-fed PTKO showed reduction in expression of pro-survival genes and Wnt pathway genes. However, expression of other pro-inflammatory cytokines and growth pathway genes were largely unchanged or increased further suggesting modulation and/or compensatory increase in expression. This was confirmed with proteomic analysis on the same kidney tissue.

**Conclusions:** WD-feeding is associated with increased expression of DPP4 and genes in the pro-inflammatory, pro-survival and growth pathways. In PTKO mice, DPP4 expression is much reduced and those of select genes is modulated. Taken together, these results suggest that proximal tubular DPP4 activation contributes to pathophysiological changes in ORKD.

### Tubulovascular Protection of Protease-Activated Receptor-1 Deficiency During AKI-to-CKD Transition

Sarah W.Y. Lok, Wai Han Yiu, Yixin Zou, Jingyuan Ma, Loretta Y.Y. Chan, Sydney C. Tang. The University of Hong Kong, Hong Kong, Hong Kong.

**Background:** Thromboembolic event is evident in CKD patients with high risk of cardiovascular disease due to aberrant activation of the coagulation system. Endothelial cell injury leading to renal microvascular damage and rarefaction is a prominent feature in CKD. Our previous study demonstrates that protease-activated receptor-1 (PAR-1) inhibition by a clinically approved antagonist vorapaxar mitigates kidney fibrosis. However, its role in vascular damage following AKI contributing to CKD progression remains unexplored.

**Methods:** We employed the animal model of unilateral ischemia reperfusion (UIRI)-induced CKD to explore tubulovascular crosstalk of PAR-1 in AKI-to-CKD transition using transgenic PAR-1 deficient mice and vorapaxar treatment at different disease stages. Evans blue vascular permeability assay was performed to assess endothelial injury at both AKI and CKD stages.

**Results:** During AKI, mice with PAR-1 deficiency exhibited reduced renal inflammation, vascular injury and preserved capillary permeability. PAR-1 deficiency preserved kidney function and diminished tubulointerstitial fibrosis via TGF- $\beta$ /Smad during transition phase to CKD. Maladaptive repair in the microvasculature after AKI exacerbated focal hypoxia with capillary rarefaction, which was rescued by Akt/GSK-3 $\beta$ -regulated stabilization of HIF and increase in VEGF in PAR-1 deficient mice. Chronic inflammation was prevented in PAR-1 deficient mice with reduced recruitment of infiltrating macrophages, and both M1- and M2- polarized macrophages. Finally, vorapaxar post-treatment after UIRI exerted greatest anti-fibrotic effect with alleviated ECM proteins and TGF- $\beta$ 1. Importantly, vascular regenerative capacity was higher in mice treated with vorapaxar during AKI, particularly showing significant increase of VEGF in full treatment and VEGFR2 in pre-treatment with vorapaxar.

**Conclusions:** Our findings elucidate a detrimental role of PAR-1 in vascular dysfunction and profibrotic responses upon tissue injury during AKI-to-CKD transition and provide an attractive therapeutic strategy for post-injury repair in AKI.

### Glycolysis Regulates Kidney Repair After Ischemic Injury Through the Modulation of Intracellular pH and $\beta$ -Catenin Expression

Qingqing Wei,<sup>1</sup> Zheng Dong,<sup>1,2</sup> <sup>1</sup>Augusta University Medical College of Georgia, Augusta, GA; <sup>2</sup>Charlie Norwood Department of Veterans Affairs Medical Center, Augusta, GA.

**Background:** After acute injury, kidney will try to heal itself by preservation of functional renal cells and the failed renal repair may promote chronic kidney dysfunction. Meanwhile, the metabolism switch from oxidative phosphorylation to glycolysis has been noted in kidneys post-injury and experiencing chronic dysfunction. However, the role of glycolysis in kidney repair is unknown.

**Methods:** In this study, we tested a mouse model with inducible PKM2 (a key enzyme of glycolysis) knockout in renal tubular cells and found that these mice had similar level of renal fibrosis but better preserved renal proximal tubules and better renal function after 30 minutes of unilateral kidney ischemia and 2-week reperfusion (UI30/2wk) comparing to their wild-type litter mates, suggesting that glycolysis inhibition in renal tubules may enhance renal repair. Since glycolysis induction will lead to lactate accumulation and acidosis in kidney, we further explored whether the decreased intracellular pH can suppress wound healing and kidney repair.

**Results:** In vitro in cultured renal proximal tubule cells (RPTCs) with hypoxia treatment, when intracellular lactate accumulation was induced by  $\alpha$ -Cyano-4-hydroxycinnamic acid (CyA), there was significant intracellular pH decrease, which was partially reversed by glycolysis inhibition (shikonin to inhibit PKM2) or  $\text{NH}_4\text{Cl}$  to enhance intracellular pH. Concurrently, the scratched wound was healed much slower with CyA, accompanied with b-catenin increase. Either shikonin or  $\text{NH}_4\text{Cl}$  improved the wound healing speed with declined b-catenin. The delayed wound healing by CyA treatment was significantly enhanced if b-catenin was knockdown. In mice, the lactate was significantly accumulated after UI30/2wk in wild type kidney, which was relieved by PKM2 knockout. The accumulation of lactate in wild type kidneys after UI30/2wk was associated with b-catenin induction but less significant in PKM2 knockout kidneys. When renal acidosis was reduced by  $\text{NaHCO}_3$  treatment at 4 days after kidney ischemia, the mice showed better renal function and significantly more intact renal proximal tubules in kidney after 2-week reperfusion.

**Conclusions:** Altogether, the enhanced glycolysis after acute kidney injury may intracellular pH decrease with lactate accumulation, which will further suppress renal repair, potentially through the induction of b-catenin.

### Hypermethylation of MicroRNA-219 Is an Anti-Fibrotic Mechanism in Maladaptive Kidney Repair by Preserving ALDH1L2

Qingqing Wei,<sup>1</sup> Zheng Dong,<sup>1,2</sup> <sup>1</sup>Augusta University Medical College of Georgia, Augusta, GA; <sup>2</sup>Charlie Norwood Department of Veterans Affairs Medical Center, Augusta, GA.

**Background:** Epigenetic mechanisms, such as DNA methylation and microRNAs, regulate maladaptive kidney repair including renal fibrosis. By global sequencing, we identified the hypermethylation of microRNA-219-2 (mir-219) gene in unilateral ureter obstruction (UO), 25 minutes of bilateral renal ischemia with 1 week reperfusion injury (I25/1wk), and 25 minutes of bilateral renal ischemia with 1month reperfusion injury (I25/1M). mir-219 hypermethylation was further confirmed by pyro-sequencing. The hypermethylation was associated with downregulation of mir-219. Functionally, mir-219 overexpression enhanced fibronectin expression in cultured renal cells during hypoxia or TGF- $\beta$ 1 treatment. In mice, inhibition of mir-219 with anti-mir-219 LNA suppressed fibronectin accumulation in UO kidneys.

**Methods:** To understand how mir-219 regulates fibronectin expression, we performed RNA-induced silencing complex (RISC, the complex for microRNA to bind to its target) immunoprecipitation, followed by RNA-seq to identify the potential targets of mir-219.

**Results:** The potential candidate targets of mir-219 were further narrowed down to 5 (CANX, ALDH1L2, SMG1, NR2C2, CRTCI) after examination of the existence of predicted mir-219 binding sites in the seed sequence of the mRNAs accumulated in RISC, the conservation of the predicted mir-219 binding sites between species (in both human and mouse), and the reported expression level of the proteins in kidney. By screening the protein expression of these candidates, we found that mir-219 overexpression significantly suppressed ALDH1L2 in renal cells. In mice, mir-219 inhibition preserved ALDH1L2 expression in ureter obstructed kidneys. The functional binding site of mir-219 in the 3'-UTR of ALDH1L2 mRNA was further confirmed by luciferase assay. When ALDH1L2 was knockdown by siRNAs, obviously more fibronectin was induced in renal cells during TGF- $\beta$ 1 treatment.

**Conclusions:** In conclusion, mir-219-2 gene hypermethylation may suppress mir-219 expression. The downregulation of mir-219 may reduce renal fibrosis by repressing ALDH1L2.

## SA-PO972

### BRCA1 Deletion Protects Mice From Kidney Fibrosis by Reducing G2/M Cell Cycle Arrest

Amrendra K. Ajay,<sup>1,2</sup> Akinwande A. Akinfolarin,<sup>1,2</sup> Venkata Sabbiseti,<sup>1,2</sup> Joseph V. Bonventre.<sup>1,2</sup> <sup>1</sup>Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Harvard Medical School, Boston, MA.

**Background:** Injury to proximal tubular (PT) epithelial cells leads to fibrotic kidney disease. Toxic, ischemic, and obstructive kidney injuries lead to replication fork arrest and DNA double strand breaks, triggering the DNA damage repair mechanisms. Breast Cancer gene 1 (*Brcal*) is upregulated in response to DNA damage to help repair the damaged DNA. The function of *Brcal* is well investigated in cancer, recruiting RAD51 to the damaged DNA. We proposed that its effect to arrest the cell cycle might implicate it in fibrotic kidney disease.

**Methods:** *Slc34a1* Cre mice were crossed with *Brcal* floxed mice yielding mouse models with PT *Brcal* exon 11 gene deletion. After tamoxifen-induced Cre induction, mice were subjected to bilateral ischemia/reperfusion (BIRI), or aristolochic acid (AA)-induced fibrosis. The deletion of *Brcal* exon 11 was confirmed by fluorescence in situ hybridization (FISH). Markers of DNA damage, cell cycle arrest, and senescence were evaluated by immunofluorescence staining. Kidney tissue lysates were evaluated using western blot, real-time PCR, and PicroSirius (PS) Red staining and markers of DNA damage, senescence, and interstitial fibrosis. HKC8 and HK-2 human PT epithelial cells (HPTECs) were transfected with either shRNA or siRNA and treated with either cisplatin or AA to investigate the injury associated with cell cycle stages, apoptosis, and senescence.

**Results:** BRCA1 protein expression was increased in human CKD kidneys. The expression of *Brcal* exon 11 was increased following BIRI or AA. *Brcal* deletion protected mice from interstitial fibrosis when compared to control mice as shown by PS staining, fibronectin, collagen 1, and  $\alpha$ -smooth muscle actin ( $\alpha$ -SMA) following BIRI and AA. Western blot analysis of whole kidney cortex revealed reduction in CTGF, fibrogenic markers, collagen1, fibronectin and  $\alpha$ -SMA. PT *Brcal* depleted mouse had fewer pH3+ cells, a marker of G2/M cell cycle phase and reduced S- $\beta$ -Gal, a marker of senescence. shRNA or siRNA-induced reduction in BRCA1 in HPTECs reduced secretion of the profibrogenic inflammatory cytokine IL-6 and sonic hedgehog following cisplatin or AA treatment.

**Conclusions:** BRCA1 induces interstitial fibrosis following tubular injury by inducing G2/M cell cycle arrest, cellular senescence, and secretion of profibrotic mediators.

**Funding:** NIDDK Support, Other NIH Support - American Heart Association

### CCL20 Blockade Mitigates the Progression of AKI to CKD

Kyung Don Yoo,<sup>1,2</sup> Mi-yeon Yu,<sup>3</sup> Kyu hong Kim,<sup>4</sup> Jehun Song,<sup>1,2</sup> Jinsuk Bae,<sup>1,2</sup> Sunhwa Lee,<sup>6</sup> Hyung Ah Jo,<sup>7</sup> Yong Chul Kim,<sup>4</sup> Dong Ki Kim,<sup>4,5</sup> Jong Soo Lee,<sup>1,2</sup> Yon Su Kim,<sup>4,5</sup> Seung Hee Yang.<sup>4,5</sup> <sup>1</sup>University of Ulsan College of Medicine, Songpa-gu, Seoul, Republic of Korea; <sup>2</sup>Ulsan University Hospital, Ulsan, Republic of Korea; <sup>3</sup>Hanyang University, Seongdong-gu, Seoul, Republic of Korea; <sup>4</sup>Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; <sup>5</sup>Seoul National University College of Medicine, Seoul, Republic of Korea; <sup>6</sup>Kangwon National University Hospital, Chuncheon, Kangwon, Republic of Korea; <sup>7</sup>Inje University Ilsan Paik Hospital, Goyang, Republic of Korea.

**Background:** Chronic kidney injury promotes renal inflammation and oxidative stress, highlighting precondition for organ fibrosis. Here, we investigated how chemokine receptor CCR6 and its ligand can alter acute kidney injury (AKI) to chronic kidney disease (CKD).

**Methods:** Unilateral ischemia-reperfusion injury (uIRI) was induced for 30 minutes in 7- to 8-wk-old male C57BL/6 mice, and the animals were observed for 4 weeks. Meanwhile, rats with 5/6 nephrectomy were performed to evaluate transcriptome changes via RNA sequencing at 8 weeks. In vitro experiments, primary-cultured human tubular epithelial cells (hTECs) were cultured on hypoxia (5% O<sub>2</sub>, CO<sub>2</sub>, and 90% N<sub>2</sub>, 4days) and H<sub>2</sub>O<sub>2</sub>-induced oxidative stress (0.125mM, 3 days) conditions with/without CCL20 blocking antibody. In addition, CCR6/CCL20 expressions in kidney tissues of patients with CKD were assessed.

**Results:** In both animal models, the expression of CCL20 increased as inflammation and fibrosis increased. Therefore, a positive correlation was observed for CCL20 in fibrosis. Furthermore, CCL20 blockade in human tubular epithelial cells ameliorated apoptotic damage in a dose-dependent manner on hypoxia and ROS injury. Interestingly, the CCL20 blockade led to a more significant reduction of intracellular ROS, 8-OHdG, and ICAM-1 level. uIRI provoked CCR6 expression that showed a similar severity as patients with acute kidney disease (AKD) phenotype. We analyzed CCR6/CCL20 expression from 22/18/16 patients with CKD stages 1-2/3/4-5, respectively. Morphometry of CCR6/CCL20 co-expression revealed that CKD stage 3 patients were more likely to possess CCR6 expressions than CKD stage 1-2 patients (10.94% vs. 5.79%, p=0.001). Together, Kidney tissues of CKD patients frequently containing CCL20 cells showed a positive correlation with interstitial inflammation (p=0.001). CCL20/CCR6 activation is associated with uIRI progression, and CCL20 may be an essential contributor.

**Conclusions:** CCR6/CCL20 inhibition could be a potential therapeutic target for managing AKD progression to CKD.

**Funding:** Other NIH Support - This work was supported by the Ulsan University Hospital Research Grant (UHH-2020-08).

## SA-PO974

**Human Immunodeficiency Virus Vpr Induces Severe Tubulointerstitial Damage With Progressive Fibrosis and Cystic Development**

Jia Fu,<sup>1</sup> Zeguo Sun,<sup>1</sup> Weijia Zhang,<sup>1</sup> Jeffrey B. Kopp,<sup>2</sup> Vivette D. D'Agati,<sup>3</sup> John C. He,<sup>1</sup> Kyung Lee.<sup>1</sup> *Icahn School of Medicine at Mount Sinai, New York, NY; <sup>2</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; <sup>3</sup>Columbia University, New York, NY.*

**Background:** HIV-positive individuals are at increased risk for CKD and ESKD. HIV leads to a wide spectrum of glomerular and tubulointerstitial injuries, but molecular pathways by which HIV injures kidney cells are partly understood. Experimental mouse studies have implicated the key roles of Nef and Vpr in HIVAN pathogenesis. These studies also indicated that tubulointerstitial injury and inflammation occur secondary to glomerular injury, whereas human studies suggested a direct effect of HIV on tubular cells. In vitro studies demonstrated a salient role of Vpr on tubular injury, where Vpr induces DNA damage response, cell cycle arrest, and cytokinesis defects, resulting in apoptosis and polyploidy in a majority of cells and hyperproliferation in small subsets. To elucidate the pathogenic effects of Vpr in tubular injury in HIVAN, we examined the consequence of tubular Vpr expression in mice.

**Methods:** We generated mice expressing Pax8-rtTA and TetO-Vpr transgenes, which were induced with doxycycline (Pax8-Vpr). Histopathologic and marker analyses of tubular injury, fibrosis, cell cycle regulators, and apoptosis were performed in Pax8-Vpr kidneys over time. scRNAseq of Pax8-Vpr kidneys was performed to elucidate the pathways altered in Vpr-injured kidneys.

**Results:** Tubular Vpr expression led to progressive tubular atrophy, diffuse tubulointerstitial inflammation, and fibrosis, which were accompanied by prominent cortical cysts and kidney failure, but without proteinuria. Tubular cells of Pax8-Vpr kidneys displayed significant DNA damage and aberrant cell division, consistent with previous in vitro findings. scRNAseq analysis showed changes consistent with impairments in mitochondrial function and fatty acid oxidation and activation of various cell death pathways including ferroptosis in specific tubular cell subsets. Other subsets of tubular cells showed changes consistent with cell cycle deregulation and proliferation, suggestive of mechanisms involved in the expansion of cystic cells.

**Conclusions:** Our study demonstrates for the first time that the induction of an HIV gene specifically in tubular cells leads to severe tubulointerstitial injury and fibrosis, independent of HIV-mediated glomerulosclerosis and proteinuria. It also demonstrates tubular cell-specific gene expression changes induced by Vpr and its consequences in vivo.

## SA-PO975

**Loss of Soluble (Pro) Renin Receptor Attenuates Adenine Induced Kidney Disease**

Nirupama Ramkumar, Chunyan Hu, Deborah Stuart. *University of Utah Health, Salt Lake City, UT.*

**Background:** Cleavage of the extra-cellular domain of the (pro)renin receptor (PRR) yields a soluble fragment termed soluble PRR (sPRR). Elevated plasma sPRR levels have been described in patients with kidney disease and correlates with the stage of kidney disease. We previously demonstrated that loss of sPRR attenuated angiotensin-II induced hypertension and kidney injury. To further characterize the role of sPRR in chronic kidney disease and fibrosis, we used adenine diet to induce kidney disease in control and mutant mice with loss of sPRR.

**Methods:** Using CRISPR-Cas9, we developed a mouse model with site-directed mutagenesis of the PRR cleavage site. Male, 3-month old, mutant sPRR mice and littermate controls were treated with adenine diet (alternating between 0.25% and 0.15%) for 8 weeks. Only male mice were studied as the PRR gene is on the X-chromosome.

**Results:** Compared to controls, male mutant sPRR mice had markedly lower plasma sPRR levels (control:  $21.5 \pm 2.5$  vs mutant  $0.2 \pm 0.03$  ng/ml). Metabolic balance studies at the end of the study showed similar food intake and body weight between the two groups although water intake (control:  $6.9 \pm 0.4$  vs mutant:  $3.6 \pm 0.3$  ml/24 hrs,  $p < 0.001$ ) and urine volume (control:  $5.9 \pm 0.2$  vs mutant:  $2.9 \pm 0.5$  ml/24 hrs,  $p = 0.001$ ) was significantly lower in mutant sPRR mice. Mutant sPRR mice also had lower BUN (control:  $67.4 \pm 3.1$  vs mutant:  $42.9 \pm 2.2$  mg/dl  $p < 0.01$ ), serum creatinine (control:  $1.59 \pm 0.1$  vs mutant:  $1.21 \pm 0.04$  mg/dl,  $p < 0.01$ ) and urinary excretion of albumin (control:  $92.6 \pm 7.5$  vs mutant:  $47.1 \pm 5.7$  ug/day,  $p < 0.01$ ) and kidney injury molecule (KIM-1) (control:  $155 \pm 10$  vs  $75 \pm 5$  ng/day,  $p < 0.01$ ) compared to controls. Renal histology demonstrated significant tubular and interstitial injury with minimal glomerulosclerosis in control mice treated with adenine diet while injury was significantly reduced in mutant sPRR mice. Bulk RNA sequencing of whole kidney lysates showed 135 upregulated genes and 167 downregulated genes with pathway analyses suggesting downregulation of Jak/Stat, Mapk and TGF- $\beta$  signaling in the mutant sPRR mice.

**Conclusions:** Loss of sPRR attenuates adenine diet induced kidney disease likely via downregulation of inflammatory and fibrotic signaling pathways. Studies to delineate how sPRR mediates renal tubular injury and fibrosis are currently ongoing.

## SA-PO976

**Decreasing T-Cell Activation Inhibits Progressive Renal Injury in Obese Dahl Salt-Sensitive Rats Before Puberty**

Ubon S. Ekperikpe, Denise C. Cornelius, Jan M. Williams. *The University of Mississippi Medical Center, Jackson, MS.*

**Background:** Childhood obesity is growing at an alarming rate and is now considered a risk factor for renal injury and the development of chronic kidney disease later in life. Recently, we reported that the obese Dahl salt-sensitive leptin receptor mutant (SS<sup>Lepr</sup> mutant) rat develops renal injury before puberty that was associated with increased T-cell infiltration and activation. The current study investigated the effect of abatacept on renal inflammation and the progression of renal injury in SS<sup>Lepr</sup> mutant rats before puberty.

**Methods:** Four-week-old SS and SS<sup>Lepr</sup> mutant rats were treated with either vehicle (PBS) or abatacept (1 mg/kg; ip, every other day) for 4 weeks. Proteinuria was measured every two weeks until the rats reached 8 weeks of age. At the end of the study, MAP (via chronic catheter) was measured, and the kidneys were collected to measure renal cytokine levels and the infiltration of immune cells (via ELISA and flow cytometry). Renal histopathology analysis was performed as well to determine glomerular/tubular injury and renal fibrosis.

**Results:** We did not observe any differences in MAP across the groups. While proteinuria rose from  $8 \pm 3$  to  $47 \pm 18$  mg/day in SS rats, proteinuria markedly increased from  $68 \pm 17$  to  $434 \pm 73$  mg/day in SS<sup>Lepr</sup> mutant rats. Treatment with abatacept decreased proteinuria by almost 50% in SS<sup>Lepr</sup> mutant rats ( $265 \pm 47$  mg/day;  $p < 0.05$ ) without affecting SS rats ( $26 \pm 7$  mg/day). We observed a significant increase in T-cell infiltration and activation in SS<sup>Lepr</sup> mutant rats versus SS rats, and treatment with abatacept significantly reduced this response. Renal macrophage inflammatory protein-3 alpha (MIP-3 $\alpha$ ) was significantly increased, while interleukin-4 (IL-4) was markedly decreased in SS<sup>Lepr</sup> mutant vs SS rats ( $20 \pm 2$  vs  $6 \pm 1$  pg/mg, and  $15 \pm 2$  vs  $42 \pm 6$  pg/mg, respectively;  $p < 0.05$ ), and treatment with abatacept significantly decreased renal MIP-3 $\alpha$ , while increasing IL-4 in SS<sup>Lepr</sup> mutant rats, without affecting SS rats. We observed significant increases in glomerular and tubular injury and renal fibrosis in SS<sup>Lepr</sup> mutant rats compared to SS rats, and treatment with abatacept decreased these renal parameters in SS<sup>Lepr</sup> mutant rats.

**Conclusions:** These data suggest that anti-inflammatory strategies may be beneficial in managing renal injury associated with childhood obesity.

**Increased Renal Elimination of Endogenous and Synthetic Pyrimidine Nucleosides in Concentrative Nucleoside Transporter 1 Deficient Mice**

Rajgopal Govindarajan,<sup>1</sup> Shipra Agrawal,<sup>2</sup> Tejinder Kaur,<sup>1</sup> Syed Saqib Ali,<sup>1</sup> Debasis Nayak.<sup>1</sup> *<sup>1</sup>The Ohio State University, Columbus, OH; <sup>2</sup>Nationwide Children's Hospital, Columbus, OH.*

**Background:** Concentrative nucleoside transporters (CNTs) are active nucleoside influx systems, but their in vivo roles are poorly defined.

**Methods:** We generated and characterized global CNT1 knockout (KO) mice to study the role of CNT1 in the renal reabsorption of pyrimidine nucleosides. Mass Spectrometry based metabolomic analyses of mouse urine and plasma samples were conducted to identify changes in small molecules. Orthotopic implantation of pancreatic cancer cells in WT and KO mice was conducted to study the efficacy of chemotherapeutics in tumor-bearing mice. IVIS bioluminescence imaging was conducted to evaluate tumor burden. Kaplan-Meier analysis was conducted to changes in survival.

**Results:** CRISPR/Cas9 deletion of CNT1 in mice increased the urinary excretion of endogenous pyrimidine nucleosides with compensatory alterations in purine nucleoside metabolism but without impairment of fertility or survival. In addition, CNT1 KO mice exhibited high urinary excretion of the intravenously administered nucleoside analog drug gemcitabine (dFdC), which resulted in decreased systemic drug exposure. However, the increased urinary clearance of dFdC rendered this chemotherapeutic drug ineffective in controlling tumor burden and preventing mortality in CNT1 KO mice orthotopically implanted with syngeneic Kras/p53-mutated mouse pancreatic ductal adenocarcinoma cells. Interestingly, increasing the dFdC dose to attain an area under the concentration-time curve level equivalent to that achieved by wild-type (WT) mice rescued antitumor efficacy and survivability in CNT1 KO mice.

**Conclusions:** These findings provide new insights into how CNT1 regulates reabsorption of endogenous and synthetic nucleosides in murine kidneys and suggest that the functional status of CNTs should account for the optimal action of pyrimidine nucleoside analog therapeutics in humans. In addition, our studies propose that CNT1 KO mice are an excellent model to further study the role of CNT1 in nucleoside drug-drug interactions, CNT1 genetic polymorphisms, and SLC28A1-mutated human inborn errors of metabolism.

## SA-PO978

**Role of Apoptotic Cells in Mediating Progressive CKD**

Sylvia Cechova, Nabin Poudel, Mark D. Okusa, Peter I. Lobo. *Division of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine University of Virginia, Charlottesville, VA.*

**Background:** Chronic kidney disease (CKD) is primarily caused by diabetes, hypertension, and acute kidney injury (AKI), but the pathophysiological mechanism leading to the progression of CKD is still not completely understood. Primarily, CKD

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

progression is attributed to intra-glomerular hypertension and renal tubular damage induced by hyperglycemia leading to proteinuria. Recently, several investigators have suggested that failed repair of renal tubules, damaged during AKI, contribute to pathogenesis of CKD progression. In this present study, we investigated the role of continued apoptotic cell death, post-AKI, in mediating CKD progression.

**Methods:** We performed unilateral ischemia reperfusion injury (u-IRI; 30 min) on C57BL/6 mice to induce CKD. Group 1 mice were subjected to nephrectomy on the non-ischemic contralateral kidney on day 4, and were euthanized on day 7. Group 2 mice underwent nephrectomy on day 27 and were euthanized on day 28. We collected plasma and kidney tissues. The relative mRNA expression of fibrotic, and pro-apoptotic genes were estimated by real-time PCR. To evaluate extent of kidney injury, we measured plasma creatinine and stained kidney section with Masson's Trichrome to quantitate the degree of fibrosis. Additionally, we performed Western blotting to quantify the level of cleaved Caspase 3 in the kidney tissue lysates and stained kidney section with cleaved Caspase 3 antibody.

**Results:** We observed significant upregulation of fibrotic and pro-apoptotic genes in Group 1 mice compared to Group 2 mice. IRI injured kidney progressed to CKD: day 7 plasma creatinine  $0.72 \pm 0.13$  mg/dl for Group 1 and day 28 plasma creatinine:  $2.44 \pm 0.29$  mg/dl;  $P=0.0006$ ;  $n=5$  for Group 2. Masson's Trichrome staining revealed that Group 1 mice sustained significantly less injury when compared to Group 2. Additionally, there was no decrease in apoptosis with CKD progression; with Western blotting (Relative c-cleaved Caspase 3 protein level: Group 1:  $1.01 \pm 0.13$ ; Group 2:  $1.43 \pm 0.18$ ,  $P=NS$ ;  $n=3$ ), and with HRP-cleaved Caspase 3 staining, on day 28, there was more apoptosis and more CKD injury than on day 7 after IRI.

**Conclusions:** Our data suggest that apoptotic cells play a role in both phases i.e. during the acute phase of IRI and in the progressive CKD phase. However, further studies are necessary to elucidate the contribution of apoptotic signaling pathway to progression of CKD.

**Funding:** NIDDK Support

### Chemerin/ChemR23 Axis: A New Therapeutic Target for Uraemic Sarcopenia

Luke A. Baker,<sup>1,2</sup> Thomas J. Wilkinson,<sup>1,2</sup> Milly Abbott,<sup>1</sup> Daniela F. Cardoso,<sup>3</sup> Nicola Parker,<sup>1</sup> Matthew Graham-Brown,<sup>1,4</sup> Joao L. Viana,<sup>3</sup> Emma L. Watson,<sup>1,2</sup> Alice C. Smith,<sup>1,2</sup> <sup>1</sup>University of Leicester College of Life Sciences, Leicester, United Kingdom; <sup>2</sup>NIHR Leicester Biomedical Research Centre, Leicester, United Kingdom; <sup>3</sup>Instituto Universitario da Maia, Castelo da Maia, Portugal; <sup>4</sup>University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.

**Background:** People with chronic kidney disease (CKD) often experience muscle quality, wasting and dysfunction contributing to a reduced quality of life and increased risk of morbidity and mortality. The adipokine chemerin is associated with CKD progression and involved in inflammatory-related signalling processes. With chronic inflammation recognised as a key factor in uraemic sarcopenia, we aimed to investigate the potential role of chemerin as a uraemic toxin in CKD and identify the mechanisms of action to elucidate therapeutic opportunities in uraemic sarcopenia.

**Methods:** Chemerin levels from EDTA-plasma and urine samples were quantified via ELISA on basal samples from non-CKD controls (CON,  $n=32$ ), CKD patients (CKD,  $n=100$ ), and kidney transplant recipients (KTR,  $n=20$ ). Chemerin levels were correlated with eGFR and measures of body composition, physical performance, muscle mass, and muscle quality. A sub-set of participants from each group underwent skeletal muscle biopsies and samples were processed for gene and protein analysis, or cells extracted for *in-vitro* experimentation.

**Results:** Higher chemerin concentrations were found in the urine of those with CKD compared to non-CKD controls ( $p<0.001$ ). Higher circulating chemerin was associated with lower eGFR ( $p<0.001$ ,  $r=-0.571$ ). Positive correlations with body fat % and BMI were noted in CKD patients. Higher circulatory chemerin was associated with poorer muscle quality ( $r=0.396$ ,  $p=0.003$ ). No associations were noted across other *in-vivo* muscle related assessments. Molecular analysis detected the presence of 2 out of 3 receptors of interest for chemerin in skeletal muscle, but no significant elevation in the expression in of chemerin itself in this tissue type in those with CKD. *In-vitro* analysis showed that the exposure of CKD derived muscle cells to chemerin induced a significant inflammatory response (IL-6  $p<0.001$ ; TNF $\alpha$   $p=0.0215$ ), which was halved using the ChemR23 receptor inhibitor  $\alpha$ NETA (IL-6  $p<0.001$ ; TNF $\alpha$   $p<0.001$ ).

**Conclusions:** We report that chemerin is a uraemic toxin in those with CKD and that it may contribute to poorer muscle quality in these people. Chemerin can moderate indicators of inflammation within skeletal muscle via the activation of ChemR23 and as such proposes a new therapeutic target to alleviate the symptoms of uraemic sarcopenia.

## SA-PO980

### Urine Ammonium Excretion Helps Identify High Dietary Acid Intake in Patients With Early-Stage CKD and Eubicarbonatemic Acidosis

Nimrit Goraya,<sup>1</sup> Nicolaos E. Madias,<sup>2</sup> Abdullah A. Mamun,<sup>4</sup> Jan Simoni,<sup>5</sup> Donald E. Wesson.<sup>3</sup> <sup>1</sup>Baylor Scott and White Central Texas, Temple, TX; <sup>2</sup>Tufts University School of Medicine, Boston, MA; <sup>3</sup>The University of Texas at Austin Dell Medical School, Austin, TX; <sup>4</sup>Baylor Scott & White Health, Dallas, TX; <sup>5</sup>Texas Tech University, Lubbock, TX.

**Background:** Better estimated glomerular filtration rate (eGFR) preservation in patients with Stage 2 chronic kidney disease (CKD) and normal plasma total CO<sub>2</sub> (PTCO<sub>2</sub>) despite acid (H<sup>+</sup>) retention (i.e., with eubicarbonatemic acidosis) was associated

with lower H<sup>+</sup> retention. Reduced dietary H<sup>+</sup> with either oral NaHCO<sub>3</sub> or base-producing foods reduced H<sup>+</sup> retention and so dietary H<sup>+</sup> reduction might be kidney-protective in this setting. Even so, tabulating food intake then estimating potential renal acid load (PRAL) is challenging in clinical settings. We explored if urine excretion of citrate (UcitV), a metabolite that defends against H<sup>+</sup> accumulation, or ammonium (UNH<sub>4</sub>+V), a buffer whose urine excretion increases with an H<sup>+</sup> challenge, can evaluate dietary H<sup>+</sup> assessed by PRAL in patients with early-stage CKD (stage 2) and eubicarbonatemic acidosis for whom kidney protective interventions are most beneficial.

**Methods:** We measured 8-hour UcitV (8h UcitV) and 8-hour (8h UNH<sub>4</sub>+V) in participants with PTCO<sub>2</sub>  $\geq 22$  mM and CKD 2 (eGFR [mean (SD) ml/min/1.73 m<sup>2</sup>] =  $73.8$  (6.3),  $n=167$ ) or CKD 1 [eGFR =  $99.2$  (7.3),  $n=62$ ] due to macroalbuminuric, non-diabetic nephropathy. We compared these urine parameters across groups and performed linear regressions (LR) with PRAL within groups. We assessed H<sup>+</sup> retention by comparing observed to expected increase in PTCO<sub>2</sub> in response to retained HCO<sub>3</sub><sup>-</sup> (dose-urine excretion) 2 hours after an oral NaHCO<sub>3</sub> bolus (0.5 mEq/Kg bw), assuming 50% body weight HCO<sub>3</sub><sup>-</sup> space of distribution.

**Results:** H<sup>+</sup> retention [mean (SD), mmol] was higher in CKD 2 than CKD 1 [ $18.2$  (12.4) vs.  $3.8$  (12.5), mmol,  $p<0.01$ ]. CKD 2 vs. CKD 1 had lower 8h UcitV [ $1.00$  (0.22) vs.  $1.14$  (0.03) mmol,  $p<0.01$ ] but 8h UNH<sub>4</sub>+V (mEq/8h) was not different [ $14.1$  (2.6) vs.  $14.7$  (2.5),  $p=0.24$ ]. LR for 8h UcitV vs. PRAL was negative for CKD 1 ( $p<0.01$ ,  $r^2=0.15$ ) and negative but not significant for CKD 2 ( $p=0.65$ ,  $r^2=0.01$ ). LR for 8h UNH<sub>4</sub>+V was positive and significant for both CKD 1 ( $p<0.01$ ,  $r^2=0.14$ ) and CKD 2 ( $p<0.01$ ,  $r^2=0.08$ ). Adding UNH<sub>4</sub>+V to UcitV in the regression increased  $r^2$  for CKD 1 (0.15 to 0.21) but not CKD 2 (0.08 to 0.06).

**Conclusions:** In patients with CKD and eubicarbonatemic acidosis, UNH<sub>4</sub>+V was positively associated with dietary H<sup>+</sup> intake as assessed by PRAL and should be further explored as an indicator of high dietary H<sup>+</sup>.

## SA-PO981

### Urine Excretion of Citrate and Ammonium to Non-Invasively Identify Eubicarbonatemic Acidosis in Patients With CKD

Nimrit Goraya,<sup>1</sup> Nicolaos E. Madias,<sup>2</sup> Abdullah A. Mamun,<sup>4</sup> Jan Simoni,<sup>5</sup> Donald E. Wesson.<sup>3</sup> <sup>1</sup>Baylor Scott and White Central Texas, Temple, TX; <sup>2</sup>Tufts University School of Medicine, Boston, MA; <sup>3</sup>The University of Texas at Austin Dell Medical School, Austin, TX; <sup>4</sup>Baylor Scott and White North Texas, Dallas, TX; <sup>5</sup>Texas Tech University System, Lubbock, TX.

**Background:** Increasing acid (H<sup>+</sup>) retention while plasma total CO<sub>2</sub> (PTCO<sub>2</sub>) remained normal (eubicarbonatemic acidosis) during chronic kidney disease (CKD) progression was associated with decreasing urine citrate excretion (UcitV). Increasing positive H<sup>+</sup> balance while PTCO<sub>2</sub> remained normal in patients with CKD progression was associated with decreased urine ammonium excretion (UNH<sub>4</sub>+V). We explored if the combination of UcitV and UNH<sub>4</sub>+V, than either alone, better identified H<sup>+</sup> retention, in patients with CKD and eubicarbonatemic acidosis.

**Methods:** We recruited 313 macroalbuminuric, non-diabetic participants with eGFR [mean (SD), ml/min/1.73 m<sup>2</sup>] for CKD 1 [ $n=62$ ,  $99.2$  (7.3)], CKD 2 ( $n=167$ ,  $73.8$  (6.3)), and CKD 3 ( $n=84$ ,  $39.9$  (6.7)) without metabolic acidosis (PTCO<sub>2</sub>  $\geq 22$  mmHg). We assessed H<sup>+</sup> retention by comparing observed to expected increase in PTCO<sub>2</sub> in response to retained HCO<sub>3</sub><sup>-</sup> (dose-urine excretion) 2 hours after an oral NaHCO<sub>3</sub> bolus (0.5 mEq/Kg bw), assuming 50% body weight HCO<sub>3</sub><sup>-</sup> space of distribution. We compared 8-hour UcitV (8h UcitV) and UNH<sub>4</sub>+V (8h UNH<sub>4</sub>+V) across groups and performed linear regressions (LR) with H<sup>+</sup> retention within groups.

**Results:** With advancing CKD, H<sup>+</sup> retention [mean (SD), mmol] progressively increased [CKD 1 =  $3.8$  (12.5), CKD 2 =  $18.2$  (12.4), CKD 3 =  $25.6$  (9.0),  $p<0.01$ ]. With advancing CKD, 8h UcitV (mmol/8h) progressively decreased [CKD 1 =  $1.14$  (0.03), CKD 2 =  $1.00$  (0.22), CKD 3 =  $0.87$  (0.9),  $p<0.01$ ]. By contrast, 8h UNH<sub>4</sub>+V (mEq/8h) was not different between CKD 2 vs. CKD 1 [ $14.1$  (2.6) vs.  $14.7$  (2.5), respectively,  $p=0.24$ ] but was lower in CKD 3 [ $13.0$  (2.3)] than either CKD 2 or CKD 1 ( $p<0.01$ ). LR for UcitV vs. H<sup>+</sup> retention was negative for both CKD 2 ( $p<0.01$ ,  $r^2=0.61$ ) and CKD 3 ( $p<0.01$ ,  $r^2=0.75$ ) but was not significant for CKD 1 ( $p=0.50$ ,  $r^2=0.04$ ). LR for UNH<sub>4</sub>+V vs. H<sup>+</sup> retention was positive for CKD 2 ( $p<0.04$ ,  $r^2=0.05$ ) and negative for CKD 3 ( $p<0.01$ ,  $r^2=0.80$ ) but not significant for CKD 1 ( $p=0.14$ ,  $r^2=0.05$ ). Adding UNH<sub>4</sub>+V to UcitV in the regression increased  $r^2$  marginally for CKD 2 (0.61 to 0.63) and CKD 3 (0.75 to 0.79).

**Conclusions:** The data show that lower UcitV identified higher H<sup>+</sup> retention in eubicarbonatemic patients with CKD 2 or CKD 3 but the UNH<sub>4</sub>+V vs. H<sup>+</sup> retention relationship diverged between CKD 2 and CKD 3. Adding UNH<sub>4</sub>+V to UcitV marginally enhanced its predictive power.

## SA-PO982

### Urine Citrate Excretion Better Identifies Eubicarbonatemic Acidosis Than Plasma Acid-Base Parameters in Patients With CKD

Nimrit Goraya,<sup>1</sup> Nicolaos E. Madias,<sup>2</sup> Abdullah A. Mamun,<sup>4</sup> Donald E. Wesson,<sup>3</sup> Jan Simoni.<sup>5</sup> <sup>1</sup>Baylor Scott & White Medical Center Temple, Temple, TX; <sup>2</sup>Tufts Medical Center, Boston, MA; <sup>3</sup>Dell Seton Medical Center at The University of Texas, Austin, TX; <sup>4</sup>Baylor Scott & White Health, Dallas, TX; <sup>5</sup>Texas Tech University Health Sciences Center, Lubbock, TX.

**Background:** Acid (H<sup>+</sup>) mitigating mechanisms help maintain normal plasma total CO<sub>2</sub> (PTCO<sub>2</sub>) in patients with chronic kidney disease (CKD) and reduced estimated glomerular filtration rate (eGFR) despite H<sup>+</sup> retention or positive H<sup>+</sup> balance (i.e., eubicarbonatemic acidosis). Current guidelines recommend oral alkali treatment of metabolic acidosis in CKD only for patients with PTCO<sub>2</sub>  $< 22$  mM, thereby excluding

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

those with eubicarbonatemic acidosis for whom oral alkali might slow CKD progression (AJP 317: F502, 2019). We tested if variances in urine excretion of citrate (UcitV), a metabolite that defends against H<sup>+</sup> retention, better identifies eubicarbonatemic acidosis in early-stage CKD (stage 2) than variances in plasma acid-base parameters.

**Methods:** We compared H<sup>+</sup> retention, plasma acid-base parameters, and UcitV between participants with PTCO<sub>2</sub> ≥22 mM and CKD 2 (eGFR [mean (SD) ml/min/1.73 m<sup>2</sup>] =73.8 (6.3), n=167) or CKD 1 [eGFR=99.2 (7.3), n=62] due to macroalbuminuric, non-diabetic nephropathy. We assessed H<sup>+</sup> retention by comparing observed to expected increase in PTCO<sub>2</sub> in response to retained HCO<sub>3</sub><sup>-</sup> (dose-urine excretion) 2 hours after an oral NaHCO<sub>3</sub> bolus (0.5 mEq/Kg bw), assuming 50% body weight HCO<sub>3</sub><sup>-</sup> space of distribution. We measured venous plasma bicarbonate (PHCO<sub>3</sub><sup>-</sup>), PCO<sub>2</sub>, pH (PpH), PTCO<sub>2</sub>, and 8-hour UcitV (8h UcitV).

**Results:** H<sup>+</sup> retention [mean (SD), mmol] was higher in CKD 2 than CKD 1 [18.2 (12.4) vs. 3.8 (12.5), mmol, p<0.01]. CKD 2 vs. CKD 1 participants had lower PTCO<sub>2</sub> [25.2 (1.2) vs. 25.9 (1.2) mM, p<0.01], PHCO<sub>3</sub><sup>-</sup> [24.0 (1.3) vs. 24.7 (1.2) mEq/L, p<0.01], PCO<sub>2</sub> [40.1 (1.2) vs. 41.0 (0.9) mm Hg, p<0.01] but no difference in PpH [7.397 (0.014) vs. 7.399 (0.016), p=0.31]. CKD 2 vs. CKD 1 8h UcitV was lower [1.00 (0.22) vs. 1.14 (0.03) mmol, p<0.01].

**Conclusions:** Substantially greater H<sup>+</sup> retention in CKD 2 than CKD 1 participants was associated with statistically but quantitatively minor decreases in plasma acid-base parameters, supporting the effectiveness of body mechanisms that mitigate against retained H<sup>+</sup> but challenging utility of plasma acid-base parameters to identify eubicarbonatemic acidosis. Conversely, UcitV was both statistically and substantially lower in CKD 2 than CKD 1, supporting this parameter as a better indicator of eubicarbonatemic acidosis in patients with early-stage CKD.

## SA-PO983

### Increased Severity of CKD in Response to High Potassium Intake Depends on Mineralocorticoid Receptor Activation

Valerie Olivier, Eric Feraille. PHYME Université de Geneve, Geneve, Switzerland.

**Background:** Dietary treatment is seminal for the management of chronic kidney disease (CKD). The effects of potassium intake on CKD progression are controversial. The aim of the project was to assess the effects of potassium intake on CKD progression.

**Methods:** We used 2 mouse models of CKD to analyze the effects of potassium diet on kidney injury: the unilateral ureteral obstruction (UO) performed in wild type mouse, as an obstructive CKD model, and the POD-ATTAC mouse, as a glomerular CKD model. The POD-ATTAC mouse model displays a podocyte-specific apoptosis after the administration of a chemical inducer. We also studied the role of the mineralocorticoid receptor (MR) using the MR antagonist spironolactone in POD-ATTAC mice and UO in kidney tubule epithelial cell-specific MR KO mice.

**Results:** In UO and POD-ATTAC mice, high potassium diet increased interstitial fibrosis quantified by Sirius red staining of kidney slices (Fig.1). High potassium diet also increased the abundance of the extracellular matrix protein fibronectin and decreased the expression levels of the epithelial marker Na<sup>+</sup>-K<sup>+</sup> ATPase, assessed by Western blot. Consistently, POD-ATTAC mice fed with high potassium diet displayed lower glomerular filtration rate (Fig.1) and decreased peritubular capillary network assessed by CD34 staining. Spironolactone decreased fibrosis induced by high potassium diet in POD-ATTAC mice. However, tubular-specific MR knockdown did not improve the fibrotic lesions induced by UO under normal or high potassium diet. High potassium diet led to enhanced kidney inflammation and to a proinflammatory macrophage phenotype, which were reversed under spironolactone.

**Conclusions:** High potassium intake induces enhanced inflammation and accelerated fibrosis leading to decreased kidney function in 2 mouse models of CKD. Non-tubular MR plays a pivotal role in potassium-induced fibrosis. The effect of reducing potassium intake, as a way to slowdown CKD progression should be assessed in future clinical trials.

**Funding:** Private Foundation Support

**Figure 1:** Mice were subjected to low (LK), normal (NK) or high potassium (HK) diet before urinary obstruction (UO) or induction of glomerular disease (POD-ATTAC) until the end of experiment. Kidney fibrosis was then assessed by Sirius red staining of collagen and the fibrotic area was quantified. GFR was measured in POD-ATTAC mice.

## SA-PO984

### Suppressing Delayed Rectifier Potassium Channels (Kv1.3) in T Lymphocytes and Its Therapeutic Efficacy in Rats With CKD

Itsuro Kazama, Miyagi Daigaku, Kurokawa-gun, Japan.

**Background:** T lymphocytes predominantly express delayed rectifier K<sup>+</sup>-channels (Kv1.3) in their plasma membranes. In our previous study, we revealed that the overexpression of lymphocyte Kv1.3-channels contributed to the progression of chronic kidney disease (CKD) by promoting cellular proliferation and interstitial fibrosis. On the other hand, by suppressing the lymphocyte Kv1.3-channels, some drugs exert immunosuppressive properties.

**Methods:** Employing the standard patch-clamp whole-cell recording technique in murine thymocytes, we examined the effects of commonly used drugs, such as anti-hypertensive drugs, on Kv1.3-channel currents. Additionally, using male Sprague-Dawley rats that underwent 5/6 nephrectomy followed by a 14-week recovery period, we actually examined the therapeutic efficacy of these drugs in advanced CKD.

**Results:** In addition to some anti-hypertensive drugs, non-steroidal anti-inflammatory drugs, antibiotics and anti-cholesterol drugs, effectively suppressed the Kv1.3-channel currents in murine thymocytes. Among them, benidipine, a long-acting 1,4-dihydropyridine Ca<sup>2+</sup> channel blocker, most effectively and persistently inhibited the channel currents. Therefore, using the rat model with advanced CKD, we examined the effects of benidipine (5mg/kg) on the histopathological features of the kidneys, cellular proliferation of leukocytes and the cortical expression of pro-inflammatory cytokines. In the cortical interstitium of advanced CKD rat kidneys, benidipine significantly ameliorated the progression of renal fibrosis without affecting glomerular injury. This drug also reduced the number of proliferating leukocytes with a significant decrease in the pro-inflammatory cytokine expression.

**Conclusions:** Taken together, these *in vitro* and *in vivo* findings suggested the therapeutic potency of Kv1.3-channel inhibitors, such as benidipine, in the treatment or prevention of CKD.

## SA-PO985

### Observation of Circadian Clock Genes Associated With Rhythmic Variation of the Aldosterone Signaling Pathway

Ryanne S. Thelwell, Michelle L. Gumz, G. R. Crislip, Lauren G. Douma. University of Florida, Gainesville, FL.

**Background:** Circadian rhythms regulate several physiological functions. In renal function, blood pressure is circadian regulated. The renin-angiotensin-aldosterone-system (RAAS) plays a major role in blood pressure homeostasis. Chronic kidney disease is primarily a disease of aging. The impact of circadian clock gene function with age requires further study. Variations in the rhythmically expressed genes (REGs) of this study play a role in the loss of the circadian nature of the aldosterone signaling pathway in older mice.

**Methods:** 6 month, 18 month, and 27 month old male mice from National Institute on Aging (NIA) were used to observe molecular clock transcriptional output after subsequent light/dark cycles. RNA sequencing performed on hypothalamus, kidney, lung, gastrocnemius, adrenal gland, and heart tissue. Data from RNA sequencing was processed using R software and circadian rhythmicity was analyzed using the cosinor model available in the diffCircadian software. REGs observed for their effect in aldosterone signaling pathway include Scnn1a, Scnn1b, Scnn1g, Nr3c1, Nr3c2, Hsp90, Atpl1a1, Slc9a3, Slc12a1, Slc12a3, Prkca, Mapk1, Kras, Map2k1, Raf1, Pik3ca, Pdk1, Nedd4L, Sahl, Hsd11b1 and Hsd11b2.

**Results:** Kras expression rhythmically circadian in young and aged mice (p<0.05) but not at all in old mice (p=0.943). Pik3ca expression was rhythmically circadian in young, aged mice (p<0.05) but not at all in old mice (p=0.403). There was also a significant drop in basal expression levels (125 and 124 to 97 for young, aged, and old respectively). Most gene expression rhythmically circadian in young and aged mice (supported by lowest p values).

**Conclusions:** The decline in transcriptional output of rhythmically expressed genes throughout each tissue with age suggest a loss of circadian regulation. Variation in REGs' transcription observed in the aldosterone signaling pathway support loss of circadian patterns with increasing age in mice.

## SA-PO986

### Effects of the Loop Diuretic Furosemide on Renal Hemodynamics and Synchronization Among Nearby Nephrons

Shayan Poursharif, Shereen M. Hamza, Branko Braam. University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada.

**Background:** Autoregulation of renal blood flow (RBF) among nearby nephrons is presumably synchronized via tubuloglomerular feedback (TGF). TGF controls macula densa solute delivery by adjusting afferent arteriolar diameter and thereby single nephron GFR. As high doses of the diuretic furosemide impair TGF via inhibition of NKCC2 transporters and thus macula densa sodium sensing, we hypothesized that deactivating TGF with furosemide would impair nephron synchronization.

**Methods:** Mean arterial pressure, RBF, urine flow and GFR were measured in anesthetized rats (300-400 g). Left kidney cortical perfusion was recorded using laser speckle imaging, to assess surface perfusion and TGF-mediated nephron synchronization. After baseline, furosemide was infused (10, 20 or 30 mg/kg; n=8) to inhibit TGF. Mean phase coherence (PC), which assesses the degree of phase-locking (synchronization) among multiple oscillators (TGF-driven rhythmic changes of multiple afferent arterioles

resistance), the magnitude of decay of TGF PC and length constant associated with initial decay of TGF PC were used to assess strength of synchronization among nephrons.

**Results:** Furosemide did not change MAP ( $101 \pm 10$  to  $105 \pm 39$  mmHg, NS) or RBF ( $7.1 \pm 2.3$  to  $6.9 \pm 2.5$  ml/min, NS). Right kidney GFR increased after furosemide ( $1.10 \pm 0.22$  to  $1.27 \pm 0.27$  ml/min,  $p < 0.05$ ), while left kidney GFR was slightly reduced ( $1.06 \pm 0.22$  to  $0.92 \pm 0.16$  ml/min,  $p < 0.05$ ). Furosemide strongly increased right ( $8 \pm 5$  to  $134 \pm 18$  uL/min,  $p < 0.001$ ) and left ( $10 \pm 3$  to  $124 \pm 16$  uL/min,  $p < 0.001$ ) urine flow. Furosemide decreased the magnitude of the decay of TGF PC ( $0.46 \pm 0.06$  to  $0.42 \pm 0.06$ ,  $P < 0.05$ ) and length constant associated with initial decay of TGF PC ( $-0.28 \pm 0.11$  to  $-0.53 \pm 0.06$ ,  $P < 0.001$ ). Furosemide did not affect average PC. Correlation analysis of urine flow, RVR and GFR with parameters of synchronization did not reveal any further support for a decrease in synchronization after furosemide.

**Conclusions:** High dose furosemide decreased the magnitude of decay of TGF PC and length constant associated with initial decay of TGF PC. This indicates weaker synchronization among nephrons within lobules. However, the absence of a change in mean PC makes it likely that mechanisms other than the TGF sensing step in the macula densa differentially affect synchronization amongst nephrons.

### High Phosphate Diet Induces the Development of Tertiary Lymphoid Structures and Fibrosis in Murine Kidneys

Beatrice Richter,<sup>1</sup> Nina Weingartner,<sup>1</sup> Isabel Vogt,<sup>1</sup> Tamar G. Kapanadze,<sup>2</sup> Dieter Haffner,<sup>1</sup> Maren Leifheit-Nestler.<sup>1</sup> <sup>1</sup>Hannover Medical School, Department of Pediatric Kidney, Liver and Metabolic Diseases, Hannover, Germany; <sup>2</sup>Hannover Medical School, Department of Nephrology and Hypertension, Hannover, Germany.

**Background:** Tertiary lymphoid structures (TLS) are immune cell aggregates found in non-lymphoid organs, including the kidneys, and are associated with chronic inflammation. Similar to secondary lymphatic organs, TLS can initiate adaptive immune reactions. Among others, TLS are described in aging kidneys as well as in autoimmune diseases including IgA nephropathy, ANCA-associated glomerulonephritis and lupus nephritis. Recently, the role of vascular endothelial cells is discussed for the initiation of TLS. Here, we identify for the first time a chronically high phosphate load as a novel trigger for TLS formation in kidneys from mice.

**Methods:** C57BL/6N male mice received a 2% high phosphate diet (HPD) for 1-6 months and were compared to animals on a 0.8% normal phosphate diet (NPD). Renal tissue was collected for histology, flow cytometry, gene expression analyses and cytokine array.

**Results:** Starting after 2 months, in renal tissue from mice on HPD larger immune cell aggregates were found. In parallel, the renal mRNA levels for venous markers and cell adhesion molecules were significantly elevated. Distinctive TLS occurred in mice on HPD after 3 months. At the later time points, perivascular TLS formation in the corticomedullary junction and renal cortex was found for all mice on HPD. No TLS were detected in renal tissue derived from NPD controls. Flow cytometry analysis and histological staining showed a significant increase of CD3+ T cells and CD45R+ B cells starting after 3 months of HPD. Furthermore, an increased accumulation of collagen 3, podoplanin+ fibroblastic reticular cell networks, LYVE+ lymphatic vessel, and Cxcr4+ cells were found. F4/80+ macrophages accumulated in the periphery of TLS. Cluster of proliferating B cells, the presence of plasma cells and detection of IgG secretion in month 4 pointed to the existence of phosphate-induced mature TLS. The induction of Cxcl13, an important chemokine for recruitment and differentiation of B cells, was found in histology and confirmed by cytokine array.

**Conclusions:** Our results indicate that chronically increased phosphate intake leads to de novo formation of fully mature perivascular TLS in kidneys of mice, which was associated with significant interstitial fibrosis.

## SA-PO988

### Knockdown of TMEM30A Resulted in Reduced Uric Acid Absorption

Pei S. Chen, Guisen Li. Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China.

**Background:** Uric acid is the end product of purine metabolism in human body, and the main organ of its excretion is the kidney, accounting for about 70% of the daily excretion of uric acid. The reabsorption and secretion of uric acid in renal tubules are mainly completed by different transporters, among which uric acid anion transporter 1 is considered to be an important uric acid reabsorption transporter, accounting for more than 90% of the reabsorption. URAT1 is mainly expressed at the brush border of renal tubular epithelial cells and transports uric acid from the lumen to the renal tubular epithelial cells. P4-ATPase works together with  $\beta$  subunit TMEM30A to mediate the asymmetric distribution of aminoacyl phospholipids such as phosphatidylserine (PS) and phosphatidylethanolamine (PE), promote the fusion of plasma membrane and internal vesicles, and facilitate vesicular protein transport. We observed decreased TMEM30A expression in the renal tubules of DKD and IgA patients, suggesting a potential role for TMEM30A in renal tubular cells.

**Methods:** To study the role of Tmem30a in renal tubules, we constructed a TMEM30A knockdown cell model by transfecting renal tubular epithelial cells with TMEM30A siRNA. Subsequently, the expressions of TMEM30A, URAT1 and related proteins were detected by immunohistochemical staining, qPCR and Western blotting. At the same time, uric acid with different concentrations of 0, 0.1, 0.5 and 1.0 mmol/L was added, and its absorption was detected after 24, 48 and 72 h of treatment, respectively.

**Results:** The mRNA and protein expressions of URAT1 and vesicle transporter Rab6 were significantly decreased after TMEM30A knockdown, and the absorption of uric acid was significantly reduced.

**Conclusions:** Knockdown of TMEM30A in TCMK-1 cells reduces the synthesis of vesicular transporters, resulting in decreased transport and expression of URAT1, which in turn reduces the absorption of uric acid. Our data suggest that TMEM30A plays a crucial role in renal tubules.

## SA-PO989

### SAMP1/YitFc as an Enteric Hyperoxaluria Mouse Model

Nadim Zaidan, Melody Ho, Lama Nazzal. NYU Langone Health, New York, NY.

**Background:** Enteric hyperoxaluria (EH) is a consequence of increased absorption of dietary oxalate secondary to fat malabsorption. Inflammatory bowel diseases, especially Crohn's disease, are one of the most prevalent conditions causing EH. This hyperoxaluric state accounts for the increased incidence of kidney stones in this population. Urinary oxalate was also linked with the progression of chronic kidney disease. SAMP1 is a mouse model that spontaneously develops ileitis and AKR is its closest genetic relative. We hypothesized that SAMP1 mice will develop an EH phenotype.

**Methods:** This study assessed the impact of fat and oxalate-enriched diets in mice with and without ileitis. Two outcomes were evaluated: urinary oxalate and kidney function by measuring plasma creatinine. We fed 7-10 weeks old male SAMP1 and AKR mice with increasing amounts of dietary fat every two weeks (10%, 45%, and 60%) without oxalate. This was followed by the addition of 1% oxalate (Ox) to the diet and a parallel decrease in dietary fat.

**Results:** At the start of the study, UOx levels were comparable in the AKR and SAMP1 mice ( $10.1 \pm 1.46$   $\mu$ mol/L for SAMP1 vs  $8.7 \pm 0.62$   $\mu$ mol/L for AKR,  $p = 0.09$ ). Increasing dietary fat did not affect UOx in either group, however, the addition of Ox in the diet led to a disproportional increase in UOx in SAMP1 mice as compared to AKR. On a 60% fat + 1% Ox, UOx levels were  $27.3 \pm 2.55$   $\mu$ mol/L in SAMP1 mice vs  $24.3 \pm 1.45$   $\mu$ mol/L in AKR ( $p = 0.05$ ). On 10% fat + 1% Ox at the end of the study, UOx from the SAMP1 mice was significantly higher than UOx from AKR mice ( $123 \pm 9.55$   $\mu$ mol/L vs  $48.9 \pm 7.48$   $\mu$ mol/L ( $p < 0.001$ ). Plasma creatinine (PCr) was 17.5% higher in SAMP1 mice compared with AKR mice at baseline ( $p < 0.01$ ) and at sacrifice, PCr concentration were 70% higher in the SAMP1/YitFc compared to its control population ( $p < 0.001$ ).

**Conclusions:** We were able to establish the presence of the EH phenotype in the SAMP1 mouse model. We also witnessed the development of kidney injury, highlighting the nephrotoxicity of high UOx levels. The next steps will involve the characterization of the factors causing the increased absorption of dietary oxalate and the enteric hyperoxaluria phenotype (intestinal inflammation, gut permeability, oxalate transporter epithelial expression, and gut microbiome differences).

### Drp1 Activates ROS/HIF-1 $\alpha$ /EZH2 and Triggers Mitochondrial Fragmentation to Deteriorate Hypercalcemia-Associated Neuronal Injury in a Mouse Model of CKD

Xitong Li,<sup>1</sup> Yaochen Cao.<sup>1,2</sup> <sup>1</sup>Charite Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>Hainan Medical University, Haikou, China.

**Background:** Chronic kidney disease (CKD), characterized as renal dysfunction, is regarded as a major public health problem which carries a high risk of cardiovascular diseases. The purpose of this study is to evaluate the functional significance of Drp1 in hypercalcemia-associated neuronal damage following CKD and the associated mechanism.

**Methods:** Initially, the CKD mouse models were established. Next, RT-qPCR and Western blot analysis were performed to measure expression of Fis1 and Drp1 in CKD. Chromatin immunoprecipitation (ChIP) assay and dual-luciferase reporter gene assay were utilized to explore the relationship among Drp1, HIF-1 $\alpha$ , EZH2, and ROS with primary cortical neurons isolated from neonatal mice. Next, CKD mice were subjected to Calcitonin treatment or manipulation with adenovirus expressing sh-Drp1, so as to explore the effects of Drp1 on hypercalcemia-induced neuronal injury in CKD. TUNEL assay and immunofluorescence staining were performed to detect apoptosis and NeuN-positive cells (neurons) in brain tissues of CKD mice.

**Results:** It was found that hypercalcemia could induce neuronal injury in CKD mice. An increase of Fis1 and Drp1 expression in cerebral cortex of CKD mice correlated with mitochondrial fragmentation. Calcitonin suppressed Drp1/Fis1-mediated mitochondrial fragmentation to attenuate hypercalcemia-induced neuronal injury after CKD. Additionally, Drp1 could increase EZH2 expression through the binding of HIF-1 $\alpha$  to EZH2 promoter via elevating ROS generation. Furthermore, Drp1 knockdown inhibited hypercalcemia-induced neuronal injury in CKD while overexpression of EZH2 could reverse this effect in vivo.

**Conclusions:** Taken together, the key findings of the current study demonstrate the promotive role of Drp1 in mitochondrial fragmentation which contributes to hypercalcemia-induced neuronal injury in CKD.

**Funding:** Private Foundation Support

## SA-PO991

## Quantitative In Situ Assessments of Mitochondrial Impairment Are Associated With Progressive Kidney Disease

Huihui Huang,<sup>1</sup> Zsuzsanna K. Zsengeller,<sup>1</sup> Vasantha Jotwani,<sup>4</sup> Heather Thiessen Philbrook,<sup>2</sup> Ronit Katz,<sup>5</sup> Joachim H. Ix,<sup>6</sup> Chirag R. Parikh,<sup>2</sup> Dan Arking,<sup>2</sup> Mark J. Sarnak,<sup>7</sup> Michael Shlipak,<sup>4</sup> Sushrut S. Waikar,<sup>8</sup> Samir M. Parikh,<sup>3</sup> <sup>1</sup>Beth Israel Deaconess Medical Center, Boston, MA; <sup>2</sup>Johns Hopkins University, Baltimore, MD; <sup>3</sup>The University of Texas Southwestern Medical Center, Dallas, TX; <sup>4</sup>University of California San Francisco, San Francisco, CA; <sup>5</sup>University of Washington, Seattle, WA; <sup>6</sup>University of California San Diego, La Jolla, CA; <sup>7</sup>Tufts University, Medford, MA; <sup>8</sup>Boston University, Boston, MA.

**Background:** Mitochondrial impairment in the kidney tubule has been experimentally linked to the progression of chronic kidney disease (CKD). However, the relationships among in situ assessments of mitochondrial abundance, biogenesis capacity and oxidative phosphorylation and classical histopathological features remain under-explored in human CKD.

**Methods:** Among voluntary participants in a nephrectomy cohort for renal cell cancer who contributed non-tumor specimens to a CKD biorepository (n=42), we undertook blinded quantitative histochemical evaluation of several features related to mitochondria: immunostaining for mitochondrially encoded cytochrome C oxidase I (MTCO1) to assess mitochondrial abundance; PPAR-gamma-coactivator-1-alpha (PGC1a) to assess biogenesis capacity; and enzyme histochemistry for cytochrome C oxidase (COX-EHC) to assess mitochondrial oxidative phosphorylation. ImageJ was used to score staining intensity in ten randomly selected high-power fields per assessment, and the mean score was obtained from each specimen for the three mitochondrial assessments. These scores were compared to estimated glomerular filtration rate (eGFR) and to blinded semiquantitative assessments of glomerulosclerosis (GLOMSCL), arteriosclerosis (ARTSCL), and interstitial fibrosis/tubular atrophy (IFTA).

**Results:** The mean age was 61±11 years and the mean eGFR was 68±22 ml/min/1.73m<sup>2</sup>. The three mitochondrial parameters were significantly inter-correlated and were directly correlated with eGFR (**Figure**). COX-EHC was significantly and inversely correlated to GLOMSCL, ARTSCL, and IFTA. Conversely, IFTA was inversely correlated to all three mitochondrial assessments.

**Conclusions:** Quantitative in situ assessments of mitochondrial abundance, biogenesis, and oxidative phosphorylation are significantly correlated with functional and histopathological hallmarks of kidney disease. These results suggest that progressive mitochondrial impairments may be intimately linked to worsening kidney disease.

**Funding:** NIDDK Support, Other NIH Support - NIA 2R01AG027002

**Figure:** Correlation matrix of Spearman rank coefficients comparing mitochondrial parameters (MTCO1, PGC1a, and COX-EHC) to age and functional and histopathological hallmarks of kidney disease (eGFR, GLOMSCL, IFTA, ARTSCL). Abbreviations defined in text.

## SA-PO992

## Inhibition of Hypoxia-Inducible Factor Hydroxylases in Proximal Tubules Alleviates CKD Progression After Ischemia-Reperfusion Injury

Midori Sakashita,<sup>1</sup> Mai Sugahara,<sup>1</sup> Tetsuhiro Tanaka,<sup>2</sup> Motoko Yanagita,<sup>3</sup> Masaomi Nangaku.<sup>1</sup> <sup>1</sup>Tokyo Daigaku, Bunkyo-ku, Japan; <sup>2</sup>Tohoku Daigaku, Sendai, Japan; <sup>3</sup>Kyoto Daigaku, Kyoto, Japan.

**Background:** Hypoxia-inducible factor (HIF) is essential in many disease processes, including acute kidney injury (AKI) and the subsequent transition to chronic kidney disease (CKD). HIF-prolyl hydroxylase (HIF-PH) inhibitors stabilize HIF and promote erythropoietin (EPO) production; thereby currently utilized as a novel treatment for anemia in CKD patients. Systemic HIF activation alleviates acute ischemic kidney injury, but the role of HIF or HIF-PH inhibition in the proximal tubule during AKI-to-CKD transition remains unclear because of the difficulty in separating the possible beneficial effects of EPO on renal protection. Since the proximal tubules are strongly damaged in AKI and the degree of injury, dedifferentiation, and regeneration play a major role in the pathogenesis of AKI to CKD, we aimed to determine the role of HIF and HIF-PH in the proximal tubules in the recovery period after AKI.

**Methods:** *Ndrp1<sup>CreERT2/+</sup>; Phd1<sup>lox/lox</sup>/Phd2<sup>lox/lox</sup>/Phd3<sup>lox/lox</sup>* mice were subjected to bilateral renal ischemia-reperfusion injury (IRI). Tamoxifen was administered for 5 consecutive days starting 2 days after IRI to induce proximal tubule-specific HIF-PH deletion. Four weeks after IRI, the kidney function and pathology were evaluated to assess the severity of CKD after AKI.

**Results:** The expression of proximal tubule-specific HIF-1α in the knockout mice was confirmed by highly sensitive immunohistochemistry. HIF-PH deletion after IRI resulted in lower creatinine levels, decreased albuminuria, and improved fibrosis on picro-Sirius red staining after 4 weeks compared to the control group. Plasma EPO and hematocrit levels were comparable between the knockout and control mice.

**Conclusions:** HIF-PH inhibition in the proximal tubules alleviated renal damage during the transition to CKD independent of EPO production.

## SA-PO993

## Hypoxia-Inducible Long Non-Coding RNA, MIR210HG, Contributes to the Stability of HIF1α via miR-93-5p in Renal Tubular Epithelial Cells

Hanako Saigusa, Imari Mimura, Masaomi Nangaku. Tokyo Daigaku Daigakuin Igakuei Kenkyuka Igakubu, Bunkyo-ku, Japan.

**Background:** Chronic hypoxia in the renal tubular interstitium is involved in the progression of chronic kidney disease. Hypoxia inducible factor (HIF1α), which is considered to be the master transcriptional regulator of response to hypoxia, is also subject to various regulation. Recently, there have been increasing reports that non-coding RNAs such as micro RNA (miRNA)s and long non-coding RNA (lnc RNA)s regulate the expression of HIF1α.

**Methods:** We exposed human renal proximal tubular cell lines (RPTEC) to 1% O<sub>2</sub> hypoxia for 1 to 48 hours, and examined the role of MIR210HG regulated by HIF1α.

**Results:** Micro RNA 210 host gene (MIR210HG) was up-regulated from 1 hour after the start of hypoxic stimulation, and maintained the rise until 48 hours. Knockdown of HIF1α decreased the expression of MIR210HG under hypoxia and the exposure of cobalt chloride promoted MIR210HG expression. Knockdown of MIR210HG significantly reduced both mRNA and protein levels of HIF1α, and promoted cell apoptosis. MiR-93-5p has the sequence predicted to bind to both MIR210HG and HIF1α and was previously reported to bind to HIF1α 3' untranslated region. Knockdown of MIR210HG increased the expression of miR-93-5p, and overexpression of miR-93 reduced the level of both HIF1α and MIR210HG. Luciferase assay confirmed that miR-93-5p binds to MIR210HG directly.

**Conclusions:** We revealed that MIR210HG was induced shortly after hypoxia under the regulation by HIF1α, and also modulated HIF1α by competing for miR-93-5p. Under the chronic hypoxia in the renal tubular cells, MIR210HG plays an important role in the biological response to hypoxia and cell survival.

## SA-PO994

## The Urothelium Deactivates Hematuria

Tian Shen, Katherine Xu, Uddhav Neupane, Jonathan M. Barasch. Columbia University, New York, NY.

**Background:** American Urological Association reports that urine contains ~3 million RBC/day ("Addis Count"), containing 3x10<sup>15</sup> heme-bound iron atoms, sufficient to cause urothelial damage and promote growth of 3x10<sup>10</sup> bacteria. Hemolytic UTI increases uHeme by 5 fold, further promoting infection and cell damage. These data suggest that bladder expresses a heme detoxification system.

**Methods:** We used Hmox1 reporter mice and novel Nile Red-Palladium based probes to detect carbon monoxide (CO) with IVIS. *Slc48a1* knockouts and *Hmox1<sup>fl/fl</sup>* mice were kind gifts of Iqbal Hamza (UMaryland) and Anupam Agarwal (UAlabama), respectively. We also created nascent RNA capture from urothelia using uracil phosphoribosyl transferase expression (*Rosa-Upr<sup>fl/+</sup>;Upk2Cre-ERT*) and 4-thiouracil pulse. RNAScope and immunostaining confirmed gene expression. Male and female mice were inoculated with 10<sup>7</sup> UPEC.

**Results:** Infected urothelium demonstrated the expression of heme metabolic genes (*Hp*, *Bach1*, *Hmox1*, *Slc48a1*, *Hebp*) and heme regulatory proteins Bmal and Npas2 within 4-6hrs of bacterial inoculation. To determine gene activity, we identified contemporaneous activation of *Hmox1* and release of CO (breakdown product of heme) 4-8hrs post infection (Heme or RBC lysis were positive controls). In addition, iron disposal

genes (*Lcn2*, *lactoferrin*, *ferritin*, *Slc11a1*, *Slc40a1*), downstream of heme metabolism were co-activated by UTI. The metabolism of heme contributed to the detachment and shedding of urothelial cells between 8-12hrs, since deletion of *Slc48a1*, the heme intake transporter (I.Hamza) and *Hmx1*, mitigated the denudation of bladder mucosa from 70% to 40% of surface area (Padj=0.02).

**Conclusions:** We have identified an endogenous heme metabolic pathway in urothelia that is superactivated by excess heme or UTI likely mitigating bacterial growth. However the capture of excess heme in the setting of hematuria or UTI likely contributes to urothelial death and shedding.

**Funding:** NIDDK Support, Other NIH Support - Columbia Obrien Center for Benign Urology

#### SA-PO995

##### A New Role of Acute Phase Proteins: Local Production Is an Ancient, General Stress-Response System of Mammalian Cells

Peter Hamar, *Semmelweis Egyetem, Budapest, Hungary.*

**Background:** The prevailing general view of acute-phase proteins (APPs) is that they are produced by the liver in response to the stress of the body as part of a systemic acute-phase response. We demonstrated a coordinated, local production of these proteins upon cell stress by the stressed cells.

**Methods:** Mouse left kidneys were subjected to 30 minutes ischemia. Contralateral right kidneys were removed on day 7. Furthermore, miR-193 transgenic renal fibrosis and bacterial endotoxin (LPS) induced acute renal injury and modulated electro-hyperthermia treatment of breast cancer were investigated. Fibrosis progression (blood urea, renal fibronectin, collagen and TGF- $\beta$  expression) of the post-ischemic kidneys were assessed on day 8, 10, 14, 28 and 144. Next generation sequencing results were verified by nanostring and qPCR analysis. Protein level expression was profiled by mass spectrometry.

**Results:** Postischemic kidneys deteriorated resulting in a non-functional renal scar tissue within 28 days. This deterioration was delayed to 144 days by removal of the contralateral healthy kidney. The miR-193 transgene induced renal failure in 8 weeks and LPS induced AKI demonstrated by functional, morphologic and molecular data. Multiplex analysis of these models demonstrated a coordinated upregulation of several acute phase proteins on the mRNA and protein level in all 3 renal models. The similar APP response was demonstrated by us also in a breast cancer mouse model treated with hyperthermia.

**Conclusions:** The local, stress-induced APP production has been demonstrated in different tissues (kidney, breast cancer) and with different stressors (hypoxia, fibrosis and electromagnetic heat). Thus, this local acute-phase response (APR) seems to be a universal mechanism. Papers presented: 10.3390/ijms23062972, 10.3390/ijms21155316, 10.3390/ijms21113825, 10.3390/ijms21010200

#### SA-PO996

##### Impact of Uremia on Regulatory T Lymphocytes Proliferation and Phenotype

Nicolas Valentini,<sup>1,2</sup> Maxime Raymond,<sup>1</sup> Caroline Lamarche,<sup>1,3</sup> <sup>1</sup>Hopital Maisonneuve-Rosemont Centre de Recherche, Montreal, QC, Canada; <sup>2</sup>Universite de Montreal Departement de Pharmacologie et Physiologie, Montreal, QC, Canada; <sup>3</sup>Universite de Montreal Faculte de Medecine, Montreal, QC, Canada.

**Background:** Chronic kidney disease (CKD) patients have a dysfunctional immune system that is chronically and non-specifically activated, leading to low grade inflammation. Inflammation is now considered both a risk factor and a consequence of reduced kidney function and is highly associated with cardiovascular disease, which is the

leading cause of mortality on dialysis. Regulatory T cells (Tregs) are important inhibitors of proinflammatory responses. While Tregs numbers are decreased in patients with CKD, their state and effectiveness remain poorly understood. We aim to investigate the impact of uremia on those cells.

**Methods:** Tregs and conventional CD4+ cells from hemodialysis (HD) patients and healthy donors were fluorescence-activated cell sorting (FACS)-sorted and serum was collected. We analyzed the Treg transcriptome using single cell RNA sequencing (scRNA-seq). Tregs and conventional CD4+ T cells from healthy donors were also expanded *in vitro* with media (IL-2 500U/mL) containing healthy donors' or HD patients' serum. After 7 and 12 days in culture, we used flow cytometry to compare changes in phenotype, viability, apoptosis and assess their function.

**Results:** We identified 11 Treg clusters from the scRNA seq data. From those, one is more present in HD patients, irrespective of donor's sex (FDR <0.05 & abs(Log2FD)>0.26) and 3 less present in HD patients. *In vitro* cultures show decreased Tregs number in uremic serum after 7 days compared to healthy donors (fold expansion 11.35 vs 19.27; p<0.001) and no significant impact on conventional CD4+ T cells (fold expansion 17.88 vs 19.52; p=0.34). They were no significant differences in Treg expansion or function, as assessed by a suppression assay, after 12 days (p>0.99). Staining for apoptosis with Annexin V/PI indicate no difference in viability or apoptosis between serums after 7 and 12 days. Markers associated with Tregs functions and activation such as CTLA4, GARP, LAP, CD69 and CD71 were expressed similarly in HD and healthy donors' serum after 7 days (p=0.82, 0.77, 0.73, 0.23 and 0.44 respectively).

**Conclusions:** Serum from HD patients selectively delays Tregs proliferation *in vitro* and not conventional CD4+ T cells, with no impact on cell death, activation and Tregs markers' expression. HD patients also have different Treg cluster composition. Further studies are needed to identify the causes and impacts of those changes.

#### SA-PO997

##### Angiotensin II Type 1 Receptor-Associated Protein Interacts With Transferrin Receptor 1 and Promotes Its Internalization

Eriko Abe,<sup>1</sup> Hiromichi Wakui,<sup>1</sup> Keigo Hirota,<sup>1</sup> Yamaji Takahiro,<sup>2</sup> Shingo Urate,<sup>1</sup> Toru Suzuki,<sup>1</sup> Shohei Tanaka,<sup>1</sup> Shinya Taguchi,<sup>1</sup> Shunichiro Tsukamoto,<sup>1</sup> Kengo Azushima,<sup>1</sup> Kouichi Tamura,<sup>1</sup> Department of Medical Science and Cardioresenal Medicine <sup>1</sup>Yokohama City University Graduate School of Medicine, Yokohama, Japan; <sup>2</sup>Duke-NUS Medical School, Singapore, Singapore.

**Background:** Angiotensin II type 1 receptor (AT1R)-associated protein (ATRAP) was originally identified as a binding protein of AT1R. ATRAP promotes constitutive internalization of AT1R so as to inhibit the pathological activation of its downstream signaling. Also, we reported that genetic knockdown of ATRAP exacerbates kidney fibrosis in mice along with functional mitochondrial abnormalities and subsequent increases in ROS production. These effects of ATRAP were suggested to be AT1R-independent actions. Thus, this study aimed to explore a novel interacting protein involved in the mechanism that ATRAP protects against kidney fibrosis independent of the interaction with AT1R.

**Methods:** We established Human Embryonic Kidney 293 cells which were able to induce the expression of Flag-ATRAP. In this cell line, after immunoprecipitation with anti-Flag antibodies, the Flag-ATRAP complex was analyzed with a mass spectrometer. Among identified proteins, we focused on transferrin receptor1 (TfR1). To confirm the molecular interaction, co-immunoprecipitation was performed. Additionally, to validate functional interactions, we analyzed intracellular iron concentrations using fluorescent probe of iron. Furthermore, to verify TfR1 expression and localization, immunofluorescence staining of TfR1 in the whole cell or on the cell surface only.

**Results:** Mass spectrometry analysis revealed various proteins associated with vesicular trafficking including TfR1. We confirmed the molecular interaction between ATRAP and TfR1 by co-immunoprecipitation. Enhanced ATRAP expression decreased the cellular iron levels and downregulate TfR1 expression on the cell surface despite no significant difference in whole cell.

**Conclusions:** We propose a molecular and functional link between ATRAP and TfR1. ATRAP would regulate TfR1 availability via downregulation of cell surface TfR1 via promotion of its internalization. TfR1 promotes intracellular localization of the iron-bound transferrin. Iron is a key factor in the process of kidney fibrosis via production of ROS in relation to deterioration of mitochondrial function. Taken together, this novel ATRAP-TfR1 axis might be the mechanism relevant to the ROS/mitochondrial dysfunction-mediated process of kidney fibrosis.

#### SA-PO998

##### Deficiency of Angiotensin II Type 1 Receptor Prevents Muscle Atrophy due to Denervation

Suguru Takayama,<sup>1</sup> Takeshi Sugaya,<sup>1</sup> Yugo Shibagaki,<sup>1</sup> Atsuko Ikemori,<sup>1,2</sup> <sup>1</sup>Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; <sup>2</sup>Department of Anatomy, St. Marianna University School of Medicine, Kawasaki, Japan.

**Background:** Because chronic kidney disease (CKD) is a high risk of muscle wasting, managing CKD is clinically important for promoting the health and well-being of patients with CKD in aging society. Although angiotensin II (Ang II) type 1 receptor blocker was reported to attenuate muscle atrophy after muscle injury model, its model does not reflect human pathophysiological conditions. The aim of this study is to reveal whether suppressed activation of angiotensin II type 1 receptor (AT1) prevents severe muscle atrophy after denervation which mimics disuse atrophy.

**Methods:** To induce severe muscle atrophy, the sciatic nerves in right and left inferior limbs were cut in AT1a knockout homo (AT1a<sup>-/-</sup>) male mice and wild type (AT1a<sup>+/+</sup>) male mice. Both leg muscle tissues were removed and were categorized as gastrocnemius muscle at 3-, 7- and 21-day post-denervation.

**Results:** Muscle weight and cross-sectional areas of type IIb muscle fibers in gastrocnemius muscle decreased at 7- and 21-day post-denervation in both AT1a<sup>-/-</sup> mice and AT1a<sup>+/+</sup> mice, and the degree was significantly milder in the denervated muscle of AT1a<sup>-/-</sup> mice than in the denervated muscle of AT1a<sup>+/+</sup> mice. Regarding activation of muscle protein degradation system, upregulated expressions of phosphorylated nuclear factor-κB at 3-day and two E3 ubiquitin ligases (muscle RING-finger protein-1 and atrogin-1) at 7- and 21-day were significantly downregulated in the denervated muscle of AT1a<sup>-/-</sup> mice compared to the AT1a<sup>+/+</sup> mice. In addition, while muscle apoptosis evaluated by gene expressions of Bcl-2-associated X protein and TUNEL staining was induced in both AT1a<sup>-/-</sup> mice and AT1a<sup>+/+</sup> mice, the degree was significantly suppressed in the AT1a<sup>-/-</sup> mice. On the other hand, there were not significant differences in activations of protein synthesis and autophagy which were evaluated by protein expressions of phosphorylated ribosomal protein S6 kinase b-1 and LC3B-II/I, between the AT1a<sup>-/-</sup> mice and AT1a<sup>+/+</sup> mice.

**Conclusions:** Inactivation of the AT1 receptor prevented muscle atrophy due to denervation via suppressions of protein degradation system and apoptosis. Ang II type 1 receptor blocker may be useful for prevention of muscle atrophy in elder patients with CKD.

## SA-PO999

### Establishment of Quantitative Proteomics Platform for Urine Biomarker Discovery and Validation

Keiko Yamamoto,<sup>1,2</sup> Tadashi Yamamoto,<sup>1,2</sup> <sup>1</sup>Niigata Daigaku Igakubu Igakuka Daigakuin Ishigaku Sogo Kenkyuka, Niigata, Japan; <sup>2</sup>Shinrakuen Byoin, Niigata, Japan.

**Background:** Proteomics has been introduced for discovery of biomarkers in biological fluids such as plasma, urine and others. Recent advance of the data-independent acquisition (DIA) method of proteomics has improved the quantitative evaluation. We employed the method for urine biomarker discovery and adapted it for validation of the biomarkers.

**Methods:** Urine samples were collected in Biofluid Biomarker Center (BBC), Niigata University, Japan from patients with various diseases and healthy persons received medical examinations at several hospitals according to a guide proposed by Human Kidney & Urine Proteome Project of Human Proteome Organization and stored in -20°C freezers. Urine proteins were separated from 1ml of the frozen urine by a methanol/chloroform precipitation method and digested with trypsin to prepare peptides, purified through C-14 spin column. The urine peptide samples of 200 ng each were analyzed by liquid chromatography-mass spectrometry (LC-MS, tims-TOFpro, Bruker Daltonics) sequentially in data-dependent acquisition (DDA) and data-independent acquisition (DIA) manners. The platform was applied to urine samples from diabetic patients (n=200) and healthy volunteers (n=200).

**Results:** More than 100,000 urine samples have been collected from about 12,000 patients and healthy persons, indicating serial urine collections from the same patients. Approx. 2,000 proteins were identified by the DDA LC-MS and quantified by the DIA LC-MS using 200 ng peptides each. Qualities of the peptide samples and LC-MS analysis were certified by consistent identification and quantification of quality control proteins of high to low abundance, selected in BBC. The urine biomarker candidates were selected by comparing quantities of proteins, evaluated in about 50-100 sample analyses by the DIA-LC-MS between men and women and between DM patients and healthy people. The selected biomarker candidates were examined in another set of about 50-100 sample analysis data for validation of the urine biomarkers. Several urine biomarkers for gender identification and for DM-induced kidney injuries are demonstrated in the presentation.

**Conclusions:** The quantitative proteomics platform is powerful to find and validate new urine biomarkers since it is efficient to quantitate thousands of proteins in a single analysis and also consistent for quantitation by using several quality controls.

### SGLT2 Inhibitors Reduce Urinary Mitochondrial DNA Copy Number in Both Diabetic and Non-Diabetic CKD Patients

Haekyung Lee,<sup>1,2</sup> Junghyun Cho,<sup>1</sup> Eui Suk Chung,<sup>1</sup> Hyounghae Kim,<sup>1,2</sup> Jin seok Jeon,<sup>1,2</sup> Soon hyo Kwon,<sup>1,2</sup> <sup>1</sup>Soonchunhyang University Hospital, Yongsan-gu, Seoul, Republic of Korea; <sup>2</sup>Soonchunhyang University Hospital Kidney Center, Yongsan-gu, Seoul, Republic of Korea.

**Background:** Sodium-glucose co-transporter 2 (SGLT2) inhibitors improve renal and cardiovascular outcomes in patients with chronic kidney disease (CKD) regardless of the presence of type 2 diabetes mellitus (T2DM). In this work, we aimed to investigate whether SGLT2 inhibitors improve mitochondrial dysfunction in patients with T2DM or CKD.

**Methods:** We prospectively recruited SGLT2 inhibitor naïve patients with T2DM (n = 16), non-diabetic CKD (n = 16) and normal control (n = 22). Copy numbers of urinary mitochondrial DNA (mtDNA) in the form of mitochondrial nicotinamide adenine dinucleotide dehydrogenase subunit-1 (mtND-1) and cytochrome-c oxidase 3 (mtCOX-3) were measured at baseline and after 3 months of treatment with SGLT2 inhibitors (empagliflozin in the T2DM group and dapagliflozin in the non-diabetic CKD group).

**Results:** Immunoglobulin A nephropathy was the most common underlying kidney disease (50%) in the non-diabetic CKD group. Estimated glomerular filtration rate was higher and albuminuria was lower in the T2DM group than in the non-diabetic CKD group (both p < 0.001). Baseline urinary mtDNA levels were significantly higher in either T2DM or non-diabetic CKD group than in healthy controls (p < 0.001 for mtND-1 and mtCOX-3, respectively), with mtDNA copy numbers comparable between the diabetic and non-diabetic CKD groups. SGLT2 inhibitors reduced urinary copy numbers of mtND-1 and mtCOX-3 in both the T2DM (p < 0.001 for mtND-1 and mtCOX-3, respectively) and non-diabetic CKD groups (p < 0.05 for mtND-1 and mtCOX-3, respectively) (Figure 1). The amount of reduction in urinary mtDNA copy number did not differ according to each SGLT2 inhibitor.

**Conclusions:** SGLT2 inhibitors reduce the elevated urinary mtND-1 and mtCOX-3 copy numbers in patients with T2DM or non-diabetic CKD, suggesting that SGLT2 inhibitors improve mitochondrial injury regardless of the presence of T2DM.

Figure 1. Change in urinary mitochondrial DNA copy numbers after sodium-glucose co-transporter 2 inhibitor treatment. (A) mtND-1, (B) mtCOX-3

### Therapeutic Potential of Adipocyte Implantation in Experimental Uremic Cardiomyopathy by Antagonism of Na,K-ATPase Signaling

Sneha S. Pillai,<sup>1</sup> Duane G. Pereira,<sup>1</sup> Muhammad A. Chaudhry,<sup>1</sup> Joseph I. Shapiro,<sup>1</sup> Komal Sodhi,<sup>1</sup> Marshall University Joan C Edwards School of Medicine, Huntington, WV.

**Background:** The putative method of implantation of adipocytes has been shown to improve systemic inflammatory milieu and metabolic homeostasis in different disease models. We have recently demonstrated that administration of NaKtide, antagonist of Na/K-ATPase signaling, coupled to adipocyte-specific promoter can improve adipocyte phenotype and further attenuated experimental uremic cardiomyopathy. In the present study, we investigated the pathophysiological changes in recipient mice that underwent partial nephrectomy (PNx) surgery and implanted with NaKtide transfected human mesenchymal stem cell (MSC) derived adipocytes.

**Methods:** Human adipose-derived MSC were transfected with or without lentivirus with adipocyte-specific NaKtide/ scrambled NaKtide and cells were cultured for 15 days with adipocyte differentiation medium. For in vivo adipocyte implantation, Male Fox Chase severe combined immunodeficiency (SCID) (10-12 weeks old) mice were injected with 2x10<sup>6</sup> adipocytes/ml in the dorsal subcutaneous region of randomly divided groups of mice followed by PNx surgery on the same day. The tissues were harvested for morphological and molecular analyses after 4 weeks of transplantation. Statistical analysis was performed by one-way analysis of variance.

**Results:** The implantation of NaKtide transfected adipocytes improved adipocyte phenotype, systemic inflammation, and improved cardiac morphological and biochemical function in recipient PNx mice. The changes in plasma microRNA secretion, that act in a paracrine fashion to actively regulate cardiac inflammatory processes, were also ameliorated by NaKtide, implicating a possible mechanism of intra organ crosstalk. The results were compared with the implantation of control and Scrambled NaKtide transfected adipocytes. The study demonstrates that adipocyte-specific NaKtide reprograms the adipocyte phenotype and transplantation of these metabolically healthy adipocytes in PNx exhibits improved systemic and cardiovascular function, through intra-organ crosstalk between adipose and cardiac tissue.

**Conclusions:** The study establishes the clinical utility of targeting adipocyte Na/K-ATPase signaling as well as explores the therapeutic potential of transplanting healthy adipocytes in attenuating uremic cardiomyopathy.

## SA-PO1002

### GSTM1 Deficient Kidney Primary Tubular Epithelial Cells Have Augmented NF-κB p65 Signaling in Response to Angiotensin II

Luojing Chen,<sup>1</sup> Timothy J. Beane,<sup>1</sup> Yves T. Wang,<sup>1</sup> Jason J. Cunningham,<sup>1</sup> University of Rochester, Rochester, NY.

**Background:** Glutathione-S-transferase Mu-1 (*Gstm1*) gene encodes an enzyme that functions in the detoxification of electrophilic compounds. The common *GSTM1* deletion variant in humans is associated with increased risks of chronic kidney disease (CKD) progression and incident end stage kidney failure. We previously reported that, in angiotensin II-induced hypertension (AngII-HTN), *Gstm1* knockout (KO) mice display increased kidney inflammation, characterized by increased inflammatory cell infiltration

(by flow cytometry), and increased kidney expression of CXCL1, MCP-1/CCL2, and IL-6, independent of blood pressure. Moreover, bone marrow cross-transplantation revealed GSTM1 deficiency in the parenchyma, not in bone marrow derived cells, determined kidney inflammation. Much of the proinflammatory effect of AngII is mediated via the canonical NF- $\kappa$ B pathway. We set to determine the influence of GSTM1 on NF- $\kappa$ B p65 signaling pathway in renal tubular cells.

**Methods:** Primary tubular epithelial cells (PTECs) were isolated from *Gstm1* KO and wild-type (WT) kidneys, and grown on pre-coated cover slips until ~ 70% confluent. Cells were then starved for 4 hours before treatment with AgII (100 nM) for 24 hours, fixed, and stained with anti-NF- $\kappa$ B p65 antibody. Images were taken with a fluorescence microscope (Olympus BX51).

**Results:** NF- $\kappa$ B p65 nuclear staining was quantified as percentage of p65 nuclei-positively stained cells to the total cells. Five random fields were counted for each group and similar results were obtained from two independent experiments. At baseline, there was no statistically significant difference. After 24 hrs of Ang II, there was a significant increase in intensity and localization of p65 in nuclei in KO compared to WT PTECs (% p65 positive cells: WT  $9.8 \pm 1.6$ , KO  $23.8 \pm 2.5$ ;  $p = 0.0014$ ).

**Conclusions:** Deletion of *Gstm1* augments AngII activation of NF- $\kappa$ B p65 signaling pathway in PTECs. This may explain the increased kidney inflammation in *Gstm1* KO mice in Ang II-HTN. Further studies are under way to determine the functional significance, including expression of CXCL1 and MCP-1 in PTECs, and whether this drives migration of inflammatory cells.

## SA-PO1003

### Tubule-Specific Overexpression of Krüppel-Like Factor 6 (KLF6) Is Detrimental After Nephrotoxic Kidney Injury

Sian Piret, Merin Davis, Samaneh Gholami, Nehaben A. Gujarati, Bismark Owusu Frimpong, Sandeep K. Mallipattu. *Stony Brook University, Stony Brook, NY.*

**Background:** Transcriptional control of transition to chronic kidney disease (CKD) after nephrotoxic injury is poorly understood. We previously showed that proximal tubule (PT)-specific knockdown of the transcription factor Krüppel-like factor 6 (KLF6) was protective after DNA damage using the PT-specific toxin aristolochic acid I (AAI). Our aim was to determine whether tubular overexpression (OE) of human (h)KLF6 (hKLF6<sup>TOE</sup>) attenuates remodeling of the kidney post-AAI.

**Methods:** hKLF6<sup>TOE</sup> mice were generated by breeding TRE-hKLF6 and Pax8-rtTA mice, with doxycycline (DOX) added to the diet. Controls were single transgenic TRE-hKLF6 mice. AAI was injected at 2mg/kg every 3 days for 2 weeks, followed by 2 weeks without AAI for development of CKD. Serum was collected for urea nitrogen and creatinine measurements, and kidneys for histology and gene expression analyses. Single nuclear RNA-sequencing (snRNA-seq) was undertaken on global hKLF6-OE mice 24 hours after one AAI injection. Locations of p53 and KLF6 binding sites (BS) from published ChIP-seq data were mapped against regions of open chromatin in published data from mouse nephron.

**Results:** To determine whether hKLF6 OE alone would induce injury, hKLF6<sup>TOE</sup> and control mice were fed DOX for 18 weeks. There were no functional or histological differences between hKLF6<sup>TOE</sup> and control mice at baseline. AAI-treated hKLF6<sup>TOE</sup> mice had elevated serum creatinine and urea nitrogen, and more PT injury, inflammation, and fibrosis as compared to AAI-treated controls. To determine potential mechanisms, we utilized snRNA-seq in global hKLF6-OE mice. The most highly upregulated pathway both in PT from control mice with AAI versus no AAI, and in an injured-PT cluster, was p53 signaling, which was further elevated in hKLF6-OE mice. *In silico* ChIP-seq showed p53 and KLF6 occupy the promoters of key p53 downstream targets. In hKLF6<sup>TOE</sup> mice cortex, expression of two p53 pathway members, *Cngl1* (which has KLF6 BS) and *Mdm2* (p53 and KLF6 BS), was significantly correlated with hKLF6 expression. Total KLF6 expression also correlated with serum creatinine and urea nitrogen levels in AAI-treated control and hKLF6<sup>TOE</sup> mice.

**Conclusions:** Induction of tubule-specific KLF6 exacerbates the AKI to CKD transition post-nephrotoxic injury, which may be mediated through enhanced p53 signaling.

## SA-PO1004

### Altered Bone Marrow Myelopoiesis Contributes to Renal Injury

Ryan Spear,<sup>1</sup> Yan Xu,<sup>1</sup> Flavio Vincenti,<sup>2</sup> Yanxia Cao,<sup>1</sup> Steve Mangos,<sup>1</sup> Jochen Reiser,<sup>1</sup> Eunsil Hahm.<sup>1</sup> <sup>1</sup>Rush University Medical Center, Chicago, IL; <sup>2</sup>University of California San Francisco, San Francisco, CA.

**Background:** Altered hematopoiesis in bone marrow (BM) is commonly found in diverse disease conditions associated with CKD, including infection, chronic inflammation, diabetes, CVD, cancer and aging. However, the BM-kidney axis is poorly understood. Here, we tested if inflammatory signals alter BM myelopoiesis leading to renal injury.

**Methods:** We explored the phenotypic changes of BM components in renal disease by collecting BM aspirates and plasma from CKD patients and healthy donors. We used an *in vitro* differentiation system to examine how inflammatory signals affect myelopoiesis and cellular functions. Briefly, human CD34+ hematopoietic stem cells (HSC) were isolated from healthy donors and cultured in myeloid expansion media. TNF $\alpha$  was added to mimic inflammatory conditions. Cells and supernatants were subjected to Seahorse, flow cytometric and secretome analyses. The link between BM alteration and renal injury was tested *in vivo* using two animal models.

**Results:** CKD patients have high levels of TNF $\alpha$  and suPAR in both plasma and BM, indicative of chronic inflammation. These patients show myeloid-biased hematopoiesis and an increase in inflammatory CD14<sup>+</sup>CD16<sup>+</sup> BM monocytes expressing uPAR. Consistently, myeloid-lineage differentiation assays showed that TNF $\alpha$  skews HSC differentiation towards monocytic lineage at the expense of granulocytes. Along with altered myelopoiesis, TNF $\alpha$  markedly increases uPAR expression, suPAR secretion and promotes production of proinflammatory cytokines including TNF $\alpha$ , IL-8 and IL-6. Additionally, TNF $\alpha$  stimulates monocyte subsets to become metabolically active. Soluble factors from TNF $\alpha$ -driven myeloid cells cause filtration dysfunction in a transgenic zebrafish functional assay. Injecting mice with TNF $\alpha$  and IFN $\gamma$  (essential for myelopoiesis) leads to significantly elevated ACR, BUN and suPAR levels, along with an increase in uPAR expressing CD11b<sup>+</sup> BM myeloid cells, suggesting that TNF $\alpha$  contributes to renal injury by altering BM.

**Conclusions:** Our findings suggest that TNF $\alpha$  reprograms BM myelopoiesis. Renal injury results from the generation of metabolically active myeloid cells that secrete proinflammatory cytokines and soluble permeability factors. These observations provide important groundwork for the exploitation of the BM-kidney axis as a novel therapeutic target for immune-mediated nephrotic syndrome currently categorized as 'idiopathic'.

## SA-PO1005

### Myeloid-Specific Mitochondrial Fusion Proteins MFN1 and MFN2 Regulate Lung Injury Associated With CKD

Divya Bhatia, Maria Platacki, Mary E. Choi. *Weill Cornell Medicine, NY, NY.*

**Background:** Association of chronic kidney disease (CKD) and lung injury is under-recognized. Studies suggest increased prevalence of CKD in idiopathic pulmonary fibrosis (IPF) patients associates with worse survival than patients without CKD. We sought to understand mechanistic link between kidney and lung injury and role of macrophage mitochondrial fusion proteins, mitofusin (MFN)1 and MFN2.

**Methods:** Myeloid-specific *Mfn1* (*Mfn1*<sup>fl/fl</sup>, *LysM-Cre*<sup>-/-</sup>), *Mfn2* (*Mfn2*<sup>fl/fl</sup>, *LysM-Cre*<sup>-/-</sup>), or *Mfn1/Mfn2* double knockout (DKO) and corresponding *floxed/floxed* *LysM-Cre*<sup>-/-</sup> wild-type (WT) mice were subjected to unilateral ureteral obstruction (7-days) or sham surgery, or adenine (AD) or control (Ctl) diet (4 or 8-weeks). Lungs, bronchoalveolar lavage (BAL), and blood were collected and analyzed by flow cytometry and western blot.

**Results:** Pro-inflammatory monocytes (Ly6C+CD11b+), macrophages (infiltrated: CD11b+ CD64+SiglecF-; resident: SiglecF+CD11b-), and fibrotic response (arginase-I, galectin-3, YM-1, CD86, fibronectin, collagen-I) increased while anti-inflammatory monocytes (Ly6C-CD11b+) and MFN1 and MFN2 expression decreased in lungs from WT mice after UUO or AD than sham or Ctl respectively. Circulating pro-inflammatory (Ly6C+CCR2+) and profibrotic (galectin-3+, TGF- $\beta$ +) markers on monocytes but not on other (CD11b-) cells increased in WT mice after AD than Ctl. AD-fed WT but not *Mfn2*<sup>fl/fl</sup>, *LysM-Cre*<sup>-/-</sup> or DKO mice displayed an increase in infiltration of pro-inflammatory monocytes in lungs than Ctl. *Mfn2*<sup>fl/fl</sup>, *LysM-Cre*<sup>-/-</sup> mice displayed lower expression of fibrotic markers while higher total MFN2 expression in lungs during CKD than WT mice. Alveolar type II epithelial cells (AEC II, EpCAM+CD45-) from AD-fed *Mfn2*<sup>fl/fl</sup>, *LysM-Cre*<sup>-/-</sup> mice had a higher expression of MFN2 than AD-fed WT mice. *Mfn1*<sup>fl/fl</sup>, *LysM-Cre*<sup>-/-</sup> mice also displayed lower expression of galectin-3 and exhibited a compensatory increase in MFN1 expression in lungs than WT mice after AD. BAL from WT but not DKO mice displayed an increase in pro-inflammatory monocytes after AD than Ctl.

**Conclusions:** Pro-inflammatory monocytes/macrophages and fibrotic response in lungs were increased in experimental CKD in WT mice, with increases in circulating pro-inflammatory and profibrotic monocytes. Myeloid-specific *Mfn1* or *Mfn2*-deficiency resulted in attenuation, potentially mediated by compensatory induction of MFN1 and MFN2 expression in AEC II.

**Funding:** Other NIH Support - NHLBI

## SA-PO1006

### Renal Klotho Provides Inter-Organ Protection of Bone Marrow Hematopoiesis Against Phosphate Toxicity

Ke Yang,<sup>1</sup> Changhong Du.<sup>2</sup> <sup>1</sup>Xinqiao Hospital, Army Medical University (Third Military Medical University), Chongqing, China; <sup>2</sup>Institute of Combined Injury of PLA, Army Medical University (Third Military Medical University), Chongqing, China.

**Background:** Hematopoietic disorders including arterial thrombosis, innate immune inflammation and adaptive immunodeficiency are prevalent in patients with chronic kidney disease (CKD). However, the pathogenetic mechanism and the interactions between kidneys and bone marrow (BM) hematopoiesis remain poorly understood.

**Methods:** The role of kidney and renal Klotho in the regulation of BM hematopoiesis were evaluated *in vivo* and *ex vivo*, and confirming in targeted gene knockout and kidney-specific knockout mice.

**Results:** We found that CKD was characterized by myeloid-biased hematopoiesis and renal Klotho deficiency contributed to myeloid bias in CKD via impairing BM hematopoietic stem cell (HSC) maintenance. Using kidney-specific Klotho deletion mice and a CKD mouse model, we revealed that kidney-secreted soluble Klotho maintained pool size and differentiation propensity of human and mouse HSCs in an inter-organ manner through regulating inorganic phosphate (Pi) homeostasis of HSCs. Mechanistically, soluble carrier family 20 member 1 (SLC20A1) mediated Pi absorption and diphosphoinositol pentakisphosphate kinase 2 (PPIP5K2) mediated Pi sensing and signal transduction to Akt in HSCs; whereas renal Klotho restrained SLC20A1-mediated Pi absorption of HSCs. Klotho/Pi perturbation-induced Pi toxicity in CKD and high Pi diet (HPD) hyperactivated SLC20A1-PPIP5K2-Akt pathway to self-amplify Pi toxicity and boost GATA2 and mitochondrial activities in HSCs, which promoted expansion and

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

megakaryocyte/myeloid-biased differentiation of HSCs and ultimately megakaryocyte/myeloid-biased hematopoiesis. Furthermore, single-cell RNA-sequencing revealed a heterogeneous Pi metabolic signature, which might underlie the distinct response of HSCs to Pi toxicity. Importantly, targeting Klotho/Pi-SLC20A1-PP1P5K2-Akt axis prevented Pi toxicity to BM hematopoiesis in CKD and HPD.

**Conclusions:** Our study uncovers a hitherto unrecognized role of kidneys in the regulation of BM HSC maintenance through secreting Klotho, and identifies that soluble Klotho and Pi are critical extrinsic factors that govern BM HSC maintenance. The findings not only provide deep insight into the function and composition of BM niches, but also extend our understanding of inter-organ regulation of BM hematopoiesis. Targeting Klotho/Pi-SLC20A1-PP1P5K2-Akt axis holds promise in protecting BM hematopoiesis against Pi toxicity such as in CKD and HPD.

**Funding:** Government Support - Non-U.S.

### Changes in the Human Kidney Cellular Architecture During Fibrosis

Ghazal Z. Quinn,<sup>1</sup> Amin Abedini,<sup>1</sup> Xin Sheng,<sup>1</sup> Guannan Gao,<sup>3</sup> Lynda Vuong,<sup>2</sup> Matthew Palmer,<sup>1</sup> Jonathan Hill,<sup>3</sup> Steven S. Pullen,<sup>3</sup> A. A. Hakimi,<sup>2</sup> Katalin Susztak.<sup>1</sup> <sup>1</sup>University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; <sup>2</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>3</sup>Boehringer Ingelheim International GmbH, Ridgefield, CT.

**Background:** Chronic diabetic and hypertensive kidney disease account for more than 75% of all end stage renal disease cases. The underlying mechanisms of disease progression are poorly understood. We hypothesized that changes in the cellular composition of kidney tissue might highlight disease-causal cell types or mechanisms.

**Methods:** We analyzed human kidney tissue samples (n=593) of patients with diabetic and hypertensive kidney disease or controls. We obtained associated clinical and histopathological information and generated corresponding bulk RNA sequencing information from kidney tissue. Histopathologic features such as interstitial fibrosis were scored by a renal pathologist. Human kidney single cell gene expression was generated to obtain cell type-specific gene expression changes. We used *in silico* deconvolution (CIBERSORTx) to estimate cell proportions in bulk tissue RNA sequencing data. We validated changes in immune cell fractions using flow cytometry analyses.

**Results:** We found strong correlations between kidney proximal tubule (PT) cells, regulatory T cells, Natural Killer cells, effector T cells and the degree of kidney dysfunction including interstitial fibrosis ( $r^2=0.51$ ,  $p<0.001$ ) and estimated glomerular filtration rate (eGFR,  $r^2=0.39$ ,  $p<0.001$ ). *In silico* deconvolution and flow cytometric analyses highlighted the association between T cells and eGFR. We found patients with low PT cell fractions (i.e., <45% PT cells) had significantly higher immune cell types such as Th17 cells, and more rapid eGFR decline over time ( $p<0.05$ ).

**Conclusions:** In summary, kidney fibrosis is characterized by marked changes in kidney proximal tubules. Changes in immune and lymphocyte fractions are a key feature of diabetic and hypertensive CKD. Cell fraction changes predict the rate of kidney function decline.

## SA-PO1008

### ULK1-Regulated AMP Sensing Mechanism by AMPK Is Disrupted in CKD

Tomoki Yanagi,<sup>1</sup> Hiroaki Kikuchi,<sup>2,1</sup> Koh Takeuchi,<sup>3</sup> Koichiro Susa,<sup>1</sup> Naohiro Takahashi,<sup>1</sup> Yuta Nakano,<sup>1</sup> Fumiaki Ando,<sup>1</sup> Shintaro Mandai,<sup>1</sup> Takayasu Mori,<sup>1</sup> Shinya Honda,<sup>1</sup> Satoru Torii,<sup>1</sup> Shigeomi Shimizu,<sup>1</sup> Tatemitsu Rai,<sup>1</sup> Shinichi Uchida,<sup>1</sup> Eisei Sohara.<sup>1</sup> <sup>1</sup>Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan; <sup>2</sup>National Heart Lung and Blood Institute, Bethesda, MD; <sup>3</sup>Tokyo Daigaku, Bunkyo-ku, Japan.

**Background:** AMP-activated protein kinase (AMPK) is a kinase that plays a major role in energy homeostasis. Increase in intracellular AMP causes AMPK activation through binding of AMP to AMPK  $\gamma$ -subunit, however, this phenomenon is impaired in chronic kidney disease (CKD). To date, the molecular mechanism of regulation of AMP sensing ability of AMPK, and the mechanism by which this AMP sensitivity is disrupted in CKD are totally unclear. We show a possible role for Unc-51-like kinase 1 (ULK1), whose expression is markedly decreased in CKD, in the regulation of this AMP sensing of AMPK.

**Methods:** *Ulk1*<sup>-/-</sup> mice were used in this study. Sub-total nephrectomy was applied as CKD mouse model. Purified AMPK $\gamma$  protein and fluorescently labeled AMP were used to measure the amount of AMP that binds to the AMPK $\gamma$  subunit.

**Results:** The activation of AMPK by AMP was impaired in *Ulk1*<sup>-/-</sup> mice, in spite of increased AMP/ATP ratio. We identify that ULK1 directly phosphorylates AMPK $\gamma$ 1, which is required for the activation of AMPK, and that this phosphorylation is decreased in *Ulk1*<sup>-/-</sup> and CKD mouse kidney. Fluorescence binding assay reveals that the amount of AMP bound to AMPK $\gamma$ 1 is regulated by phosphorylation of AMPK $\gamma$ 1. Structural information also indicated that this phosphorylation could affect the AMP binding loops' conformation, modifying the AMP binding affinity to AMPK $\gamma$ 1. Absence of ULK1 promote more severe kidney dysfunction and renal fibrosis, due to AMPK inactivation.

**Conclusions:** We discovered an entirely new mechanism of energy homeostasis, in which ULK1 increases AMPK activity promoting AMP binding to AMPK  $\gamma$ 1 subunit, providing potential insight into the role of this new mechanism for AMP sensing failure of AMPK in CKD.

## SA-PO1009

### Ablation of the Non-Receptor Tyrosine Kinase c-Abl in Renal Tubular Cells Alleviates Renal Fibrosis in Mice

Qianyi Bao,<sup>1,2</sup> Anyu Wang,<sup>2</sup> Xiao-Dong Yuan,<sup>3</sup> Lin He,<sup>2</sup> Gang Ma.<sup>2</sup> <sup>1</sup>Department of Gynecology & Obstetrics, Medical School, Southeast University, Nanjing, China; <sup>2</sup>Key Laboratory for the Genetics of Developmental and Neuropsychiatric Disorders (Ministry of Education), Bio-X Institutes, Shanghai Jiao Tong University, Shanghai, China; <sup>3</sup>Department of Urology, Renji Hospital, Shanghai Jiaotong University, School of Medicine, Shanghai, China.

**Background:** Renal fibrosis is the uppermost symptom of chronic kidney disease (CKD). The renal tubules, particularly the proximal tubule cells (PTCs), are easily damaged and the injured PTCs are associated with the occurrence of CKD. C-Abl (encoded by the *Abl1* gene) is a member of the Abelson family of non-receptor tyrosine kinases and plays a fundamental function in organ fibrosis. However, the role of c-Abl in the pathogenesis of PTCs and CKD remains elusive.

**Methods:** Western blotting and immunofluorescence (IF) were used to determine the expression pattern of c-Abl in clinical samples and fibrotic kidneys from CKD mice treated with unilateral ureteral obstruction (UUO) and unilateral ischemia-reperfusion injury (uIRI). Next, c-Abl was deleted specifically in PTCs by using *Ksp-Cre* mice to generate *Ksp-Cre*; *c-Abl*<sup>fl/fl</sup> knockout mice which subsequently were treated with UUO and uIRI to obtain fibrosis models to understand the function of c-Abl. The role of c-Abl was further confirmed in human proximal tubule epithelial cells (HK-2 cell line) stimulated with TGF- $\beta$ 1. C-Abl knockout was induced in myofibroblasts to generate *aSMA-CreERT*; *c-Abl*<sup>fl/fl</sup> mice which were treated with UUO and uIRI to determine if targeting c-Abl in myofibroblasts was beneficial in alleviating established renal fibrosis and kidney dysfunction.

**Results:** The expression and kinase activity of c-Abl were elevated in human and mouse fibrotic kidneys, and were positively correlated with fibrogenic genes. IF staining showed that c-Abl was localized in parenchymal fibroblasts and myofibroblasts, notably enriched in PTCs of fibrotic kidneys. The specific deletion of c-Abl in *Ksp-Cre*; *c-Abl*<sup>fl/fl</sup> mice attenuated renal fibrosis through inhibiting PTCs activation and parenchymal collagen production. In HK-2 cells, c-Abl was shown to be essential and sufficient to induce  $\alpha$ -SMA expression and collagen deposition as downstream of TGF- $\beta$  signaling pathway. Finally, ablation of c-Abl in myofibroblasts in *aSMA-CreERT*; *c-Abl*<sup>fl/fl</sup> mice significantly mitigated the progression of kidney fibrosis in established CKD mouse models.

**Conclusions:** This study primarily found that c-Abl is involved in renal fibrosis by regulating the activity of PTCs and the production of renal interstitial collagen, implying that c-Abl might be a new target for the prevention and treatment of renal fibrosis in the progression of CKD.

**Funding:** Government Support - Non-U.S.

## SA-PO1010

### Intra-Organ Cross-Talk via YB1 in the Kidney

Berend H. Isermann,<sup>1</sup> Jayakumar Manoharan,<sup>1</sup> Ahmed Elwakiel,<sup>1</sup> Silke Zimmermann,<sup>1</sup> Jonathan A. Lindquist,<sup>2</sup> Dheerendra Gupta,<sup>1</sup> Shrey Kohli,<sup>1</sup> Khurram Shahzad,<sup>1</sup> Sabine Brandt,<sup>2</sup> Peter R. Mertens,<sup>2</sup> Rajiv Rana.<sup>1</sup> <sup>1</sup>Institut für Laboratoriumsmedizin, Klinische Chemie und Molekulare Diagnostik, Universitätsklinikum Leipzig AöR, Leipzig, Germany; <sup>2</sup>Clinic of Nephrology and Hypertension, diabetes and Endocrinology, Magdeburg, Germany.

**Background:** Renal intra-organ glomerular-tubular crosstalk has been proposed, but the paracrine signals remain largely unknown. The ubiquitously expressed cold-shock protein YB1 regulates inflammation and renal diseases. Importantly, besides its intracellular functions, YB1 can be secreted upon acetylation, conveying extracellular effects. The role of podocyte YB1 remains unknown.

**Methods:** We analysed morphological and molecular changes in mice with podocyte-specific deletion of YB1 (YB1<sup>APod</sup>) and in mice expressing a nonsecretable YB1 mutant specifically in podocytes (YB1<sup>K2A</sup>) to evaluate YB1's role for glomerular-tubular cross-talk.

**Results:** Albuminuria was increased in unchallenged YB1<sup>APod</sup> mice compared to YB1<sup>WT</sup> mice. Albuminuria in YB1<sup>APod</sup> mice was associated with increased tubular dilation and damage, but – surprisingly – reduced glomerular mesangial area expansion and podocyte foot process effacement. The increased tubular injury in YB1<sup>APod</sup> mice was associated with increased tubular TLR4 expression, NLRP3 inflammasome activation and increased renal inflammatory cell infiltrate. Mice expressing a nonsecretable YB1 mutant (YB1<sup>K2A</sup>) specifically in podocytes phenocopied the changes observed in YB1<sup>APod</sup> mice. In vitro, pre-treatment of TLR4 overexpressing tubular cells with recombinant YB1 inhibits NLRP3 inflammasome activation, suggesting that exogenous YB1 negatively modulates sterile inflammation in tubular cells via TLR4.

**Conclusions:** YB1 secreted from podocytes suppresses TLR4- and NLRP3-mediated sterile inflammation in the tubular compartment, thus maintaining tubular physiology and kidney function. This uncovers a molecular mechanism of glomerular-tubular cross-talk required for normal renal physiology.

**Funding:** Government Support - Non-U.S.

### Unsupervised Characterization of the NURTURE Cohort Reveals Gene Expression and Tissue Remodeling Dynamics Along a Synthetic CKD Progression Axis

Tobias Bohnenpoll,<sup>1</sup> Mykola Dergai,<sup>1</sup> N. E. Olson,<sup>2</sup> Jennifer H. Cox,<sup>3</sup> Johannes Pospiech,<sup>1</sup> Niklas Michel,<sup>1</sup> Simone Romoli,<sup>3</sup> Seamus Ragan,<sup>2</sup> Mark McConnell,<sup>2</sup> Olivier Radresa,<sup>1</sup> Uwe Andag,<sup>1</sup> Andrew J. King,<sup>4</sup> <sup>1</sup>Evotec International GmbH, Göttingen, Germany; <sup>2</sup>Chinook Therapeutics, Inc., Seattle, WA; <sup>3</sup>Chinook Therapeutics, Inc., Vancouver, BC, Canada; <sup>4</sup>Chinook Therapeutics, Inc., Oakland, CA.

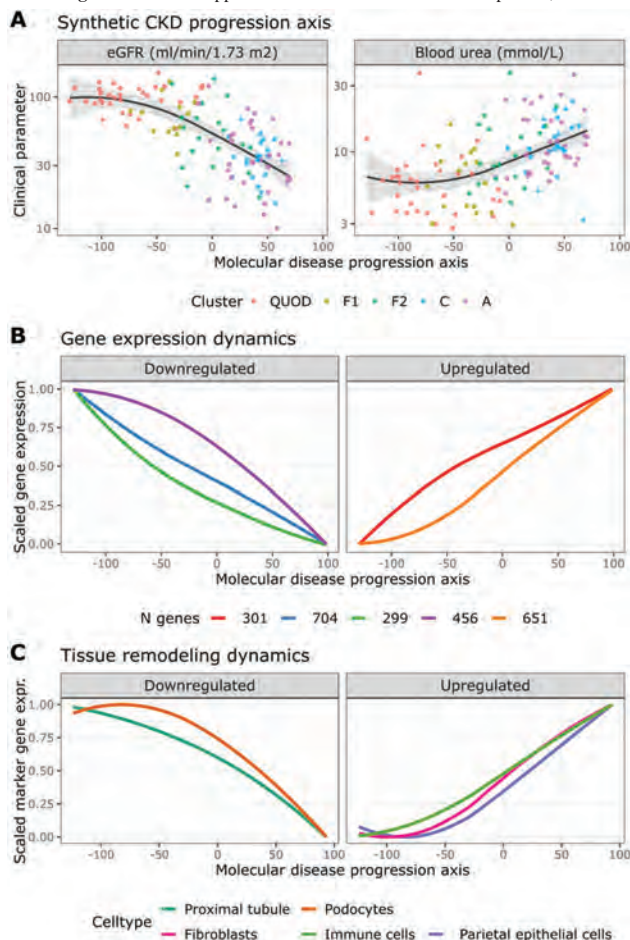

**Background:** We combined molecular groups identified by unsupervised characterization of the QUOD and NURTURE patient cohorts into a synthetic disease progression axis (sDPA) ranging from healthy to severe CKD. We aim to explore gene expression and tissue remodeling dynamics along this pseudotime trajectory to drive the discovery of new precision treatments.

**Methods:** A data-driven selection of QUOD (healthy, n = 36) and NURTURE (CKD, n = 139) kidney transcriptomes (FFPE, RNAseq) was combined into a sDPA via principal component analysis. Clusters of genes with similar expression dynamics were derived by local regression and hierarchical clustering. Cell specific signatures were employed to explore tissue remodeling dynamics.

**Results:** Molecular stratification aligned with clinical CKD progression, with eGFR and urea decreasing or increasing along the sDPA, respectively (Fig. A). Clustering genes by their expression dynamics revealed early, intermediate and late changes with stable or variable slopes, potentially reflecting disease initiating events and adaptive responses (Fig. B). Exploration of cell-type specific signature expression suggested that gene expression dynamics correspond to tissue remodeling, with the loss of proximal tubules preceding podocyte loss (Fig. C). Interestingly, increasing parietal epithelial cell signature dynamics resembled interstitial remodeling as reflected by increasing immune and fibroblast signatures.

**Conclusions:** Unsupervised cohort characterization of kidney transcriptomes and integration into a pseudotime disease progression axis has the potential to unravel cellular and molecular mechanisms of CKD.

## SA-PO1012

### Gene Expression in Kidney Tissue From CKDu Patients in Central America and Sri Lanka

Julia Wijkström,<sup>1,2</sup> Angelina Schwarz,<sup>1</sup> Marvin A. Gonzalez,<sup>3,4</sup> Ricardo A. Leiva,<sup>5,6</sup> Zulma C. Cruz,<sup>6</sup> Channa Jayasumana,<sup>7</sup> Carl G. Elinder,<sup>1,2</sup> Annika Wernerson.<sup>1,2</sup> <sup>1</sup>Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Karolinska Universitetssjukhuset, Stockholm, Sweden; <sup>3</sup>Universidad Nacional Autónoma de Nicaragua Leon, Leon, Nicaragua; <sup>4</sup>University College London, London, United Kingdom; <sup>5</sup>Universidad de El Salvador, San Salvador, El Salvador; <sup>6</sup>Hospital Nacional Rosales, San Salvador, El Salvador; <sup>7</sup>Ministry of Health Sri Lanka, Colombo, Sri Lanka.

**Background:** Chronic kidney disease of unknown etiology (CKDu) or Mesoamerican Nephropathy was first reported from Central America and later from other countries such as Sri Lanka and India. CKDu in Central America and Sri Lanka have many clinical and morphological similarities, but if the disease has the same etiology or pathophysiological mechanisms has not been firmly established. We have previously conducted kidney biopsy studies in El Salvador, Nicaragua and Sri Lanka, where we have stored tissue for RNA-sequencing. In the current study we have analyzed the different gene expression in Central America and Sri Lanka and compared with healthy controls.

**Methods:** Kidney biopsy tissue stored in RNAlater<sup>TM</sup> from previous studies in El Salvador (n=7), Nicaragua (n=11), and Sri Lanka (n=10) and control tissue from Swedish living kidney donors (n=11) were microdissected into glomerular and tubulointerstitial fractions and RNA-sequencing was performed.

**Results:** Principal component analysis displayed a distinct separation of glomerular and tubulointerstitial fractions. RNA profiles of the tubulointerstitial fractions from Central America (El Salvador and Nicaragua) compared to Sri Lanka did not show any significant difference, i.e. genes in the tubules display similar expression. The glomerular fraction displayed some difference in the RNA profile between Central America and Sri Lanka but not as pronounced as between cases and controls. Preliminary results from differentially expressed gene analysis indicates significant differences in genes expression in both glomerular and tubulointerstitial fractions in cases compared to controls. Upregulated genes are involved in inflammation like the complement system and chemokine signaling. Further analysis of the results is ongoing.

**Conclusions:** Tubulointerstitial fractions in kidney biopsies from Central America and Sri Lanka show a strikingly similar gene expression. However, the glomerular fractions show some differences that will be further explored. The gene expression profile in this study suggests that the pathophysiological mechanisms behind CKDu in Central America and Sri Lanka are the same and a joint etiology is probable. Preliminary analysis of upregulated genes shows involvement in inflammatory pathways.

## SA-PO1013

### V-Set and Ig Domain Containing 4 Is Upregulated in Doxorubicin-Induced Kidney Injury Model

Sang Youb Han,<sup>1</sup> Jungyeon Ghee,<sup>2</sup> Jin Joo Cha,<sup>2</sup> Dae R. Cha.<sup>2</sup> <sup>1</sup>Inje University Ilsan Paik Hospital, Goyang, Republic of Korea; <sup>2</sup>Korea University Ansan Hospital, Ansan, Gyeonggi-do, Republic of Korea.

**Background:** V-set Ig domain containing 4 (VSIG4) is related to fibrosis in several diseases. However, the role of VSIG4 in the kidney diseases is still not clear. We investigated the expression of VSIG4 in doxorubicin-induced mice and doxorubicin-induced podocyte injury model.

**Methods:** Doxorubicin-induced animal model was observed for 4 weeks. In addition, cultured podocytes were treated by doxorubicin.

**Results:** In doxorubicin-induced model, the levels of urinary albumin and VSIG4 for 24 h were significantly higher in doxorubicin group than control mice: albumin, median, 12.7 µg (IQR, 9.48-13.03) vs. 6.12, (IQR 2.56-9.26), P=0.006; VSIG4, median, 104.1 pg (IQR 66.3-135.1) vs. 46.3 (IQR 40.9-67.2), P=0.006. Interestingly, urinary VSIG4 levels were significantly correlated with urinary albumin levels (r = 0.912, P<0.001). The expression of intrarenal VSIG4 mRNA showed 2.69-fold higher in the doxorubicin mice than the control mice. To confirm expression of VSIG4 protein, the expression of VSIG4 protein was determined by Western blot. It was significantly higher in the doxorubicin mice than the control mice. In cultured podocytes, the expression of VSIG4 mRNA and protein was significantly higher in doxorubicin (1.0 and 3.0 µg/mL) than the control at 12 and 24 hours. The mRNA expression showed 20.7-fold higher in doxorubicin (3.0 µg/mL) group at 24 hours. The protein expression determined by western blot also showed a similar pattern to the mRNA expression.

**Conclusions:** In conclusion, the expression of VSIG4 was upregulated in the UUO and doxorubicin-induced models. VSIG4 would be involved in the pathogenesis of renal progression in chronic kidney diseases model.

## PUB001

**Hyperkalemia Is Associated With Increased Mortality Rates in COVID-19 Patients**

Lucas Wang, Victor A. Canela, Methodist Dallas Medical Center *Methodist Dallas Medical Center, Dallas, TX.*

**Background:** Abnormal potassium (K) levels are strongly associated with higher mortality rates among all hospitalized patients. In this study we aim to identify a correlation between abnormal K levels and mortality in coronavirus disease (COVID-19) patients may likely optimize inpatient management.

**Methods:** Using an observational database, we analyzed 3310 unvaccinated hospitalized COVID-19 PCR-positive patients at Methodist Health System from March 2020 to December 2020. We compared in-hospital death or hospice referral rates between patients with normal K levels ( $K = 3.5$  to  $5.0$  meq/L), hypokalemia ( $K < 3.5$  meq/L), or hyperkalemia ( $K > 5.0$  meq/L) on first encounter. Chi-square ( $\chi^2$ ) and odds ratio tests were used to analyze observed variables.

**Results:** Of the 3310 COVID-19 patients, 463 (14.0%) died in the hospital or were discharged to hospice and 2747 (86.0%) were discharged home or to a post-acute care facility. In this study cohort, 285 (8.6%) patients had hyperkalemia, 453 (13.7%) had hypokalemia, and 2572 (77.7%) had normal K levels. Patients with abnormal K levels on initial encounter had a higher mortality rate than those who had normal K levels (OR 1.32, 95% CI 1.05 – 1.64,  $p = 0.02$ ). However, upon closer examination we found that hyperkalemia had a strong association with increased mortality in COVID-19 patients compared to normal K levels (OR 2.00, 95% CI 1.49 – 2.69,  $p < 0.001$ ); however, hypokalemia did not ( $p = 0.66$ ).

**Conclusions:** Hyperkalemia on presentation is associated with a significantly increased risk of in-hospital death or hospice discharge among hospitalized COVID-19 patients.

## PUB002

**COVID-19, ACE2, Plus Human Angiotensin II: The Perfect Storm**

Sean Barnett, *United States Air Force, Dayton, OH.*

**Background:** SARS-CoV-2 causes a disease unlike any we have seen before. The virus is similar to some, but the resultant disease is vastly different in the short and long term. This appears to be due to the Cytokine Storm (CS). The connection between COVID and the CS is likely related to Angiotensin II. Specifically, the Angiotensin II Type 1 Receptor (AT1R) which is regulated via the ACE2 Receptor (ACE2R). The AT1R pathway is the primary pro-inflammatory pathway that promotes endothelial activation, cellular recruitment and differentiation, T and B cell co-stimulation, and complement activation. This would explain the exact findings in the Cytokine Storm.

**Methods:** Extensive literature search including international publications and presentations as well as clinical experience. Direct clinical observation of the impact of RAAS on pathophysiology in COVID patients.

**Results:** The connection between COVID and the ACE2 Receptor (ACE2R) is the best explanation for the CS. COVID induced ACE2R endocytosis, decreased expression, and decreased transcription facilitates unchecked activation of AT1R. In addition to controlling AT1R mediated endothelial inflammation, the ACE2R is also the regulatory mechanism for the Bradykinin mediated coagulation pathway. This would enhance the explanation of not just the inflammation, but the clotting as well.

**Conclusions:** The ACE2R and AT1R connection is the best explanation for the tissue damage from COVID. AT1R mediated inflammation and vascular complications would explain the laboratory findings, histology findings, and clinical symptoms found in the Cytokine Storm. Furthermore, one of the key differences between SARS-CoV-2 and other recent virus outbreaks is the affinity with which SARS-CoV-2 binds to the ACE2R. It has the highest binding affinity of all current coronaviruses. This may explain the different outcomes in certain patients also. Any patients that would be at a higher RAAS baseline (Diabetes, Kidney Disease, Heart Disease) would be more likely to have complications. This is what we have seen clinically. Finally, this pathway gives us a mechanism for certain therapies that have shown promise such as Tocilizumab and Baricitinib. It also offers further treatment potentials for RAAS. In my experience, adequate blood pressures and ongoing diuresis are beneficial. Of particular benefit is diuresis with Hypertonic Saline, which has the best RAAS suppression and diuresis capabilities of any diuretic adjunct.

## PUB003

**Collapsing Glomerulopathy in a Patient With Recent COVID-19 and APOL-1 High-Risk Genotype**

Nang San Hti Lar Seng,<sup>1,2</sup> Michael J. Ross,<sup>3,2</sup> Daniel Schwartz,<sup>3,2</sup> Rimon Golovey,<sup>3,2</sup> *Jacobi Medical Center, Bronx, NY;* <sup>2</sup>*Albert Einstein College of Medicine, Bronx, NY;* <sup>3</sup>*Montefiore Medical Center, Bronx, NY.*

**Introduction:** Collapsing glomerulopathy (CG) is an aggressive subtype of focal segmental glomerulosclerosis, associated with poor renal outcomes. Risk factors for CG include HIV infection, APOL1 high-risk genotypes, and CG has also recently been reported in patients with COVID-19. We report a case of CG with acute kidney injury (AKI) in a patient with a high risk APOL1 genotype, who had renal recovery after prednisone treatment.

**Case Description:** A 43-year-old male with no past medical history presented with fever, myalgia, hemoptysis, vomiting, and diarrhea of 2 weeks duration. Initial exam was remarkable for temperature 103 degrees Fahrenheit, SpO2 95% on room air, and inspiratory crackles without peripheral edema. Labs were notable for serum creatinine

2.6 mg/dL (unknown baseline), peak creatine kinase 4037 U/L, and urine protein creatinine ratio 19 g/g without RBCs. Chest CT was consistent with multilobar pneumonia. SARS-CoV2 PCR was repeatedly negative but COVID-19 spike and nucleocapsid IgG were positive. Extensive serologic workup for causes of glomerulonephritis and nephrotic syndrome was negative. He was empirically treated with antibiotics for pneumonia but cultures remained negative. Bronchoscopy revealed no evidence of alveolar hemorrhage. His renal function worsened, requiring hemodialysis. Kidney biopsy revealed collapsing glomerulopathy associated with thrombotic microangiopathy, few myoglobin casts suggestive of rhabdomyolysis, and acute tubular injury. Prednisone was initiated at 1mg/kg daily and tapered over 2 months. Lisinopril was initiated for proteinuria. After 5 months, serum creatinine was 1.3 mg/dL and urine protein creatinine ratio improved to 0.6g/g. Genetic testing revealed APOL1 G1/G1 genotype.

**Discussion:** In this patient, SARS-CoV2 PCR was likely negative because he presented weeks after symptom onset but the clinical course and serologic evidence of prior SARS-CoV-2 infection supports the diagnosis of COVID-19 associated CG in the setting of APOL1 high-risk G1/G1. Proposed mechanisms of COVID-19-related CG include increased cytokines, that upregulate podocyte expression of toxic APOL1 variants and AKI with tubular injury is often found. Our patient improved with steroid treatment but the treatment of COVID-19 associated CG requires further study.

## PUB004

**Pseudolung Cancer Lymphadenopathy, Development of Idiopathic Tubulointerstitial Nephritis, and Dense Deposit Disease Following Pfizer-BioNTech COVID-19 Vaccination**

Hironori Nakamura, Michiko Ueda, Anayama Mariko, Masaki Nagasawa, Yasushi Makino. *Department of Nephrology, Shinonoi General Hospital, Nagano, Japan.*

**Introduction:** Despite reports of glomerulonephritis associated with COVID-19 mRNA vaccines, no study has reported about the dense deposit disease (DDD). Here we present a case of pseudolung cancer lymphadenopathy following COVID-19 mRNA vaccine, following which the patient developed idiopathic tubulointerstitial nephritis (TIN) and DDD.

**Case Description:** A 74-year-old man received his second dose of the mRNA vaccine, and he developed fever, urticaria, and dyspnea. On further examination, he had pleural effusion and right hilar lymphadenopathies, which were improved with conservative therapy. On 48 days after the second vaccination, he developed renal dysfunction and new-onset hematuria. Light microscopy findings by a renal biopsy demonstrated apparent mesangial cell proliferation and diffuse inflammatory cell infiltration in the interstitium. Immunofluorescence analysis revealed 1+ positive results for IgG and IgM, negative results for IgA, and 2+ positive results for C3 with a garland pattern on the capillary walls. Electron microscopy detected that continuous and thickened highly dark-stained spotty dense deposits in the glomerular basement membrane. Based on the decrease in C3 and pathological findings, idiopathic TIN accompanied with DDD was diagnosed.

**Discussion:** After vaccination acute allergic reaction, pseudolung cancer lymphadenopathy, hematuria, and hypocomplementemia were observed. Thus, both coincidental onset with DDD and TIN following acute allergic response that occurred about 7 weeks before made us think that each event or disease might be associated with COVID-19 mRNA vaccination as part of immunological reactions. In complement activation related pseudoallergy syndrome, it is recently recognized that several modern-day therapeutic molecules may activate complements via the nonIgE mediated mechanism with the C3a and C5a anaphylatoxins binding to mast cells, triggering that the release of a number of several vasoactive mediators that cause the clinical features associated with hypersensitivity reactions. mRNA vaccine might have contributed to the development of lymphadenopathies, TIN and DDD in this case. Moreover, TIN and DDD might be associated with the activated alternative pathway induced by the mRNA vaccine.

## PUB005

**Predicting In-Hospital Mortality Among COVID-19 Pneumonia Patients With AKI**

David J. Wilhelm, T'shura Ali, Michael E. Brier, Dawn J. Caster, Forest W. Arnold, Jiapeng Huang. *University of Louisville, Louisville, KY.*

**Background:** COVID-19 has been identified as a disease causing respiratory failure but is now known to affect the kidneys among other organs. Several studies among COVID-19 patients have shown a significant association between acute kidney injury (AKI) and mortality. There is limited data examining if the effect of AKI on mortality is different across variants. The main objective of this study is to examine the association between AKI and in-hospital mortality among COVID-19 pneumonia (PNA) patients during the original strain and the delta variant.

**Methods:** Data was obtained from a retrospective analysis of patients hospitalized with COVID-19 PNA from March 2020 until March 2021. The database had two cohorts: the original strain and the delta variant. The presence of AKI was confirmed by an examination of medical records for 612 patients using the AKIN criteria (creatinine  $\geq 0.3$  mg/dL above baseline). Chronic kidney disease was defined by estimated Glomerular Filtration Rate (eGFR) calculated using the CKD-EPI 2021 equation. Logistic regression was used to estimate relative risk (RR) for mortality using factors in Table 1.

**Results:** AKI was present in 414 patients (67.6%). Of the 612 patients reviewed, there were 443 survivors and 169 non-survivors at discharge. Among the non-survivors, there were a higher proportion of AKI (84%) and males (64%) and a lower proportion of African Americans (30%). The non-survivors were younger (67 years) and had a lower eGFR (37 mL/min). Logistic regression results are shown in Table 1.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Conclusions:** Analyses showed that among patients hospitalized with COVID-19 PNA, the RR of in-hospital mortality was 3.28 times higher for those with AKI compared to those without AKI. We found no significant difference for in-hospital mortality between the two cohorts when adjusted for presence of AKI. Other findings showed that males may have a greater risk of mortality as compared to females and those of African American race may have a potential survival advantage.

Table 1

Factor	P value	Relative Risk
AKI vs non-AKI	<0.001	3.278
COVID-19 Cohort	0.486	0.868
Age (years)	0.085	1.013
Male vs Female	0.055	1.460
African American vs other races	0.108	0.713
eGFR (mL/min)	0.225	0.985

## PUB006

### Lactic Dehydrogenase Is Associated With Renal Function Tests in Adults Hospitalized With SARS-CoV-2 Infection

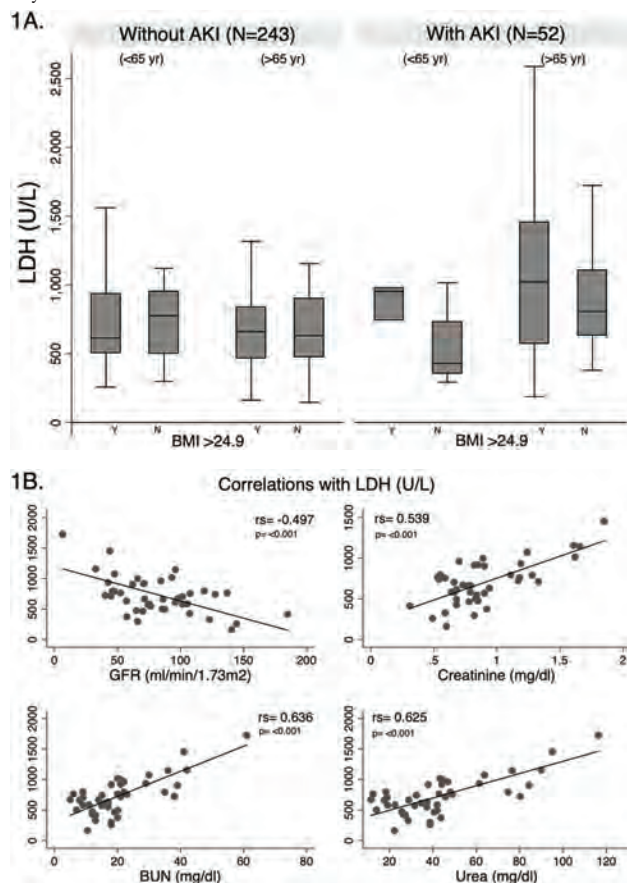

Karen Hopf, J. Perez, Edwing Campos, Damayanty Gomez, Damayanty Solis, Nuri P. Campos. *Hospital General Tacuba, Mexico City, Mexico.*

**Background:** Lactic dehydrogenase (LDH) is considered an inflammatory biomarker and its levels rise in many illnesses. Inflammation plays a critical role in the progression of kidney damage leading to lowering of glomerular filtration rate (GFR) and altering of kidney function tests including creatinine, blood urea nitrogen (BUN) and urea. The following trial has as its main goal to identify the degree of association between LDH levels and kidney function tests.

**Methods:** A retrospective, transversal study that took place in Tacuba General Hospital. Adults hospitalized with SARS-CoV-2 infection from May 2020 to December 2021 were included. Descriptive statistical analysis was made using Mann-Whitney U test. A boxplot graph was drawn comparing subjects that developed acute kidney injury (AKI) with those who did not (Figure 1A). Spearman's rank correlation coefficient was calculated. The risk of developing AKI with LDH above its cutoff value was calculated with logistic regression. The analysis was made using the STATA 14 program.

**Results:** 295 subjects, 64% men, mean age  $61 \pm 14$  years. We obtained the following correlation using LDH as dependent variable: for GFR a  $r = -0.497$ ; for creatinine a  $r = 0.539$ ; urea  $r = 0.625$ ; BUN  $r = 0.636$  (Figure 1B). The risk of developing AKI with LDH above its cutoff value had an odds ratio of 3.64 [CI 95% (1.57-8.43)]. Statistical significance was considered with  $p < 0.05$ .

**Conclusions:** Our results suggest that LDH serum levels are associated with every kidney function test.

## PUB007

### Podocytopathy After COVID-19 Vaccine Administration in a Patient With Autosomal Dominant Polycystic Kidney Disease

Armando T. Cardenas, Ramesh Saxena. UT Southwestern *The University of Texas Southwestern Medical Center, Dallas, TX.*

**Introduction:** Development of vaccines against SARS-CoV-2 has resulted in considerable reduction in severe complications and mortality. Several cases of glomerular disease have been recently reported such as Minimal Change disease and Focal Segmental Glomerulosclerosis. We describe a patient with autosomal dominant polycystic kidney disease (ADPKD) who developed nephrotic syndrome, soon after receiving COVID-19 vaccine.

**Case Description:** 40-year-old male with history of chronic kidney disease stage-3 due to ADPKD diagnosed 20 years ago. Baseline serum creatinine 2 - 2.5 mg/dL and minimal proteinuria. Other comorbidities include well-controlled type 2 diabetes mellitus and hypertension. Received two doses of Covid-19 vaccine on February 25 and March 24, 2021. He had malaise, myalgia, and fatigue after vaccination. On April 2021, was noted to have 3+ protein on dipstick, no quantification done. In May of 2021 patient presented to hospital with heart failure and ejection fraction of 39% in association with acute coronary syndrome due to ST elevation myocardial infarction, underwent placement of a drug-eluting stent and placement on dual antiplatelet therapy (DAPT). He had 3+ protein on dipstick. In June 2021 developed abdominal pain with hematuria which was attributed to cyst-hemorrhage, underwent decortication of left renal cyst. However, the patient continued having gross hematuria requiring multiple blood transfusions and cessation of DAPT. Patient was admitted to UTSW in September 2021 and was noted to have nephrotic syndrome with proteinuria of 3925 mg, low serum albumin of 2.0 g/dL and pedal edema concerning for podocytopathy associated with COVID-19 vaccine. Kidney biopsy was deferred due to active bleeding. Patient was empirically started on Prednisone 60mg with rapid taper. At discharge 12 days later, proteinuria was down to 0.6 g/g of creatinine, serum albumin 3.2 g/dL and hematuria resolved. On his last follow up, proteinuria was 0.3 g/g, serum albumin 3.6 g/dL and serum creatinine 2.67 mg/dL.

**Discussion:** Millions of mRNA vaccines have been administered since the development of the COVID-19 vaccine. Proposed mechanisms when mounting a response to the vaccine are toll-like receptors promoting podocyte damage in the glomeruli. These glomerulopathies once noted have been treated with immunosuppression and there has been remission reported.

## PUB008

### An Unusual Case of ANCA Associated Vasculitis (AAV) After a COVID-19 Vaccine

Maria Lanau,<sup>1</sup> Loreto Fernandez.<sup>1,2</sup> <sup>1</sup>Hospital Universitario de Navarra, Pamplona, Spain; <sup>2</sup>Instituto de Investigacion Sanitaria de Navarra, Pamplona, Spain.

**Introduction:** COVID-19 vaccines have been related to immune mediated adverse events and recently some case reports of AAV precipitated after either RNA or viral vector vaccines have been reported.

**Case Description:** A 83 year old woman with past records of polymyalgia rheumatica (2017) treated with low dose prednisone, was admitted to our hospital because of malaise, hyporexia and weight loss in the context of urinary symptoms. These started since the second COVID-19 Pfizer-BioNTech vaccine dose administered 3 months ago. Initial blood test revealed anemia, acute kidney injury (serum creatinine 1.7mg/dL), leucocytosis and elevated CRP. Urinalysis showed microhematuria and mild proteinuria in the context of a positive urine culture. She had normal kidneys on ultrasonography. Diuretics and antibiotics were started, but few days after renal function continued worsening (sCr 4.3 mg/dL) with an active sediment. For this reason, immunology tests were ordered with positive high MPO-ANCA antibodies. Hence, a kidney biopsy was performed showing 11 normal glomeruli but severe arteritis in two small-middle sized arterioles with fibrinoid necrosis. Steroids and Rituximab were given as induction therapy with good renal response.

**Discussion:** AAV after COVID-19 vaccine administration has been reported previously, and it could be related to its molecular mimicry and immune crossreaction. Most of them were typical forms of pauci-immune crescentic glomerulonephritis, but none with isolated vascular damage. Although cases reported appeared shorter time after vaccine administration, our patient was on low dose prednisone which may explain a subacute onset of the disease. Moreover, she clearly presented constitutional symptoms ever since the second vaccine dose was administered. Finally, although the efficacy and safety of the COVID-19 vaccines have been demonstrated, particular attention should be paid to patients with known or suspected autoimmune diseases.

## PUB009

### Impact of Kevzara on the Survival and the Need for Renal Replacement Therapy (RRT) in the Alpha-Wave of COVID-19 Patients: Retrospective Cohort Study

Nehemias Guevara,<sup>1</sup> Claudia G. Olano,<sup>3</sup> Andrea L. Urrutia,<sup>2</sup> Sami M. Akram.<sup>4</sup>  
<sup>1</sup>St Barnabas Hospital, Bronx, NY; <sup>2</sup>FOMAT Medical Research, Los Angeles, CA; <sup>3</sup>Harbor-UCLA Medical Center, Torrance, CA; <sup>4</sup>Loma Linda University, Loma Linda, CA.

**Background:** The alpha wave of COVID-19 brought death and dismay to patients and to providers respectively. Remdesivir nor plasma was available. We studied this cohort to evaluate the need for mechanical ventilation (MV) and Renal replacement therapy and the outcome of hospital discharge. It is well known that the covid-19 causes Cytokine Release Syndrome (CRS), therefore, producing dysregulation and an increase in the immune response, interleukine 6, plays a central role in triggering the (CRS) and stimulating other inflammatory markers.

**Methods:** A retrospective-observational study. We reviewed the patients admitted to the intensive care unit of a metropolitan hospital in the Los Angeles area from February 17th, 2020, till March 14th, 2020. There was 24 patient who was in the ICU. At the time, Remdesivir was not available at the hospital.

**Results:** Eight of the 24 patients received Kevzara. Of the 8 patients, 2 required RRT while of the 16 patients who did not receive Kevzara, 6 required RRT. All 8 patients who received RRT also had MV for varying number of days and all were alive at 28 days. Among the 16 patients who did not receive Kevzara, 11 required mechanical ventilation, and 6 got RRT. 5 patients got both MV and RRT. The number of days of RRT was required was 12 in the Kevzara group and 4.25 in the none-Kevzara group. Chi Square value of 5.3706 p value = <0.5

**Conclusions:** Kevzara reduced 28-d mortality in the alpha wave of covid-19. There is incremental value in the use of Kevzara and Organ support technologies such as MV and RRT in the ICU. As the patient's life is prolonged in critical care units, there is increased demand for renal replacement therapy resources

	Kevzara - 1	Kevzara-0	Marginal Row Totals
Alive	7 (4.33) [1.64]	6 (8.67) [0.82]	13
Dead	1 (3.67) [1.94]	10 (7.33) [0.97]	11
Marginal Totals	8	16	24 (Grand Total)

Chi square value is 5.3706. The p-value is .020479. Significant at  $p < .05$

While Kevzara significantly prolonged life, the number of dialysis days per patient increased. The number of dialysis days per patient (DDPP) was 12 in the Kevzara group whereas DDPP was 4.25 in the non-Kevzara group. All patients who had RRT also received Mechanical ventilation except one patient in the non-Kevzara group.

	Alive	Dead	Marginal Row Totals
No support	2 (4.25) [1.19]	4 (1.75) [2.89]	6
Support	15 (12.75) [0.4]	3 (5.25) [0.96]	18
Marginal Totals	17	7	24 (Grand Total)

The chi-square statistic is 5.4454. The p-value is .01962. Significant at  $p < .05$ .

This suggests that organ support in the form of mechanical ventilation, and renal replacement therapy was provided to most patients who were alive at four weeks.

	Alive	Dead	Marginal Row Totals
No support	2 (4.5) [1.39]	4 (1.5) [4.17]	6
Support	16 (13.5) [0.46]	2 (4.5) [1.39]	18
Marginal Totals	18	6	24 (Grand Total)

The chi-square statistic is 7.4074. The p-value is .006496. Significant at  $p < .05$ .

The chi-square statistic with Yates correction is 4.7407. The p-value is .029456. Significant at  $p < .05$ .

## PUB010

### Transient Elevation of Serum $\beta_2$ -Microglobulin in Hemodialysis Patients After COVID-19 Vaccination: A Retrospective Case Series Study

Hiroki Uchida, Takeshi Nakata, Jun Okita, Akiko Kudo, Akihiro Fukuda, Hirotaka Shibata. *Oita Daigaku Igakubu Daigakuin Igakukei Kenkyuka, Yufu, Japan.*

**Background:** Serum  $\beta_2$ MG (beta2-microglobulin) is an indicator of dialysis efficiency; however, it is also elevated in immune diseases and infections. The mRNA vaccines for corona virus disease 2019 (COVID-19) have been reported to produce stronger immune responses than conventional vaccines. In this study, we examined whether mRNA vaccination increases serum  $\beta_2$ MG levels in hemodialysis patients.

**Methods:** This was a single-center, case series study. A total of 23 maintenance hemodialysis patients who received Pfizer's vaccine (brand name: BioNTech SE) were included and observed between January 1, 2021 and December 31, 2021. We analyzed changes in serum  $\beta_2$ MG levels before and after vaccination. The pre-vaccination  $\beta_2$ MG value (baseline) was measured within 3 months prior to the first vaccination, and the post-vaccination  $\beta_2$ MG values were evaluated at 2 weeks, 1 month, and 3 months.

**Results:** Twenty-one patients were finally enrolled in this study. Fifteen (71.4%) patients were male, mean age was 70.7 $\pm$ 12.8 years, and dialysis period was 5.3 (2.0 – 12.7) years (median, interquartile range). Some side effects were observed, fever in six cases (28.6%) and diarrhea in one case (4.8%). Serum  $\beta_2$ MG levels transiently increased from 27.6 $\pm$ 5.7  $\mu$ g/L to 32.1 $\pm$ 8.4  $\mu$ g/L before and after vaccination ( $P < 0.001$ ), and C-reactive protein (CRP) levels also increased transiently from 0.24 $\pm$ 0.37 mg/dL to 0.59 $\pm$ 0.66 mg/dL before and after vaccination ( $P < 0.05$ ). These transient elevations were restored to baseline levels over time. Serum  $\beta_2$ MG and CRP levels showed no significant differences after 1 and 3 months compared with baseline. During this observational period, no patient had changes in dialysis condition, size or type of dialyzer, modality, and blood volume flow.

**Conclusions:** In hemodialysis patients, a transient increase in serum  $\beta_2$ MG levels after vaccination may be caused by an immune response to vaccination and should be differentiated from worsened dialysis efficiency.

Fig.  $\beta_2$ MG and CRP levels before and after vaccination.

## PUB011

**A Third Dose or Booster Dose of SARS-CoV-2 mRNA-1273 Vaccine Increases Antibody Levels Among Dialysis Patients**

Linda Ficociello,<sup>1</sup> Joanna Willets,<sup>1</sup> Curtis D. Johnson,<sup>2</sup> Sandra E. Alexander,<sup>3</sup> Claudy Mullon,<sup>1</sup> Jeffrey L. Hymes.<sup>1</sup> <sup>1</sup>Fresenius Medical Care, Waltham, MA; <sup>2</sup>Spectra Laboratories, Milpitas, CA; <sup>3</sup>Fresenius Medical Care North America, Waltham, MA.

**Background:** To help protect dialysis patients from COVID-19, efforts have been made to ensure widespread vaccination, however, reports have shown waning antibody (AB) levels that may decline faster than the general population. The current analysis examines AB response to a 3<sup>rd</sup> or booster dose of mRNA-1273 vaccine among dialysis patients across 7 dialysis clinics in Massachusetts.

**Methods:** All patients received 2 mRNA-1273 doses and had AB measured 250+ days after 2<sup>nd</sup> dose (when additional/booster doses were available). Covid-19 positive/suspected cases were not included in the analysis. As part of a quality improvement project, patients were classified into 3 groups based on further doses received: mRNA booster (Booster 50 mcg), mRNA additional dose (Additional; 100 mcg), and no second dose or booster (Primary). AB response was measured in remnant blood with semiquantitative chemiluminescent assay detecting IgG AB directed against receptor binding domain of S1 subunit of SARS-CoV-2 spike antigen (Siemens); AB index >1 was considered reactive, >7 as adequate, and > 750 was maximum detected. For time periods with multiple AB measurements, the latest AB value was utilized.

**Results:** Distribution of AB levels before and after booster/additional dose are presented in figure. Before booster/additional dose few patients had AB levels > 750 (2%). After booster or additional dose, 58% and 50% had AB levels > 750, respectively. AB response ≤ 7 was common (46%) before and rare after booster and additional dose (2% and 0%).

**Conclusions:** After the administration of booster/additional doses of mRNA COVID-19 vaccines, nearly all patients had at least adequate AB response and the majority had maximum response. This is contrasted with the patients not receiving booster/additional dose, where 72% had adequate AB response and 27% had maximum response.

## PUB012

**Outcomes of COVID-19 Hospitalization in Kidney Transplant Recipients: A Single Center Experience**

Michael Turk,<sup>1</sup> Ali W. Rizvi,<sup>1</sup> Laith Alhuneafat,<sup>1</sup> Naman Gupta,<sup>1</sup> Shane Mealy,<sup>1</sup> Alisha Sharma,<sup>1</sup> Omar Osman,<sup>1</sup> Ramya Gutta,<sup>1</sup> Aaisha Shah,<sup>1</sup> Tabeer Rana,<sup>1</sup> Katherine Barnett,<sup>1</sup> Kalathil K. Sureshkumar.<sup>1</sup> *Allegheny Health Network, Pittsburgh, PA.*

**Background:** COVID-19 infection is associated with worse outcomes in kidney transplant recipients (KTRs). Despite wide availability of safe and effective vaccines, transplant recipients are disproportionately affected. We aim to investigate our center's experience with COVID-19 hospitalization in KTRs and measure their clinical outcomes.

**Methods:** In this retrospective observational cohort study, we identified KTRs who developed COVID-19 infection between March 2020 and January 2022 within our integrated health network. Through chart review, patient characteristics and outcomes were collected.

**Results:** Among 186 patients who tested positive for COVID-19, 114 (61%) required hospitalization out of which 53 received at least one dose of vaccine and 61 were unvaccinated. Among the unvaccinated, 26 (43%) patients were admitted prior to January 2021 when vaccines were not yet widely available. Vaccination rate among patients admitted after January 2021 was 53/88 (60%). Baseline characteristics between vaccinated and unvaccinated patients were similar. There were 24 deaths during admission and another 7 deaths within 90 days, for a total of 31/114 (27%). There was a trend towards lower mortality in vaccinated patients (10/53 (19%) vs. 21/61 (34%),  $p=0.06$ ). The need for dialysis was significantly lower in vaccinated patients (9/53 (17%) vs. 21/61 (34%),  $p=0.03$ ) (Table).

**Conclusions:** COVID-19 infection is associated with higher mortality in KTRs with a mitigating effect from vaccination. Decreased dialysis requirement in vaccinated but hospitalized KTRs with COVID-19 infection likely reflects less severe infection, indicating that vaccination confers allograft protection. Every effort should be made to encourage and educate KTRs regarding COVID-19 vaccination including booster doses in order to reduce morbidity and mortality.

## Outcomes by Vaccination Status

Variables	Vaccinated (n=53)	Unvaccinated (n=61)	p-value
Mortality during admission	8 (15%)	16 (26%)	0.15
Mortality within 90 days	10 (19%)	21 (34%)	0.06
DVT/PE during admission or within 30 days	2 (3.8%)	6 (9.8%)	0.21
Required supplemental oxygen during admission	28 (53%)	36 (59%)	0.51
AKI on or during admission	33 (62%)	44 (72%)	0.26
Need for new dialysis during admission or on discharge	9 (17%)	21 (34%)	<b>0.03</b>
Length of stay (days)	8.3 ± 9.1	8.1 ± 6.2	0.86

## PUB013

**COVID-19-Associated Collapsing Glomerulopathy: A Report of Three Patients With African Ancestry**

Maryam Saleem, Bharat Neelam Raju, Scott C. Stockholm, Bjorn Anderson, Tingting Li. *Washington University in St Louis, St Louis, MO.*

**Introduction:** Collapsing glomerulopathy has become an important cause of acute kidney injury (AKI) in COVID-19 patients. Reports on presentation & outcomes of COVID-19-associated collapsing glomerulopathy (COVAN) have been published. We report 3 patients who presented with COVID-19, AKI & nephrotic range proteinuria.

**Case Description: Patient 1:** 58 year-old African American (AA) male with hypertension presented with dyspnea, was diagnosed with COVID-19 & found to have serum creatinine (SCr) of 21.5 mg/dL (baseline 0.8 mg/dL) & urine protein of 9.3 g/day. Renal biopsy showed collapsing glomerulopathy, acute tubular injury (ATI) & severe podocyte foot process effacement. APOL1 genotyping revealed high-risk genotype (G1/G1). Patient required 4 sessions of hemodialysis (HD) & recovered enough kidney function to discontinue HD. At 6 months follow-up, SCr was 1.6 mg/dL. **Patient 2:** 29 year-old AA female with sickle cell disease & previous history of collapsing glomerulopathy in remission presented with dyspnea & was diagnosed with COVID-19. SCr was 3.6 mg/dL (baseline 0.9 mg/dL) & urine protein of 28 g/day. Renal biopsy showed focal collapse of capillary loops, severe podocyte foot process effacement, & moderate interstitial fibrosis/tubular atrophy. APOL1 genotyping revealed high-risk genotype (G1/G1). Patient was started on prednisone. SCr stabilized between 2-2.5mg/dL on discharge. At 6-month follow-up, SCr was 2.6mg/dL. **Patient 3:** 53 year-old AA male with hypertension presented with cough and was diagnosed with COVID-19. SCr was 3.2 mg/dL (baseline 1.1 mg/dL), with nephrotic range proteinuria (5.6 g/day). Work up revealed new diagnosis of HIV & syphilis. Renal Biopsy showed collapsing glomerulopathy. APOL-1 genotyping showed high risk genotype (G1/G1). Patient was started on treatment for COVID-19 pneumonia & penicillin G for syphilis. Renal function & proteinuria improved within a few days, prior to initiation of HIV therapy. At 1 month follow-up, SCr was 3.0 mg/dL & at 2 years, SCr was 1.6 mg/dL.

**Discussion:** Our report supports the published findings that COVAN manifests as AKI, heavy proteinuria, can occur even in the absence of severe respiratory symptoms, & is strongly associated with high-risk APOL1 genotype. Although AKI & proteinuria improved all 3 patients, all are left with some degree of chronic kidney disease

## PUB014

**Acute Pericarditis in ESRD due to COVID-19 Despite Vaccination**

Muhammad Khalid Tahir,<sup>1</sup> Usman Kazi,<sup>2</sup> Arun U. Mahtani,<sup>1</sup> Angela Grigos,<sup>1</sup> Farhang Ebrahimi,<sup>1</sup> Syed Rizwan A. Bokhari.<sup>3</sup> <sup>1</sup>Richmond University Medical Center, Staten Island, NY; <sup>2</sup>HCA Florida Citrus Hospital, Inverness, FL; <sup>3</sup>Bassett Healthcare, Cooperstown, NY.

**Introduction:** - Myocarditis, cardiomyopathy, and heart failure; common cardiac manifestations of Coronavirus infectious disease (COVID-19).<sup>1-3</sup> - Acute pericarditis is rare.<sup>4</sup> - We report a case of a new-onset pericardial rub diagnosed as acute pericarditis due to COVID-19 in a patient with end-stage renal disease (ESRD) despite vaccination.

**Case Description:** - A 61-year-old male with a history of chronic kidney disease stage 5 (CKD 5) approaching dialysis, status post renal transplant twice (first in 1997 and second in 2010) presented with dyspnea of a few days' duration. - Medications: amlodipine, atorvastatin, calcitriol, clonidine patch, hydralazine, sevelamer, tacrolimus, and tamsulosin. - Physical examination: 2+ pitting edema and rales over bilateral lung fields. - Laboratory tests: Blood urea nitrogen (BUN) and Creatinine (Cr) of 154/13.6, respectively. Initial COVID-19 serologies were negative. - Electrocardiogram (EKG) and echocardiogram (ECHO) at admission were unremarkable. - Received seven hemodialysis sessions that improved his symptoms. - Subsequently, he spiked a fever with a recurrence of dyspnea and pleuritic chest pain. - Auscultation: New onset pericardial rub. - Laboratory test: BUN/Cr of 54/5.3. Tested positive for COVID-19. - Repeat ECHO: Pericarditis and moderate-sized pericardial effusion with normal left ventricular systolic function and ejection fraction. - Treated with heparin-free intensive hemodialysis and colchicine.

**Discussion:** - Acute pericarditis presentation; Two or more of the following symptoms: chest pain, friction rub, diffuse ST-elevations, PR depressions on EKG, and new or worsening pericardial effusion.<sup>5</sup> - Can lead to cardiac tamponade if left untreated.<sup>6</sup> - In ESRD, important to consider differential diagnoses of pericarditis; uremia, and fluid overload causing effusion. Due to the recent pandemic, COVID-19 must be taken into consideration irrespective of vaccination status.

Parasternal Long Axis View Showing Pericardial Effusion

## PUB015

**Impact of Hypertension on Long-Term Humoral and Cellular Response to SARS-CoV-2 Infection**

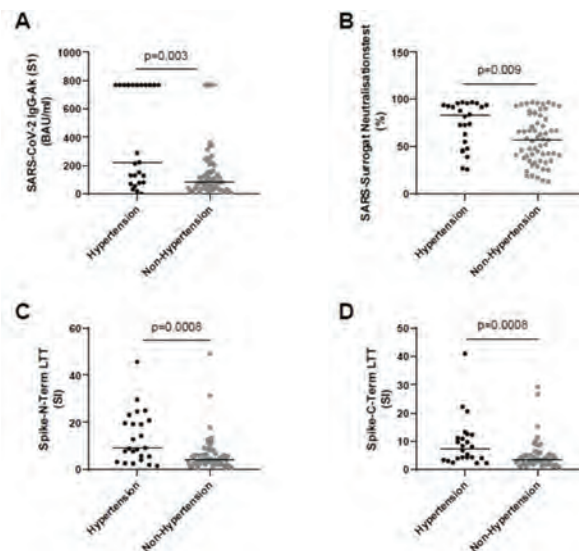

Chang Chu,<sup>1</sup> Anne Schönbrunn,<sup>3</sup> Volker von Baehr,<sup>3</sup> Bernhard K. Krämer,<sup>2</sup> Saban Elitok,<sup>4</sup> Berthold Hoher.<sup>2</sup> <sup>1</sup>Charite Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>Ruprecht Karls Universität Heidelberg, Heidelberg, Germany; <sup>3</sup>Institute of Medical Diagnostics, Berlin, Germany; <sup>4</sup>Klinikum Ernst von Bergmann GmbH, Potsdam, Germany.

**Background:** It was shown that hypertension delays SARS CoV-2 viral clearance and exacerbates airway hyper-inflammation in the respiratory tract. However, it is unknown whether hypertension determines the long-term cellular and humoral response to SARS CoV-2.

**Methods:** Health care workers (HCWs) after an outbreak of SARS CoV-2 infections were recruited. Two groups were analyzed, infected and fully vaccinated HCWs. Clinical data were recorded. Blood was drawn and the humoral and cellular immune responses were examined.

**Results:** 5-14 months (median 7 months) after detection of SARS CoV-2 infection, blood was taken to analyze humoral response (S1 IgG and SARS CoV-2 neutralizing antibodies) and cellular (T cell responses to SARS-CoV-2 with Lymphocyte Transformation Test). Infected hypertensive HCWs more often developed anosmia, myalgia and needed to be hospitalized as compared to non-hypertensive HCWs. The long-term humoral and cellular immune response was significantly strengthened in hypertensive versus normotensive infected HCWs. Multivariate regression analysis revealed that only hypertension but not age, BMI, sex, diabetes, smoking, COPD, asthma and time between PCR positivity and blood taking was independently associated with the humoral and cellular response to SARS CoV-2 infection.

**Conclusions:** In conclusion, SARS CoV-2 infection strengthened humoral and cellular immune response to SARS CoV-2 infection in hypertensive HCWs independent of other risk factors and also severity of symptoms.

**Figure 1.** (A) SARS-CoV-2 IgG-Abs (S1) (BAU/ml) in SARS-CoV-2 infected health care workers (HCWs) with and without hypertension. (B) SARS surrogate neutralization test (%) in SARS-CoV-2 infected HCWs with and without hypertension. (C) Spike-N-Term LTT (SI) in SARS-CoV-2 infected HCWs with and without hypertension. (D) Spike-C-Term LTT (SI) in SARS-CoV-2 infected HCWs with and without hypertension. Lines show median. Comparison was made by Mann-Whitney U test.

## PUB016

**A Study of ESRD Patients on Maintenance Haemodialysis With COVID-19**

Lakshmi Aishwarya Pavuluri,<sup>1</sup> Venkata A. Yalamanchili,<sup>2</sup> Ram Rapur.<sup>1</sup> Nephrology, SVIMS, Tirupati <sup>1</sup>Sri Venkateswara Institute of Medical Sciences, Tirupati, India; <sup>2</sup>Dallas Nephrology Associates, Dallas, TX.

**Background:** This study presents the data of ESRD patients on maintenance haemodialysis (MHD) with COVID-19 disease from Sri Padmavathi Medical College (SPMC) Hospital, SVIMS University, Andhra Pradesh, India which had been ordained as the State COVID Hospital in March 2020.

**Methods:** We collected the data from March 2020 to December 2021 of ESRD patients on MHD in a retrospective observational study and identified the risk factors for mortality.

**Results:** At SPMC Hospital, the total number of COVID-19 disease patients managed was 15,719. The number of deaths reported was 2,878 (18.3%). We identified a total of 714 ESRD patients who required MHD during this period. We analyzed data for 595 patients (83.3%). The rest of patient files could not be traced owing to mismatch in the medical record numbers and patient names. The number of ESRD patients on MHD with COVID-19 disease who died were 203 out of 595 (34.1%). We identified age, SpO<sub>2</sub> at admission, number of dialysis sessions, total leucocyte count, neutrophils, lymphocytes, blood urea, serum glutamic-oxaloacetic transaminase (SGOT), serum glutamic-pyruvic transaminase (SGPT), C-reactive protein (CRP), serum ferritin, serum lactate dehydrogenase (LDH), male, diabetes mellitus, oxygen requirement at admission, non invasive ventilation (NIV) at admission and NIV in hospital as significant risk factors for mortality (P<0.001). On multivariate analysis age, NIV during hospital stay and serum LDH returned significant.

**Conclusions:** The mortality rate in ESRD patients on MHD with COVID-19 disease at our institution was not divergent from the published studies; however, we identified several different risk factors.

## PUB017

**Pauci-Immune Crescentic Glomerulonephritis (PICGN) Following SARS-CoV-2 Vaccination**

Lakshmi Aishwarya Pavuluri,<sup>1</sup> Venkata A. Yalamanchili,<sup>2</sup> Ram Rapur.<sup>1</sup> Nephrology, SVIMS, Tirupati <sup>1</sup>Sri Venkateswara Institute of Medical Sciences, Tirupati, India; <sup>2</sup>Dallas Nephrology Associates, Dallas, TX.

**Introduction:** We report two patients (pt) of PICGN following administration of Indian vaccines (COVISHIELD and COVAXIN) against COVID-19.

**Case Description:** Pt 1: A 41-year old woman with no hypertension or diabetes received COVAXIN in June 2021. Six days later she developed joint pain, fever, cough and hemoptysis along with frothy urine, pedal edema but no hematuria. Serological work up was negative for ANA, Anti GBM and pANCA. She had a positive cANCA (PR3) titer. Renal biopsy showed fibrocellular crescents with segmental sclerosis. Basement membrane showed no spikes or double contour. No endocapillary proliferation or necrotizing lesion seen. Immunofluorescence (IF) was negative. We initiated intravenous (IV) methylprednisolone 15 mg/kg/d for three days followed by PO prednisolone

0.5 mg/kg/d and IV cyclophosphamide 500 mg monthly for 3 months. Five daily sessions of plasmapheresis with 1.5 times volume exchange followed by alternate day exchanges for five more sessions was completed. Serum creatinine improved to 2.0 mg/dl from a peak creatinine of 7.6 with out requiring hemodialysis (HD). Pt 2: A 45-year old woman with history of hypertension treated with telmisartan and amlodipine received COVISHIELD vaccine against COVID-19 in June 2021. Next day she had vomiting and abdominal pain. No joint pains, fever, cough, hemoptysis, hematuria or frothy urine reported. Serum Creatinine was elevated at 2.85 mg/dl. ANA and Anti-GBM negative but ANCA (PR3, MPO) was positive. Renal biopsy showed a cellular crescent and a fibrocellular crescent in one glomerulus each. IF was negative. She was started on IV methylprednisolone 15 mg/kg/d for three days followed by prednisolone 0.5 mg/kg/d PO and IV cyclophosphamide 500 mg monthly for 4 months. Five daily sessions of plasmapheresis with 1.5 times volume exchange followed by alternate day exchanges for five more sessions was done. Serum creatinine improved to 2.7 mg/dl from a peak of 3 without requiring HD.

**Discussion:** Both COVAXIN and COVISHIELD are developed using Whole-Virion Inactivated Vero Cell derived platform technology. Inactivated vaccines do not replicate and are therefore unlikely to revert and cause pathological effects. In our pt, causality of PICGN with these two vaccines is based on temporal association. The appearance of ANCA and PICGN shortly after vaccination raises suspicion that the two events are more than coincidence.

## PUB018

### Outcomes of Patients in Advanced CKD Consultation With COVID-19 Infection

Juan Carlos Herrero. *University Hospital Severo Ochoa, Leganes, Spain.*

**Background:** The coronavirus disease 2019 (COVID-19) has affected to our patients in renal replacement therapy (RRT). But also, has affected to patients in Advanced Chronic Kidney Disease (ACKD) consultation. Our aims are to assess the impact of COVID-19 in a group of patients of our ACKD consultation.

**Methods:** Retrospective observational study in our center of patients from ACKD consultation with hospitalization due to COVID-19 infection in the period from March to December/2020. We have studied demographic parameters, characteristics during hospitalization, analytics values (3 months before and 1, 3, 6, and 12 months after infection), and final status at the end of follow up on December 31, 2021. Values comparison is made with the Wilcoxon test for paired data.

**Results:** In ACKD consultation with ninety patients, 12 (13%) required hospitalization due COVID-19. 75% was male, mean age 77.6 years (SD 7) (range 59-89), 25% due to Diabetic Kidney Disease. Mean time in consultation 28 months (SD 14) (range 12-58). Mean Comorbidity Charlson Index 8.2 (SD 1.2) (range 7-11), all hypertensive, 42% treatment with insulin, 25% ischemic heart disease and 42% chronic obstructive pulmonary disease. In COVID-19 hospitalization, 83% they had pneumonia, only two required tocilizumab, none required admission to intensive care unit. During hospitalization, 3 (25%) patients died, and one during follow-up, all males. Comparison before and during COVID, hemoglobin and albumin was lower, and white cell, ferritin, creatinine, and C-reactive protein increase with significant value. From 6 months after COVID, the analytics results are like 3 months after disease. The consequences after infection: 42% pneumology (cough, varying degrees of shortness of breath), 8% neurological (headaches, varying degrees of memory loss) and 8% loss of smell (from 1 to 6 months). At the follow up, only one patient needs RRT with hemodialysis (at 19 months after COVID-19).

**Conclusions:** With the important limitation of few patients and without control group, ACKD patients with hospitalization to COVID-19, show similar patterns to those with RRT: more frequent in males, advanced age, lung comorbidity and diabetic, elevation of inflammatory parameter, anemia and increase of creatinine during hospitalization. Recovery to values prior to admission occurs from the first month after infection.

## PUB019

### One Year Antibody Response to COVID-19 mRNA Vaccinations in Hemodialysis Patients

Mingyue He,<sup>1</sup> Zakir Shaik,<sup>1</sup> Crystal A. Gadegbeku,<sup>2</sup> Louise Enderle,<sup>3</sup> Christina Petyo,<sup>3</sup> Sally B. Quinn,<sup>1</sup> Zoe Pfeffer,<sup>1</sup> Kathleen Murphy,<sup>3</sup> Aaron D. Mishkin,<sup>1</sup> Jean Lee,<sup>1</sup> Avrum Gillespie.<sup>1</sup> <sup>1</sup>Lewis Katz School of Medicine at Temple University, Philadelphia, PA; <sup>2</sup>Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH; <sup>3</sup>DCI, Dialysis Clinic Inc, Philadelphia, PA.

**Background:** The hemodialysis patients have a high risk of contracting SARS-CoV2 and high COVID-19 related mortality. We examined the durability and persistence of antibody response to a series dose of COVID19 vaccination in a single-center cohort of hemodialysis patients.

**Methods:** We conducted a longitudinal SARS-CoV2 antibody surveillance study of a cohort of 30 hemodialysis patients between March 2021 to March 2022. Participants received a two-dose mRNA vaccine and a booster as clinically indicated independent of the study. Antibody levels were measured using the Beckman Coulter Access SARS-CoV-2 IgG Antibody Test<sup>®</sup> on the day of enrollment, and every month after enrollment.

**Results:** The mean age of participants was 61±14 years old, 97% self-identified as African America, and 53% identified as male. The mean dialysis vintage was 4.6±3.7 years. None received immunosuppressive therapy. Participants were divided into those who had COVID19 infection prior to enrollment (8/30) and those who did not (22/30). Those with a previous infection had a durable antibody response 10 to 12 months post the first dose of mRNA vaccine as well as a response to the booster. Of those without previous COVID19 infection, 91% (20/22) had positive antibodies after two doses of the vaccine. Two patients (9%) remained seronegative until receiving the third dose (booster), 5-9 months post the first vaccine series. Half of the previously uninfected patients (11/22) did not

have a durable antibody response at 6 ± 2 months but had a positive response to the booster. There were no demographic differences associated with antibody response. Two participants developed a COVID19 infection in March 2022.

**Conclusions:** mRNA vaccines induced antibody responses in all patients receiving dialysis in our cohort. However, we observed delayed and foreshortened antibody response to COVID19 vaccination in patients without previous COVID exposure. By contrast, patients who have recovered from COVID19 had lasting antibody titers. Booster immunization was efficacious in counteracting the waning of vaccine-induced antibody response over time and induced antibody response in patients who did not respond to a standard two-dose immunization. Post-vaccination measurement of antibody titers may help make personalized vaccination schedules.

## PUB020

### Titration of Trimeric Antibodies of SARS-CoV-2 in Hemodialysis Patients at the Hospital Metropolitano de Santiago (HOMS), Dominican Republic

Eliana Dina-Battle,<sup>1,2</sup> Nicole M. Suárez,<sup>1</sup> Anthony J. Gutierrez,<sup>2</sup> Carlos Jimenez,<sup>1</sup> Liz M. Portorreal Gómez,<sup>1</sup> Hector A. Pantaleon,<sup>1</sup> Eliana Bencosme,<sup>1</sup> <sup>1</sup>Hospital Metropolitano de Santiago, Santiago De Los Caballeros, Dominican Republic; <sup>2</sup>Pontificia Universidad Catolica Madre y Maestra, Santiago de los Caballeros, Dominican Republic.

**Background:** Knowing that the immune response can be limited in hemodialysis patients, and as a consequence of the that, the antibody production can be impaired, the evaluation of the titer of trimeric antibodies against SARS-CoV-2 after standard vaccination of patients in a regular hemodialysis program can be a useful tool in our regular practice.

**Methods:** A descriptive, observational, cross-sectional study conducted at the Hemodialysis Center of the Hospital Metropolitano de Santiago (HOMS), Dominican Republic from June to August 2021. All patients in the hemodialysis unit with a complete vaccination schedule against COVID-19 and with SARS-CoV-2 trimeric antibody test for at least 1 month after the last dose were enrolled.

**Results:** A total of 23 patients were evaluated, 56.52% being male. The median (and IQR) age was 61 years (44-68). The time from administration of the first dose was 109 (72-120) days, and 81 (35-92) days for the second dose. A 17.39% of the patients had at some point a positive diagnosis of COVID-19; 8.69% were admitted for the same cause. Antibody titer yielded a median of 74.80 (31.63 - 829.50).

**Conclusions:** Infection and hospitalization rates were comparable to the 80/20/5 rule of asymptomatic, symptomatic, and hospitalized. 75% of the patients eventually infected by COVID-19 presented antibodies > 1,400Au/mL, considering a positivity range equal to 33.8Au/mL. A study showed a less effective response, both in magnitude and time, which can be seen by lower trimetric antibody levels compared to the general population, taking a positive titer of 13 Au/ml as a cut-off point. This explains why the response to a full schema is poor but satisfactory. Follow-up at 6-8 months is recommended to verify that this response is maintained.

## PUB021

### Systemic Lupus Erythematosus (SLE) Flare Following Second Dose of mRNA COVID-19 Vaccine

Miguel A. Cota, Martha D. Rodriguez. *Universidad de Monterrey, San Pedro Garza Garcia, Mexico.*

**Introduction:** Inclusion of patients with rheumatic diseases in COVID vaccine trials is limited. Here we present a 28-year-old male with no comorbidities nor family history who developed lupus nephritis, pneumonitis and heart failure.

**Case Description:** He presented with a four day history of non-bloody diarrhea three days after his second dose of the Moderna vaccine. He reported thoracic petechiae and arthralgia five years ago treated with steroids but without a definitive diagnosis. Initial Cr was 5.2 mg/dL with a BUN:Cr of 15.6, positive ANA 1:3200, Anti-La >200 and hypocomplementemia. HD was started due to a decline in kidney function and hyperkalemia. A TTE reported a LVEF of 25% and pericardial effusion. Treatment with 1g of MPRed every 24 hours, IgIV for 4 days and 5 sessions of plasmapheresis showed no response. Kidney biopsy was programmed twice but had to be postponed. Steroids, hydroxychloroquine and mycophenolic acid were given, but despite 35 days of in-patient care, the patient passed away

**Discussion:** Based on our research, there hasn't been a correlation between mRNA vaccine administration and the development of SLE, despite multiple cases reported. According to current guidelines, patients with autoimmune and inflammatory rheumatic diseases (AIIRD) should be prioritized for vaccination before the general population, even though there is a theoretical risk for a flare following COVID-19 vaccination; the benefit of it trumps the potential risk. The Moderna vaccine encodes the SARS-CoV-2 spike protein, responsible for host cell attachment and viral entry. The RNA enters the host cells and elicits high levels of antibodies and antigen-specific CD8+ and CD4 cytokine response involving Th1 cells. Phase III trials reported a low risk of serious adverse events, however patients treated with immunosuppressants and those with a history of autoimmune disease were excluded from phase I, which makes data limited. The mechanisms behind the flares are elusive, mRNA technology has been shown to induce a potent immune response, this is the reason why post vaccination surveillance of serologic markers, renal function and symptoms is essential in the population at risk or with previously known rheumatic pathologies. To our knowledge, our case report is the first to describe a case of a severe flare leading to a patient's death after vaccine administration, despite adequate inpatient management.

## PUB022

**Pauci-Immune Crescentic Glomerulonephritis Post COVID-19 Vaccination**

Maria Izabel N. de Holanda,<sup>1,3</sup> Marcelo Dessen,<sup>1</sup> Janaina F. Ferreira,<sup>1</sup> Claudia D. Silva,<sup>1</sup> Lilian M. Palma,<sup>2</sup> Joao Luiz Ferreira Costa.<sup>1</sup> <sup>1</sup>Hospital Pro-Cardiaco, Rio de Janeiro, Brazil; <sup>2</sup>Universidade Estadual de Campinas, Campinas, Brazil; <sup>3</sup>Hospital Federal de Bonsucesso, Rio de Janeiro, Brazil.

**Introduction:** COVID-19 is a problem for the humanity. Since now, 526.534.751 of confirmed cases. The world campaign vaccination started in the end of 2020. Until now, we had almost 12 billions people vaccinated. We never had in the world a massive vaccination campaign like that. Considering that medications and vaccines can present adverse events, some cases of glomerulopathies were described.

**Case Description:** We describe 50 yea-old white male patient who was obese and presented hypertension well controlled with Six months before admission, routine blood and urine tests were normal. He received two doses of Coronavac (Sinovac, China) inactivated virus vaccine for Covid-19 (28 day interval between doses). On December 2021, he received a third dose (booster) Covid-19 vaccine from Pfizer-BioNTech (RNA). One day later, he began to experience high fever lasting one day, severe and progressively chest pain. The patient was hospitalized with pericarditis and AKI KDIGO 1. Corticosteroids and support measures were taken leading to an improvement in the cardiac condition. Two weeks later, renal function progressively worsened, and hematuria and proteinuria ensued. Investigation was negative for autoimmune diseases, serum levels C3 and C4 were normal, and viral serologies were negative. The creatinine level risen to 5 mg/dL (440 mmol/L). A pulse of 1 g methylprednisone was initiated for 3 days. Renal biopsy showed necrotizing glomerulonephritis, with fibrocellular crescents and immune paucity. Two doses of Rituximab 1g was added and prednisone 1 mg/kg and azathioprine were used as maintenance regimen. After 4 months of treatment, the patient presented partial recovery of renal function with a creatinine of 1.7 mg/dL (150 mmol/L).

**Discussion:** Glomerulopathies related to Covid infection and vaccines are scarce. Rocatello et al reported 17 cases of post-vaccination glomerulopathies, most of which were of minimal change disease with no case of necrotizing pauci immune-negative being related. Few cases were reported with positive ANCA-related necrotizing GN, and in the present case the patient had all negative antibodies. A causal relationship cannot be stated, but with mass vaccination, cases of rare adverse effects must be monitored and reported to better clarify their mechanisms and evolution.

## PUB023

**Virtual Mindfulness-Based Intervention for Hemodialysis Patients During COVID-19 for Chronic Pain, Stress, Anxiety, and Depression**

Mona Ben m'rad,<sup>1</sup> Christina Rigas,<sup>2,3</sup> Katie Bodenstein,<sup>2,3</sup> Karin Cinalioglu,<sup>2,3</sup> Maryse Gautier,<sup>2,3</sup> Harmehr Sekhon,<sup>2,3</sup> Soham Rej.<sup>2,3</sup> <sup>1</sup>Hopital du Haut-Richelieu, Saint-Jean-sur-Richelieu, QC, Canada; <sup>2</sup>McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada; <sup>3</sup>Sir Mortimer B Davis Jewish General Hospital, Montreal, QC, Canada.

**Introduction:** Up to 50% of hemodialysis (HD) patients experience stress, anxiety, depression and chronic pain. With COVID-19, these symptoms are often exacerbated, and healthcare services are harder to access due to distancing measures and staff shortages. Mindfulness-based interventions (MI) are effective in reducing these symptoms. As part of our institution's standard clinical practice, we offered a virtually-delivered adapted Mindfulness-Based Stress Reduction (MBSR) program to patients during their HD sessions given by an MBSR-certified psychologist.

**Case Description:** A 35-year-old female, on HD since age 6, received five 20-40 minutes individual sessions of the virtual adapted MBSR program over 3 weeks. Perceived stress (Perceived Stress Scale), anxiety (Generalized Anxiety Disorder-7), depression (Patient Health Questionnaire-9) and chronic pain (Questionnaire de Saint-Antoine which is a french adapted version of the McGill pain questionnaire) levels were measured prior to starting the program, and 2 weeks after the last session. Over 5 weeks, the patient's stress decreased by 1 point (PSS = 17; PSS = 16, both moderate), anxiety decreased by 50% (GAD-7 = 14, moderate; GAD-7 = 7, mild), depression decreased by 15 points (PHQ-9 = 15, moderately severe; PHQ-9 = 0, none/mild), and chronic pain decreased by 19 points (QDSA = 22, moderate; QDSA = 3, mild). The patient also reported successful withdrawal from her restless-legs syndrome and insomnia medications, due to the MBSR breathing techniques she learnt for pain-management and sleep. Using the same MBSR techniques, 18 months after the program, she reported continuing self-management of her insomnia, chronic pain, and restless-legs syndrome without medication and feeling capable of coping with new health challenges, managing difficult emotions, and being able to calm and detach herself from worries and negative self-talk.

**Discussion:** This case illustrates that an adapted MI delivered during HD sessions: 1) may help in managing symptoms of chronic pain, sleep disorders, anxiety and depression, 2) can be delivered virtually, 3) may be a viable short-term and long-term non-pharmacological alternative to managing symptoms in HD patients, for which polypharmacy is a high safety concern.

## PUB024

**Vocal Fold Paralysis Following COVID-19 Vaccination in a Patient on Hemodialysis**

Syed U. Haider, Nupur N. Uppal, Tanazul T. Pariswala. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

**Introduction:** With the increase in number of the people receiving COVID-19 vaccination, different adverse effects associated with vaccine are being described. While vocal fold paresis (VFP) after both COVID-19 disease and COVID-19 vaccination has been rarely reported, data on this entity in dialysis population is still lacking. We present a case of VFP in a hemodialysis patient following the administration of Pfizer-BioNTech COVID-19 vaccine.

**Case Description:** 45-year-old West Indian female with DM, HTN and End Stage Kidney Disease 2/2 Focal Segmental Glomerulosclerosis s/p kidney transplant that failed after 16 years (on low dose tacrolimus) requiring to start hemodialysis presented to the ED with complaints of voice hoarseness with dysarthria and throat itching that started ~30-45 minutes after having received the first dose of Pfizer-BioNTech COVID-19 vaccine. She underwent Fiberoptic Indirect Laryngoscopy that showed widely patent airway with mobile vocal cords bilaterally. Symptoms were thought to be secondary to a reaction to the vaccine vs mild GERD. She received steroids and was discharged home within 24 hours after symptomatic improvement on steroid therapy. Her voice normalized within a week. Six months later, she received the second dose of Pfizer-BioNTech vaccine, ~30 minutes after which again developed dysphonia and dysarthria. This time, she was found to have bilateral VFP with incomplete closure. Steroid therapy was reinitiated and is slowly being tapered. Her dysarthria has improved; however, she continues to have hoarseness of voice even after 9 months of having received 2nd dose of vaccine. She has not received the booster dose of vaccine.

**Discussion:** Current guidelines recommend booster doses of COVID-19 vaccine for immunocompromised individuals including those on dialysis. The benefits of vaccination markedly outweigh the risk of very rarely reported development of VFP after vaccination. Further research is needed to determine the prevalence of this complication in dialysis patients and to elucidate the underlying mechanisms leading to it.

## PUB025

**Glucocorticoid Therapy in the Prevention of COVID-19-Associated AKI**

Fehlin Stone, Robert Nee, Christina M. Yuan, Maura A. Watson. *Walter Reed National Military Medical Center, Bethesda, MD.*

**Background:** COVID-19 is a global pandemic, with acute kidney injury (AKI) as one of the major complications amongst hospitalized patients. We assessed if glucocorticoid therapy can reduce the incidence of acute kidney injury.

**Methods:** We compared the demographics, clinical characteristics, and COVID -19 disease severity in a large adult cohort of 140 patients, hospitalized from March to December 2020, comparing their glucocorticoid treatment status with their odds of developing AKI using data from the US Department of Defense health care network.

**Results:** Forty two patients received glucocorticoid therapy and 98 patients did not receive glucocorticoid therapy. Five patients in the treatment group and 10 patients in the non-treatment group developed AKI during admission. Per multivariate analysis, when adjusting for age, gender, and chronic kidney disease status, there appeared to be no difference in the odds of developing an AKI (odds ratio (OR) 1.08; 95% confidence interval (CI) 0.265 to 3.87; P=1.00). However, when also adjusting for COVID-19 disease severity, the treatment group had a statistically significant lower odds of developing an AKI compared to the non-treatment group (OR 0.180; 95% CI 0.0244 to 0.950; P=0.0415).

**Conclusions:** In hospitalized patients with COVID-19, glucocorticoid therapy decreased the odds of developing an AKI. COVID-19 disease severity was found to be a major confounder to the development of AKI. *The views expressed are those of the authors and do not reflect the official policy of the Department of the Army/Navy/Air Force, the Department of Defense, or the United States government.*

## PUB026

**Mental Health in Dialysis Nurses During COVID-19**

Soo min Jang,<sup>1,3</sup> Danquynh C. Bui,<sup>1</sup> Paul Gavaza,<sup>1</sup> Rita Hanna Al-Kass,<sup>1</sup> Reem H. Hanna Al-Kass,<sup>1</sup> Charilyn L. Fox,<sup>3</sup> Sergio Infante.<sup>2,3</sup> <sup>1</sup>Loma Linda University School of Pharmacy, Loma Linda, CA; <sup>2</sup>Loma Linda University School of Medicine, Loma Linda, CA; <sup>3</sup>Loma Linda University Kidney Center, Loma Linda, CA.

**Background:** Dialysis nurses have long working hours and provide high-quality care for immunocompromised patients. During COVID-19, dialysis nurses are confronted with life and death situations in fast-paced and demanding environments. Thus, they are vulnerable to mental health problems which may influence organizational productivity and pose serious health and safety hazards.

**Methods:** This was a quality improvement project to evaluate depression (Patient Health Questionnaire-9, PHQ9), anxiety (General Anxiety Disorder-7, GAD7) and stress (Perceived Stress Scale, PSS) in dialysis nurses between November 2021 and January 2022 at a large academic medical center. Descriptive statistics were computed for all variables.

**Results:** A total of 24 nurses [54% outpatient hemodialysis (HD), 17% outpatient peritoneal dialysis, 25% inpatient HD nurses] with a mean age of 49 (SD=10) years old participated in the survey. Most were female (71%), married or with a significant other (79%), and had children (75%). Majority was Asian (63%), followed by Caucasian (29%), Hispanic (4%) and African American (4%). Almost half of them had a bachelor's

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

degree (46%), were licensed vocational nurses (29%), had an associate degree (13%), and had a master's or doctoral degree (13%). The majority (75%) worked full-time, 13% worked overtime and 7% worked part-time. The mean PHQ9 score was 4±4 (minimal depression), GAD7 score was 4±4 (minimal anxiety) and PSS score was 21±3 (moderate stress). Eighteen (75%) dialysis nurses had prayed to control their mood and 85% of these said praying helped. Four nurses (16.7%) started or tried counseling to control their mood and three (75%) of them mentioned it helped. Two nurses (8.3%) started a new medication to control their mood and both nurses said it helped.

**Conclusions:** Dialysis nurses showed minimal depression and anxiety despite the moderate stress level associated with their work. Most dialysis nurses found praying to be helpful to control their moods.

PUB027

Effect of Sodium-Glucose Cotransporter-2 Inhibitors on Cardiovascular Outcomes in COVID-19 Patients

Lucas Wang, Victor A. Canela, Manavjot Sidhu. *Methodist Dallas Medical Center, Dallas, TX.*

**Background:** Recent data has shown that sodium-glucose cotransporter-2 (SGLT-2) inhibitors decrease cardiac related mortality in patients with and without diabetes. In this study we aim to explore the relationship between outcomes in patients hospitalized with coronavirus disease 19 (COVID-19) and whether they did or did not take SGLT-2 inhibitors.

**Methods:** Using an observational database, we analyzed 3293 unvaccinated hospitalized COVID-19 PCR-positive patients at Methodist Health System from March to December 2020. We compared incidence of in-hospital death or hospice referral rates, major acute cardiovascular event (MACE), and acute respiratory failure requiring mechanical ventilation between patients who did or did not take SGLT-2 inhibitors on first encounter. In this study, MACE was identified as congestive heart failure (CHF) exacerbation, pericarditis, pericardial effusion, myocardial infarction (MI), stroke, pulmonary embolism (PE), deep venous thrombosis (DVT), or shock. We used Chi-square and odds ratio tests to analyze observed variables.

**Results:** Of the 3293 COVID-19 patients, 149 (4.5%) took SGLT-2 inhibitors prior to admission while 3144 (95.5%) did not. A statistically significant difference was observed when comparing mortality as an outcome between patients who took SGLT-2 prior to admission and those who did not (OR 0.54, 95% CI 0.29-0.98, p = 0.04). Interestingly, an opposite trend was seen in these two groups when comparing whether they had an incidence of MACE during hospitalization (OR 2.36, 95% 1.69 – 3.29, p < 0.01). In specific, patients who took SGLT-2 prior to admission had higher incidences of MI (OR 2.02, 95% CI 1.43 – 2.85, p < 0.01) and stroke (OR 1.28, 95% CI 2.87 – 7.82, p < 0.01). Finally, we noted that there was no statistically significant difference in incidence of acute respiratory failure leading to intubation (p = 0.35), or mortality of intubated patients (p=0.18) when comparing these two groups.

**Conclusions:** SGLT-2 inhibitors use was associated with a decreased incidence of in-hospital mortality of patients admitted with COVID-19 infection even in a patient population that had a significantly higher number of MACE during hospitalization. We also show that SGLT-2 inhibitors had no association with change in incidence of acute respiratory failure requiring intubation in this patient population.

PUB028

In ICU Patients With COVID-19, Estimating Glomerular Filtration Rate From Creatinine and Cystatin C

Ayesha Khader, Leila R. Zelnick, Eric D. Morrell, Mark M. Wurfel, Bryan R. Kestenbaum, Pavan K. Bhatraju. *University of Washington Department of Medicine, Seattle, WA.*

**Background:** Accurate estimation of the glomerular filtration rate (eGFR) in critical illness is essential for judging the severity of kidney injury and informing medication dosing. Many drugs used to treat COVID-19 require dose adjustment (baricitinib) or are withheld (remdesivir) based on kidney function. Cystatin C provides more accurate and precise estimation of GFR than serum creatinine in outpatient settings, but the relationship of creatinine and cystatin C in critically ill patients with and without COVID-19 is less known.

**Methods:** We prospectively enrolled 253 ICU patients, including 176 (70%) patients with COVID-19 and 77 (30%) patients without COVID-19. We collected plasma on days 1, 3, 7, 10 and 14 leading to a total of 643 samples. Plasma creatinine was measured using the modified Jaffe method and plasma cystatin C was measured using an immunoturbidimetric assay (Gentian AS) on a Beckman DXC Unicell clinical analyzer.

**Results:** Among 486 plasma samples in 176 unique COVID-19 patients, plasma cystatin C and creatinine were correlated (r=0.79) but calculated eGFR differed. Values of eGFRcr were, on average, 16-41 mL/min/1.73m<sup>2</sup> higher than those of eGFRcys during hospitalization (p <0.001) (Figure 1). Each 15 mL/min/1.73m<sup>2</sup> lower eGFRcys was associated with an estimated 11% greater risk of hospital mortality (RR =1.11, 95% CI, 1.03 to 1.21) compared to an estimated 6% greater risk of hospital mortality with eGFRcr (RR = 1.06; 95% CI: 0.97 to 1.16). Among non-COVID-19 patients there was a similar trend with higher eGFRcr than eGFRcys but the difference on ICU admission was non-significant.

**Conclusions:** In COVID-19 ICU patients eGFRcr was consistently higher than eGFRcys, and eGFRcys may more strongly associate with clinical outcomes. Our findings suggest that in COVID-19, calculating eGFR using creatinine or cystatin C could have implications on which treatments are available to patients.

**Funding:** Other NIH Support - NIH Grant

Figure 1. Creatinine compared to cystatin C consistently estimated a higher eGFR until an eGFR of 120 mL/min/1.73 m<sup>2</sup>

**Figure legend.** Plotted is the eGFR calculated using plasma creatinine and cystatin C in 176 COVID-19 patients with blood collected on days 1, 3, 7, 10 and 14 after ICU admission for a total of 643 samples. Each dot is an individual patient on a given day during hospitalization. eGFR was calculated using either creatinine or cystatin c and age and gender. eGFR was limited to 150 mL/min/1.73 m<sup>2</sup>. Differences in eGFR calculation can have implications of which patients would receive remdesivir, which is held in patients with an eGFR<60 mL/min/1.73 m<sup>2</sup>. For example, on ICU admission, eGFRcys identified 49 patients (41%) with an eGFR less than 60 mL/min/1.73 m<sup>2</sup> compared with only 37 (31%) using eGFRcr.

PUB029

Effects of SARS-CoV-2 Vaccination on Outcomes of COVID-19 in ESKD Patients on Dialysis

Jing Miao, Elsa Olson, John J. Dillon, Ziad Zoghby. *Mayo Clinic Minnesota, Rochester, MN.*

**Background:** COVID-19 is associated with increased morbidity and mortality in patients with ESKD on chronic dialysis. Vaccination against other viruses is known to be less effective in these patients compared to the general population. Data on the titers of antibody following SARS-CoV-2 vaccination in these patients is inconsistent. The efficacy of SARS-CoV-2 vaccination to prevent severe disease in ESKD patients with COVID-19 remain unknown. We compared the incidence of hospitalization and COVID-19 related death after COVID-19 disease in dialysis patients based on SARS-CoV-2 vaccine status.

**Methods:** Single-center, retrospective cohort study. We included all adults on dialysis (in-center and home) within the Mayo Clinic Health System in the Midwest (USA) with laboratory proven SARS-CoV-2 infection between 1/1/2020 and 3/30/2022 (n=225). Patients' demographics, clinical characteristics, laboratory data including SARS-CoV2 infection test results, and SARS-CoV-2 vaccination information were collected. The primary outcome was the incidence of hospitalization and COVID-19 related death after COVID-19 disease.

**Results:** 244 infections occurred in 225 patients, 119 (49%) were vaccinated and 8.4% (n=19) died. Among those who died, 73.7% (n=14) were not vaccinated compared to 49.3% of those who were alive (p=0.041). A total of 78 patients had 83 hospitalizations; 71.1% were not vaccinated compared to 41% not hospitalized (p<0.001) (Table).

**Conclusions:** The incidence of hospitalization and COVID-19 related death after COVID-19 disease was significantly higher in non-vaccinated compared to vaccinated dialysis patients. This data suggests that SARS-CoV-2 vaccination improves outcomes in dialysis patients who develop COVID-19 disease.

Table - Death and hospitalization in vaccinated and non-vaccinated dialysis patients

	Total (n=225) a	Vaccinated	Not vaccinated	P value
Death, n (%)	19 (8.4)	5 (26.3)	14 (73.7)	0.041
Alive, n (%)	206 (91.6) b	114 (50.7)	111 (49.3)	
Hospitalization, n (%)	83 (34.7) c	24 (28.9)	59 (71.1)	<0.001

a Total 244 infections. 18 patients had reinfection (1 with 2 reinfections and 17 with one reinfection). Among the 18 patients with reinfection, 2 died, 8 were not hospitalized, 4 were hospitalized after 1st COVID, and 5 were hospitalized after 2nd COVID. b Total 225 infections. c Among 78 patients.

PUB030

Clinical Outcomes of COVID-19 in Critically Ill Patients Treated With Hemoperfusion in a Tertiary Hospital in Davao City, Philippines

Joy Blossom Anne Y. Lacang, Mark anthony A. Tom. *Davao Doctors Hospital, Davao City, Philippines.*

**Background:** The excessive immune response against COVID-19 results in a cytokine storm from overproduction of pro-inflammatory cytokines. Hemoperfusion has a potential role in improving clinical symptoms and reducing mortality in critically ill

patients by eliminating circulating inflammatory mediators. This study aims to look into the clinical outcomes of COVID-19 critically ill patients who underwent hemoperfusion.

**Methods:** This study utilized a descriptive research design conducted among critically ill COVID-19 patients who completed hemoperfusion treatment admitted from October 2020 to October 2021 in Davao Doctors Hospital.

**Results:** Most patients who received hemoperfusion treatment expired ( $n = 11$ , 57.89%), while 9 of the patients survived (42.11%). The oxygen saturation for both patients increased after hemoperfusion, but patients who did not survive had the lowest oxygen saturation before hemoperfusion treatment (0.78 vs. 0.89). Among those who died, all inflammatory markers were elevated post hemoperfusion except for C Reactive Protein (CRP) (-16.50%). Meanwhile, for patients who survived, all inflammatory markers: Lactate dehydrogenase (LDH) (-17.31%), CRP (-77.69%), ferritin (-30.95%), and procalcitonin (-34.74%) decreased after hemoperfusion (Table 1). The median time between symptoms onset to hospital admission and hemoperfusion treatment was longer in patients who did not survive (6.3, 10.2 vs. 3.3, 8.5).

**Conclusions:** The mean inflammatory markers decreased after hemoperfusion treatment among those who survived. Patients with lower baseline oxygen saturation and longer time of hemoperfusion initiation from symptoms onset were less likely to survive even with hemoperfusion. It is highly recommended that hemoperfusion be performed at the earliest possible time before severe clinical manifestations occur. Overall, our study shows a higher number of critically ill patients who died from COVID-19 disease.

	Expired			Survived		
	Pre	Post	% Variance	Pre	Post	% Variance
Oxygen Saturation	0.78	0.96	22.86	0.89	0.97	9.04
LDH	539.64	1459.36	128.16	484.50	400.63	-17.31
CRP	106.86	89.24	-16.50	67.06	14.98	-77.69
Ferritin	4417.97	5570.65	26.09	2771.45	1913.61	-30.95
Procalcitonin	0.50	1.28	154.18	0.19	0.12	-34.74

## PUB031

### Impact of Development and Severity of AKI on In-Hospital Outcomes Among Patients With COVID-19

Jin Huang, Te Du, Arrsh Bajaj, David J. Gemmel, Erdal Sarac. *Mercy Health St Elizabeth Youngstown Hospital, Youngstown, OH.*

**Background:** Acute kidney injury (AKI) is a common complication of COVID-19 and is associated with poor outcomes. The aim of this study was to describe the incidence of AKI and to compare its clinical impact with other risk factors on the severity and outcomes of hospitalized COVID-19 patients.

**Methods:** We conducted a retrospective study on patients  $\geq 18$  years old who were admitted to our institution with a laboratory-confirmed diagnosis of COVID-19 infection from March 2020 to December 2020. Data on demographics, kidney function prior to and during hospitalization, inflammatory biomarkers, comorbidities, medications, and outcomes including mortality, mechanical ventilation (MV) and renal replacement therapy (RRT) were collected from electronic medical record. Definition and staging of AKI were based on the KDIGO guidelines. Survival and use of MV by AKI and AKI stage was analyzed using Chi-square test; strength of association was measured using correlation coefficients; and significance was assessed at  $p < 0.05$ .

**Results:** Of 240 inpatients admitted for COVID-19, 153 (63.7%) survived to discharge. A total of 121 (50.4%) patients developed AKI during hospitalization: 43.7% stage 1, 34.5% stage 2, and 21.8% stage 3. Almost 1 in 4 patients with AKI (23.1%) required RRT. Fifty-eight (49.2% overall, 37.3%, 51.2%, and 70.8% for AKI stage 1, 2, and 3, respectively) patients with AKI required mechanical ventilation, compared to 15 (13.5%) with normal renal function ( $p < 0.001$ ). Age, presence of AKI, AKI stage, history of coronary artery disease, and initial lactate dehydrogenase were significantly associated with in-hospital death. Development of AKI ( $r = 0.33$ ,  $p < 0.001$ ) and AKI stage ( $r = 0.38$ ,  $p < 0.001$ ) were more strongly associated with in-hospital mortality than the remaining bivariate associations. Survival at discharge was strongly associated with renal function, with survival declining from 79.5% among patients with normal renal function to 61.5%, 41.5%, and 30.7% among AKI stage 1, 2, and 3 patients ( $p < 0.001$ ).

**Conclusions:** AKI is more strongly associated with increased mortality among patients with COVID-19 infection compared with demographics, comorbidities, and inflammatory biomarkers. Patients with Stage 2-3 AKI are more likely to have greater severity and worse outcomes.

## PUB032

### Changes in Physical Activity, Physical Function, and Depressive Symptoms Associated With the Coronavirus Disease 2019 Pandemic in Japanese Patients Undergoing Hemodialysis

Takuya Nakajima,<sup>1</sup> Keigo Imamura,<sup>1,2</sup> Yuta Suzuki,<sup>3</sup> Narumi Fukuzaki,<sup>1</sup> Juri Uchida,<sup>1</sup> Shohei Yamamoto,<sup>4</sup> Shun Yoshikoshi,<sup>1</sup> Manae Harada,<sup>5</sup> Atsuhiko Matsunaga.<sup>1</sup> <sup>1</sup>Department of Rehabilitation Sciences, Kitasato University Graduate School of Medical Sciences, Kanagawa, Japan; <sup>2</sup>Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan; <sup>3</sup>Center for Outcomes Research and Economic Evaluation for Health, National Institute of Public Health, Saitama, Japan; <sup>4</sup>Department of Epidemiology and Prevention, Center for Clinical Sciences, National Center for Global Health and Medicine, Tokyo, Japan; <sup>5</sup>Department of Rehabilitation, Sagami Circulatory Organ Clinic, Kanagawa, Japan.

**Background:** There are concerns about the impact of the coronavirus disease 2019 (COVID-19) pandemic on physical and mental health. This study aimed to investigate changes in physical activity, physical function, and depressive symptoms during the COVID-19 pandemic in Japanese hemodialysis patients.

**Methods:** This retrospective longitudinal study included 159 clinically stable outpatients (mean age,  $66.8 \pm 10.9$  years; men, 62.2%; median hemodialysis vintage, 8 years) who underwent maintenance hemodialysis at two Japanese dialysis centers between April 2019 and March 2021. Participants' physical activity (steps taken per non-dialysis day), physical function (walking speed and leg strength), and depressive symptoms (Center for Epidemiologic Studies Depression [CES-D] score) before and during the COVID-19 pandemic were compared.

**Results:** The steps on non-dialysis day was significantly lower during than before the COVID-19 pandemic ( $P < 0.01$ ). On the other hand, there were no significant differences in walking speed, leg strength, and CES-D score before and during the COVID-19 pandemic (Figure).

**Conclusions:** Although a decline in physical activity during the COVID-19 pandemic was not prevented, no negative impacts of declining physical activity on physical function and depressive symptoms were observed. This is likely because we have implemented a long-term disease management program, such as regularly assessing the physical function and mental status of the patients. Our findings may provide insight into disease management in hemodialysis patients after the COVID-19 pandemic.

## PUB033

### Effect of the COVID-19 Pandemic on Clinical Phenotype of Glomerular Disease: Single Centre Experience

Katie Chu, Sharad C. Sinha, Philippa G. Boothroyd, Kazi M. Fardeen, Bhriagu Raj Sood, David Makanjua. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

**Background:** Presenting features for glomerular disease can be varied, including but not exclusively, acute kidney injury, nephrotic syndrome or haemo-proteinuria. At our regional tertiary centre we conducted a retrospective study to see whether clinical presentations of glomerular diseases had changed during the COVID-19 pandemic.

**Methods:** In this study, new and repeat native renal biopsies were included from January 2018 to October 2021. Glomerular pathologies of interest included minimal change disease, membranous nephropathy, IgA nephropathy, lupus nephritis and pauci-immune glomerulonephritis. We looked at three periods of time: prior to the start COVID-19 pandemic in 2018/19; during the COVID-19 pandemic in 2020; and after the introduction of COVID-19 vaccines in 2021.

**Results:** 263 biopsies were identified over the 4-year period. IgA nephropathy -  $n = 13$ . Lupus nephritis -  $n = 43$ . The different classes of lupus nephritis are shown in (see figure 1) Minimal change disease -  $n = 57$ . All presented with the nephrotic syndrome. Between 6-25% over the study period presented with AKI (mean 19%) Pauci-immune glomerulonephritis -  $n = 85$ . Between 81%-91% over the study period presented with AKI, or AKI on CKD (mean 84%) Membranous glomerulopathy -  $n = 66$ . 50%, presented with the nephrotic syndrome. 20% presented with AKI in addition to proteinuria.

**Conclusions:** Our analysis has not shown a significant change in clinical presentations of glomerular disease. There has not been an increased propensity in presenting with AKI in minimal change disease or membranous nephropathy. We saw the highest proportion of class IV lupus nephritis in 2021.

Figure 1: Class of lupus identified on biopsy from 2018-2021

## PUB034

## COVID-19 Diagnosis by Computed Tomography in Renal Replacement Therapy Patients

Lilian Carmo,<sup>1</sup> Tiago L. Cerqueira,<sup>1</sup> Pedro Augusto B. Lemos,<sup>1</sup> Mariana O. Vieira,<sup>2</sup> Mariana d. Oliveira,<sup>3</sup> Bráulio R. Couto,<sup>1</sup> Camila A. Souza,<sup>2</sup> Yan L. Goll,<sup>2</sup> Vitor S. de Souza,<sup>2</sup> Pedro Alves Soares Vaz de Castro,<sup>2</sup> Ana cristina Simões e Silva,<sup>2</sup> Gabriel A. Carmo.<sup>1</sup> <sup>1</sup>Hospital Evangelico, Belo Horizonte, Brazil; <sup>2</sup>Universidade Federal de Minas Gerais, Belo Horizonte, Brazil; <sup>3</sup>Hospital Felício Rocho, Belo Horizonte, Brazil.

**Background:** Lung diseases are common in Patients with End Stage Kidney Disease (ESKD) making the differential diagnosis with COVID-19 a challenge. This study describes pulmonary chest tomography (CT) findings in hospitalized ESKD on renal replacement therapy (RRT) patients with clinical suspicion of COVID-19 and compare image characteristics of positive versus negative cases.

**Methods:** ESKD individuals referred to Emergency Department older than 18 with clinical suspicion of COVID-19 were recruited. Epidemiological, baseline clinical information was extracted from electronic health records. Pulmonary CT was classified as typical, indeterminate, atypical or negative. We then compare CT findings of positive and negative COVID-19 patients.

**Results:** We recruited 109 patients (62.3% COVID-19 positive) between March and December 2020. Mean age was  $60 \pm 12.5$  years-old, 43% were female and the most common etiology of ESKD was diabetes. Median time on dialysis was 36 months, Interquartile range=12-84. The most common pulmonary lesion on CT was ground glass opacities. Typical CT pattern was more common in COVID-19 patients (40(61%) vs 0(0%),  $p < 0.001$ ). Sensitivity was 60.61% (40/66) and specificity was 100% (40/40). Positive predictive value and negative predictive value were 100% and 62.3%, respectively. Atypical CT pattern was more frequent in COVID-19 negative patients (9(14%) vs 24(56%),  $p < 0.001$ ), while the indeterminate pattern was similar in both groups (13(20%) vs 6(14%),  $p = 0.606$ ), and the negative pattern was more common in COVID-19 negative patients (4(6%) vs 12(28%),  $p = 0.002$ ).

**Conclusions:** In hospitalized patients with ESKD on RRT an atypical chest CT pattern cannot adequately rule out the diagnosis of COVID-19.

## PUB035

## Membranous Nephropathy in the Era of COVID-19 and Vaccines: Is There a Story to Tell?

Sharad C. Sinha, Philippa G. Boothroyd, Katie Chu, Kazi M. Fardeen, Bhriju Raj Sood, David Mankajula. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

**Background:** Membranous nephropathy is a relatively common glomerular pathology that manifests with either nephrotic or sub-nephrotic range proteinuria. Evidence is emerging of COVID-19 and its vaccines having an influence on various glomerular diseases, including IgA nephropathy and minimal change disease, with limited information on membranous nephropathy. Data from our tertiary centre suggested a rise in cases of membranous nephropathy within a month after vaccination.

**Methods:** Patients who had renal biopsies in 2021 were identified from pathology results and online clinical records. Information on COVID-19 status, COVID vaccinations and biochemical results were compared. Patients were then split into 2 groups; those presenting within 1 month of vaccination or COVID infection and those who hadn't had vaccinations or a COVID infection within 4 weeks of presentation.

**Results:** Complete vaccination and COVID infection history was present in 17 of the 24 patients. Of the 17 patients, 6 were in group 1 and 11 in group 2. 16 out of the 17 patients had nephrotic range proteinuria, 6 also had an AKI at presentation. There was no significant difference in presentation between the groups (see table 1).

**Conclusions:** Our data has not conclusively shown a difference between the two groups probably because of the low numbers. But further studies are needed to see if there is a link between either COVID infections or COVID vaccinations and glomerular disease

	Group 1 (n=7)	Group 2 (n=10)

## Clinical Characteristics of Hemodialysis Patients Hospitalized With COVID-19: A Case Series of 70 Cases From the Dominican Republic

Denazir Atizol Rodriguez,<sup>1</sup> Nicole M. Suárez,<sup>1</sup> Irvianny Madera,<sup>1</sup> Jordy Batista,<sup>1</sup> Eliana Dina-Battle,<sup>1</sup> Nicole M. Battle.<sup>2</sup> <sup>1</sup>Hospital Metropolitano de Santiago, Santiago De Los Caballeros, Dominican Republic; <sup>2</sup>Pontificia Universidad Católica Madre y Maestra, Santiago de los Caballeros, Dominican Republic.

**Introduction:** The Coronavirus disease (COVID-19) is more severe in patients with pre-existing comorbidities; therefore, dialysis patients fall into this category. Not to mention the risk among patients receiving in-center dialysis, since they are known to be at higher risk of contracting this disease. Information about the clinical characteristics among hemodialysis patients with COVID-19 in Latin America and low-and middle-income countries are limited. Considering the importance of this topic, the aim of this study was to describe the clinical characteristics along with the outcome of 70 hemodialysis patients hospitalized for COVID-19.

**Case Description:** The mean age of the patients was 58 (range 19-87), where 65.7% were male. The most prevalent comorbidities were Hypertension (98.6%) and Type 2 Diabetes (54.3%). The most common presenting symptoms were dyspnea (71.4%), fever (68.6%) and cough (58.6%). In addition of abnormal pulmonary auscultation in most patients (78.6%). Lymphocytopenia and elevated inflammatory markers as Procalcitonin, ESR, D-dimer and CRP were the main prevalent lab findings. At admission 90.1% had ground-glass abnormalities in the CT findings, being CO-RADS 3 the most frequent category between these patients. The average hospital stay was  $8.51 \pm 6.39$  days, 35.7% of these patients were admitted to ICU with a median of 5.00 (IQR: 2.5-11) days and only 4 (5.7%) required mechanical ventilation. Therapeutic management included statins and antithrombotic therapy for all the patients at prophylactic doses. Treatment options were Remdesivir, corticosteroids, hydroxychloroquine, antibiotics, and other immunosuppressant drugs. A total of 8 (11.4%) patients died during hospitalization and 62 (88.6%) were discharged.

**Discussion:** Even though dialysis patients are at higher risk of death, especially in developing countries, our findings suggest that the mortality rate were lower in comparison with other studies in Latin America and similar to some developed countries. The use of statins and antithrombotic prophylaxis in all hospitalized patients seems to be associated with a lower risk of death in conjunction with other therapeutic regimens according to the guidelines. No major adverse consequences were observed with Remdesivir in these patients.

## PUB037

## AKI From Cholesterol Embolization Syndrome Treated With Corticosteroids

Kelly V. Liang, Kamal Gupta. *University of Kansas School of Medicine, Kansas City, KS.*

**Introduction:** Cholesterol atheroembolism is a dreaded complication of interventional vascular procedures, causing renal atheroembolism, gastrointestinal ischemia, and peripheral limb gangrene. Although renal atheroembolic disease can be self-limited, it is often progressive. It is unclear whether corticosteroids are beneficial. We present a case of renal atheroembolism that was successfully treated with corticosteroids.

**Case Description:** A 69 year-old male with history of hypertension, hyperlipidemia, coronary artery disease s/p coronary artery bypass graft twice (1998 and 2008), multiple percutaneous coronary interventions (PCI), peripheral arterial disease, renal artery stenosis, diabetes mellitus type 2, heart failure with reduced ejection fraction (HFrEF) (EF 45%), and chronic kidney disease (CKD) stage 3, underwent PCI with stent placement on 12/20/21 and 1/24/22. After his Jan 2022 procedure, he noted onset of painful bluish bilateral toe discoloration, concerning for cholesterol embolization. His creatinine (Cr) progressively worsened from baseline of 1.3-1.7 mg/dL to 2.63 over a period of 6 weeks. Differential diagnosis included low cardiac output related AKI (cardiorenal syndrome), overdiuresis, contrast nephropathy, and cholesterol emboli. Right heart catheterization on 3/7/22 showed normal filling pressures and cardiac output, ruling out cardiorenal syndrome or overdiuresis. Presence of toe gangrene, increased urine eosinophils, and a diffuse maculopapular rash made cholesterol embolism the most likely diagnosis. There was no improvement in renal function with conservative treatment with lipid-lowering therapy for 6 weeks, so he was treated with steroids with rapid taper. His Cr started improving steadily from 2.63 to 1.96 within 5 days and declined to 1.1 over 3 weeks in April 2022, and his rash resolved.

**Discussion:** We present a rare case of cholesterol embolization in which rapidly tapering corticosteroids improved renal function. Supportive care is the mainstay of therapy for renal atheroembolism. However, renal dysfunction often is progressive despite conservative treatment. Corticosteroids may ameliorate the inflammatory reaction at the site of embolization in distal arteries, thereby preventing irreversible ischemia. Therefore, corticosteroids should be considered early in atheroembolic disease to prevent persistent inflammation, irreversible ischemia, and renal failure.

### Features and Long Term Follow Up of Collapsing Glomerulopathy in Three Patients of COVID-19 Infection Presenting With Severe AKI

Reshub R. Pendyala,<sup>1</sup> Prashant Pendyala,<sup>2</sup> <sup>1</sup>Nichols School, Buffalo, NY; <sup>2</sup>Buffalo General Medical Center, Buffalo, NY.

**Introduction:** Collapsing Glomerulopathy has been well described in patients with COVID 19. However their long term outcomes are still not clear. This is a case report of 3 patients who had relatively mild COVID 19 symptoms but were in severe acute kidney injury (AKI). They were followed for 18 months till date.

**Case Description:** The patients were 42, 50 and 55 yrs of age. All the three were Black. Their COVID 19 symptoms were limited to fever, cough and myalgia. None of the three needed supplemental oxygen. Only the 50 yr old had hypertension and was on Amlodipine. The other two did not have any significant past history and were not on any regular medications. Their hospitalization was triggered by the blood work. They did note some decrease in their urine output and increased fatigue. None of them had hypotension, though all three were febrile and tachycardic. They did not have any edema. Their creatinine was 12.5, 14 and 9.6 at admission. WBC count was mildly elevated. Bicarbonate was low and potassium was normal in range. All the three had proteinuria of 5.6 gm, 4.8 gm and 6.2 gm. All the three needed renal replacement therapy in the ensuing 1-3 days. All the three underwent kidney biopsy and it confirmed presence of Focal Segmental Glomerulosclerosis with features of the Collapsing variant. The three were on dialysis for 32, 58 and 46 days. All the three recovered enough kidney function to be able to discontinue dialysis. They were followed for the next several months. Currently the 42 yr old is on a single anti hypertensive and so is the 50 yr old that is continuing his need for medication. The current creatinine after 14, 16 and 20 month follow up are 3.5, 2.9 and 3.1. They still have 5gm, 4.8 gm and 3.8 gm of urine protein and have been tolerating angiotensin receptor blockers and spironolactone.

**Discussion:** Obviously this is a study of only 3 patients but the presentation and course and current residual disease are in line with prior literature of COVID 19 associated Collapsing Glomerulopathy. They presented with relatively mild COVID 19 symptoms and had severe AKI needing dialysis. All the three patients were black. They did not have hemodynamic instability. They did recover enough to be off dialysis but have significant residual disease with advanced Chronic Kidney Disease and severe proteinuria.

## PUB039

### Cefepime-Induced Neurotoxicity in the Setting of AKI Requiring Renal Replacement Therapy

Natalia Plotskaya, Cristine K. Arcilla. <sup>1</sup>Capital Health System Inc, Trenton, NJ.

**Introduction:** Cefepime is a commonly used parenteral antibiotic for severe infections. 85% of the drug is excreted renally and crosses the blood-brain barrier. Cefepime-induced neurotoxicity (CIN) manifests as encephalopathy, myoclonus and seizures. It is reported in patients with renal impairment if administered in high dosage. CIN is reversible after drug discontinuation and faster clinical recovery is achieved by intermittent hemodialysis (IHD).

**Case Description:** A 53-year-old female with a history of sleep apnea, obesity, recent COVID pneumonia presented with worsening dyspnea on exertion for 5 days. Physical examination revealed tachycardia, tachypnea, diminished breath sounds at lung bases. Admission laboratory results were a creatinine (Cr), 0.96 mg/dl; BUN, 18 mg/dl. Chest x-ray showed bilateral ground glass pulmonary opacities. Patient was started on Vancomycin 2 g IV every 12 hours and Cefepime 2 g IV every 8 hours. On day 2 she was in septic shock due to E. Coli bacteremia, intubated and started on pressors. Vancomycin was discontinued. On day 8 Cr increased to 1.49 mg/dl. Patient remained on Cefepime without dosage change for six more days despite glomerular filtration rate decreased to 20 ml/min/1.73 m<sup>2</sup>. On day 18 patient was noted to have altered mental status and jerking movements of upper extremities and head. Cefepime was stopped, Cr peaked at 3.95 mg/dl, BUN was 130 mg/dl at that time. CT scan of head was negative for acute findings. EEG showed focal cortical hyperexcitability, no seizure activity. Cr increased to 4.41 mg/dl, IHD was started. After two IHD sessions jerking movements disappeared, and consciousness improved. Work up for acute kidney injury (AKI) revealed negative Hepatitis B, C, HIV serology. ANA, ANCA serology was negative. Patient regained renal function within 1 week after six IHD sessions.

**Discussion:** CIN is a known complication in patients with renal dysfunction but remains challenging to recognize in critically ill patients. Our patient had various causes of altered mental status: shock, hypoxemia, uremia. Despite decline in renal function cefepime dose was not adjusted and patient developed CIN which required emergent hemodialysis initiation. A high index of suspicion for CIN is critical when evaluating a patient with AKI. Discontinuation of cefepime and emergent IHD initiation leads to resolution of neurological symptoms within 48 hours.

## PUB040

### Acute Renal Failure With Severe Flank Pain Following Binge Drinking and Non-Steroidal Anti-Inflammatory Medication Intake

Meloney Oliveira, Steven T. Heidt, Roger A. Rodby, Pravir V. Baxi. *Rush University Medical Center, Chicago, IL.*

**Introduction:** An acute kidney injury (AKI) syndrome with severe flank pain following the combination of binge alcohol drinking with NSAID intake was first described by Elsasser et al. in 1988. We present two such cases.

**Case Description:** Case 1 - A 24-year-old healthy man presented with severe bilateral flank pain after a night of binge alcohol drinking followed by ibuprofen the next day for a

hangover. His physical exam was unremarkable and without flank tenderness. His serum creatinine (SCr) was 2.8 mg/dL. He was non-oliguric. A urinalysis had no proteinuria, pyuria, hematuria or casts. The fractional excretion of sodium FeNa was 1.9%. The creatinine kinase (CK) and lactate dehydrogenase (LDH) were normal. A retroperitoneal ultrasound (RPUS) demonstrated no abnormality. He was initially treated with intravenous fluids without improvement in renal function. His SCr peaked at 4.8 mg/dL (Figure 1) but he did not require dialysis. His renal function spontaneously improved on day 3 and his flank pain resolved. Case 2 - A 34-year-old woman with hypothyroidism presented with severe bilateral flank pain. Prior to admission, she had been using ibuprofen for back pain. She admitted to drinking excessive amounts of alcohol on a daily basis. Her SCr was 5.0 mg/dL. She was non-oliguric. A urinalysis had no proteinuria, pyuria, hematuria or casts. The CK and LDH were normal. A RPUS was unremarkable. Her SCr peaked at 5.8 mg/dL (Figure 1) and did not require dialysis. Her renal function spontaneously improved on day 2 and her flank pain resolved.

**Discussion:** AKI with flank pain following excessive alcohol intake and NSAID usage is a rare idiosyncratic reaction to these not unusual behaviors. Both cases presented as complete mysteries until an internet search led us to this previously described syndrome. While the risk factors are known, the pathophysiology is not but would be especially interesting as both AKI diagnoses were recognized only as a result of an evaluation for acute flank pain. Both patients had an uneventful recovery.

## PUB041

### The Sickest COVID-19 Patients During the First Wave of the Epidemic: Strong Clinical Evidence for Acute Tubular Injury

Phoenix Xu,<sup>1</sup> Harshad Chaudhari,<sup>1</sup> Smita Mahendrakar,<sup>1</sup> Jennine Michaud,<sup>2</sup> Joshua Kaplan,<sup>1</sup> Alex Plamm,<sup>1</sup> Sacha Balmir,<sup>2</sup> Michael Yudd.<sup>2</sup> <sup>1</sup>Rutgers New Jersey Medical School, Newark, NJ; <sup>2</sup>VA New Jersey Health Care System, East Orange, NJ.

**Background:** From March through June 2020, SARS-CoV-2 virus surged through the New York Metropolitan area, killing 43,000 in NY and NJ. The sickest patients had both respiratory failure and severe acute kidney injury (AKI), were intubated and on dialysis.

**Methods:** Seventy intubated patients with severe covid and severe AKI requiring dialysis were treated in 2 north Jersey hospital ICU during this period. Their records were reviewed, focusing particularly during the period of AKI onset to identify potential renal insults – hypotension and shock, secondary infections, and inflammation markers.

**Results:** Following admission, respiratory failure quickly progressed, and intubation occurred 3.3 ± 3.7 days after admission. AKI became evident 1.5 days later (4.7 ± 4.8 days after admission), and dialysis was initiated 5.4 ± 6.6 days after AKI onset. Serum creatinine at the start of dialysis was 6.44 ± 3.40 mg/dl. Around the onset of AKI (start of dialysis ± 5 days), hemodynamic and clinical instability were rampant. Hypotension requiring vasopressors occurred in 83%; oliguria developed in 79% and worsened to anuria in 33%. Bacteremia and fungemia complicated this period in 28% and 10%. The inflammatory markers – CRP, d-dimer, ferritin, interleukin-6 and ESR, were extremely elevated. Fifty-two patients (74%) died during the hospitalization, 17.7 ± 11.8 days from admission. Renal function improved in only 1 of these patients. Eighteen patients (26%) survived, and were discharged 63 ± 15 days after admission. Fifteen (83%) of them regained renal function after requiring dialysis for 20 ± 15 days. Their serum creatinine decreased to 1.15 ± 0.63 mg/dl at discharge. Some went through a polyuric phase. Most of these survivors had severe medical problems. Over the next 3.5 months, 5 of them died.

**Conclusions:** The following clinical aspects were highly suggestive of acute tubular injury: - onset of AKI during severe hemodynamic instability, intubation, pressor use, secondary infections and intense inflammation; - the rapid progression to uremia; - oliguria early in AKI; some with polyuric phase that preceded improvement of renal function; - short period of dialysis and marked improvement of renal function 8 weeks after onset in 83% of the survivors.

## PUB042

**A Rare Case of Magic Mushroom (Psilocybin) Related AKI and Hypertensive Emergency**

Syed Rizwan A. Bokhari,<sup>1</sup> Ahmed Abdullah,<sup>2</sup> Zamir A. Zamir,<sup>3</sup> Raquel M. Rosen.<sup>1</sup> <sup>1</sup>Bassett Healthcare, Cooperstown, NY; <sup>2</sup>King Edward Medical University, Lahore, Pakistan; <sup>3</sup>University of Chicago Pritzker School of Medicine, Chicago, IL.

**Introduction:** Magic (Psilocybin) mushrooms are used as hallucinogens, renal dysfunction as a rare side effect has been reported in literature. We chronicle a rare case of acute kidney injury and hypertensive emergency precipitated by psilocybin ingestion in a young female.

**Case Description:** A 31-year-old female with good overall health and medical history of well controlled Hypertension (HTN) and metabolic syndrome presented with AKI in the setting of hypertensive emergency. Initial blood pressure (BP) on presentation was 210/140, with transient visual loss and elevated troponin >6000. Her other past medical history was significant for nephrolithiasis and COVID-19 few months ago. Physical examination was significant for HTN; no significant edema was present. Remaining physical examination was unremarkable. Laboratory evaluation demonstrated serum creatinine 4.6 mg/dL (baseline creatinine 0.9 mg/dL), 24-hr urine protein 920 mg/g, and serum albumin 3.0 g/dL. A blood film revealed occasional schistocytes. Urinalysis showed proteinuria and microscopic hematuria. Urine toxicology screen was negative. Routine blood and urine cultures showed no growth. Her serology, infectious disease workup and workup for paraproteinemia were inconclusive. Workup for secondary hypertension was negative. Computed tomography of the brain in the setting of transient visual loss, and ultrasound of the kidneys and bladder were unremarkable. Her transthoracic echo (TTE) showed severe concentric left ventricular hypertrophy, with grade II diastolic dysfunction. Renal biopsy showed features suggestive of vascular-predominant acute thrombotic microangiopathy. Patient was managed conservatively and did not require renal replacement therapy. Her serial follow up labs from last several months revealed the new baseline creatinine of 2.2-2.4 mg/dL, resulting in CKD as a sequel of partial recovery from AKI in the setting of psilocybin poisoning.

**Discussion:** Psilocybin use can be associated with AKI leading to CKD and secondary hypertension. Mechanisms of renal injury are thought to be secondary to vasoconstricting effects and endothelial reaction, which needs to be further investigated. Nephrologists and primary providers should be vigilant to identify this rare cause of AKI.

## PUB043

**Reducing the Incidence of Hospital Acquired AKI (HAAKI) by Careful Assessment and Intervention on the Trend of Abnormal Vital Signs**

Harshil Fichadiya, Raghu Tiperneni, Rana Prathap Padappayil, Ahmad S. Al-Alwan, Farah Heis, Charmee H. Vyas, Doantrang Du. *Monmouth Medical Center, Long Branch, NJ.*

**Background:** HAAKI is associated with increased mortality and prolonged duration of hospitalization. The incidence of HAAKI in the US is 2-5%. The most common identified etiologies of HAAKI are hemodynamic changes from volume depletion, sepsis and from use of nephrotoxic drugs. We attempted to reduce the incidence of HAAKI by assessing and intervening on the trend of abnormal vital signs to prevent further clinical deterioration from the hemodynamic perspective. Clinical deterioration was measured by the number of Rapid Response Team (RRT) and sepsis alert triggered on abnormal vital signs.

**Methods:** All patients admitted to medical service during the study period were included with the exclusion of those admitted with pre-existing AKI, AKI explained by etiologies except those related to abnormal vital signs. The primary team carefully evaluated the trend of abnormal vital signs and intervened on them based on a guideline sheet (approach to abnormal vital signs) provided to correct the abnormal trend. This allowed early detection and correction of clinical deterioration which was measured by a reduction in number of RRT and sepsis alert triggered by abnormal vital signs. Urine output and serum creatinine were measured on daily basis to assess for the evolution of an AKI using the KDIGO criteria (rise in creatinine >0.3mg/dl in 24 hr, >1.5X in 1 week, urine output <0.5 mL/kg/h for 6 hours. The incidence of AKI was compared with the national incidence of HAAKI. Number of RRT and sepsis alert were compared between the one month study period and the month prior.

**Results:** National incidence of HAAKI: 2-5% Incidence of HAAKI in our study: 0.7% % of RRT triggered on abnormal vital sign during pre-study period: 53% VS study period: 42% Number of sepsis alert during pre-study period: 86 VS study period: 59

**Conclusions:** -Our intervention of assessing abnormal vital sign trend and correcting them using interventions suggested on the guideline sheet helped in early detection of clinical deterioration as evidenced by reducing in the % of RRT and sepsis alert triggered on abnormal vital signs -It helped in reduction of the incidence of HAAKI from hemodynamic and septic etiologies -It contributed to resident education by helping them in assessing and intervening on abnormal vital sign trends

## PUB044

**Inadequate Diuresis due to AKI in Cardiorenal Syndrome Patients**

Sushma Medikayala,<sup>1</sup> Kristi A. Njaravelil,<sup>2</sup> Surafel K. Gebreselassie.<sup>1</sup> <sup>1</sup>Cleveland Clinic Florida, Weston, FL; <sup>2</sup>Nova Southeastern University, Fort Lauderdale, FL.

**Background: Objective:** To find out if patients with CHF are underdiuresed due to AKI. **Background:** 20-40% of inpatients with acute CHF develop AKI. Providers in dilemma to continue diuretics to treat fluid overload or reduce diuretics to avoid dialysis. This is a grey zone with no clear answers, consensus or treatment protocols. Renal parameter used to define AKI is creatinine (Cr). In AKI, Cr relates to glomerular function and does not represent true tubular injury. Is the AKI present on admission (CRS) or developed with the use of diuretics? In patients that receive diuretics, elevation of Cr could be due to: i) Redistribution of fluid occurs within different body compartments. Increase in Cr is a reflection of changed hemodynamic and hormonal changes. ii) hypovolemia with prerenal state due to diuresis- as kidney sees less volume, it will increase reabsorption of Na, Urea, Uric acid, Creatinine, leading to elevated Cr and Bun. At this stage, there is no anatomic injury to the nephrons. iii) True AKI - either directly from long standing CRS or persistent hypovolemia from aggressive diuresis, ATN develops. Here, there is real damage to the tubules. It is a common myth that Lasix is nephrotoxic. In reality, Lasix is not Nephrotoxic. But why does the creatinine rise with diuretics? It is due to the hypovolemia, prerenal state caused by Lasix. Lasix does not cause direct toxic injury to the tubules. iv) Acute GN- Patient has concomitant Glomerulo nephritis unrelated to CRS. v) ineffective diuresis due to hypoalbuminemia as albumin is the carrier for Lasix to the site of action in renal tubules. vi) Nephrotic syndrome- albumin in the tubules binds Lasix and effective circulatory Lasix is reduced. i-iii - not associated with true renal tubule damage. There is a critical need for guidelines and best clinical practice models for management of diuresis in cardiorenal syndrome patients.

**Methods:** Retrospective Chart Review

**Results:** Pts with CHF and AKI-145. Pts with AKI as per RIFLE classification- 16, 3 with inadequate data. Pts with CRS 10, developed AKI due to diuresis 3. Of the 10 CRS patients, at the time of discharge, 5 gained wt, 5 lost wt, 4 readmissions. AKI due to diuretics-3, at the time of discharge, 2 gained wt, 1 lost wt and 1 readmission.

**Conclusions:** Though small sample size, study indicates that CRS patients are underdiuresed due to AKI leading to readmissions. Future prospective studies needed.

## PUB045

**AKI and Renal Recovery After Lung Transplantation: The Experience in México**

Lilia M. Rizo Topete,<sup>1,2</sup> Patricia Rodriguez,<sup>1</sup> Sergio Saul Sanchez-Salazar,<sup>1</sup> Uriel Chavarria-Martinez,<sup>1,2</sup> Manuel Wong-Jaen,<sup>1</sup> Alicia Estela López-Romo,<sup>1</sup> Mariana N. Zavala,<sup>1</sup> Adrian Camacho-Ortiz.<sup>2,1</sup> Lung Transplant Program in Christus Muguerza, Monterrey, México <sup>1</sup>Christus Muguerza Sistemas Hospitalarios SA de CV, Monterrey, Mexico; <sup>2</sup>Universidad Autonoma de Nuevo Leon, San Nicolas de los Garza, Mexico.

**Background:** Few centers around the globe have a lung transplant (LT) program in Mexico there is only one. The possible complications are associated tppe transplant time, surgical and the post-surgical recovery, common one is AKI (20 to 90%), 15% need KRT. The AKI will complicate the in hospital evolution, time in ICU, risk of infections, also increase mortality and possibility of no renal recovery (RR).

**Methods:** Is a Retrospective and Descriptive study. patients 18y who performed LT in Christus Muguerza from January 2017 to May 2022. Data was collected in excel and the analysis was performed in SPSS V21. The confidentiality agreement is accordance with Helsinki declaration.

**Results:** 24 patients had LT, 62.5% men, average age is 54 y, average BMI 23kg/m2. Idiopathic pulmonary fibrosis the most common diagnosis (58.3%) follow by COVID-19 (16.6%), 15 receive bi-pulmonary transplant. Survival rate is 66%. 37.5% developed AKI with the need of KRT all CKRT as initial therapy. 7 patientes where discharge with a complete renal recovery after KRT. 32% patients were in ECMO and 75% from these need CKRT.

**Conclusions:** The involvement of kidney function is essential for the decision to go forward to LT, some patients develop AKI before surgical time, these should be evaluated from the crosstalk organ view, remembering that a high possibility of RR exist if the lung recovery is successful. Our work demonstrate that nephrology intervention in a team work help patient to RR.

Rehabilitation before lung trasplant with ECMO and CKRT and after lung trasplant without KRT, two days before catheter withdrawal.

**Treatment of Cisplatin-Induced AKI With Renal Selective Nanotherapy**  
Chintan H. Kapadia,<sup>1</sup> Daniel A. Heller,<sup>2</sup> Magdalini Panagiotakopoulou,<sup>2</sup> Edgar A. Jaimes.<sup>2</sup> *Goldilocks Therapeutics Inc., Wilmington, DE; <sup>2</sup>Memorial Sloan Kettering Cancer Center, New York, NY.*

**Background:** Acute kidney injury (AKI) occurs in up to 30% of cancer patients treated with cisplatin, and accounts for approximately 1% of total hospital admissions. Further, up to 25% of patients in intensive care develop AKI and up to 25% of these patients require renal replacement therapy with mortality rates up to 60%. Despite the prevalence and associated morbidities of AKI, there are no therapeutics that specifically treat this disease.

**Methods:** We synthesized proprietary nanoparticles from biodegradable materials which preferentially target renal proximal tubular epithelial cells. Nanoparticles were loaded with free radical scavenger molecule, Edaravone. In previously published studies, our nanoparticles exhibited significant therapeutic efficacy in cisplatin-induced kidney injury in mice. For the successful clinical translation of our lead therapeutics, we have developed cisplatin induced AKI model in pigs.

**Results:** After administration of 5 mg/kg cisplatin intravenously, blood urea nitrogen (BUN) and creatinine were significantly elevated from baseline post 72 hours. Currently, we are evaluating, biodistribution, pharmacokinetics and efficacy of our lead therapeutics, Edaravone nanoparticles, in our pig model of CI-AKI.

**Conclusions:** The results of this work will provide pharmacokinetic, safety, and efficacy data of a lead candidate in a large animal model of CI-AKI. Results from these studies will provide essential final validation before initiating the remaining CMC/IND-enabling studies.

**Funding:** NIDDK Support

### Hemoperfusion in a COVID-19 Patient With Severe Burn Injuries

Lorraine S. Vergara-Rejante, Maria kristina Alolod. *Saint Luke's Medical Center, Quezon City, Philippines.*

**Introduction:** Severe burn injury can cause effects in cellular mechanisms known as systemic inflammatory response syndrome. Survival rate is decreased in patients with severe burns with the added insult of this inflammatory response. Optimizing management for these patients can include utilization of hemoperfusion to decrease inflammatory response and mortality rate. The use of hemoperfusion is not usually included in the initial treatment but few studies showed promising benefits.

**Case Description:** A 29-year old male who works in smelting industry, had a flame burn injury. Upon arrival in the ER, COVID-19 RT PCR oral and nasopharyngeal swab turned out to be positive, and he was transferred to a COVID critical care unit. Altogether there was ~67% TBSA affected. Fluid resuscitation was started with saline alternating with Lactated Ringer's solution. Surgeries were done sequentially. There was a high inflammatory state on the 2nd hospital day as shown by high-grade fever with a temperature of 38-39°C and elevated CRP of 48 and Procalcitonin at 22.51 ng/mL. Hemoperfusion was done for three consecutive days from 2nd to 4th hospital day using HA330 cartridge. Urine output and biochemical markers eventually improved (Fig. 1).

**Discussion:** Hemoperfusion is indicated to remove cytokines in patients with sepsis and systemic inflammatory response syndrome. There were several studies with conflicting evidence for the use of hemoperfusion and other forms of extracorporeal therapies in an inflammatory state. Hemoperfusion done in this case involves the use of a standard hemodialysis machine done for 3 consecutive days using the HA330 cartridge for 3 hours each session. The return of levels to baseline or normal procalcitonin plasma concentrations have a high negative predictive value to rule out severe systemic inflammation. The indication for hemoperfusion in severe burn injury patients with severe inflammatory response syndrome still remains experimental. There is no current recommendation for the use of hemoperfusion specifically on burn patients, and further clinical trials were recommended.

### Late-Onset Scleroderma Renal Crisis: A Case-Control Study

Manal Alotaibi, Xuan Cai, Cybele Ghossein. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

**Background:** Scleroderma renal crisis (SRC) is a life-threatening complication of Scleroderma (SSc) that occurs in the first 4 years of disease. Here we report a case series of late-onset SRC (SRC-l) (>5years from SSc onset) and compare clinical presentation and outcomes to our early-onset(<5years) SRC (SRC-e) cohort.

**Methods:** Retrospective chart review of SRC patients at Northwestern Memorial Hospital from 2000-2019. History, demographics, lab values, medication exposure, clinical presentation and outcomes were compared.

**Results:** 42 patients had SRC-e and 6 patients (12%) met the criteria for SRC-l. There was no difference in baseline demographics between SRC-e and SRC-l patients. 33% of SRC-l had positive anti-RNP antibodies as compared to 7% of SRC-e (p<0.05). Prior exposure to steroids and ACE inhibitors (ACEI) was significantly associated with SRC-e but not SRC-l. Microscopic hematuria was a presenting sign in 75% of SRC-e patients but in none of SRC-l patients (p<0.001) TABLE 1. There was no significant difference in risk of death or renal replacement between SRC-e and SRC-l during the acute SRC episode at years 1 and 3.

**Conclusions:** 12% of all SRC patients present more than five years after SSc diagnosis. RNP antibody positivity, lack of microscopic hematuria, and no increased risk of exposure from the use of steroids and ACEI differentiate SRC-l from SRC-e. Most of our current understanding of SRC is based on early-onset disease, more research is needed to better elucidate late-onset SRC.

### A Strange Case of Prolonged Anuric AKI Following a Urethral Surgery: Reflex Anuria?

Alan Segal. *Maine Medical Partners--Nephrology MaineHealth, Portland, ME.*

**Introduction:** Anuria lasting more than a week is rare. An entity called “reflex anuria” has been associated with urological procedures performed on one kidney or ureter. Here, we present a case of prolonged anuria following manipulation of the urethra.

**Case Description:** A 41-year-old man with a chronic urethral stricture from remote trauma and baseline [creatinine] of 0.96 mg/dL underwent an attempted urethral repair under general anesthesia at an outside hospital. Approach from the distal urethra was complicated by creation of a false lumen so a proximal approach via the bladder was attempted but this also failed. A supra-pubic bladder catheter (SPBC) was placed and the procedure was aborted. Purportedly, the patient had MAPs in the 50s transiently in

the OR. The patient was sent home but returned 6 hours later because of complete anuria despite a patent catheter. He was given copious amounts of IV saline. Anuria persisted and hypervolemia supervened so he was placed on dialysis. Following 4 HD treatments over 5 days, he requested transfer to our hospital. On admission, serum [creatinine] was ~11 mg/dL with no urine output. CK and LDH were normal. Imaging showed normal appearing kidneys with no evidence of hydronephrosis. A cystogram performed via the SPBC did not show any leak. He remained normokalemic but anuria persisted so a tunneled dialysis catheter was placed. Urine output remained less than 50 mL/day for a total of 12 days and he required 10 HD treatments before oliguria resolved. He made 3-4 L of urine/day for 5 days and initial sediment showed granular casts, then urine output normalized. Serum [creatinine] recovered to 1.2 mg/dL 7 weeks after the surgery.

**Discussion:** Complete anuria is rare but can be caused by shock, bilateral urinary tract or renal artery obstruction, cortical necrosis, or RPGN. An entity called “reflex anuria” is a very rare (<100 cases since 1948) complication of trauma or manipulation of a kidney or ureter. The mechanism is thought to relate to reflex vasoconstriction of arterioles or reflex spasm of both ureters causing a functional obstruction. It is a diagnosis of exclusion and seems to respond to percutaneous nephrostomy. Unlike our patient—who had *urethral* surgery—the anuria typically lasts 5 days or less and few patients have required RRT. We conclude that our patient most likely had severe ATN seemingly well out of proportion to the purported inciting event.

## PUB050

### Outpatient Recovery From Acute Kidney Injury Requiring Dialysis (ORKID): A Pilot Trial

Ian McCoy, Yuenting D. Kwong, Kathleen D. Liu, Chi-yuan Hsu. *University of California San Francisco, San Francisco, CA.*

**Background:** After leaving the hospital, patients with dialysis-requiring AKI (AKI-D) are currently treated largely the same as patients with end-stage kidney disease. Routine outpatient dialysis may result in low blood pressure during the dialysis session, which may further damage the kidneys and inhibit recovery. There is currently limited infrastructure supporting AKI-D recovery at outpatient dialysis facilities.

**Methods:** The ORKID trial (NCT05158153) is a single-center, single-arm pilot trial with target recruitment of 20 subjects with a primary aim to test the feasibility of providing a bundle of five interventions: chilled dialysate (35-36°C), high sodium dialysate (145 mmol/L), high dose diuretics (160 mg oral furosemide twice daily), high ultrafiltration hold threshold (SBP > 110 mmHg), and active dialysis weaning to patients with AKI-D being treated with outpatient hemodialysis. The bundled intervention aims to prevent intradialytic hypotension, recognize renal recovery, and wean dialysis off safely as soon as recovery occurs. Recruitment occurs before discharge from the University of California San Francisco (UCSF) hospitals and study investigators implement the intervention for participants during the first 90 days of outpatient dialysis at dialysis facilities within 30 miles of UCSF. The primary outcome is feasibility; secondary outcomes include tolerability (dropout to day 90), safety (including electrolyte abnormalities and emergent dialysis treatments), rates of recruitment, intradialytic hypotension, renal recovery, and patient reported outcomes.

**Results:** We identified 15 patients discharged with AKI-D still requiring HD. 10 patients lived outside the 30-mile radius for study inclusion (mean > 100 miles from UCSF). Four patients were excluded for clinician refusal or other reasons. One patient was recruited and underwent intervention but subsequently transitioned to hospice care. The trial was terminated after six months due to inadequate recruitment.

**Conclusions:** Given that outpatient dialysis facilities are often located far from the hospitals where AKI-D occurred, dialysis-unit based recruitment rather than hospital-based recruitment may be superior for trials of outpatient AKI-D recovery. Whether this bundled intervention to decrease intradialytic hypotension and support AKI-D recovery is feasible in outpatient dialysis units remains unknown.

## PUB051

### Contrast-Induced Nephropathy Resulting in a Persistent Nephrogram

Tanner Bond, Jacob Delalla, Christian Dias. *Erlanger Baroness Campus, Chattanooga, TN.*

**Introduction:** Acute kidney injury (AKI) within 24 to 48 hours after iodine containing contrast historically has been the third most common cause of hospital-related AKI. Patients at highest risk typically have baseline CKD, but other important risk factors include older age and other coincident exposures such as hypovolemia, heart failure, or sepsis. The injury can be attributed to various mechanisms including vasoconstriction of the afferent arterioles, medullary ischemia, renal epithelial cell necrosis, and direct renal tubular toxicity due to oxidative stress.

**Case Description:** A 59-year-old female with a BMI of 14.5 kg/m<sup>2</sup> was admitted to the hospital with failure to thrive and a large palpable breast mass. During workup, the patient underwent various CT imaging with a total of 150 ml of iodinated contrast (Iohexol). Imaging and biopsy revealed extensive breast cancer with metastatic disease to the liver, spleen, orbits, & axial skeleton. In the subsequent days, she developed a sudden decline in mentation with respiratory distress and was taken for repeat CT scan without contrast (hospital day 6). CT scan report revealed that the kidneys demonstrated uniform enhancement suggesting contrast nephropathy with a persistent nephrogram (figure 1). Intermittent straight catheterization with 30cc of black colored urine with muddy brown casts seen under urine microscopy. Unfortunately, the patient decompensated followed by family electing to pursue comfort focused care.

**Discussion:** This clinical scenario highlights the risk a physician must discern when ordering imaging for each patient. The case details the clinical syndrome of a patient with metastatic disease and hypovolemia complicated by unusual abrupt anuric AKI shortly after undergoing CT imaging with contrast. Most patients with CI-AKI are nonoliguric, with only the most severe and rare cases presenting with anuria, such as in this case.

CT without contrast, axial view. Both kidneys demonstrate persistent uniform enhancement which suggests contrast nephropathy.

## PUB052

### Exploring a Unique Case of Renal Oxalosis Secondary to Diabetes Mellitus: A Case Report and Literature Review

Bair Cadet, Kettia N. Guillite, Oshin M. Bansode, Dimitri P. Archer German, Alejandro Alvarez Betancourt. *Nassau University Medical Center, East Meadow, NY.*

**Introduction:** Hyperoxaluria causes kidney disease via obstruction from calcium-oxalate crystal, tubular epithelial cell injuries, & inflammation. This is seldomly observed in CKD Pts w/ Diabetes Mellitus (DM). DM is one of the most common causes of CKD & ESRD, but is unclear if DM associates w/ renal oxalosis, or if hyperoxaluria increases CKD in DM.

**Case Description:** 74-yr-old asymptomatic Caucasian male with HTN, T2DM, sent to ER for AKI stage 3 with SCr 6.2. No h/o alcohol, drug use, and smoking. No family Hx of kidney problems. Unremarkable physical examination. CBC normal, HbA1c 6.9%; blood gas non-anion gap metabolic acidosis, BUN 73 mg/dL, normal LFT; urine protein 34 mg/dL, IF no mAb, UPEP glomerular proteinuria. Uniform and echogenic b/l kidneys on ultrasound. Normal C3 & C4; neg. ANA, anti-Smith, anti-dsDNA, MPO, proteinase 3. Bx ATN 70% interstitial fibrosis, tubular atrophy & calcium oxalate deposit. Serum oxalate 69 mcmol/L w/ normal urine oxalate. B1 & B6 normal level. SCr raised to 17 mg/dL, renal replacement therapy was initiated. Remained dialysis dependent

**Discussion:** This case highlights a diabetic Pt w/oxalate nephropathy w/o other risk factor. Pt had rapidly declining kidney function w/ calcium oxalate deposition, severe ATN & interstitial fibrosis. DM causes systemic organ dysfunction, & targets kidneys causing ESRD. In a study by Furuichi K, et al., 600 Bx specimens of diabetic nephropathy were analyzed, w/diffuse lesions in majority; some w/nodular lesions & mesangiolysis. Interstitial cell infiltration, tubular atrophy, arteriolar hyalinosis, vascular hyperplasia, & arteriosclerosis were found. DM is independent risk factor for urinary oxalate excretion/ nephrolithiasis. Oxalate nephropathy of CKD results from deposits calcium oxalate crystals in tubular epithelial cells or kidney parenchyma w/inflammation & worsening kidney function. In a 2015 study by Muji, et al., 3 cases of AKI occurring in diabetic Pts, & renal Bx diagnosed acute oxalate nephropathy which can be primary hyperoxaluria or secondary enteric malabsorption. Similarly, cases of oxalate nephropathy have been reported in DM but highlighted other factors (gastric bypass/ increased dietary oxalate). Though it demonstrated that DM have higher urinary oxalate concentrations, it does not imply that DM causes oxalate nephropathy.

## PUB053

### Mortality Associated With Acquired AKI at General Regional Hospital No. 46 of the Mexican Institute of Social Security

Juan O. Romero Tafoya, Renato Parra Michel, Javier Soto-Vargas, Jorge fernando Topete reyes, Marcos A. Elias Lopez, Jesus A. Vega Lopez de Nava, Mónica L. Morales Guillén, Roxana Villanueva Macedo, Fabiola V. Rios Rios, Mario Valdez Avendaño. *Universidad de Guadalajara, Guadalajara, Mexico.*

**Background:** Acute kidney injury is a group of syndromes that leads to an abrupt decline in kidney function, occurring in 2-7% of hospitalized patients and up to 50% of patients in intensive care units, in which 5% of them will require renal replacement therapy. The aim of the study is to associated the mortality associated with hospital-acquired acute kidney injury.

**Methods:** Retrospective cohort study. We included hospitalized patients over 18 years of age who presented acute kidney injury assessed by the Nephrology service in the January-December 2019. Objective: assessing mortality in patients with in-hospital

acute kidney injury. Variable of interest: mortality. Inclusion and exclusion: Hospitalized patients diagnosed with acute kidney injury by a nephrologist, excluding glomerular diseases and G4-G5 chronic kidney disease.

**Results:** A total of 165 patients were included, 78 (47.3%) hospitalized and 87 (52.7%) acquired in the community. With a history of (35.2%) hypertensive, (47.9%) diabetic, (29.7%) chronic kidney disease, (15.2%) congestive heart failure, (9.7%) diagnosis of solid tumor, (9.1%) liver disease and (6.1%) coronary artery disease. AS for the severity AKI (6.1%) KDIGO 1, (15.8%) KDIGO 2 and (78.2%) KDIGO 3. Mortality was found in 44.9% of in-hospital AKI, which increased to 50% at 90 days. The mean rate of survival was 73.6 days.

**Conclusions:** In this study, is possible to show that acute kidney injury is an entity of great importance due to the increased in-hospital mortality in a second-level hospital unit, evidencing the associated risk factors. Is desirable to continue evaluating this entity with prospective studies, identifying other factors associated with mortality for early intervention.

PUB054

**Results of Patient Experience Surveys 30 Days After Kidney Biopsy**  
Hannah C. Melchinger, Jason N. Weinstein, Frida S. Calderon Gutierrez, Melissa M. Shaw, Candice Kent, Randy L. Luciano, Francis P. Wilson, Dennis G. Moledina. *Yale School of Medicine, New Haven, CT.*

**Background:** The kidney biopsy procedure is important for both clinical diagnosis and research. However, patient experiences during and after kidney biopsy are not sufficiently characterized.

**Methods:** We conducted a participant experience survey 30 days after kidney biopsy in participants enrolled in the Yale Kidney Biopsy Biobank to assess biopsy-related pain, anxiety, complications, and attitude toward future biopsies.

**Results:** Of the 42 participants contacted, 38 (90%) responded to the survey. Biopsy-related pain was common, occurring in 29 (76%) participants during the biopsy (median (IQR) severity, 1 (0, 5) on a scale of 1-10 with 10 being most severe) and 26 (68%) after the biopsy (severity, 1.5 (1, 4)). Pain lasted for over 1 week in 5 (14%) participants and 9 (24%) participants reported limitation in their day-to-day functioning after biopsy. Anxiety during biopsy was reported by 26 (68%) participants with a median severity of 3 (0, 5.5). Blood in urine was reported by 8 (21%) participants. When asked if they would be willing to undergo another biopsy for clinical reasons, 32 (87%) participants responded positively with 26 (81%) of these willing to donate kidney tissue for research during such a procedure. Only 8 (23%) were willing to undergo a biopsy solely for research purposes.

**Conclusions:** In this prospectively administered survey conducted 30 days after kidney biopsy, pain and anxiety were common during kidney biopsy but did not deter participants from willing to undergo another biopsy if indicated.

**Funding:** NIDDK Support

Table. Results of participant experience survey from Yale Kidney Biopsy Biobank	
Experience category	N (%) or median (IQR)
Was pain experienced?	
During biopsy	29 (76%)
Severity (Scale 1-10)	1 (0, 5)
After biopsy	26 (68%)
Severity (Scale 1-10)	1.5 (1, 4)
1 week after biopsy	5 (13%)
1 month after biopsy	1 (3%)
Limited day-to-day functioning	9 (24%)
Was there anxiety during biopsy	26 (68%)
Severity (Scale 1-10)	3 (0, 5.5)
Was there blood in urine?	8 (21%)
Duration, days	2 (1.5, 4)
Willingness to undergo repeat kidney biopsy	
For clinical reasons	32 (87%)
Allow tissue taken for research during clinical biopsy	26 (81%)
Research purpose biopsy	8 (23%)

PUB055

**Antineutrophil Cytoplasmic Antibody (ANCA) Positive Infective Endocarditis Complicated by AKI**  
Shilpa Sannapaneni, Louis Damian, Wesley Hiser, Akinwande A. Akinfolari, Harold M. Szerlip. *Baylor University Medical Center at Dallas, Dallas, TX.*

**Introduction:** Kidney injury related to infectious etiologies have been well described in literature. Here we present an interesting case of a patient with infective endocarditis, antineutrophil cytoplasmic antibody (ANCA) positivity complicated by acute kidney injury without evidence of vasculitis.

**Case Description:** A 63-year-old male presented to the emergency department with elevated creatinine detected on outpatient testing. Past medical history was significant for intellectual disability, cardiac defibrillator placement in 2010 for ventricular tachycardia that was partially ex-planted in 2017 due to infectious complications, however, a residual ventricular lead was left in place. He had initially presented to an outpatient clinic with hematuria, a petechial rash, generalized weakness and was found to have elevated ANCA titers. He was started on steroids based on symptoms, elevated ANCA titer and rash improved but hematuria and fatigue persisted which prompted a visit to the emergency department. On presentation his vital signs were normal. Cardiovascular exam was remarkable for a new systolic murmur. Labs showed creatinine 4 mg/dl and a positive anti-proteinase 3 ANCA (PR3-ANCA) 26.1 U/mL. His urinalysis revealed microscopic hematuria with >100 red blood cells/ HPF, 2+ protein, no casts, while urine protein creatinine ratio was 3.2. Two sets of blood cultures were positive for staphylococcus epidermidis. He had a vegetation involving the aortic valve on trans-esophageal echocardiography. A kidney biopsy showed acute interstitial nephritis and acute tubular injury, immunofluorescence was negative, electron microscopy was significant for wide spread foot process effacement, negative immune complex deposits. There was no evidence of vasculitis. He was started on antibiotics and underwent replacement of his aortic valve. At the time of discharge his creatinine had decreased and follow-up testing revealed negative ANCA titers.

**Discussion:** ANCA is detected in 18% - 33% of patients with infective endocarditis. Anti-PR3 is the predominant antibody. Most patients test negative for ANCA once the infection resolves. PR-3 positivity does not appear to represent an active vasculitis. This unique case emphasizes the importance of distinguishing infectious etiologies from an auto-immune process to guide appropriate therapy.

PUB056

**Use of Polymyxin (PMX) B Cartridge in a Patient With AKI and Septic Shock**  
Sobia N. Khan,<sup>1</sup> Sandeep K. Mallipattu,<sup>1,2</sup> <sup>1</sup>*Stony Brook University, Stony Brook, NY;* <sup>2</sup>*Northport VA Medical Center, Northport, NY.*

**Introduction:** Polymyxin (PMX) B cartridge has been reported to remove endotoxin from the bloodstream and decrease mortality in patients with AKI and septic shock.

**Case Description:** 36-year-old female with HTN and history of opioid use admitted with severe lethargy. Vitals: Tmax 39.6, HR 110, BP 85/58. wbc 12.91, H/H 14.7/49.4, platelets 182, BUN/Cr 45/5.56, Na 138, K 6.5, Hco 17, Ua bland. CXR: bilateral patchy opacities concerning for aspiration pneumonia. CT abdomen/pelvis negative for fracture or hardware complication. Blood cultures negative. She received intravenous fluid, antibiotics, norepinephrine for suspected septic shock in the setting of possible aspiration Pneumonia and was intubated. For acute kidney injury and shock liver required continuous renal replacement therapy and N-acetylcysteine. Screened for septic shock, multiple organ dysfunction score (MODS) above 9 and high endotoxin activity levels (> 0.60). She qualified for randomized clinical study [NCT03901807] for comparison of hemoperfusion treatment of cartridge containing polymyxin-B affixed to polystyrene fibers versus standard medical management for sepsis and was randomized to the treatment arm. As per protocol, she received two sessions of 2-hour hemoperfusion treatment 24 hour apart. EAA and hemodynamics monitored. Post treatment, hemodynamics improved, weaned off norepinephrine and oxygen requirement, 100% to 40%. CRRT was discontinued after 2 days. Multiorgan failure improved but no improvement in mental status, attributed to anoxic brain injury secondary to aspiration pneumonia. EEG showed diffuse slowing. MRI brain revealed diffuse hypoxic ischemic encephalopathy. She was discharged from hospital after 3 weeks, to Rehab, was responding to verbal stimuli and would grunt, stayed at rehab for 4 months and with intense therapy, returned to baseline.

**Discussion:** Our patient was a candidate for the study using Polymyxin B hemoperfusion treatment based on MODS > 9 and high EAA (0.62). Her blood cultures were negative. Elevated endotoxin activity likely translocated from the GI tract. Following treatment with PMX, MODS improved from >9 to 5, hemodynamics improved, her FiO2 requirement decreased to 40%, she was weaned off norepinephrine, AKI resolved, and she was off CRRT. PMX cartridge has shown to remove endotoxin from the bloodstream.

PUB057

**Impact of Intense Physical Activity in Renal Risk**  
Henrique S. Sousa, Ana Fernandes, Pedro A. Cruz. *Hospital das Forças Armadas, Lisboa, Portugal.*

**Background:** Intense physical activity is associated with dehydration and risk of AKI. Army citizens are subjected to intense exercise and it is not well known what happens to their renal function immediately after exercise.

**Methods:** The authors designed a trial to evaluate renal risk immediately after intense exercise, and features associated. Inclusion criteria: Army citizens; Used to do intense physical exercise; Healthy Exclusion criteria: Participants who did not finish the

exercise or who were identified at renal risk before the exercise Renal risk was defined by a positive result in nephrocheck<sup>®</sup> test. Participants did forced marches (16Km) outside during three hours carrying weight. We evaluated their clinical condition before and after the activity. Moreover, renal function was evaluated by creatinine and nephrocheck previously and after the exercise.

**Results:** 44 subjects enrolled, 41 conclude the exercise and 6 excluded because at renal risk before the exercise. Mean age of the participants was 20±3.5 years, their body mass index was 22.51±1.75. The mean weight each participant had to carry was 37.35Kg. Participant's lost an average of 1.7±0.64 kg, corresponding to a loss of 2.35% of their weight. After the intense physical activity: 13 patients were in renal risk according to nephrocheck; 18 patients had AKI according to KDIGO definition, 8 patients had both AKI and positive nephrocheck. Neither the percentage of lost weight or the % of added weight were associated with increased renal risk.

**Conclusions:** On one hand the population of the study is healthy, fitted, homogeneous, which is unusual in these kind of studies. On the other hand, the sample is small and follow up of the participants was short. We were able to identify 18 subjects in AKI, 8 of whom were identified at renal risk by nephrocheck, which do not allow us to use it straightforward in this population.” We think that nephrocheck maybe can be added to renal risk evaluation since a single measurement is worth valuable.

**He Tried to Get Drunk but Got Dialyzed Instead: A Case of Ethylene Glycol Intoxication**  
Safa Moursy, Priyanka Jagannath, Khaled Shawwa. *West Virginia University, Morgantown, WV.*

**Introduction:** Ethylene glycol (EG) is a toxic alcohol found in antifreeze solutions. It's ingested w/ the intent of suicide or inebriation. EG intoxication presents w/ neurologic, pulmonary, cardiac, & renal dysfunction.

**Case Description:** 31 y/o M brought to the ED after found unresponsive. Labs: Na 143, K 7.8, Cl 106, CO2 5, BUN 30 mg/dL, Cr 2.59, Ca 9.6, Phos 10.8, lactic acid 3.8, pH <6.81, pCO2 51, lactate >17.5, serum Osm 346 mOsm/kg. UDS (+): benzos, meth, cannabinoids, & fentanyl. Serum EG levels returned 4 days later at 505.7 mg/L. Urine examined under Wood's lamp was fluorescent. He was started on Fomepizole & HD. Renal biopsy showed diffuse ATN w/ associated calcium oxalate deposition w/in tubular lumens, consistent w/ h/o EG intoxication leading to hyperoxaluria. His renal function gradually improved & returned to normal w/in 2 weeks.

**Discussion:** The harmful effects of EG occur due to accumulation of its toxic byproducts, oxalic & glycolic acid. ADH plays a key role in this process by catalyzing oxidation. An increased osmolal gap is prominent early due to accumulation of unionized alcohols. As metabolism proceeds, osmolal gap decreases w/ formation of ionized metabolites. Conversely, anion gap is lowest before EG is metabolized & increases w/ formation of ionized metabolites. Early recognition of toxic alcohol ingestion is crucial as early treatment w/ antidotes serve as inhibitors of ADH which prevents their metabolism to their toxic end products. HD can be used to remove the parent alcohol & its toxic byproducts. EG has a low molecular weight, high water solubility, low protein binding, & small volumes of distribution, all of which favor rapid removal by ECTR.

PUB059

**Tubulointerstitial Nephritis (TIN) in a 36-Year-Old Woman With Crohn Disease and Iritis**  
Trey Richardson,<sup>1</sup> Antonette Veronica B. Hernandez,<sup>1,2</sup> William H. Fissell,<sup>1,2</sup> Mark Lusco.<sup>1,3</sup> <sup>1</sup>*Vanderbilt University Medical Center, Nashville, TN;* <sup>2</sup>*Vanderbilt University Division of Nephrology and Hypertension, Nashville, TN;* <sup>3</sup>*Vanderbilt University Medical Center Department of Pathology Microbiology and Immunology, Nashville, TN.*

**Introduction:** TIN is due to infiltration of inflammatory cells into the renal interstitium. TIN is a frequent cause of acute kidney injury (AKI) and is typically due to drugs, infections, or systemic inflammatory conditions including inflammatory bowel disease and tubulointerstitial nephritis with uveitis (TINU). What follows is a patient with a classic presentation of ischemic ATN later found to have TIN on kidney biopsy.

**Case Description:** A 36-year-old woman with Crohn's disease (on ustekinumab & mesalamine), HLA-B27 positivity, RA, and remote history of iritis, presented with 2 months of hematochezia, anorexia, and weight loss. Her Scr was 6.24 mg/dL (baseline 0.7 mg/dL). A UA showed moderate protein, LE, 288 WBCs, 7 RBCs. UPCr was 0.2 mg/g. Serologic work up and SPEP/UPEP were negative. Infectious work up including *C.difficile* testing and urine culture was negative. Her omeprazole was changed to famotidine and her mesalamine was stopped. Her Scr improved to 3.55 mg/dL with volume expansion. Her Scr remained elevated at 2.7-2.9 mg/dL 2.5 months later. Kidney biopsy was pursued and showed TIN with moderate interstitial lymphocytic infiltrate, occasional tubulitis, ATI, interstitial edema, 60% fibrosis. She was started on prednisone 40mg daily which was tapered after 2.5 months due to side effects. Her most recent Scr was 2.1mg/dL.

**Discussion:** Here we present a case of AKI with persistent renal dysfunction initially felt to be the result of ATN. However, her history of iritis prompted a renal biopsy out of suspicion for TINU syndrome. Her biopsy did in fact reveal TIN and initiation of glucocorticoids led to some improvement in renal function. In systematic reviews, TINU syndrome is more common in the pediatric population. Adult presentation is a risk for AKI and progression to CKD. No randomized control trials exist to guide therapy for TIN, however, retrospective studies have suggested early initiation of glucocorticoids is associated with improvement in renal function.

Interstitial infiltrate with tubulitis on silver stain

PUB060

Two Cases of Postpartum Thrombotic Microangiopathy (TMA) Associated With Renal Cortical Necrosis (RCN) Treated With Eculizumab

Nurit S. Katz, Karim Yatim, Yael Kushner Heher, Reza Zonozi, John Niles, Anushya Jeyabalan. Massachusetts General Hospital, Boston, MA.

**Introduction:** Postpartum TMA is a rare potential cause of RCN, often with hemorrhage preceding acute kidney injury (AKI). The utility of complement blockade in this setting is unknown. We describe 2 patients who achieved renal recovery post eculizumab therapy.

**Case Description:** **Case 1:** A 35 y.o woman with history of HTN was admitted for premature rupture of membranes and chorioamnionitis at 31 weeks gestation requiring Caesarean section, complicated by hemorrhagic shock and E. Coli bacteremia. She developed abrupt anuric AKI requiring HD, concurrent microangiopathic hemolytic anemia (MAHA) and low C3 levels. Kidney biopsy revealed severe TMA with RCN (Figure 1). Eculizumab therapy resulted in rapid hematological improvement. After 8 doses of eculizumab, 3 months postpartum, her kidney function improved and both HD and eculizumab therapy was stopped (Table 1). Complement panel was negative. **Case 2:** A 37 y.o woman presented after spontaneous septic abortion at 5 weeks gestation requiring dilation and curettage complicated by significant hemorrhage and abrupt anuric AKI requiring HD. Labs revealed concurrent MAHA and disseminated intravascular coagulopathy (DIC). Contrast CT revealed bilateral RCN (Figure 2). Given ongoing MAHA and AKI, renal TMA was clinically diagnosed. After 2 doses of eculizumab, she had rapid hematological improvement and 4 months postpartum, she had adequate renal recovery to stop HD (Table 1). Functional complement panel showed mild complement dysregulation.

**Discussion:** Postpartum TMA due to alternative complement pathway defects appears to be associated with RCN, a devastating renal complication of pregnancy. Eculizumab, an inhibitor of complement protein C5, may lead to favorable renal outcomes in this population.

Creatinine trends

	baseline Cr	Day of AKI (postpartum day)	Cr on day of dialysis initiation	Cr upon discharge* *On iHD	Cr Most recent* *Off iHD

Experience of Continuous Renal Replacement Therapy in Critically Ill Patients With AKI: A Single-Center Retrospective Study

Juan D. Diaz Garcia, Claudia B. López, Irving G. Ramirez, Julio C. Nieto, Pedro Morales Molina, Pamela Prado, Beatriz R. Cerezo Samperio, Abel Humberto V. Compean, Karina Chimbo Lituma, Mario Alamilla Sanchez. Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.

**Background:** Acute kidney injury is a complication of critical patients that has been associated with a high risk of hospital mortality, where identifying modifiable and non-modifiable clinical variables at the start of dialysis that are associated with hospital survival can help, not only in prognosis, but also in clinical classification. Whether this reflects the severity of the disease or is an independent risk factor is unknown.

**Methods:** A descriptive, observational and retrospective study was carried out in patients with acute kidney injury requiring continuous renal support therapy in the intensive care units of a tertiary reference medical center, from January 2013 to March 2022.

**Results:** Of the 136 critically ill patients with acute kidney injury admitted to intensive care units, the mean age was 56.45 ± 19.81 years, with a predominance of men (61%) and the mean SOFA score was 11.8 ± 4.3 (table 1). The indications for CRRT were mainly fluid overload (22%) and acute kidney injury with oliguria and fluid overload (60%). Mean overload-adjusted serum creatinine before the start of CRRT was 3.37 ± 1.18 mg/dl, fluid overload was 12.56 ± 4.45 liters, with a percentage of 13.2 ± 6.4%. The most frequent causes of AKI were shock of any cause (72%) (of these was mainly due to cardiogenic shock (51%)), of the total number of patients, 82% required vasopressor support and 86% invasive mechanical ventilation, the most common modality of CRRT being continuous venovenous hemodiafiltration (CVVHDF) (72%). The incidence of overall survival was 27%.

**Conclusions:** The results of our study suggest that acute kidney injury in patients undergoing continuous renal replacement therapy presents a high risk of in-hospital death. This increased risk cannot be explained solely by a more pronounced severity of the disease. Our results provide strong evidence that acute kidney injury presents a specific and independent risk factor for poor prognosis.

Mucormycosis of the Lung and Kidney Presenting as Drug Induced Vasculitis

Mohamed Hassanein,<sup>1</sup> Tarek Ashour,<sup>2</sup> Jane K. Nguyen,<sup>2</sup> Sevag Demirjian.<sup>2</sup>  
<sup>1</sup>University of Mississippi Medical Center, Jackson, MS; <sup>2</sup>Cleveland Clinic, Cleveland, OH.

**Introduction:** Mucormycosis (MM) is a rare opportunistic, angio-invasive infection most commonly caused by *Rhizopus* species. Infection spreads through spore inhalation or wound inoculation to multiple organs including lungs, paranasal sinuses, brain, skin and rarely to the kidneys. We report a case of MM of the lung and kidney presenting as drug induced vasculitis.

**Case Description:** A 79-year-old gentleman with a history of coronary artery disease, hypertension (on hydralazine), heart failure and atrial fibrillation was transferred to our hospital for management of acute hypoxic respiratory failure and bronchoalveolar hemorrhage secondary to antineutrophil cytoplasmic antibody (ANCA) vasculitis. He received intravenous steroids for 10 days before being admitted to our hospital. Labs on admission showed creatinine 1.7 mg/dL (reference range 0.73 – 1.22 mg/dL), blood urea nitrogen 81 mg/dL (reference range 9 – 24 mg/dL), glucose 214 mg/dL (reference range 74 – 99 mg/dL), and white blood cell count 27 k/uL (reference range 3.7 – 11 k/uL). Urinalysis showed 3+ blood and 11-25 red blood cells per high power field. Computed tomography (CT) of the chest showed ground glass opacities suggestive for diffuse alveolar hemorrhage and two cavitary lesions in the right lung. Serological workup showed positive myeloperoxidase (MPO) ANCA, anti-nuclear antibodies (ANA) and anti-histone antibodies suggestive for drug induced vasculitis. Kidney biopsy showed tubulointerstitial and vessel wall invasion with fungal hyphae suggestive for *Mucorales* with negative immunofluorescence and no evidence of glomerulonephritis. He was started on amphotericin B but eventually transitioned to comfort care measures. Autopsy results showed disseminated MM involving the lungs, right kidney and right ureter.

**Discussion:** MM of the native kidneys is extremely rare. Risk factors include immunosuppression, diabetic ketoacidosis, disrupted skin barrier, and iron overload. Spore inhalation or direct skin inoculation leads to angioinvasion, dissemination, and multi-organ failure. We present a case of MM of the lung and kidney presenting as drug induced vasculitis. Albeit rare, MM should be considered in the differential diagnosis of hemoptysis and kidney failure. Biopsy is imperative to avoid unnecessary immunosuppression which could be fatal in such cases.

PUB063

Safety and Diagnostic Yield of Protocolized Percutaneous Kidney Biopsies in Mechanically Ventilated Patients With AKI

Christopher Estiverne, Gearoid M. McMahon, David B. Mount, Giada Bianchi, Helmut G. Rennke, Peter G. Czarnecki. *Brigham and Women's Hospital, Boston, MA.*

**Introduction:** Ultrasound-guided percutaneous kidney biopsy and renal histopathology remain the gold standard in the differential diagnosis of kidney disorders. However, kidney biopsies are rarely considered in patients in the ICU, and even less in intubated and mechanically ventilated patients. We sought to establish a protocol for kidney biopsies in mechanically ventilated patients, utilizing ICU resources to manage patient-related procedural risks.

**Case Description:** We designed a protocol, involving deep sedation, neuromuscular blockade and prone positioning of the patient. Percutaneous ultrasound-guided kidney biopsy is performed during an inspiratory pause maneuver on the ventilator, minimizing diaphragmatic motion. We approached the families of 11 mechanically ventilated patients with AKI, in whom biopsy was deemed necessary, with 7 families consenting to the procedure. 5/7 patients were already on renal replacement therapy (RRT) on day of biopsy. 6 biopsies revealed acute tubular necrosis (ATN) in different histopathological contexts: 3/6 patients had ATN with no other pathologic findings, one patient had coexisting interstitial nephritis, one had minimal change glomerulopathy resulting in ATN, and one had severe TMA leading to cortical necrosis. Another patient had no ATN, but severe arteriolar sclerosis and chronic thrombotic microangiopathy (TMA). Perinephric hematomata were detectable in 6/7 biopsied patients. Except in one patient, the extent of perinephric hematoma did not correlate with the need for additional postprocedural imaging studies or transfusion requirement. In all biopsied patients, the pathologic diagnosis led to a change in management, either through the initiation of new therapies, through discontinuation of existing therapies, or through readdressing the goals of care.

**Discussion:** Our experience demonstrates that kidney biopsies in carefully selected patients in the ICU with AKI yield highly informative histopathologic diagnoses resulting in important management decisions in all examined cases. Of the 7 patients biopsied, 6 patients eventually recovered and no longer required RRT. We conclude that in a high-risk population, a protocol like ours may optimize procedural conditions and complication management.

PUB064

Riboflavin Excretion as a Functional Biomarker of Renal Tubular Secretion

Valentina Sedlacek,<sup>1</sup> Martin Sedlacek.<sup>2</sup> <sup>1</sup>University of Rochester, Rochester, NY; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Nutritional yeast is a health food widely used in vegetarian and vegan diets that contains exceptionally high amounts of Riboflavin (vitamin B1). Riboflavin is excreted by renal tubular secretion. Here we use nutritional yeast to investigate if riboflavin could be a practical functional marker of renal tubular secretion.

**Methods:** We collected and examined urine before and after a meal containing nutritional yeast.

**Results:** Figure 1: Urine before and after a meal containing nutritional yeast with riboflavin highlighted by yellow fluorescence. This simple experiment demonstrates that riboflavin is detectable by fluorescence.

**Conclusions:** In the kidney riboflavin is filtered and both reabsorbed and secreted in the proximal tubule with secretion predominant on a normal diet. Riboflavin transport has been demonstrated in MDCK cells and hence might occur also in the distal tubule. Secretion is subject to competitive inhibition by probenecid, suggesting that organic anion transporters are involved. The measured renal clearance of riboflavin in humans is 570-680ml/min/1.73m<sup>2</sup>, several fold higher than GFR, because of secretion. Because of protein binding, free riboflavin excretion rate exceeds RBR. Riboflavin and its metabolites can be detected by spectrophotometry around 450nm at concentrations as low as 0.3 ppm. A study of the natural fluorescence of human urine with normal renal function and with CKD showed that at the range of 450nm there are no other potentially interfering endogenous substances. Tubular secretion of riboflavin is an active tubular process, while accumulation of creatinine is a passive process with changes detectable only after a time delay. Thus, urine riboflavin excretion could serve as a functional biomarker of the state of the renal tubule in various conditions, such as ATN and other forms of AKI, quantifiable by simple spectrophotometry, thanks to the fluorescent properties of riboflavin.

Riboflavine visualized by yellow fluorescence under Woods light.

PUB065

A Study of Clinical Characteristics and Outcomes of Patients With AKI Hospitalized in a Tertiary Care Centre in South India

Prafull B. Chege, Manjusha Yadla. *Gandhi Hospital Gandhi Hospital, Secunderabad, India.*

**Background:** Acute kidney injury (AKI) is a major public health concern, associated with high mortality. More than 85% of the global burden of AKI is from developing countries. AKI in developed countries tends to affect elderly patients with comorbidities, and result in higher mortality rates. The proportion of community acquired AKI is more and most often a single reversible factor such as infection, toxin, volume depletion, or drugs might be responsible. AKI is common in critical care units and is a major factor contributing to adverse outcomes. In this Study, KDIGO criteria is used for the diagnosis of AKI.

**Methods: Patients and Methods:** This retrospective study with 859 AKI patients, admitted at Gandhi Hospital, Secunderabad, from January 2020 to April 2022 at having a serum creatinine level greater than 1.4 mg/dl and blood urea greater than 40 mg/dl. The AKI patients aged less than 18 years at the time of enrollment and ultrasound evidence of bilaterally small kidneys suggestive of chronic renal failure were excluded from the study.

**Study design:** This is Observational Retrospective study.

**Results:** A total of 859 Patients were included in this Study and Analysis includes clinical profile, epidemiological data, lab parameters and outcomes.

**Conclusions:** Sepsis was most common cause for Acute Kidney Injury. Decreased urine output was most common presenting symptom followed by fever breathlessness. Patients recovered completely were 30.15%, Partially recovered 27.7% and CKD in 9.20%. Out of 859 Patients 576 (67.05%) Survived and 139(16.18%) died. Factor affecting mortality were age, thrombocytopenia and Patients on vasopressors.

Table 7: Etiologies of acute kidney injury		
Etiology	Count	Percentage

### Clinically Diagnosed Bile Cast Nephropathy in a Patient With Severe Alcoholic Hepatitis and COVID-19 Pneumonia

Gaoyuan Huang, Winston Lee, Adel S. El-Hennawy, Elena Frolova. *New York City Health and Hospitals Coney Island, Brooklyn, NY.*

**Introduction:** Bile cast nephropathy (BCN) has been underreported and there are no established treatment guidelines. Renal biopsy is the gold standard for diagnosis but could be a challenge in some situations. BCN in patients with COVID-19 has not been reported. We present a case of clinically diagnosed BCN in an alcoholic patient with COVID-19 pneumonia.

**Case Description:** A 47-year-old Caucasian man with a history of fatty liver and alcohol abuse (last drink was 4 days before admission, baseline bilirubin was normal) presented with unsteady gait and tremors. He was fully oriented on admission. ALT/AST 123/352 U/L, Total bilirubin (TB) 11.5 mg/dl, direct bilirubin (DB) 8.5 mg/dl, albumin 3.1 g/dl, INR 1.4, normal WBC and PLT. Scr normal. Urine analysis (UA) showed large bilirubin but no cast. COVID-19 pneumonia existed. Hepatitis B and C negative. Abdominal ultrasound and CT ruled out liver cirrhosis, portal hypertension or ascites. MRCP excluded biliary duct obstruction. Dexamethasone was given for 10 days. However, TB and DB further trended up to 21.8/10 mg/dl (figure 1) while ALT and AST went down to 7/106 U/L. Mental status altered with ammonemia and INR 1.9. UA showed large bilirubin, moderate bilirubin casts, no proteinuria or hematuria, no bacteria. Meanwhile, Scr rapidly increased to 6.73 mg/dl. The patient started hemodialysis (HD) and was intubated. Renal biopsy was suspended due to his unstable condition. TB began trending down on day 34, accompanied by decreasing urine bilirubin casts. Renal function subsequently improved with increasing urine output and was finally normalized. The patient was extubated later.

**Discussion:** Albumin and fluid challenge failed; prerenal azotemia was excluded. The absence of portal hypertension or ascites made hepatorenal syndrome less likely. Despite the lack of renal biopsy, the temporal coherence between severe hyperbilirubinemia, urine bilirubin casts and acute renal injury (AKI) strongly favored the diagnosis of BCN. Additionally, concurrent COVID infection may exacerbate hyperbilirubinemia and AKI.

## PUB067

### Massive Rhabdomyolysis in the Setting of Influenza A Infection Requiring Renal Replacement Therapy

Aisha Batool,<sup>1,2</sup> Shahzad Chaudhry,<sup>3</sup> Muneeba Sarosh,<sup>2</sup> Muhammad A. Omar,<sup>4</sup> Sarah E. Simon.<sup>6</sup> <sup>1</sup>Medical College of Wisconsin, Milwaukee, WI; <sup>2</sup>Ascension Columbia St Mary's Hospital Milwaukee, Milwaukee, WI; <sup>3</sup>Aurora Health Care, Milwaukee, WI; <sup>4</sup>TidalHealth Nanticoke, Seaford, DE; <sup>5</sup>Ascension Columbia St Mary's Hospital Milwaukee, Milwaukee, WI; <sup>6</sup>Midwest Nephrology Group, Milwaukee, WI.

**Introduction:** Rhabdomyolysis can range from an asymptomatic illness to severe muscle breakdown leading to Acute Renal Failure which can be life threatening. Massive rhabdomyolysis is defined as Creatine Kinase Level greater than 50,000 u/L. Acute renal failure in these patients can sometimes require renal replacement therapy in spite of aggressive fluid resuscitation.

**Case Description:** Our patient is a 36-year-old black male who presented to the Emergency Room with flu-like symptoms and generalized body aches. He tested positive for influenza A and also had massive rhabdomyolysis with serum Creatine Kinase level 1,358,480 u/L. He had overt uremic symptoms with azotemia and serum creatinine level of 7.9 mg/dl. He was profoundly hypocalcemic with a serum calcium level of 4.2 g/dl.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

He was transferred to the Intensive Care Unit and Continuous Venovenous Hemodialysis was initiated. He was eventually switched to intermittent hemodialysis and had full renal recovery in 6 weeks.

**Discussion:** Rhabdomyolysis is defined as breakdown of striated muscle fibers and release of large quantities of intracellular contents into plasma and extracellular compartment. Influenza virus being implicated in nearly 33% of known Viral-induced rhabdomyolysis. Acute Renal Failure is the most serious complication of rhabdomyolysis and develops in almost 33% of patients. Acute Renal Failure is the result of accumulation of nephrotoxic pigment myoglobin along with hypovolemia that leads to renal hypoperfusion. Mainstay of treatment remains early and aggressive fluid resuscitation along with correction of electrolytes. Early dialytic treatment in these patients allows not only to avoid life-threatening complications, moreover it's a pathogenetic treatment by removal of a great amount of myoglobin. This case is a reminder for clinicians to expect rhabdomyolysis in viral illnesses. Depending on the severity of disease, prognosis is overall good, mostly patients recover from it with less permanent damage.

### Graphical Description of Creatine Kinase and other Laboratory Parameters during hospital stay

## PUB068

### Microscopic Polyangiitis Presenting as Diffuse Alveolar Hemorrhage

Stephanie Rothweiler,<sup>1</sup> Shiguang Liu,<sup>2</sup> Raafat F. Makary,<sup>2</sup> Alaa S. Awad.<sup>1</sup> <sup>1</sup>University of Florida, Jacksonville, FL, Jacksonville, FL; <sup>2</sup>University of Florida Jacksonville Department of Pathology and Laboratory Medicine, Jacksonville, FL.

**Introduction:** Microscopic Polyangiitis (MPA) is a rare vasculitis with devastating complications leading to multiorgan failure.

**Case Description:** We present a case of a 39-year-old male with history of hypertension, and tobacco use was admitted for acute renal failure and respiratory failure. Serology was significant for hemoglobin 3.1 gm/dl, creatinine of 12.70 mg/dl. Urine studies significant for hematuria and proteinuria. Chest imaging showed extensive bilateral infiltrates predominantly in the bases consistent with diffuse alveolar hemorrhage (DAH) associated with hemoptysis. He was intubated and started on continuous renal replacement therapy. Therapeutic plasma exchange (TPE) was initiated immediately for 6 sessions in addition to pulse steroids with improvement of respiratory function; but not renal function. Renal biopsy immunofluorescence revealed pauci-immune complex crescentic glomerulonephritis, acute tubular injury with marked acute interstitial nephritis, and mild arterial and arteriolar sclerosis. Anti-myeloperoxidase antibody level of >100 U/mL, positive P-ANCA titer (1:320) consistent with MPA. Induction immunosuppressive therapy was initiated. He was extubated and transitioned to intermittent hemodialysis. The patient demonstrates no long-term sequelae of DAH, however, remains on long-term intermittent hemodialysis, steroids and rituximab as he developed hemorrhagic cystitis from Cytosan.

**Discussion:** MPA is an acknowledged cause of diffuse alveolar hemorrhage, but is observed in less than a third of cases (1). We present a case with DAH as the presenting feature of vasculitis associated with renal failure which are more commonly observed. Vasculitis with DAH and renal failure often leads to a fulminant disease course (2). Other metrics have been validated as poor prognostic factors including a history of cardiovascular disease, tobacco use, mechanical ventilation, age >60 years, and shock (3). Our patient met all parameters aside from age. Despite presenting critically ill with multi-organ failure and poor prognosis, his clinical course was likely shifted due to aggressive management with TPE and prompt immunosuppressive therapy; but remains on dialysis.

## PUB069

### Severe AKI in a Patient With G6PD Deficiency and Acute Hepatitis A Infection

Wid Yaseen,<sup>1</sup> Jonathan S. Zipursky,<sup>1,2</sup> Bourne L. Auguste.<sup>1,3</sup> <sup>1</sup>University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; <sup>2</sup>Division of Clinical Pharmacology and Toxicology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada; <sup>3</sup>Division of Nephrology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada.

**Introduction:** Hepatitis A virus (HAV) is a vaccine-preventable infection that classically causes mild illness. Less than 1% of patients with acute HAV develop fulminant liver failure, and those with comorbidities are at increased risk.

**Case Description:** A 25-year-old male presented to a community hospital with a 1-week history of fevers, night sweats, 4kg weight loss, and dark urine. Past medical history included sickle cell trait and he was not taking any medications. He returned from a 1-month trip to India 5-days prior to symptom onset. On presentation, he was afebrile and skin was jaundiced with icteric sclera. Abdominal exam showed palpable hepatomegaly. Bloodwork revealed hemoglobin 70g/L, WBC 84x10<sup>9</sup>/L (5x10<sup>9</sup>/L blasts and significant neutrophilia), creatinine 267μmol/L, lactate 5.9mmol/L, ALT 3,538, ALP 99, total bilirubin 784, LDH 10,000U/L, and undetectable haptoglobin. Given the blasts noted on peripheral smear, the patient was suspected to have acute leukemia, and an infectious and autoimmune work up was also sent. He was transferred to our hospital for management. Repeat peripheral blood film revealed spherocytes without increased blasts, and flow cytometry was consistent with a leukemoid reaction. Coomb's test was negative. The patient had rapid clinical deterioration requiring hemodynamic support in the ICU. He developed oligoanuric acute kidney injury (AKI) and renal replacement therapy was initiated. Urinalysis at that time showed bile pigmented casts and no other microscopic signs of glomerular injury. A diagnostic work up revealed hepatitis A IgM antibodies and a positive glucose-6-phosphate dehydrogenase (G6PD) deficiency screen. The patient was treated supportively and had dramatic clinical improvement with complete recovery in hepatic and renal function over the next weeks.

**Discussion:** The presentation of severe AKI, hyperbilirubinemia, and bile casts was highly suggestive of bile cast nephropathy, an uncommon cause of acute tubular necrosis. The patient's enzymopathy and acute HAV resulted in fulminant liver failure and severe oxidative hemolysis, leading to direct nephrotoxicity and renal tubular ischemia from systemic hypoperfusion. Although rare, clinicians should recognize bile cast nephropathy as an important mechanism of AKI. Prompt recognition allows for early identification of the cause of liver dysfunction and prevention of further renal injury.

PUB070

**A Case of Hydralazine Induced c-ANCA Associated Vasculitis**  
Nimit Dalal,<sup>1</sup> Ankur Shah,<sup>2</sup> Harshil Fichadiya,<sup>3</sup> <sup>1</sup>Western Reserve Health Education, Warren, OH; <sup>2</sup>Brown University, Providence, RI; <sup>3</sup>Monmouth Medical Center, Long Branch, NJ.

**Introduction:** The incidence of drug induced vasculitis in long term hydralazine users is estimated at 10 percent. The most frequent manifestation is kidney sparing drug induced lupus. A rarer, more severe manifestation is that of drug induced anti neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV). We report a case of hydralazine induced AAV presenting with acute renal failure.

**Case Description:** A 75-year old male with PMH of stage 3b chronic kidney disease, diabetes mellitus and hypertension was admitted for evaluation of acute kidney injury. 14 months prior, hydralazine had been prescribed for HTN (200 mg daily). Admission serum creatinine(Cr) was 4.9 mg/dL. Urinalysis and sediment examination were notable for hematuria, proteinuria, dysmorphic red blood cells, and hyaline casts. Serology is summarized table 1. Renal biopsy showed pauci-immune necrotizing and crescentic glomerulonephritis, with 2 out of 38 glomeruli displaying active necrotizing cellular crescents. Dual positivity of ANCA and ANA along with microscopic findings of glomerulonephritis led to a diagnosis of drug induced AAV. Hydralazine was discontinued. Methylprednisone 1 g daily for 3 days was prescribed followed by taper. 4 doses of rituximab were given. 3 months later, creatinine stabilized to 2.8 mg/dL.

**Discussion:** Hydralazine induced vasculitis is an underappreciated cause of autoimmune disease; the commoner drug induced lupus in about 10% of patients, and the less common but more severe AAV seen here. The incidence, risk factors, optimal management and long term outcomes are yet to be determined. Management of drug induced lupus and drug induced AAV include different immunosuppression regimens, and knowledge of these complications is critical.

ANA Homogeneous pattern	≥1:1280
ANA confirmation	Positive

**Vancomycin Induced Leukocytoclastic Vasculitis With AKI**  
Sara Alattal, Si Yuan Khor, Amira S. Kamboj. Michigan State University, East Lansing, MI.

**Introduction:** Leukocytoclastic vasculitis (LCV) is a small vessel hypersensitivity vasculitis (SVHV). Vancomycin has the potential to cause different types of immune-mediated hypersensitivity reactions, however, vancomycin-associated LCV (VA-LCV) cases are rare. We present a case of VA-LCV with worsening acute kidney injury (AKI) that improved on discontinuation of vancomycin.

**Case Description:** 45-year-old male patient with diabetes, atrial fibrillation, and ischemic cardiomyopathy presented with left foot pain for 3 days. There were no fevers or chills. Vitals were stable. Physical exam revealed a 4\*4 cm ulcer of the 4th toe and erythema of left foot. Labs were Cr 1.05 (baseline Cr 0.7), BUN 20, WBC 10.9 and ESR 96. MRI of the left foot demonstrated osteomyelitis of the 4th distal and middle phalanges. He was started on cefepime, a day later vancomycin was introduced. Over 24 hours of starting vancomycin he developed a maculopapular rash over bilateral upper and lower extremities. AKI worsened with Cr of 1.26. Punch skin biopsy of the rash showed perivascular and interstitial neutrophilic infiltrate with numerous nuclear dusts, the papillary dermis showed extravasated erythrocytes/microhemorrhage, most consistent with LCV. ANA was negative. Vancomycin was discontinued with resolution of rash and improvement of AKI.

**Discussion:** LCV is a rare SVHV with incidence of 15 cases/million/year<sup>1</sup>. LCV is usually confined to the skin with rare extracutaneous manifestations in less than 30% of cases<sup>2</sup>. When present, extracutaneous manifestations usually involve kidneys, joints and gastrointestinal tract. Reported renal involvement includes an increase in creatinine, tubulointerstitial nephritis and acute renal failure<sup>1</sup>. Different etiologies include medications, infections and malignancies. Compared to other drug induced LCV incidence, VA-LCV cases with involvement of the kidneys are rare. Onset of VA-LCV ranges from within 24hrs to as late as 1 month after drug initiation. Diagnosis is made with punch skin biopsy. Most cases are self-limited and resolve with withdrawal of vancomycin and recovery time ranges from days to weeks<sup>3</sup>. In our patient, the temporal timing between initiating vancomycin and appearance of the rash and increase in creatinine level strongly suggests that the LCV was related to vancomycin. This is further supported by the resolution of rash and AKI following cessation of vancomycin.

PUB072

**Histopathology of Adult Minimal Change Disease Comparing Those With AKI of Differing Stages to Those Without**  
Hillary Grainer,<sup>1</sup> Maria V. DeVita,<sup>1</sup> Vanesa Bijol,<sup>2</sup> Jordan L. Rosenstock.<sup>1</sup> <sup>1</sup>Lenox Hill Hospital, New York, NY; <sup>2</sup>Northwell Health, New Hyde Park, NY.

**Background:** Minimal change disease (MCD) in adults is associated with acute kidney injury in approximately 25% of cases. The pathophysiology of AKI associated with MCD is unclear but is associated with acute tubular injury (ATI) and interstitial edema in many cases. It is not clear if the severity of AKI in MCD correlates with pathologic findings.

**Methods:** We retrospectively reviewed biopsy proven MCD cases from our institution over the last 3 years. Patients less than 18 years of age, those who received kidney transplants, those whose baseline Cr could not be obtained and those with secondary causes of MCD were excluded. We stratified AKI cases based on KDIGO AKI staging and evaluated pathological characteristics including presence and extent of injury, as well as presence of interstitial inflammation.

**Results:** The total number of patients meeting criteria was 61. Those with AKI totaled 16(26%). Based on KDIGO staging 6 patients were stage 1, 7 stage 2 and 3 stage 3. Among patients with AKI, ATI was confirmed in 10/16(63%). Of these, mild ATI was seen in 8(50%) moderate in 2(12%) and no cases of severe ATI. Among those with stage 1 AKI, 3(50%) had mild ATI, 1(17%) had moderate ATI. Among those with stage 2 AKI, 4(57%) had mild ATI, 3 (43%) had no ATI. Among those with stage 3 AKI, 1(33%) had mild ATI and 2(67%) moderate. Those without AKI totaled 45(74%). Among these cases, ATI was present in 14/45 (31%). Mild ATI was seen in 13(29%) and moderate ATI in 1(2%). Interstitial nephritis and edema were noted in three cases overall.

**Conclusions:** The majority of MCD patients with AKI had ATI and this was significantly more common than those without AKI (p=0.027), supporting that ATI is a mechanism of AKI in MCD. The severity of AKI did not clearly correspond with the severity of ATI in this small population, though 2/3 cases with stage 3 AKI had moderate ATI and interstitial nephritis.

**A Unique Case of Daptomycin Induced Myoglobinuria and AKI With Normal Creatinine Phosphokinase Level**  
Brian Monk, Melinda M. Talley, Mohammad Atari. *University of Mississippi, Jackson, MS.*

**Introduction:** Myoglobinuria is the presence of excessive amount of myoglobin in the urine. Most cases are induced by a traumatic or non-traumatic muscle injury that releases myoglobin into the blood and then is filtered by the kidneys. Large amounts of myoglobin can cause acute kidney injury (AKI). Myoglobinuria is usually associated with elevated creatinine phosphokinase (CPK) serum levels. Daptomycin is associated with elevated CPK and an increased risk of rhabdomyolysis. We report on a unique case of daptomycin-induced myoglobinuria and AKI with normal CPK levels.

**Case Description:** A 73-year old man was admitted for the management of an infected diabetic foot ulcer. Initial evaluation was notable for fever and hypovolemic AKI which improved with intravenous fluids (IVF). Empiric treatment with vancomycin and cefepime was started. Antibiotics were deescalated to daptomycin after blood cultures grew *methicillin-resistant Staphylococcus aureus* (MRSA) and *Staphylococcus epidermidis*. An echocardiogram showed no vegetation. Initially, CPK was 302 U/L and creatinine was 0.88 mg/dL. Forty-eight hours after starting daptomycin, creatinine increased without major electrolyte abnormalities. Renal ultrasound was unremarkable. Urine analysis was positive for red blood cells (RBCs) and myoglobin. CPK level was normal at 106 U/L. Fractional excretion of sodium was <1%. The patient was euolemic. Urine microscopy showed numerous intact RBCs and fine granular casts, no white blood cells or RBCs casts, and no dysmorphic RBCs. The patient declined a kidney biopsy. Daptomycin was switched to vancomycin and IVF was initiated. Twenty-four hours after stopping daptomycin, creatinine stabilized and started to improve the following day.

**Discussion:** Daptomycin-induced rhabdomyolysis is one of the rarely encountered side effects of daptomycin administration and is reported in ~5% of patients. Severe myocyte injury resulting in rhabdomyolysis secondary to daptomycin is usually accompanied by muscle weakness and pain, elevated serum CPK, and myoglobinuria. Regular CPK checks and monitoring for myopathy are recommended. As emphasized in this case, myoglobinuria and renal failure can still happen with normal CPK levels. To the best of our knowledge, this is the first reported case describing daptomycin-induced myoglobinuria and AKI without an elevation in CPK serum levels.

PUB074

**Interlobar Pseudoaneurysm With Gross Hematuria 10 Days After Kidney Biopsy**  
Victor A. Canela, Roberto L. Collazo-Maldonado. *Methodist Dallas Medical Center, Dallas, TX.*

**Introduction:** Kidney biopsy remains the gold standard for the diagnosis of kidney pathologies. The procedure is simple, well tolerated and relatively safe. In the last fifteen years and for a variety of reasons, nephrologists have been doing less biopsies in favor for interventional radiology. Bleeding is a rare but important complication of biopsies. Bleeding complications include need for blood transfusion, radiology procedures to control the bleeding and even nephrectomy. Pseudoaneurysm formation are relatively rare with an incidence of <0.01%. Nephrologists, clinicians and interventionists should be aware of these complications occurring after biopsies. This case highlights a patient with gross hematuria ten days after the initial kidney biopsy.

**Case Description:** A 58 y/o AA man with history of DM2, HTN and CKD IV presented with worsening left flank pain and gross hematuria. He had undergone a left kidney biopsy ten days prior due to worsening kidney function. Medication list included torsemide, bicarbonate and amlodipine. On physical exam he was afebrile with BP 197/91 and HR of 87 bpm. There is significant left flank pain and an intact PD catheter on the LLQ. Hb was 8.9 g/dl, platelets 287x10<sup>3</sup>/U/L, K 4.8 mmol/L, BUN was 51 mg/dl, Cr 8.40 mg/dl. INR 1.1 IU and aPTT 25 sec. A CTA showed active extravasation/pseudoaneurysm in the mid pole of the left kidney, there was also edema and inflammatory changes around

the left kidney. He received 1 unit of blood transfused and underwent a successful embolization of the left interpolary artery branch that was feeding the pseudoaneurysm.

**Discussion:** Complications after kidney biopsy are rare and infrequently encountered. Factors such as advance kidney disease and uremic platelet dysfunction, increase the chances of parenchymal bleeding after the procedure. Pseudoaneurysm reports account for less than 0.01% of the total complications. We presented a case of gross hematuria and pseudoaneurysm ten days after a kidney biopsy. This case highlights the importance of Nephrologists and clinicians to recognize the possible complications occurring late after a biopsy. By early recognition, appropriate therapies can be implemented, and better outcomes can be achieved.

PUB075

**Drug Induced Obstruction? A Case of Ketamine Induced Uropathy**  
Latoya N. Gayle, Sylvia Wu, Nathaniel Berman. *NewYork-Presbyterian Hospital/Weill Cornell Medical Center, New York, NY.*

**Introduction:** The habitual use of Ketamine as a recreational drug has been increasing due to its sought after dissociative effect. Numerous nephrological abnormalities including hemorrhagic cystitis, hydronephrosis and resultant chronic kidney disease-classified as Ketamine Induced Uropathy(KIU) have been found in individuals who are regular users. We present a case of KIU in a young male with Acute Kidney Injury(AKI) and Acute Liver injury(ALI)

**Case Description:** A 29-year-old male with history of Substance Misuse–Ketamine~8g/day, occasional cocaine and recurrent hemorrhagic cystitis was brought in by EMS after being found unresponsive. Given Naloxone 4mg with mild improvement. He was found with hyponatremia, AKI and ALI as in figure 1. CT Abdomen/pelvis showed bilateral hydroureteronephrosis extending to the ureterovesical junctions-collapsed bladder, no stones or mass. Foley passed with stat return of >1L urine, then having >6L of urine daily and marked progressive improvement in Cr and electrolytes. He was also given N-acetylcysteine and had progressive improvement in his ALI. At discharge, his Cr was down to 2.11

**Discussion:** The increased recreational use of Ketamine has given rise to nephrological abnormalities, concentrated in younger healthy patients. KIU is postulated to arise from urinary tract destruction;however the exact mechanism remains uncertain. It is thought that Ketamine and its metabolites in the urine act as a direct toxin to the urinary epithelium causing microvascular changes, inflammation and an immune response in the lower and upper urinary tracts. This results in a contracted bladder with vesicoureteral reflux epithelial thickening and hydronephrosis as in our patient. Treatment is immediate decompression with Foley catheter, as in our patient, which most often results in immediate improvement. Counseling on discontinuation of Ketamine is essential as recurrent use can lead to irreversible injury and even ESRD. Clinicians should be alerted to this presentation, which outside Ketamine misuse is rare in otherwise young, healthy patients. Further study is needed into the pathophysiology, treatment and longterm outcomes of patients with KIU

**Mice, Men, and the Kidney: A Puzzling Case of AKI With Hypokalemia**  
Temitayo M. Adebile, Trixie Cruz, Steven C. Borkan, Titilayo O. Ilori, Helena Kurniawan, Kwon Soo Kim. *Boston University School of Medicine, Boston, MA.*

**Introduction:** Leptospirosis is a disease that can caused by bacteria in the urine of infected animals. Rodents are common asymptomatic carriers of Leptospira and maintain the spirochaetes in their proximal tubules (PT). Prevalence of AKI in leptospirosis ranges from 40-60%. Leptospirosis induced AKI is multifactorial and could result from PT or endothelial cell injury as well as interstitial inflammation.

**Case Description:** A 22-year-old male student living in Massachusetts presented with 5 days of non-bloody diarrhea, fever, chills, sweating, and dizziness upon standing. He was brought to the ER because he had fainted multiple times and reported headaches and muscle pains. In the ER he was febrile, tachycardic, and hypotensive with thrombocytopenia (platelets=57,000). His creatinine was elevated at 1.41 mg/dl. He was diagnosed with acute gastroenteritis, given IVF and sent home. Three days later, he presented to the ER again with fever and recurrent syncope. On exam, he had conjunctival injection, scleral icterus and splenomegaly. Lab findings at this time showed a creatinine of 1.45mg/dl, hypokalemia, thrombocytopenia, elevated CPK 4,257, hyperbilirubinemia 7.5 mg/dl, and transaminitis. His serum creatinine continued to trend up and peaked at 1.96mg/d. Peripheral blood smear didn't show schistocytes. The infectious disease and renal services were consulted. Further history revealed that he was from an African country, but he had no recent travel, no TB or other travel related infections. However,

his apartment had been infested with mice. Infectious work up revealed IgM antibodies to Leptospira. Patient had clinical improvement after 48 hours of starting empiric therapy with Ceftriaxone. He completed 7 days of doxycycline with resolution of AST, bilirubin and AKI. His creatinine reduced to 0.8mg/dL on discharge.

**Discussion:** AKI in leptospirosis can be caused by rhabdomyolysis or severe volume depletion leading to acute tubular necrosis. Spirochetes targets endothelial cells and proximal tubular cells causing inflammation and PT defects. Collecting tubules become resistant to vasopressin causing urinary concentrating defect. Hypokalemia occurs commonly due to reversible PT defect. Leptospirosis associated AKI represents a major risk factor for death hence, early diagnosis and management of leptospirosis is crucial to prevent renal involvement or progression.

PUB077

Status Epilepticus With an AKI

Ayesha M. Malik. LSU Health Shreveport, Shreveport, LA.

**Introduction:** Acute uric acid nephropathy is characterized by oliguric renal failure due to overproduction of uric acid and it's deposition in renal tubules. This typically occurs in cases of leukemias and lymphomas or following chemotherapy due to tumor lysis. A few cases have reported uric acid crystals in the urine of patients with status epilepticus (1,2,5). Seizures can cause direct nucleotide breakdown, producing adenosine which is converted to uric acid in the liver. Serum nucleotidase activity can be elevated for several hours after seizures, increased systemic breakdown of adenosine triphosphate, generating urate (1). Seizures cause dehydration and hyperthermia resulting in increased water reabsorption. This increases concentration of uric acid in urine, precipitates in renal tubules. it can cause direct damage to kidneys by activating pro-inflammatory mediators inducing renal vasoconstriction (3).

**Case Description:** 64 year old woman with history of glioblastoma multiforme status post multiple craniotomies for resection, admitted with status epilepticus. She required a midazolam drip and was intubated for airway protection. She subsequently became bradycardic, hypothermic and anuric and remained so for the next 3 days despite 5L of crystalloids. Her creatinine increased from 0.5 to 1.8mg/dl and she developed anasarca. Laboratory studies were significant for BUN 28, C02 17mmol/L, CPK 18U/L and BNP 554 pg/ml. Her renal ultrasound was normal. Initial urine analysis showed a pH of 5 with bland sediment. A second bedside urine analysis performed a few days later revealed abundant uric acid crystals, but no muddy brown casts or RTECs. In the absence of any other etiology for the AKI, a diagnosis of acute uric acid nephropathy was made and she was started on a bicarbonate drip along with furosemide to keep urine pH 6.5-7. Her urine output consequently increased and creatinine normalized.

**Discussion:** Urinalysis with microscopic examination of urine sediment is an important clinical tool for diagnosing AKI. Varghese et al showed that 20-25% cases which yielded no diagnosis on first urine microscopy, showed casts representing acute tubular injury on a second or third urine microscopy done 2-3 or 4-6 days later.(4) In our case, uric acid crystals were identified on a second urine microscopy while the first one was clear. Serial exams may be helpful in uncovering the cause of AKI which a single inspection may miss.

PUB078

Experiences of Intravenous Iron Therapy in Non-Anaemic Functional Iron Deficient Individuals With Non-Dialysis Kidney Disease: A Qualitative Study

Courtney J. Lightfoot,<sup>1,2</sup> Sharlene A. Greenwood,<sup>3</sup> Kate Bramham,<sup>3,4</sup> Alice C. Smith.<sup>1,2</sup> <sup>1</sup>University of Leicester, Leicester, United Kingdom; <sup>2</sup>NIHR Leicester Biomedical Research Centre, Leicester, United Kingdom; <sup>3</sup>King's College Hospital NHS Foundation Trust, London, United Kingdom; <sup>4</sup>King's College London, London, United Kingdom.

**Background:** In non-dialysis CKD, functional iron deficiency (low iron stores in the absence of overt anaemia) is an under-recognised state which may be associated with substantial symptoms, but iron replacement is not routinely offered. The Iron and Muscle study is a multicentre randomised trial of the impact of intravenous iron therapy on physical function in people with non-anaemic functional iron deficiency and non-dialysis CKD. Understanding the patient perspective is an essential part of the evaluation of therapeutic strategies, and to this end the Iron and Muscle study included a qualitative sub-study with the aim of exploring the patient experience of the therapeutic intervention.

**Methods:** A sample of Iron and Muscle participants (stages 3-4 CKD, Hb 110-150 g/L, Ferritin < 100 µg/L and/or Transferrin Saturations (TSAT) <20%) were interviewed three months following receipt of the therapeutic intervention (intravenous infusion of iron or placebo) and completion of 8-weeks exercise training. Semi-structured interviews explored participants' views and experiences of receiving the therapeutic intervention. Data were audio-recorded and transcribed verbatim. Thematic analysis was used to identify and report themes.

**Results:** 17 participants (7 males, average age 58 years (range:39-72 years)) were interviewed, of which 5 received intravenous iron. Interviews lasted an average of 51 minutes (range:28-83 minutes). Five themes were identified: Perceptions of therapeutic intervention received Changes in energy levels/ alertness/ concentration Impact on daily life and activities Impact on psychosocial wellbeing Impact on sleep

**Conclusions:** There were no clear differences in themes reported between treatment groups, with mixed perceptions amongst participants about which therapeutic intervention they had received. Most participants, including some who received the placebo, described increased energy levels, increased ability to perform activities, improved concentration, and better sleep quality with decreased daytime sleepiness. Increased motivation and

wellbeing were frequently discussed, with participants having a more positive outlook on life with CKD. Therapeutic interventions, with exercise components, can improve the quality of life of people living with CKD and non-anaemic functional iron deficiency.

PUB079

Association of Oral vs. Parenteral Iron Therapy With Risk of ESKD and Mortality

Shejuti Paul,<sup>1</sup> Prabin Shrestha,<sup>1</sup> Keiichi Sumida,<sup>1</sup> Fridtjof Thomas,<sup>1</sup> Satya Surbhi,<sup>1</sup> Abu Mohd Naser,<sup>2</sup> Elani Streja,<sup>3</sup> Connie Rhee,<sup>3</sup> Kamyar Kalantar-Zadeh,<sup>3</sup> Csaba P. Kovessdy.<sup>1,4</sup> <sup>1</sup>The University of Tennessee Health Science Center, Memphis, TN; <sup>2</sup>The University of Memphis, Memphis, TN; <sup>3</sup>University of California Irvine, Irvine, CA; <sup>4</sup>VA Memphis Medical Center, Memphis, TN.

**Background:** Iron deficiency can be effectively treated with oral or parenteral (IV) iron, but little is known about the comparative long-term safety of these different modalities. We aimed to investigate the association of oral vs IV iron therapy with the incidence of ESKD and all-cause mortality.

**Methods:** We identified 94,931 incident new users of iron replacement therapy (N=91,945 on oral and 2,986 on IV iron) from 2004-2018 in a large national cohort of US Veterans. We used clinical trial emulation methods including propensity score (PS) matching to account for differences in key baseline characteristics. We examined the association of oral vs IV iron with the incidence of ESKD and with all-cause mortality using competing risk regression and Cox models, respectively.

**Results:** In the PS matched cohort of 5,972 patients (2,986 on oral and 2,986 on parenteral iron), the overall mean (SD) age was 69±11 years, 95% were male, 72% were white, and the baseline eGFR, hemoglobin and ferritin levels were 68±30 ml/min/1.73m<sup>2</sup>, 9.4±1.7 gm/dL and 65 (25<sup>th</sup>-75<sup>th</sup> pctl: 17-231), respectively. There were 246 cases of ESKD (event rate 19/1000PY; 95% CI 16-21) and 3,962 deaths (290/1000PY; 95% CI 281-300) over a median follow up of 1.1 years. IV iron therapy (vs oral iron) was associated with a higher risk of ESKD (subhazard ratio, 1.58; 95% CI 1.22-2.04) and all-cause mortality (hazard ratio, 1.11; 95% CI, 1.04-1.18) (Table).

**Conclusions:** IV iron therapy was associated with a higher risk of ESKD and mortality when compared to oral iron therapy. The long-term safety of IV vs oral iron therapy needs to be examined in clinical trials.

**Funding:** Veterans Affairs Support

Therapy Software for Personalized Anemia Management in Hemodialysis Patients: Description of the Population in a Randomized Controlled Trial

Lemuel Rivera Fuentes,<sup>1</sup> David J. Joerg,<sup>2</sup> Doris H. Fuertringer,<sup>2</sup> Lin-Chun Wang,<sup>1</sup> Amrith U. Patel,<sup>1</sup> Xiaoling Ye,<sup>1</sup> Stephan Thijssen,<sup>1</sup> Peter Kotanko.<sup>1,3</sup> <sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; <sup>3</sup>Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Anemia is a common complication in patients on hemodialysis (HD). The use of erythropoiesis-stimulating agents (ESA) has become standard-of-care (SOC). The non-linear relationship between ESA administration and hemoglobin (Hgb) response is one of the biggest challenges in anemia management. Therefore, we devised a novel software that individualizes ESA-dose prescription based on mathematical modeling of anemia. We present the design of our randomized controlled trial (RCT) and a brief description of the population enrolled.

**Methods:** We conducted an RCT in subjects on HD who were randomized 1:1 to be managed by our personalized ESA-dose recommendation tool (*intervention*) or continue to be on SOC treatment (*control*). For 26 weeks the intervention group received biweekly individualized ESA-recommendations generated by our software to target an Hgb of 10-11 g/dL. These recommendations were provided to an anemia manager who evaluated the subject's clinical status before ESA administration. The software was updated biweekly with the subjects' most recent clinical parameters.

**Results:** Ninety-six subjects were enrolled, 82 were randomized and completed the study (61 [50.2-70.7] years, 58.1% male, 51.2% black, Hgb of 10.5 ± 0.4 g/dL, Ferritin 812 [489.3-1117.5] ng/mL) (Table 1). Forty subjects were randomized to the intervention arm and 42 to the control. When comparing general data (demographics, comorbidities, etc.) there was no statistical significance between the two arms (Table 1).

**Conclusions:** We successfully conducted a clinical RCT to test our therapy software for personalized anemia management in HD patients. The population enrolled and randomized was balanced between the 2 arms.

Report of the Compliance of Renal Anemia in Maintenance Hemodialysis Patients in Sichuan

Mingzhu Li, Daqing Hong. Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China.

**Background:** To investigate the compliance of hemoglobin and iron metabolism in maintenance hemodialysis (MHD) patients in various areas of Sichuan.

**Methods:** A total of 7190 maintenance hemodialysis patients in 41 dialysis centers in Sichuan were enrolled in this study. Hemoglobin, ferritin, transferrin saturation, total iron binding capacity and other indicators were collected. The standard: 110 g/L ≤ hemoglobin < 130 g/L. To analyze the hemoglobin compliance rate and the distribution of iron metabolism parameters in MHD patients.

**Results:** A total of 7190 patients in 41 hemodialysis centers were included in the final analysis, including 58.9% males, 57 (49-69) years of age, 2451 patients were reaching the standard, with a compliance rate of 34.1% (95% confidence interval 33.0%-35.2%). The compliance rate was different in different regions (p < 0.0001), 31.8% (29.5%-34.0%) in northern Sichuan, 36.8% (34.2%-39.5%) in southern Sichuan, 30.1% (27.6%-32.6%) in western Sichuan, 36.1% (33.4%-38.7%) in eastern Sichuan and 35.9% (33.6%-38.1%) in central Sichuan. The compliance rate was 32.0% (30.4%-33.7%) in female patients, 35.5% (34.1%-37.0%) in male patients. Women had a lower compliance rate than men, and the difference was statistically significant (p = 0.002). There was a significant difference in gender (χ<sup>2</sup> = 9.412, p = 0.002). The compliance rate of hemodialysis centers was 33.2% (31.5% - 34.9%) in tertiary hospitals and 34.7% (33.3% - 36.2%) in non-tertiary hospitals, the difference was not statistically significant (p = 0.121). The risk of substandard hemoglobin was increased (OR = 1.167, 95% CI: 1.057 - 1.290). Serum iron 11.4 (8.4-15.4) IU/mL, ferritin 163.3 (60.4-321.9) μg/L, transferrin saturation 25.5% (18.8%-34.1%), total iron binding capacity 48.4 (39.5-56.8) μg/dL; patients with absolute iron deficiency accounted for 18.9% (16.9%-20.9%); patients with absolute iron deficiency with hemoglobin ≥ 110 g/L accounted for 48.0% (41.9%-54.0%), patients with non-absolute iron deficiency accounted for 49.7% (46.8%-52.5%), the difference was not statistically significant (p = 0.616).

**Conclusions:** The compliance rate of hemoglobin in MHD patients in Sichuan is low, with regional differences. The compliance rate in females is lower than that in males, and about 1/4 of MHD patients have absolute iron deficiency.

PUB082

Collagen, Hemodynamics, and Wall Mechanics of Failed vs. Successful Arteriovenous Fistulas From a Single Patient

Hannah M. Northrup,<sup>1</sup> Yong He,<sup>2</sup> Brayden Fairbourn,<sup>1</sup> Timmy C. Lee,<sup>3,4</sup> Scott A. Berceci,<sup>5,6</sup> Alfred K. Cheung,<sup>1,7</sup> Yan-Ting E. Shiu.<sup>1,7</sup> <sup>1</sup>University of Utah, Salt Lake City, UT; <sup>2</sup>University of Florida, Gainesville, FL; <sup>3</sup>University of Alabama at Birmingham, Birmingham, AL; <sup>4</sup>Veterans Affairs Medical Center, Birmingham, AL; <sup>5</sup>University of Florida, Gainesville, FL; <sup>6</sup>VA Medical Center Malcom Randall, Gainesville, FL; <sup>7</sup>VA Salt Lake City Health Care System, Salt Lake City, UT.

**Background:** The low one-year patency rate of mature arteriovenous fistulas (AVFs) remains a significant clinical problem. Although vascular collagen and biomechanics have been suggested to affect AVF function, understanding their roles in AVF patency failure is challenging due to the heterogeneity within the patient population. Here we present a unique case of a patient with two upper-arm AVFs with different 1-year patency outcomes, and investigated whether they had different histological and biomechanical features.

**Methods:** The patient underwent the first AVF (AVFA) creation surgery in the left upper arm, and a piece of the vein was excised at the time of surgery. AVFA was then subject to magnetic resonance imaging (MRI) at 1 day (1D) and 6 weeks (6W), used for hemodialysis, thenbut failed 1 year after creation. The second AVF (AVFB) was created in the right upper arm, and a piece of the vein was excised intraoperatively. AVFB was subject to MRI at 1D and 6W after creation and was used for 5 years until the patient's death. Vein samples were analyzed for collagen content. MR images were used for fluid-structure interaction simulations to analyze hemodynamics and wall mechanics.

**Results:** Both AVFs had similar medial collagen content, but AVFA had more intimal collagen than AVFB (72% vs. 55%). MRI-based cross-sectional lumen area (CSA) was 21.03 and 28.80 mm<sup>2</sup> at 1D for AVFA and B, respectively, and 29.96 and 45.95 mm<sup>2</sup> at 6W for AVFA and B, respectively. At 1D AVFA had smaller average velocity than AVFB (0.46 vs. 0.67 m/s), wall shear stress (WSS) (93 vs. 187 dyne/cm<sup>2</sup>), and vorticity (686 vs. 853 1/s). These values increased from 1D to 6W in AVFA but decreased in AVFB resulting in higher values for AVFA than B (velocity: 0.70 vs. 0.40 m/s, WSS: 213 vs. 128 dyne/cm<sup>2</sup>, vorticity: 1110 vs. 641 1/s). Wall von Mises stress was smaller for AVFA than AVFB at 1D (0.013 vs. 0.017 MPa) but 0.011 MPa for both at 6W.

**Conclusions:** Despite both AVFs being from the same patient and both upper arm, there were differences in intimal collagen content, hemodynamics, and wall mechanics. Low intimal collagen content before AVF surgery and higher velocity, WSS, vorticity, and von Mises stress immediately after AVF creation surgery may be important for long-term AVF patency.

PUB083

Simple Breath Test for Ammonia (NH<sub>3</sub>) as a Potential At-Home Monitoring Method for CKD Patients

Robert A. Latour,<sup>1</sup> Sudha Garimella.<sup>2</sup> <sup>1</sup>Clemson University, Clemson, SC; <sup>2</sup>Prisma Health, Greenville, SC.

**Background:** Chronic kidney disease (CKD) patients do not have the ability to monitor azotemia via an at-home test. To address this, we have developed a simple method for measuring breath NH<sub>3</sub> and conducted a clinical trial with CKD patients (stages 1, 3, 5) with comparison to blood urea nitrogen (BUN) as a potential at-home method for monitoring kidney function.

**Methods:** The device includes a mouthpiece, pressure gauge to monitor flow rate, color-indicating disc, and breath collection bag (1-L Tedlar bag) to control exhaled breath volume (Fig. 1). The color response is read using a MatLab program to quantify the color using an RGB scale. Calibration was conducted in the lab using simulated exhaled breath (5% CO<sub>2</sub> in humidified air with NH<sub>3</sub> ranged from 0 - 10,000 ppb). The clinical trial was conducted with 10 CKD patients, including a patient immediately before and after hemodialysis. Patients exhaled through the device at a designated pressure gauge reading until the Tedlar bag was full (< 1 min), with the test done in triplicate. The color change was then read and the ppb of NH<sub>3</sub> determined using the calibration plot and plotted against the patient's BUN level.

**Results:** High correlation was found between breath NH<sub>3</sub> and BUN level (Fig. 2), with significantly different values in breath NH<sub>3</sub> between stages 1-5 and 3-5, but not between stages 1-3. Results for the patient undergoing hemodialysis showed 58 mg/dL (BUN) and 5,400 +/- 1,400 ppb (breath NH<sub>3</sub>) before hemodialysis and 11 mg/dL (BUN) and 300 +/- 100 ppb (breath NH<sub>3</sub>) after hemodialysis.

**Conclusions:** These results indicate that the developed test has potential as a simple at-home method for patients to monitor their CKD condition, especially in advanced CKD.

## PUB084

# Mechanical Rotatory Method of Anticoagulation-Free Hemodialysis Using a Hemodialysis Filter Rotator With the NxStage Hemodialysis Machine: A UVM-MC-UVM Burlington VT Research Collaboration Effort

Macaulay A. Onuigbo,<sup>1,2</sup> Nick Bowman,<sup>3</sup> Nik Cobb,<sup>3</sup> Aliza George,<sup>3</sup> Steve O'Driscoll,<sup>3</sup> Katie Thomas,<sup>3</sup> Adam Locke,<sup>2</sup> Pablo Vila-Beamonte,<sup>3</sup> Yves Dubief.<sup>3</sup> <sup>1</sup>University of Vermont College of Medicine, Burlington, VT; <sup>2</sup>University of Vermont Medical Center, Burlington, VT; <sup>3</sup>University of Vermont College of Engineering and Mathematical Sciences, Burlington, VT.

**Background:** The maintenance of blood fluidity in the extracorporeal circuit during hemodialysis (HD) often requires systemic anticoagulation. While effective, these anticoagulants cause bleeding, have other side effects, cannot be used in critically ill patients and in the peri-operative period, and add to costs. We recently described a novel mechanical rotational approach to anticoagulation-free HD using the "Locke-Onuigbo" maneuver (Figure 1).<sup>1</sup>

**Methods:** Prototype Completion: In collaboration with the University of Vermont Center for Biomedical Innovation (UVM CBI), five Senior Engineering students from the UVM, under the supervision of Yves Dubief PhD, Associate Professor of Mechanical Engineering, UVM, the first author and his Home Dialysis Program at the UVM Medical Center, have successfully prototyped an AI-modulated hemodialysis filter rotator that enables anticoagulation-free HD using the NxStage HD machine (Figure 2).

**Results:** The Hemodialysis Filter Rotator Prototype running test on the HD machine (Figure 2)

**Conclusions:** This Hemodialysis Filter Rotator enhances the capabilities of enabling sustainable Home HD for ESRD patients and represents a most welcome option in a "post-COVID" world and expands the offering of a convenient, safe and effective Home HD option to thousands of patients who prefer this choice of treatment. Moreover, we would argue that our novel prototype will deliver the unmet need for anticoagulation-free HD in critically ill patients, in the peri-operative period, and in hospitalized patients, in general. Investors and sponsors are welcome.

## PUB085

# Safety Evaluation of Balloon Dilatation of Human Veins Using the Vessel Restoration System for Autologous Arteriovenous Fistula Creation

Yong He,<sup>1</sup> Blake Anderson,<sup>2</sup> Qiongyao Hu,<sup>1</sup> Katalin Kauser,<sup>2</sup> Scott A. Berceli.<sup>1,3</sup> <sup>1</sup>University of Florida, Gainesville, FL; <sup>2</sup>Alucent Biomedical Inc, Salt Lake City, UT; <sup>3</sup>Malcom Randall VAMC, Gainesville, FL.

**Background:** Failure rates of arteriovenous fistula (AVF) maturation are high, especially when veins with suboptimal diameters are used to create vascular access. Natural Vascular Scaffolding (NVS) Therapy targets the natural extracellular matrix of a vein using a photoactivatable small molecule (4-amino-1,8-naphthalimide, 10-8-10 dimer) coated on an angioplasty balloon and activated by an intravascular light fiber (450nm wavelength) during inflation upon delivery to the vein wall before AVF creation. NVS Therapy may promote the successful maturation of small-diameter venous conduits via positive outward remodeling, but its safety needs to be evaluated.

**Methods:** We exposed n=22 freshly harvested human vein segments to intraluminal stretches between 20-106 % using the Vessel Restoration System (VRS)-AVF device. Evidence of histologic disruption (microtears in the intima/media) or loss of vein integrity (fluid leakage from the lumen when pressurized) was assessed.

**Results:** The existing hyperplasia distribution in the veins was similar to earlier reports. Intravascular balloon inflation up to 60% over-sizing from the unpressurized diameter showed no evidence of histologic disruption or loss of vein integrity. However,

distension of the veins with greater than 60% oversizing increased the risk of histologic damage and/or loss of conduit integrity.

**Conclusions:** NVS Therapy delivered to explanted veins and dilated to 60% of their native diameters appears safe and assures that the in vivo application of NVS Therapy in small vein diameters in patients with end-stage renal disease is safe.

## Relationship between Percent Over-Dilation and Vein Injury

## PUB086

# Effects of Paricalcitol on Klotho Protein, Oxidative Stress, and Micro Inflammation in Maintenance Hemodialysis Patients

Lei Tao. The Third Affiliated Hospital of Shandong First Medical University, Jinan, China.

**Background:** To investigate the efficacy of paricalcitol in the treatment of MHD patients with secondary hyperparathyroidism (SHPT), and its effects on Klotho protein, oxidative stress, and micro inflammation.

**Methods:** 10 patients with MHD complicated with SHPT (Abbvie company, the single injection dose is 5ug. After HD, the drug is injected into the patient through the dialysis pathway immediately, 3 TIW) in the Third Affiliated Hospital of Shandong First Medical University were treated with paricalcitol. Serum samples were taken before treatment, 1 month, 2 months and 3 months. The levels of Klotho protein, MDA and hs CRP in serum were measured by ELISA, the iPTH, Ca and P were detected at the same time.

**Results:** The mean levels of serum MDA, hs-CRP and PTH in 10 patients at the end of 3 months of treatment were significantly lower than those at baseline ( $P = 0.0030$ ,  $0.0009$  and  $0.0048$ ), with statistical significance; The mean levels of Klotho protein and Ca at the end of 3 months of treatment were significantly higher than those at baseline ( $P = 0.0067$  and  $0.0188$ ), with statistical significance; There was no significant difference in P.

**Conclusions:** Paricalcitol can effectively control SHPT, significantly reduce the level of iPTH and increase Ca. But it has little effect on the change of P. It can increase the expression of Klotho protein and reduce the level of oxidative stress and micro inflammation in patients.

## The Expression Characteristics and Correlation Analysis of Bone Mineral Density and Bone Turnover Biomarkers in CKD Patients

Jiyi Si,<sup>1,2</sup> Xiaoliang Zhang,<sup>1</sup> <sup>1</sup>Southeast University Zhongda Hospital, Nanjing, China; <sup>2</sup>Southeast University, Nanjing, China.

**Background:** Chronic kidney disease–mineral and bone disorder(CKD-MBD) is a common complication of CKD. It will cause renal osteopathy and vascular calcification.

**Methods:** The patients were divided into four groups: CKD1-2 stage, CKD3-5ND stage, CKD5D stage and calciphylaxis. We analyzed the differences and variation tendency among groups. Logistic regression analysis showed the protect and risk factors for osteoporosis. Finally, we drew the ROC curves to explore if the BTMs can predict the osteoporosis.

**Results:** 326 CKD patients was included. With the progression of the CKD, bone mineral density (BMD) decreased and bone turnover biomarkers(BTMs) became disordered, calciphylaxis patients were more serious than general dialysis patients. Logistic regression analysis showed that male(OR=0.558;OR=0.554)and BMI(OR=0.890;OR=0.911) were the protect factors of both left total hip and lumbar bone loss. LogPTH(OR=5.140)was risk factor of left total hip bone loss. ALP(OR=1.008) was risk factor for lumbar bone loss. The AUC of PTH and ALP were the highest one in the ROC curve of left total hip and lumbar respectively.

**Conclusions:** When the GFR decreased, BMD and BTMs became abnormal gradually. The BMD of calciphylaxis patients were lower than other patients. PTH and ALP were risk factors and best predictors for osteoporosis in CKD patients.

## PUB088

## Prevalence of Secondary/Tertiary Hyperparathyroidism Among Patients With CKD Stage 5 on Hemodialysis at the Victoriano Luna Medical Center

Grace Haziell C. Manarang, Rafael Montepio. *Armed Forces of the Philippines, Quezon City, Philippines.*

**Background:** A common complication of renal failure is Secondary Hyperparathyroidism (SHPT) which if left untreated, can lead to Tertiary Hyperparathyroidism (THPT). Baseline prevalence data is highly required to reduce the risk of complications since both of these can lead to significant morbidity, mortality and additional healthcare cost.

**Methods:** Medical Record of patients with CKD stage 5 on hemodialysis in Victoriano Luna Medical Center were reviewed. Excluded were those who underwent Hemodialysis due to Acute Kidney Injury, those with history of thyroid or parathyroid surgery, those with hypoparathyroidism or primary hyperparathyroidism, active pulmonary tuberculosis, active malignancy and vitamin D disorder. Data collected were age, sex, presence of comorbidities, etiology of CKD, duration and frequency of Hemodialysis, maintenance medication and Laboratory parameters such as intact PTH (iPTH), serum phosphorus, ionized calcium. All data were statistically analyzed.

**Results:** 101 patients were included in the study. 42.5% (43 out of 101) of them have SHPT, while 4.95% (5 out of 101) have THPT. Among those with SHPT, majority were female(74.4%), have single comorbidity (69.7%), and with Chronic Glomerulonephritis (34.5%) as the most common etiology of CKD. On the other hand, all patients with THPT were male, majority(80%) have single comorbidity, but with Hypertensive Nephrosclerosis (40%) as the most common etiology of CKD. In patients with elevated iPTH, majority (71.4%) have iPTH of <300pg/mL, while 16.6% have iPTH level between 300-500pg/mL, and 11.9% have iPTH level of >500pg/mL. Majority of patients with iPTH level of <300pg/mL and between 300-500pg/L were on 2x a week schedule of hemodialysis as compared 3x a week schedule of Hemodialysis in patients with iPTH level of >500pg/mL. Based on data collected, increasing level of iPTH is associated with increasing trend of serum phosphorus and ionized calcium.

**Conclusions:** Factors such as duration and frequency of hemodialysis and medications taken may influence level of iPTH. iPTH level is congruent with level of serum phosphorus and serum calcium, indicating possible progression of the disease which may be due to inadequacy of calcium, Vitamin D, Phosphate binder supplement and hemodialysis frequency schedule.

## PUB089

## Severe Hyperparathyroidism Associated With Increased Functional and Mobility Impairment in Ecuadorian Hemodialysis Patients With Prolonged Time in Hemodialysis

Juan C. Santacruz, Ana K. Vásquez Perez, Layla N. Baez, Paola K. Arévalo, Paulo Reinoso, Angel C. Santacruz. *Clínica de los Riñones Menydia, Quito, Ecuador.*

**Background:** Secondary hyperparathyroidism (SH) is associated with increased morbidity and mortality in hemodialysis (HD) patients which worsens with long HD stay. Vitamin D, phosphate-binders and calcimimetics are used, however their high cost make them unavailable for some Latin-American patients. Few is known about SH behavior in Ecuadorian patients with prolonged HD stay and lack of IV vitamin D agonists/calcimimetics. The aim of the study was to describe SH behavior in one Ecuadorian cohort of HD patients and the effect mobility and functional status as the relation with time in HD.

**Methods:** Observational-retrospective study in Ecuadorian HD cohort in “Clinica de los Ríones Menydia”. Inclusion criteria: Age  $\geq 18$  years, time in HD  $\geq 3$  meses. Patients younger 18 years, less of 3 months in HD, prior parathyroidectomy were excluded. Karnofsky state, mobility status, PTH values, time in HD, age and sex were collected for analysis.

**Results:** A total of 152 patients were included, 57% were male with mean age 57 ( $\pm 15.2$  years), time in HD 6 ( $\pm 4.3$  years), median PTH 321.6 (126.1–700.6 pg/L), 21% had mobility restriction and 27% of patients had Karnofsky score  $< 70\%$ . PTH values above 1000 pg/L had a prevalence of 15%, significantly related with prolonged HD stay (7.1  $\pm 3.1$  vs 5.4  $\pm 4.7$  years), impaired mobility ( $p = 0.014$ ) and pathological Karnofsky scale (below 70) ( $p = 0.03$ ). It was observed that extreme pathological PTH values (above 1000 pg/L) was more frequent in patients with HD stay above 80 months (6.6 years).

**Conclusions:** HD time over 6 years contributes to severe secondary hyperparathyroidism which is associated with impaired mobility and functional status. Lack of IV vitamin D agonists/calcimimetics complicates SH treatment and should call for other treatment options to avoid deleterious effects on functional status, impaired mobility and quality of life of severe secondary hyperparathyroidism. Kidney transplant programs must be more active to avoid prolonged HD time.

## PUB090

### Outcomes of Symptomatic Kidney Stone Formers

Young Eun Choi, Sungyeon Kim, Suk Min Chung, Yina Fang, Myung-Gyu Kim, Sewon Oh, Sang-Kyung Jo. Korea University Anam Hospital Korea University Anam Hospital, Seoul, Republic of Korea.

**Background:** Recent epidemiologic studies have shown that incidence of urolithiasis is increasing and these stone formers are at increased risk for end stage kidney disease (ESKD). However, most of the studies are population-based historical cohort studies with the use of diagnostic codes including both symptomatic and asymptomatic stone formers.

**Methods:** Given that urolithiasis is a highly heterogenous conditions potentially linked to different clinical outcomes according to stone compositions, we performed a single center retrospective study of symptomatic stone formers with known compositions.

**Results:** Baseline characteristics and prevalence of diverse comorbid conditions and long-term mortality were compared according to different subtypes of stones. As expected, calcium-oxalate stone (45.0%) was the most common type followed by struvite stone (32.9%) and urate stone (15.7%). Uric acid stone formers were significantly older and more likely to have various comorbidities including diabetes, hypertension, ischemic heart disease, heart failure, dementia and chronic kidney disease and acute kidney injury. Long-term mortality rate was also significantly higher in carbonate stone (3.4%) and urate stone (6.1%) formers.

**Conclusions:** These data suggest that clinical characteristics and short and long-term kidney outcomes might be significantly different according to subtypes of stones. Larger studies to identify different risk factors and outcome according to different types of stones are needed.

## PUB091

### The Impact of Calcimimetics in the CMS Perspective Payment System

Skylar Malone,<sup>1</sup> Stuart M. Sprague,<sup>2</sup> Jennifer Robinson.<sup>1</sup> <sup>1</sup>Spherix Global Insights, Exton, PA; <sup>2</sup>NorthShore University HealthSystem, Evanston, IL.

**Background:** Etelcalcetide, an IV calcimimetic, was approved by the FDA in February 2017, and fully launched in Q1 2018. In 2018, etelcalcetide was reimbursed at ASP+6%, as of January 2020 etelcalcetide was reimbursed at ASP+0%, then was added to the bundle payment rate in 2021. During this period, cinacalcet became generic in March 2019. In 2021, etelcalcetide and oral cinacalcet transitioned into the bundled payment system. CMS increased the bundle reimbursement rate by \$10.09 per treatment to account for utilization of calcimimetics during its TDAPA period, Q1 2018 to Q4 2019. Initial clinical experience and reimbursement clarity led dialysis organizations to update their protocols.

**Methods:** Using a HIPAA-compliant, online chart review tool, 158 nephrologists submitted de-identified clinical and non-clinical information for 1,003 dialysis patients in Fall 2021. Data were then merged with physician demographic profiles and attitudinal responses; the data set was analyzed in SPSS.

**Results:** Nephrologists believe treating SHPT early will improve outcomes and yet mean iPTH initiation levels in the dialysis community continue to increase. Physicians prefer etelcalcetide over oral cinacalcet because they believe it offers better compliance and improves SHPT control in HD patients. While physicians prefer to use etelcalcetide, most dialysis organizations require a patient to fail oral cinacalcet first. To address compliance issues, many dialysis organizations have shifted from once daily dosing to three-times-weekly dosing with dialysis. The FDA has not evaluated the use of cinacalcet in this manner. Over two-thirds of nephrologists would like to use etelcalcetide with more of their dialysis patients but are prevented from doing so due to the reimbursement rate and strict protocols. Physicians prefer to use etelcalcetide in 44% of their patients, and yet in a this study of in-center HD patients revealed etelcalcetide is currently prescribe to 4.4% of patients.

**Conclusions:** This study suggests the perspective payment system does not provide ample time for dialysis organizations and physicians to determine where and how to use new agents. Dialysis organizations have implemented protocols that may be inconsistent with FDA labeling. The cost, reimbursement, and limited clinical experience has led dialysis organizations to favor oral cinacalcet over etelcalcetide regardless of physician preference.

## PUB092

### FABP4 Is Involved in High Glucose-Induced Ferroptosis in HK2 Cells

Jiasi Chen, Keping Wu, Hui Guan, Yan Lei, Xiaohua Wang, Zhihua Zheng. The Seventh Affiliated Hospital Sun Yat-sen University, Shenzhen, China.

**Background:** Ferroptosis is involved in the progression of diabetic kidney disease, and is regulated by lipid metabolism. Previous studies showed that inhibition of fatty acid  $\beta$ -oxidation (FAO) increases the sensitivity of cells to ferroptosis. Upregulation of fatty acid binding protein 4 (FABP4) can inhibit FAO. Thus, we hypothesized that FABP4 may be involved in renal injury mediated by ferroptosis in DKD.

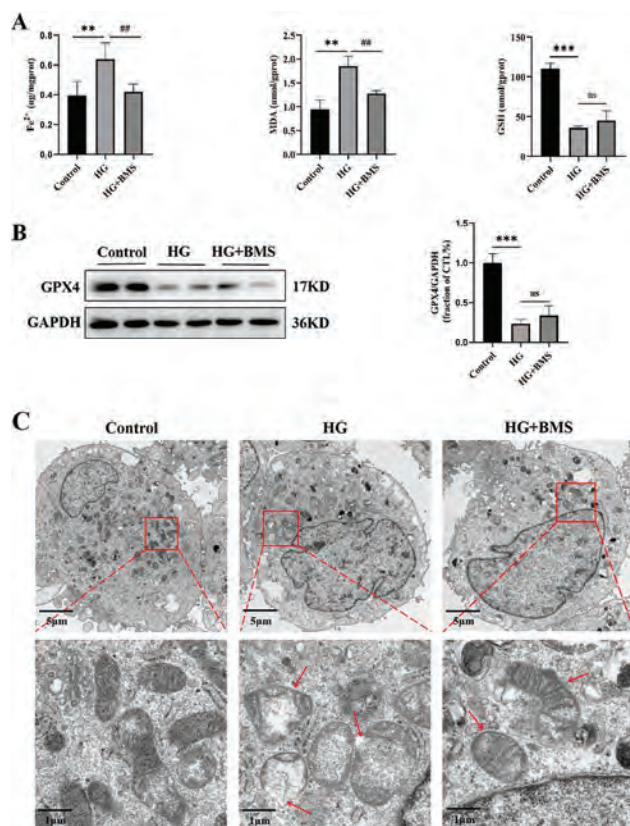

**Methods:** HK2 cells were cultured with high glucose (HG) and treated with FABP4 inhibitor BMS to analyze ferroptosis-related indexes.

**Results:** FABP4 was upregulated in HK2 cells under HG, accompanied by elevated lipid deposition and ROS, which can be reversed by BMS. Iron ( $\text{Fe}^{2+}$ ) and malondialdehyde (MDA) were increased in HG group, while glutathione (GSH) and glutathione peroxidase 4 (GPX4) were decreased. Cells in HG group presented mitochondrial cristae reduction and outer membrane rupture. The ferroptosis-related changes described above can be reversed with the treatment of BMS.

**Conclusions:** FABP4 is involved in HG-induced ferroptosis in HK2 cells.

BMS reduces lipid deposition and ROS in HK2 cells. (A) FABP4 levels. (B) Oil Red O staining. (C) ROS levels.

Effect of BMS in HG-induced ferroptosis in HK2 cells. (A)Iron, MDA and GSH content. (B)GPX4 levels. (C)Mitochondrial morphology.

## PUB093

### Tetracyclines Abrogate the Development of Proteinuria by Reducing Kidney Protein Synthesis in a Diabetic Mouse Model

Anne Long,<sup>1,2</sup> Amy Zollman,<sup>1</sup> Jessica Overstreet,<sup>2</sup> Takashi Hato,<sup>1</sup> Pierre C. Dagher,<sup>1</sup> Timothy A. Sutton.<sup>1</sup> <sup>1</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>2</sup>Eli Lilly and Company, Indianapolis, IN.

**Background:** Diabetes remains a major cause of chronic kidney disease and end stage kidney disease. The pathophysiologic processes leading to the development of kidney disease in diabetes are poorly understood because it is not common practice to obtain kidney biopsies in diabetic patients without diabetic kidney disease (DKD). We have previously demonstrated that translation, the fundamental process in protein synthesis, is increased in the kidney in a mouse model of diabetes. This increase in translation was observed prior to the onset of DKD. Here we investigate whether direct inhibitors of protein translation, such as tetracyclines, can mitigate the development of proteinuria.

**Methods:** We used Db/Db mice on a Kaliss strain background which are prone to developing manifestations of DKD over time. These mice demonstrate an increase in translation starting as early as eight weeks. Treatment with minocycline (50mg/kg daily x 3 days by gavage) was started at 8 weeks and the kidneys were harvested for polyribosomal profiling. In a parallel set of experiments, 6-week old Db/Db mice (n=10) were treated for up to 10 weeks with minocycline (50mg/kg daily in drinking water) and urine was collected weekly for measurement of albuminuria.

**Results:** Treatment with minocycline resulted in a 30% reduction in protein translation as measured by polyribosomal profiling. Fifty percent of the vehicle control-treated mice developed significant albuminuria (albumin/creatinine ratio between 0.6-6 μg/μg). All mice treated with minocycline had albumin/creatinine ratios < 0.5 μg/μg.

**Conclusions:** Increased protein synthesis in the kidney is a feature of diabetes before the onset of DKD. Pharmacologic strategies to reduce protein synthesis may serve as a new therapeutic avenue to prevent the development of DKD.

**Funding:** NIDDK Support

## PUB094

### Urinary Angiotensinogen in Patients With Type 1 Diabetes With Microalbuminuria: Effect of Gender and Insulin Modality

Jessica Z. Navarro Motta, Alejandro Sanchez, Sheeba H. Ba aqeel, Minghao Ye, Mohammed Z. Rehman, Jan Wysocki, Alfred Rademaker, Mark E. Molitch, Daniel Batlle. Northwestern University Feinberg School of Medicine, Chicago, IL.

**Background:** Angiotensinogen (AOG) is the precursor of peptides of the renin angiotensin system (RAS). Since insulin up-regulates transcriptional factors that normally repress kidney AOG synthesis, we evaluated urinary AOG in patients with type 1 diabetes (T1D) and microalbuminuria to examine the effect of intensive versus conventional insulin therapy as well as possible gender differences.

**Methods:** Urine samples from participants of the Diabetes Control and Complications Trial (DCCT) who had albumin excretion rate (AER) in the microalbuminuric range at the entry of the study were used for: a) Measurements of AOG/creatinine (ng/mg) in 103 patients with T1D and microalbuminuria (AER 30-300 mg/24hrs) as compared to controls with normalalbuminuria (AER < 30 mg/24hrs), matched for age, gender, disease duration and allocation to insulin therapy and b) Measurements of AOG/creatinine from patients with microalbuminuria allocated to intensive or conventional insulin therapy using samples after 3 years on either modality.

**Results:** The uAOG/creatinine was higher in patients who started with microalbuminuria than in those with normoalbuminuria (6.65 vs. 4.0 ng/mg, p < 0.01). uAOG was higher in females than males with microalbuminuria (11.7 vs. 5.4 ng/mg, p = 0.015). The uAOG was lower in patients with microalbuminuria allocated to intensive than in conventional insulin therapy (3.98 vs. 7.42 ng/mg, p < 0.01), while AER was not (20 vs 21 mg/24hrs p = 0.68).

**Conclusions:** In patients with T1D and microalbuminuria, uAOG is increased and the excretion varies with gender and the type of insulin modality, independently of AER. This suggests that AOG production in females is increased and that intensive insulin therapy decreases it. The reduction in uAOG production with intensive insulin therapy, can lead to kidney RAS down-regulation, and therefore may contribute to the known renoprotective action associated with improved glycemic control.

## PUB095

### Presence of Retinopathy and Kidney and Cardiovascular Events in Type 2 Diabetes and Normoalbuminuria: A Post Hoc Analysis of the PRIOR-ITY Study

Viktor Rotbain Curovic,<sup>1</sup> Nete Tofte,<sup>1</sup> Christian Delles,<sup>3</sup> Marie Fridmott-Moller,<sup>1</sup> Harald Mischak,<sup>2</sup> Frederik Persson,<sup>1</sup> Heiko von der Leyen,<sup>4</sup> Tine Hansen,<sup>1</sup> Peter Rossing,<sup>1</sup> the PRIOR-ITY Study Group <sup>1</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>2</sup>Mosaiques Diagnostics, Hannover, Germany; <sup>3</sup>University of Glasgow Institute of Cardiovascular and Medical Sciences, Glasgow, United Kingdom; <sup>4</sup>Hannover Clinical Trial Center, Hannover Medical School, Hannover, Germany.

**Background:** To evaluate the association between diabetic retinopathy and development of albuminuria, impaired kidney function and cardiovascular events in persons with type 2 diabetes and normoalbuminuria.

**Methods:** Post-hoc analysis of the prospective observational PRIOR-ITY study including 1756 persons with type 2 diabetes and normoalbuminuria followed for three

years. The study was originally designed to investigate the prediction of a urinary proteomic risk classifier (CKD273) for development of albuminuria. Diabetic retinopathy included information from medical records on non-proliferative and proliferative changes, presence of macular oedema and history of laser treatment. Cox proportional hazard models were fitted to investigate baseline retinopathy status to development of 1) microalbuminuria (urinary albumin-creatinine ratio >30mg/g on ≥ 2 out of 3 urine samples); 2) chronic kidney disease (eGFR <60 ml/min/1.73m<sup>2</sup>); and 3) cardiovascular events (myocardial infarction, stroke, coronary intervention, and hospitalization for heart failure). Adjustment included sex, baseline age, diabetes duration, HbA<sub>1c</sub>, systolic blood pressure, eGFR, urinary albumin-creatinine rate and urinary proteomic risk classifier status. Baseline LDL cholesterol, body mass index and history of cardiovascular disease were also included in the adjustment for cardiovascular events.

**Results:** At baseline, 287 (16.3%) had retinopathy. Compared to persons without retinopathy, they were older (mean ±SD: 62.7±7.7 vs 61.4±8.3 years, p=0.019), had longer diabetes duration (17.9±8.4 vs. 10.6±7.0 years, p<0.001) and higher HbA<sub>1c</sub> (62±13 vs. 56±12 mmol/mol, p<0.001). The adjusted hazard ratios of retinopathy at baseline for development of albuminuria (n=197), chronic kidney disease (n=166) and cardiovascular events (n=64) were: 1.54 (95%CI: 1.06, 1.73), 0.89 (95%CI: 0.57, 1.38), and 2.56 (95%CI: 1.40, 4.66), compared to persons without retinopathy.

**Conclusions:** Individuals with normoalbuminuric type 2 diabetes and retinopathy had higher risk of developing albuminuria, but not impaired kidney function, and had a markedly higher risk of cardiovascular disease during the 3-year follow-up, compared to individuals without retinopathy.

Design and Methodology of the PRIMETIME1 Cohort Study: Precision Medicine Based on Renal Tissue Molecular Interrogation in Diabetic Nephropathy

Karina Haar<sup>1,2</sup>, Hanan Amadid<sup>2</sup>, Frederik Persson<sup>2</sup>, Ditte Hansen<sup>3,4</sup>, Iain O. Bressendorff<sup>3</sup>, Marie Møller<sup>3</sup>, Peter Rossing<sup>2,4</sup>, Rikke Borg<sup>1,4</sup>  
PRIMETIME<sup>1</sup>Clinical Research Unit, Zealand University Hospital, Roskilde, Denmark; <sup>2</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>3</sup>Department of Nephrology, Herlev and Gentofte Hospital, Herlev, Denmark; <sup>4</sup>Department of Clinical Medicine University of Copenhagen, Copenhagen, Denmark.

**Background:** The diagnosis of diabetic kidney disease (DKD) is practically based on clinical characteristics. However, clinical features of DKD alone cannot reliably differentiate between DKD and non-DKD in diabetes. A kidney biopsy is necessary to make the definitive diagnosis of diabetic nephropathy (DN). However, there is no clear clinical guideline on when to perform a biopsy in individuals with diabetes and kidney disease. Furthermore, the implication of non-DN versus DN in diabetes on management, morbidity, and kidney prognosis is unclear. The long-standing tradition of national population registration in Scandinavia offers a unique possibility of working with high-quality registry data and a long period of follow-up. With the potential to perform comprehensive studies, we aimed to create a national cohort of individuals with diabetes who had a kidney biopsy performed – the PRIMETIME1 cohort.

**Methods:** We performed a retrospective cohort study, intending to include all Danish adults diagnosed with diabetes between 1997 and 2020 and who had a kidney biopsy performed - excluding tumor, donor and transplant biopsies. We established the cohort by linking a nationwide diabetes register, The Steno Diabetes Center Copenhagen Diabetes Registry, and The Danish Pathology Registry. Data from eleven nationwide registries and databases are comprised and stored at Statistics Denmark. Epidemiologic studies and stratified analyses will be founded on the classification of kidney disease in subgroups based on the histopathological diagnosis of DN, non-DN, and mixed disease. Classification of kidney disease is defined by doing a three-step analysis of SNOMED (Systematized Nomenclature of Medicine) IDs.

**Results:** The PRIMETIME1 cohort contains information on 3592 individuals. A variety of demographic, socioeconomic, clinical, and prognostic variables have been gathered and data analysis is ongoing.

**Conclusions:** A large cohort with comprehensive data has been created. The PRIMETIME1 cohort has the ability to perform epidemiologic studies on comorbidity and kidney disease, to study the predictive value of clinical variables on disease course, the prognostic value of findings in kidney biopsies, and how to guide risk stratification of individuals with diabetes and kidney disease.

PUB097

Empagliflozin Associated Severe Hyponatremia in the Setting of Subclinical Diabetes Insipidus: A Case Report

Maha Ahmed<sup>1</sup>, Tai Truong<sup>2</sup>, Clay A. Block<sup>2,1</sup> Dartmouth Geisel School of Medicine <sup>1</sup>Dartmouth College Geisel School of Medicine, Hanover, NH; <sup>2</sup>Dartmouth-Hitchcock Medical Center, Lebanon, NH.

**Introduction:** SGLT2i are an important class of drug in the management of diabetes, diabetic nephropathy, chronic kidney disease and heart failure. We describe a case in which the introduction of empagliflozin resulted in severe hyponatremia by unmasking previously unrecognized chronic lithium induced nephrogenic diabetes insipidus (NDI).

**Case Description:** A 67-year-old veteran with longstanding hypertension, obesity, chronic kidney disease stage 3A, and bipolar disorder on lithium was admitted for

management of a hyperosmolar hyperglycemic state with glucose levels exceeding 900 mg/dL. The corrected sodium concentration was 153 mEq/L. After treatment with insulin and IV fluid, the patient was discharged on metformin and 10mg of empagliflozin. Lithium was discontinued and sodium valproate was initiated. On discharge glucose concentration was 267 mg/dL, serum sodium 148 mEq/L, and creatinine 1.41 mg/dL. Four days after discharge, the patient returned with worsening fatigue, confusion, polyuria, and polydipsia. Serum chemistries revealed glucose level at 267 mg/dL, serum sodium at 156 mEq/L, serum osmolality 338 Osm/L, creatinine 2.08 mg/dL, urine sodium 38 mEq/L, urine osmolality was 500 Osm/L, and urine glucose concentration greater than 500 mg/dL (beyond detected range). Hydration was provided along with insulin; empagliflozin was discontinued. Serum sodium continued to climb to a peak of 161 mEq/L on hospital day 4 and subsequently improved. Glycemic control was achieved with glipizide. Despite resolution of his hyperglycemia, polyuria persisted. Daily urine specific gravity measurements were below 1.005 and urine osmolality was less than 200 mosmol/kg. NDI was inferred related to his history of long standing lithium use. Hydrochlorothiazide and a low salt diet were initiated. On hospital day 10, his serum sodium level remained stable at 144 mEq/L without need of intravenous fluid. Follow up sodium level 1 month later was 142 mEq/L.

**Discussion:** In this clinical vignette, we described a patient who developed severe hyponatremia in the setting of diabetes mellitus and concurrent diabetes insipidus. To our knowledge, our case report is the first to describe severe hyponatremia with empagliflozin in a patient with diabetes insipidus and uncontrolled diabetes mellitus.

PUB098

Conserving Renal Function With a Novel Care Model: A 3-Year Retrospective EHR-Based Analysis of eGFR in 1,871 Elderly Patients With CKD 3/Diabetes After Switching to Cano Health

R. B. Aguilar<sup>1,2</sup>, Re Kenney<sup>1,2</sup>, E. Antunez<sup>1,2</sup>, R. S. Busch<sup>4</sup>, M. E. Herman<sup>5</sup>, M. Aguilar<sup>3</sup>, M. Conger<sup>6</sup> Cano Health <sup>1</sup>Nova Southeastern University, Fort Lauderdale, FL; <sup>2</sup>Florida International University, Miami, FL; <sup>3</sup>Gonzaga University, Spokane, WA; <sup>4</sup>Albany Medical Center, Albany, NY; <sup>5</sup>University of Illinois System, Urbana, IL; <sup>6</sup>Oregon State University, Corvallis, OR.

**Background:** The Cano Health (CANO) Model of Care (CMC; launched in 2014), has demonstrated improvements in chronic disease management for Medicare Advantage patients (1-6). The current 3Y retrospective study was designed to evaluate the potential of the CMC to slow the decline of renal function and positively impact clinical outcomes in an at-risk population.

**Methods:** Between 1/1 and 12/31/2018, 1,871 patients newly enrolled in CANO (≤3 mos) with CKD 3/diabetes were identified. Clinical care was guided by the CMC including adherence to structured data protocols and input from a proprietary care management tool, CanoPanorama™(2). eGFR, A1C, albuminuria, BMI, SBP/DBP were collected at baseline and to 36 mos. CHF, MI, Stroke/TIA, dialysis, all-cause mortality, medication use, hospitalizations, and ER visits, were tracked using claims data.

**Results:** Mean age 76.5-Y with mean f/u of 2.4 Y. Mean eGFR significantly improved for 15 mos and was preserved over 36 mos (Table 1). Death from any cause, dialysis, MI, CHF, stroke/TIA events, ER visits, and hospitalization per 1000 patient-yr were 33.0, 3.2, 4.5, 8.1, 15.4, 96.4 and 55.0 respectively. Mean A1C decreased from 7.1% to 6.9% at 24 mos while BMI decreased from 30.7 to 29.9 over the same period.

**Conclusions:** Outpatient management of CKD with diabetes has been suboptimal and will be of greater consequence as our population ages (7). The CMC model reduced the need for dialysis and durably slowed decline of renal function while positively impacting clinical outcomes when compared to reference clinical studies on similar populations (8). This scalable model of care offers an opportunity to improve the short- and long-term health of these patients in the primary care setting.

Predictors and Facility-Level Variation in SGLT2i Prescription Among US Veterans

L Parker Gregg,<sup>1,2</sup> David J. Ramsey,<sup>1,2</sup> Liang Chen,<sup>1,2</sup> Julia Akeroyd,<sup>1,2</sup> Salim S. Virani,<sup>1,2</sup> Sankar D. Navaneethan.<sup>1,2</sup> <sup>1</sup>Baylor College of Medicine, Houston, TX; <sup>2</sup>Michael E DeBakey VA Medical Center, Houston, TX.

**Background:** Sodium-glucose cotransporter-2 inhibitors (SGLT2i) are recommended for patients with type 2 diabetes mellitus (T2DM), and chronic kidney disease (CKD). We studied the facility level variation in prescription patterns and factors associated with SGLT2i prescription among patients with atherosclerotic cardiovascular disease (ASCVD), CKD, and T2DM.

**Methods:** Using a nationally representative data from the Veterans Affairs (VA) Corporate Data Warehouse from January 1, 2020 to December 31, 2020, we identified individuals with ASCVD, T2DM, and CKD stage 3 (defined as eGFR 30-59 mL/min/1.73 m<sup>2</sup>). Associations between patient and treatment characteristics with SGLT2i prescription were studied using logistic regression. Facility-level variation in SGLT2i prescription was described using median rate ratio, which is the likelihood that two randomly selected facilities differ in use of SGLT2i among similar patients.

**Results:** Of 378,469 patients with ASCVD, T2DM and CKD, 59,755 (15.8%) were prescribed a SGLT2i. Those on SGLT2i were younger (69±8 vs. 72±9 years), had higher hemoglobin A1c levels (8.0±1.4 vs. 7.5±1.5), and more likely to have heart failure (25.8% vs. 20.8%), P<0.001 for each. In the multivariable model, younger age, male sex, non-Hispanic White race, hypertension, higher HbA1c, ischemic heart disease, and heart failure were associated with higher odds of SGLT2i prescription (Figure). The mean (SD) proportion prescribed a SGLT2i per individual VA facility was 15.3% (5.2). The adjusted median rate ratio for facility level variation was 1.56 (95% CI 1.47-1.64) indicating an unexplained 56% difference in the probability of two similar patients with T2DM, and CKD receiving SGLT2i at two random facilities.

**Conclusions:** Prescription rate of SGLT2i for eligible patients was low, with significant variation between individual facilities. Further health services research should target improving guideline-based prescribing of these agents to improve cardiovascular and kidney outcomes.

Unhealthy Body Composition Phenotype Correlates With Intraglomerular Hemodynamic Dysfunction in Adolescents With Type 1 Diabetes

Kalie L. Tommerdahl,<sup>1,2</sup> Jessica B. Kendrick,<sup>1</sup> Carissa Vinovskis,<sup>1</sup> Laura Pyle,<sup>1,3</sup> Daniël H. van Raalte,<sup>4</sup> Ian H. de Boer,<sup>5</sup> Robert G. Nelson,<sup>6</sup> Petter Bjornstad.<sup>1</sup> <sup>1</sup>University of Colorado Denver School of Medicine, Aurora, CO; <sup>2</sup>University of Colorado Denver Barbara Davis Center for Childhood Diabetes, Denver, CO; <sup>3</sup>University of Colorado School of Public Health Department of Biostatistics & Informatics, Aurora, CO; <sup>4</sup>Amsterdam UMC Locatie VUmc, Amsterdam, Netherlands; <sup>5</sup>University of Washington Department of Medicine, Seattle, WA; <sup>6</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ.

**Background:** High fat mass and central adiposity are associated with cardiovascular and kidney dysfunction in youth and adults with type 1 diabetes (T1D), yet little is known regarding the association between body composition and direct measures of intraglomerular hemodynamic function in youth with T1D of short duration. We evaluated the relationships between body composition (i.e., lean mass, fat mass, and trunk mass) and estimated insulin sensitivity and markers of intraglomerular hemodynamic function in adolescents with T1D of less than 10 years duration.

**Methods:** Baseline evaluation of glomerular filtration rate (GFR) and renal plasma flow (RPF) by iohexol and p-aminohippurate clearance during a hyperglycemic clamp, and body composition assessments by dual-energy x-ray absorptiometry for lean, fat, and trunk mass, were completed. Intraglomerular pressure (P<sub>GLO</sub>) was estimated using Gomez equations. Insulin sensitivity was estimated (eIS) using the SEARCH equation. Urine albumin to creatinine ratio (ACR) was assessed using the average of two collections during a single study visit. Pearson correlations and multivariable linear regression analyses were performed on all reported outcomes.

**Results:** Fifty adolescents with T1D (aged 16±3 years, 50% female, HbA1c 8.6±1.2%, BMI 23.4±5.1 kg/m<sup>2</sup>, T1D duration 5.7±2.6 years) were included. Trunk mass and fat mass were strongly positively correlated with GFR, RPF, P<sub>GLO</sub>, and ACR (Table).

Lean mass was inversely correlated with ACR and eIS with GFR, RPF, P<sub>GLO</sub>, and ACR. Most relationships remained statistically significant after multivariable adjustment for age, sex, and hemoglobin A1c.

**Conclusions:** Central adiposity is strongly associated with early intraglomerular hemodynamic dysfunction in youth with T1D of short duration. The effects of central adiposity on the onset and progression of diabetic kidney disease remains to be determined.

**Funding:** NIDDK Support, Private Foundation Support

Table. Relationships between markers of intraglomerular hemodynamic function and assessments of body composition and estimated insulin sensitivity

	Fat mass (kg)	Lean mass (kg)	Trunk mass (kg)	eIS
GFR (mL/min)	r: 0.54* p<0.0001	r: -0.16* p=0.26	r: 0.60* p<0.0001	r: -0.54* p<0.0001
RPF (mL/min)	r: 0.48* p=0.003	r: -0.27 p=0.11	r: 0.44 p=0.006	r: -0.41* p=0.01
P <sub>GLO</sub> (mmHg)	r: 0.55* p=0.0004	r: -0.21 p=0.21	r: 0.65* p<0.0001	r: -0.52* p=0.0009
ACR (mg/g)	r: 0.37 p=0.009	r: -0.39 p=0.006	r: 0.38* p=0.006	r: -0.35* p=0.01

\*Denotes additional statistical significance after multivariable linear regression analyses adjusted for age, sex, and hemoglobin A1c.  
Key: ACR = urine albumin to creatinine ratio; eIS = estimated insulin sensitivity; GFR = glomerular filtration rate; P<sub>GLO</sub> = intraglomerular pressure; RPF = renal plasma flow.

PUB101

Risk of ESKD and Incidence of New-Onset Major Adverse Cardiovascular Events in a Large, Deprived Population With Type 2 Diabetes Mellitus

Saif Al-Chalabi,<sup>1,2</sup> Schanhav Santhirasekaran,<sup>1</sup> Smeeta Sinha,<sup>1</sup> Philip A. Kalra,<sup>1</sup> James Ritchie.<sup>1</sup> <sup>1</sup>Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom; <sup>2</sup>The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom.

**Background:** Chronic kidney disease (CKD) is a major public health condition. It is estimated that 2.6 million people in England are living with CKD. In this study of adults with type 2 diabetes mellitus (T2DM) living in the Salford area (amongst the top 10% deprived local authorities in England), we describe the baseline predicted population incidence of end-stage kidney disease (ESKD), and the observed incidence of major adverse cardiovascular events (MACE) over a 61-month period, medication uptake is also described.

**Methods:** A retrospective analysis using data from the Salford Integrated Record. The study population included all adult patients with T2DM who were actively registered with a general practitioner and had either a coded CKD diagnosis, a measured eGFR<60 mL/min/1.73 m<sup>2</sup> or a measured albumin-creatinine ratio >3 mg/mmol.

**Results:** The current estimated total adult population living within Salford city is 260,000. Based on the study inclusion criteria, we identified 11546 adult patients (4.4% of the total adult population in Salford). The median age was 65.5 years with a predominance of males (57.5%). For the estimated incidence of ESKD, data were available for 9841 (85.2%) and 9734 (84.3%) patients for KIDIGO CKD prognosis and kidney failure risk equation (KFRE) respectively. The KDIGO CKD prognosis estimation showed that 603 (6.1%) patients had a very high risk for ESKD determined by eGFR and albuminuria, whereas the KFRE indicated that only 94 (0.97%) patients had a >5% risk of ESKD within 5 years. Over the 61 months follow-up period (01/01/2016 to 28/02/2021), 2742 patients (23.7%) developed new-onset hypertension, 1127 (9.8%) had an acute coronary syndrome and 410 (3.5%) had new-onset heart failure. Use of key medications at end of follow-up period was renin-angiotensin-aldosterone blockade (63.6%), sodium-glucose cotransporter 2 (SGLT2) inhibitors (19.8%) with 34.8% receiving antiplatelet therapy, and 81.4% statins.

**Conclusions:** Our analysis shows a low utilisation of cardio-renal-metabolic preventive medications such as SGLT2 inhibitors. We suggest opportunities to optimize their use to reduce incidence of ESKD and new-onset MACE.

**Funding:** Commercial Support - AstraZeneca

PUB102

Molecular Signatures of Glomerular Neovascularization in a Patient With Diabetic Kidney Disease

Daria Barwinska,<sup>1</sup> Ashish Verma,<sup>2</sup> Michael J. Ferkowicz,<sup>1</sup> Ricardo Melo ferreira,<sup>1</sup> Joel M. Henderson,<sup>2</sup> Devin Steenkamp,<sup>2</sup> Carrie L. Phillips,<sup>1</sup> Mary P. Kirkpatrick,<sup>2</sup> Sushrut S. Waikar,<sup>2</sup> Timothy A. Sutton.<sup>1</sup> KPMP <sup>1</sup>Indiana University School of Medicine, Indianapolis, IN; <sup>2</sup>Boston University School of Medicine, Boston, MA.

**Introduction:** A 67-year old woman with CKD stage G3aA3, latent autoimmune diabetes (LADA), diabetic retinopathy, and hypertension underwent a kidney biopsy as a participant in the Kidney Precision Medicine Project (KPMP).

**Case Description:** Prior to biopsy the patient received 11 intravitreal VEGF inhibitor injections and had proteinuria of 1.4 grams/g, serum creatinine of 1.05 mg/dL, and eGFR of 58 mL/min per 1.73 m<sup>2</sup> at the time of kidney biopsy. Kidney biopsy tissue cores were allocated to the pathology and tissue interrogation sites according to KPMP tissue analysis protocols. Core 1 underwent standard pathology processing and examination. Core 2 was immediately frozen in OCT. Sections from Core 2 were stained with eight fluorescent probes and imaged by confocal microscopy to obtain large volume 3-dimensional (3D)-immunofluorescence (IF) images. In addition, spatial transcriptomic analysis was performed on a sequential tissue section from Core-2. Nephrectomy tissue sections underwent identical interrogation protocols and served as control.

**Discussion:** Histopathologic examination revealed diabetic nephropathy, RPS class III, with diffuse, focally nodular mesangial expansion, focal global glomerulosclerosis, and mild tubulointerstitial chronic damage. Notably, the cortical arteries and arterioles showed severe sclerosis. Large volume 3D-IF images demonstrated prominent neovascularization (PECAM1/CD31+) in the surrounding connective tissue of all glomeruli. Similar peri-glomerular neovascularization was also identified in PAS stained sections. Spatial transcriptomic deconvolution revealed increased signature of endothelial/vascular cell types in diabetic glomeruli and higher expression of associated genes when compared to the control tissue, demonstrating alignment with gene expression reported in animal models of retinal neovascularization. Although there are prior reports of glomerular neovascularization in patients with DKD, it is challenging to detect in standard thin histopathology sections and molecular information about it is sparse. Utilizing large volume 3D-IF imaging combined with spatial transcriptomics we demonstrated prominent glomerular neovascularization in a patient with DKD and its corresponding molecular signature.

## PUB103

### Association Between Carotid Artery Plaque and Albuminuria in Individuals With Type 2 Diabetes and No Clinical Cardiovascular Disease

Luis Felipe Ferreira-Divino,<sup>1</sup> Viktor Rotbain Curovic,<sup>1</sup> Christina G. Poulsen,<sup>1</sup> Lærke Urbak,<sup>3</sup> Nete Tofte,<sup>1</sup> Marie Frimodt-Møller,<sup>1</sup> Nikolaj Eldrup,<sup>3</sup> Tine Hansen,<sup>1</sup> Henrik H. Sillesen,<sup>3</sup> Peter Rossing.<sup>1,2</sup> <sup>1</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>2</sup>Københavns Universitet, København, Denmark; <sup>3</sup>Department of Vascular Surgery, Rigshospitalet, Copenhagen, Denmark.

**Background:** The association between albuminuria and subclinical atherosclerosis in type 2 diabetes (T2D) remains unclear. We investigated the association between carotid artery plaque thickness and albuminuria in individuals with T2D and no clinical cardiovascular disease (CVD) to better understand the pathophysiology of renal and vascular disease in T2D.

**Methods:** In total, 500 individuals with T2D and no clinical CVD underwent 2-dimensional ultrasound scans of the carotid arteries. The side with the highest plaque thickness (mm) was included in the analyses. Albuminuria measurements were available for 466 individuals, who were stratified based on history of two out of three consecutively recorded measurements of UAER or UACR; normal albuminuria (<30mg/24h or mg/g), moderately increased albuminuria (30-299 mg/24h or mg/g) and severely increased albuminuria (≥300mg/24h or mg/g). Association between highest plaque thickness and albuminuria was analyzed with linear regression. Adjustments included sex, age, diabetes duration, systolic blood pressure, eGFR, LDL-cholesterol, body mass index, smoking, and statin treatment.

**Results:** The study population had a mean (±SD) age of 65 ± 9 years, a mean diabetes duration of 14 ± 8 years, and two thirds (67%) were males. A total of 357 (71%) individuals had carotid plaque (>1.5mm), and 351 (75%) had normal albuminuria, 87 (19%) moderately increased albuminuria, and 28 (6%) severely increased albuminuria. In the unadjusted analysis, moderately increased albuminuria was associated with thicker carotid plaque compared to normal albuminuria (0.27 mm, 95%CI: (0.02 - 0.51); p=0.03), however, the significance was lost after adjustment (0.13 mm, (-0.13 - 0.38); p=0.34). Severely increased albuminuria was not associated with carotid plaque thickness in neither unadjusted (0.35 mm, (-0.04 - 0.75); p=0.08) nor adjusted (0.01mm, (-0.35 - 0.50); p=0.74) models compared to normal albuminuria.

**Conclusions:** In individuals with T2D but no clinical CVD, presence of albuminuria was not associated with carotid plaque thickness, a measure of subclinical CVD.

## PUB104

### Validating a Novel Prediction Model in Diabetic Nephropathy in Type 2 Diabetes Mellitus

Niveda Shekar, Dimeji O. Williams, Pius E. Ojemolon. *John H Stroger Jr Hospital of Cook County, Chicago, IL.*

**Background:** The prevalence of diabetic nephropathy (DN) among patients with type 2 diabetes mellitus (T2DM) is approximately 30-50% in the adult U.S. population. We looked at an original study done at the China-Japan Friendship Hospital which aimed to create a novel prediction model that could be utilized by clinicians to determine the probability of DN in patients with T2DM in an effort to forgo the renal biopsy. In our study, we aimed to derive the net benefit of utilizing the prediction model in an American population.

**Methods:** This is a retrospective data analysis of patients >18 years of age with T2DM who underwent a kidney biopsy at John H. Stroger, Jr. Hospital of Cook County between January 2014 and December 2019. Chart review was done to collect multiple variables including gender, diabetes duration, diabetic retinopathy, hematuria, hemoglobin A1C, anemia, blood pressure, urinary protein excretion, and glomerular filtration rate. Individual records were analyzed and assigned points as suggested in the original study. Point values correlated to probabilities, if the probability is near 0, the patient should undergo a biopsy while a probability of 1 suggests a patient should forego biopsy. A net benefit was calculated and compared to the validation dataset.

**Results:** A total of 89 records were analyzed 44% were female and 56% were male. Each of the variables listed above was collected and assigned points per the nomogram. The highest scoring variables were noted to be the duration of diabetes and the presence of diabetic retinopathy. The cumulative points correlated to the probability of DN. Thirty-three points were assigned as a 50% probability of finding DN if the patient were to

undergo a biopsy per the validation data set. This cut-off was later used to determine the number of true positives, true negatives, false positives, and false negatives. The net benefit found in our study was calculated to be 0.258. The net benefit in the validation dataset of the original study was 0.375.

**Conclusions:** This study, when compared to the validation dataset of the original study, showed an overall lower net benefit in the use of the novel model to predict diabetic nephropathy among the American population. This suggests that the training dataset of the original study would need to include a larger population from different locations for the model to be generalized.

## PUB105

### Association Between Platelet Aggregation and Albuminuria in Individuals With Type 2 Diabetes and No Clinical Cardiovascular Disease

Luis Felipe Ferreira-Divino,<sup>1</sup> Viktor Rotbain Curovic,<sup>1</sup> Christina G. Poulsen,<sup>1</sup> Nete Tofte,<sup>1</sup> Marie Frimodt-Møller,<sup>1</sup> Tine Hansen,<sup>1</sup> Anne-Mette Hvas,<sup>2</sup> Peter Rossing.<sup>1,3</sup> <sup>1</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>2</sup>Department of Clinical Biochemistry, Aarhus University Hospital, Aarhus, Denmark; <sup>3</sup>University of Copenhagen, Copenhagen, Denmark.

**Background:** To better understand the pathophysiology of renal and vascular disease in type 2 diabetes (T2D), we investigated the association between platelet aggregation and albuminuria in individuals with T2D and no clinical cardiovascular disease (CVD).

**Methods:** Cross-sectional study including 466 individuals stratified by history of normal albuminuria (<30 mg/24h or mg/g); moderately increased albuminuria (30-299 mg/24h or mg/g); and severely increased albuminuria (>300 mg/24h or mg/g) in two out of three consecutive measurements. Platelet aggregation was measured by whole blood impedance aggregometry (Multiplate® Analyzer). Three agonists were used, arachidonic acid (ASPItest), adenosine diphosphate (ADPtest), and thrombin receptor activating peptide-6 (TRAPtest). Higher test levels (area under the curve (AU<sup>3</sup>min)) indicate higher platelet aggregation. Association between platelet aggregation and albuminuria was analyzed with linear regression. Adjustments included sex, age, diabetes duration, systolic blood pressure, eGFR, LDL-cholesterol, body-mass index, smoking and statin treatment. Analyses of ASPItest were stratified by treatment with acetylsalicylic acid (ASA) and further adjusted for non-steroidal anti-inflammatory treatment.

**Results:** The study population had a mean (±SD) age of 65±9 years, a diabetes duration of 14±8 years and most (66%) were men. 351 (75%) had normal, 87 (19%) moderately increased, and 28 (6%) severely increased albuminuria. In individuals treated with ASA (n=183), the moderately increased albuminuria group had a significantly higher platelet aggregation (ASPItest: unadjusted p=0.013; adjusted p=0.004) compared to those with normal albuminuria. This was not observed in individuals without ASA. In the total population, individuals with moderately increased albuminuria had higher platelet aggregation (ADPtest and TRAPtest: unadjusted p≤0.047; adjusted p≤0.038) compared to the normal albuminuria group. No differences were observed for any of the tests between severely increased albuminuria and normal albuminuria.

**Conclusions:** Individuals with T2D, but no clinical CVD, and moderately increased albuminuria had significantly higher platelet aggregation levels compared to those with normal albuminuria.

## PUB106

### Rationale and Design of a Prospective, Clinical Study of Biopsy-Proven Diabetic Nephropathy in People With Type 2 Diabetes: Prevalence and Predictive Factors (The PRIMETIME 2 Study)

Marie Møller,<sup>1</sup> Iain O. Bressendorff,<sup>1</sup> Rikke Borg,<sup>2,3</sup> Karina Haar,<sup>2,4</sup> Eva Gravesen,<sup>5</sup> Dorrit Krstrup,<sup>5</sup> Peter Rossing,<sup>4,3</sup> Frederik Persson,<sup>4</sup> Ditte Hansen.<sup>1,3</sup> PRIMETIME <sup>1</sup>Department of Nephrology, Herlev and Gentofte Hospital, University of Copenhagen, Copenhagen, Denmark; <sup>2</sup>Department of Nephrology, Zealand University Hospital Roskilde, Roskilde, Denmark; <sup>3</sup>Department of Clinical Medicine University of Copenhagen, Copenhagen, Denmark; <sup>4</sup>Steno Diabetes Center Copenhagen, Herlev, Denmark; <sup>5</sup>Herlev Hospital Afdeling for Patologi, Herlev, Denmark.

**Background:** Diabetic kidney disease (DKD) is a severe complication of diabetes. The diagnosis is based on the clinical characteristics of persistent macroalbuminuria, hypertension, and decline in kidney function, although this definition is subject to significant uncertainty. The only way to secure an accurate diagnosis of diabetic nephropathy (DN) is by performing a kidney biopsy. The clinical presentation of DN can be associated with a heterogeneous range of histological features with many pathophysiological factors involved demonstrating the complexity of the condition. Current treatment plans aim to slow disease progression with little focus on underlying and individual pathological processes.

**Methods:** In the PRIMETIME 2 (PREclision MEDicine based on renal Tissue Molecular interrogation in diabetic nEphropathy) study, we will prospectively collect research kidney biopsies from an unselected cohort of 300 participants with type 2 diabetes (T2DM), severe albuminuria (urine albumin/creatinine-ratio ≥ 700 mg/g), and an eGFR > 30 mL/min/1.73 m<sup>2</sup>. The kidney tissue, blood, urine, feces, and saliva samples will be thoroughly investigated with cutting-edge molecular technologies for comprehensive profiling and associated with disease course and clinical outcome with annual follow-up for 20 years. We will use the tissue for a precise histological diagnosis and RNA sequencing to provide a new understanding of the molecular features of DN. Proteomic and metabolomic profiles will be made from urine and plasma. Lastly, we plan to profile the whole genome and microbiome.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Results:** We started inclusion on Dec. 2021 from one site. In the nearest future, five other sites will startup. End of Study is scheduled for Dec. 2023, but the inclusion period will probably be extended. We had included ten participants before the abstract submission deadline and performed three biopsies.

**Conclusions:** This study will investigate the prevalence of DN in individuals with T2DM and albuminuria. The deep characterization of the biopsy material and biological specimens may lead to a better understanding of the pathological processes involved and reveal new targets for individualized treatment and improve diagnostic accuracy.

### External Validation of a Predictive Model of Non-Diabetic Renal Disease in Patients With Type 2 Diabetes Mellitus

Bogdan Obriscă,<sup>1</sup> Roxana A. Jurubita,<sup>1</sup> Alexandra Vornicu,<sup>1</sup> Alexandru F. Procop,<sup>1</sup> George Terinte-Balcan,<sup>2</sup> Mihaela Gherghiceanu,<sup>2</sup> Gener Ismail,<sup>1</sup> <sup>1</sup>Fundeni Clinical Institute, Bucharest, Romania; <sup>2</sup>Victor Babes National Institute of Pathology, Bucharest, Romania.

**Background:** We aimed to evaluate predictive factors for non-diabetic renal disease (NDRD) in patients with type 2 diabetes mellitus (T2DM) and to validate a previously proposed predictive model of NDRD (Nefrologia. 2020;40:180–189).

**Methods:** 122 patients with T2DM that underwent a kidney biopsy were included in this study. The predictive model of NDRD scored the presence or absence of the following variables: diabetic retinopathy, chronic ischemia of lower limbs, insulin therapy, nephrotic-range proteinuria, evolution of diabetes  $\geq 10$  years, overweight and hematuria.

**Results:** In the study cohort, 46 patients had diabetic nephropathy (DN) alone, 37 had DN+NDRD and 39 had NDRD alone. All the variables included in the predictive model were significantly associated with the presence of NDRD. After multivariate adjustment, the independent predictors of NDRD were duration of diabetes (OR, 0.85 per 1 y; 95%CI, 0.77-0.94,  $p=0.002$ ), 24-h proteinuria (OR, 0.866 per 1 g/24h; 95%CI, 0.75-0.99,  $p=0.04$ ) and hematuria (OR, 1.016 per 1 cell/mm<sup>3</sup>; 95%CI, 1.00-1.03,  $p=0.05$ ). The predictive score was significantly lower in patients with NDRD alone ( $-0.06 \pm 2.9$ ), compared to patients with DN+NDRD ( $2.1 \pm 2.9$ ,  $p=0.003$ ) and DN alone ( $3.5 \pm 2.7$ ,  $p<0.001$ ) (Figure 1). A score  $\geq 3$  was encountered in 60.9% of patients with DN alone, 40.5% of those with DN+NDRD and 12.8% of those with NDRD alone ( $p<0.001$ ). The model had a predictive capacity for NDRD with an area under the ROC curve of 0.75 (95%CI, 0.67-0.83;  $p<0.001$ ) and an Youden Index of 0.42 (Figure 1). A score  $< 3$  had a sensitivity of 74% (95%CI, 62-83%) and a specificity of 61% (95%CI, 45-75%) to identify NDRD, with a model accuracy of 69% (95%CI, 60-77%).

**Conclusions:** This predictive model had the capacity to discriminate the presence of NDRD in patients with T2DM, albeit with a predictive capacity inferior to what was previously reported.

## PUB108

### A Proof-of-Concept Study of CD34+ Cell Therapy for Diabetic Kidney Disease

Pablo E. Pergola,<sup>1</sup> Swetha Mandava,<sup>2</sup> William K. Sietsema,<sup>2</sup> Ronnda L. Bartel,<sup>2</sup> Ann M. Schumacher,<sup>2</sup> Surabhi Sharma,<sup>2</sup> Sapna K. Ghuman,<sup>2</sup> Kristen K. Buck,<sup>2</sup> <sup>1</sup>Renal Associates PA, San Antonio, TX; <sup>2</sup>Caladrius Biosciences Inc, Basking Ridge, NJ.

**Background:** Diabetic kidney disease (DKD) is associated with renal vascular rarefaction. Bone marrow derived hematopoietic CD34+ stem cells are known from preclinical investigations to home to ischemic tissue and promote revascularization. Further, in clinical trials, treatment with CD34+ cells have been shown to improve ischemic diseases including refractory angina, coronary microvascular dysfunction, and critical limb ischemia. CLBS201 consists of autologous, mobilized peripheral blood-derived CD34+ cells. In the current investigation, the safety and potential efficacy of CLBS201 is being evaluated in the treatment of DKD.

**Methods:** In this proof-of-concept, open-label study conducted at 1 center in the US, 6 subjects with chronic kidney disease and type 2 diabetes mellitus are treated with

CLBS201 and followed for 26 weeks. At the baseline, subjects are required to have an eGFR of  $\geq 20$  to  $< 45$  mL/min/1.73m<sup>2</sup> and either UACR  $> 300$  to  $\leq 5000$  mg/g OR documented eGFR decline of at least 3 mL/min/year. Subjects are excluded for certain laboratory abnormalities or unstable disease states, or if there is an anticipated need for near term dialysis or kidney transplant. The primary endpoint for the study is change in eGFR at 6 months compared to baseline. Secondary endpoints include slope of eGFR change and change in UACR and UPCr. For preparation of CLBS201, subjects are treated with G-CSF 5  $\mu$ g/day for 5 days, then undergo apheresis to collect a mononuclear cell fraction. CD34+ cells are isolated using a magnetic separation method. CLBS201 is formulated as a cell suspension in proprietary media in a 10 mL volume for administration into the renal arteries. The first subject will receive CLBS201 to a single kidney. Subsequent subjects will receive CLBS201 in both kidneys. There will be pauses after the first and second subjects' Day 15 visit to review data for safety before proceeding with further exposures.

**Results:** The study was initiated in December 2021 and is expected to complete enrollment mid-2022. Information on study status, baseline demographics, and up-to-date observations will be presented.

**Conclusions:** CLBS201 cell therapy may be a promising treatment strategy for diabetic kidney disease.

## PUB109

### Relationship Between Plasma Fibrinogen and Prognosis of Type 2 Diabetes With CKD

Huan Li, Lu H. Ding. Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China.

**Background:** Several studies have found that plasma fibrinogen (Fib) is often elevated in type 2 diabetes mellitus (T2DM), but its correlation with the clinicopathological manifestations, prognosis, and pathogenic mechanisms of chronic kidney disease (CKD) in type 2 diabetes are not fully understood. Our study aims to investigate the relationship between plasma Fib levels and clinicopathological profile, renal prognosis in T2DM patients with CKD, to early identify high-risk patients with high likelihood of progression to end-stage renal disease (ESRD).

**Methods:** We conducted a retrospective cohort study, including a total of 277 T2DM patients with CKD (defined as biopsy proven glomerular disease). The patients were classified into diabetic nephropathy (DN) (145 cases) and non-diabetic renal disease (NDRD) (132 cases), according to the pathological findings. T2DM patients with CKD were divided into 4 groups (Q1, Q2, Q3, and Q4), based on quartiles of plasma Fib levels. The renal outcomes were defined by reaching ESRD. The influence of plasma fibrinogen levels on renal outcomes was evaluated using Cox regression analysis.

**Results:** The analysis after grouping T2DM patients with CKD based on plasma Fib level in quartiles, demonstrated that, the groups with higher plasma Fib levels tend to be associated with higher 24-hour urinary protein levels. Importantly, in adjusted analysis, higher plasma fibrinogen level is independently associated with a higher risk of progression to ESRD in T2DM patients with CKD (HR, natural log-transformed plasma Fib per 1 SD is 2.91; 95% CI, 1.43 to 5.93,  $P=0.003$ ). Compared with Q1, the HR values for Q2, Q3 and Q4 were 2.68 (95% CI 1.23-5.84,  $P=0.013$ ), 3.08 (95% CI 1.42-6.68,  $P=0.004$ ), and 2.51 (95% CI 1.15-5.50,  $P=0.021$ ), respectively. For prediction of ESRD, the addition of plasma fibrinogen to gender, age, duration of diabetes, hypertension, 24-hour urinary protein, serum creatinine level, and pathological factors etc increased the area under the receiver operating curve from 0.85 to 0.86. The same analysis was also conducted in DN patients, the area under the receiver operating curve from 0.71 to 0.74.

**Conclusions:** Plasma Fib is an independent risk factor for progression to end-stage renal disease in T2DM patients with CKD, and the addition of Plasma Fib to the traditional prediction models improves the predictive power.

## PUB110

### Impact of Implementation of a Renal Diabetes Multidisciplinary Team Clinic in District General Hospital

Senthilkumar Krishnasamy, Riaz V. Bavakunji, Mohamed Thahir Kolpurka Abdul Samad, Murad Al-Dujaili. Walsall Manor Hospital, Walsall, United Kingdom.

**Background:** Diabetic Kidney Disease (DKD) is the leading global cause of end stage kidney disease (ESKD). So far, there is no meaningful collaboration between specialists who were managing vascular complications in these patients. In recent years there have been multiple advances in the glucose-lowering agents available for the treatment of diabetes, which also have very important benefits of diminishing cardiovascular complications and ameliorating renal disease.

**Methods:** A joint MDT clinic was set up in January 2021 to bring the expertise of Diabetes and Nephrology to maximise benefit for DKD patients. We triaged GP referrals, moved patients from separate diabetes and CKD clinics with DKD. There are 112 patients in clinic out of which 92 analysed due to completeness of data and have had follow up between 6-15 months.

**Results:** The mean age for the cohort was 60 years  $\pm$  14 years; 69% were caucasians, 46% were female. The median HbA1c decreased from 71 (IQR 57-91) mmol/mol at baseline to 62.5 (IQR 48 - 74.2) mmol/mol after 6-15 months. Average body weight decreased by 4.1 kg. At baseline, median eGFR was 50.0 mL/min/1.73m<sup>2</sup> and no significant changes noted over the study period. Median UACR showed significant improvement from baseline to 6-15 months period (64.3 mg/mmol to 34.3 mg/mmol). Modest improvement in total cholesterol (0.2mmol/l) & BNP (41.5pg/ml) were noted. In

all eligible patients, RAAS inhibition was prescribed in 86.6% and 91% received sick day rule card. Most patients had more than 2 treatment changes during the initial review. We introduced GLP1RA for 34% and SGLT2i for 71% at first visit. Kidney Failure Risk Equation (KFRE) improved in 70% patients. No one approached ESRD or developed DKA/Fracture /amputations over the intervention period.

**Conclusions:** The interventions demonstrate early benefits not observed in separate specialist clinics. Patients experience with this new initiative was really positive especially with reduced clinic visit with improvement in clinical parameters. We are hopeful with this MDT Clinic, will prevent future adverse CV and renal events

Table 1. Prospective Data over 6-15 months (Change in relevant parameters)

Outcome	First visit	Follow Up	Change
Weight (Kg) (Mean +/- SD)	97.6 +/- 22.0	93.6 +/- 20.4	4.1 +/- 5.8
HbA1c (mmol/mol) (Median/IQR)	71 (57, 91)	62.5 (48, 74.2)	-7 (-20.3, 2.3)
eGFR EPI (mls/min) n=90 (Median/IQR)	50 (33, 61)	47 (35, 61)	0 (-3, 2)
Urine ACR (mg/nmol) n=75 (Median/IQR)	64.3 (15.45, 178.85)	34.35 (4.3, 117.9)	31.0 +/- 94.7 (Mean +/- SD)
Brain Natriuretic Peptide (pg/ml) (Median/IQR)	316 (108.5, 1718.25)	207 (73.25, 632.25)	41.5 (-60.5, 437)
Total Cholesterol (mmol/l) (Mean +/- SD)	4.5 +/- 1.3	4.2 +/- 1.3	-0.2 +/- 1.1

PUB111

Urine Fatty Acids as a Biomarker for Diabetic Kidney Disease Progression

Hima Sapa,<sup>1</sup> Ali Murra,<sup>4</sup> Stephen J. Ganocy,<sup>1</sup> Kinsuk Chauhan,<sup>2</sup> Steven G. Coca,<sup>2</sup> Jeffrey R. Schelling,<sup>1,3</sup> <sup>1</sup>Case Western Reserve University, Cleveland, OH; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>3</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>4</sup>MetroHealth Medical Center, Cleveland, OH; <sup>4</sup>Northeast Ohio Medical University, Rootstown, OH.

**Background:** Accurate biomarkers to identify risk for diabetic kidney disease (DKD) are not clinically available. In mice apical proximal tubule fatty acid transporter-2 (FATP2) mediates fatty acid uptake, tubular atrophy and DKD progression. Because FATP2 is a high affinity, low capacity transporter, we hypothesized that urine palmitate is a DKD biomarker in humans.

**Methods:** We employed a case-cohort design in a discovery set with family history of DKD and a validation set from the ACCORD trial. Study participants with diabetes and baseline eGFR >60 ml/min/1.73m<sup>2</sup> were evaluated for the primary outcome, incident CKD (eGFR decline by >40% and to <60 ml/min/1.73m<sup>2</sup>). We measured urine palmitate by GC-MS, which was indexed to urine creatinine. Cox regression models were used to determine the association of Upalm:creat with the primary outcome, after adjustment for co-variables (age, sex, race, smoking, baseline eGFR and UACR, diabetes duration, HbA1c, sBP, dBP).

**Results:** The discovery set (34 cases, 148 cohort) had longer follow-up, diabetes duration (18.9 ± 11.8 [SD] yrs), younger age (59.4 ± 8.3 yrs), Blacks (53.5%) and women (66.9%). Higher Upalm:creat was associated with incident CKD (adjusted HR [95% CI] 1.5 [1.3-1.8] per log<sub>e</sub> increase; 15.9 [3.3-76.7] for 4<sup>th</sup> vs. 1<sup>st</sup> quartile). For the validation set (187 cases, 463 cohort; 10.8 ± 7.2 yrs diabetes, 62.2 ± 6.8 yrs, 36.6% Black, 38.6% women), Upalm:creat was not associated with incident CKD (adjusted HR [95% CI] 1.0 [0.9-1.2] per log<sub>e</sub> increase; 0.9 [0.5-1.6] for 4<sup>th</sup> vs. 1<sup>st</sup> quartile).

**Conclusions:** In persons with diabetes and eGFR >60, higher Upalm:creat was associated with increased risk of incident CKD in the discovery set, which was not confirmed in the validation set. Discrepant findings could be due to differences in study populations, including DKD family history and less power in the discovery set. Resolution might be achieved with additional studies, such as inclusion of a well-matched third cohort.

**Funding:** Other NIH Support - Rosenberg grant (CDC grant), Other U.S. Government Support

PUB112

Plasma and Urine Biomarkers for CKD Outcomes: A Systematic Review and Meta-Analysis

Caroline Liu,<sup>1</sup> Neha Debnath,<sup>1</sup> Gohar Mosoyan,<sup>1</sup> Kinsuk Chauhan,<sup>1</sup> George Vasquez-Rios,<sup>1</sup> Celine Soudant,<sup>2</sup> Steven Menez,<sup>3</sup> Chirag R. Parikh,<sup>3</sup> Steven G. Coca,<sup>1</sup> <sup>1</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>2</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>3</sup>Johns Hopkins University, Baltimore, MD.

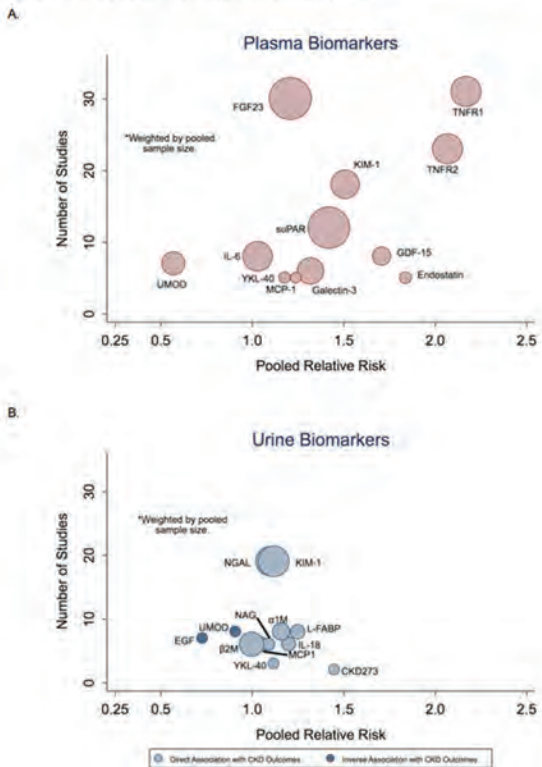

**Background:** Sensitive and specific biomarkers are needed to provide better biological insight into the risk of incident and progressive chronic kidney disease (CKD). However, studies have been limited by sample size and design heterogeneity. We conducted a comprehensive assessment of the prognostic value of preclinical plasma and urine biomarkers for CKD outcomes.

**Methods:** We searched Embase (Ovid), MEDLINE ALL (Ovid), and Scopus up to November 30, 2020 for studies exploring the association between baseline kidney biomarkers and CKD outcomes (incident CKD, CKD progression, or incident end-stage kidney disease). We used random-effects meta-analysis.

**Results:** We screened 26,456 abstracts, 352 full-text articles and included 129 studies in the meta-analysis for the most frequently studied plasma (TNFR1, FGF23, TNFR2, KIM-1, suPAR, IL-6, GDF-15, UMOD, Endostatin, MCP-1, Galectin-3, and YKL-40) and urine (KIM-1, NGAL, L-FABP, A1M, UMOD, EGF, IL-18, B2M, NAG, MCP-1, YKL-40, and CKD273) biomarkers (Figure). Pooled risk ratios [RRs (95% CI)] for CKD outcomes of the most frequently studied plasma biomarkers were: 2.17 (1.91, 2.47) for TNFR1 (n=31); 1.22 (1.15, 1.28) for FGF-23 (n=30); 2.07 (1.82, 2.34) for TNFR2 (n=23); 1.51 (1.38, 1.66) for KIM-1 (n=18); and 1.42 (1.30, 1.55) for suPAR (n=12). Pooled RRs (95% CI) of the most frequently studied urine biomarkers were: 1.10 (1.05, 1.16) for KIM-1 (n=19) and 1.12 (1.06, 1.19) for NGAL (n=19).

**Conclusions:** Biomarker studies of CKD outcomes are considerably heterogeneous, limiting comparisons of prognostic performance across studies. Plasma TNFR1, FGF23, TNFR2, KIM-1, and suPAR were among the most frequently studied for CKD outcomes.

Figure. Number of Studies and Pooled Relative Risks for Twelve Most Frequently Studied Plasma (A) and Urine (B) Biomarkers for Chronic Kidney Disease Outcomes

PUB113

Improvement of Blood Glucose Control Using Continuous Glucose Monitoring in Dialysis Patients With Diabetes

Sua Lee, Eulji University College of Medicine, Daejeon, Republic of Korea.

**Background:** Diabetes is the most common cause of end stage renal disease and as a risk factor of cardiovascular morbidity and mortality in many countries worldwide. Recently, in the management of diabetes, not only reaching the target blood glucose level but also blood glucose stability is considered important. Moreover, glycated hemoglobin A1c (HbA1c) is less accurate in dialysis patients. This study aimed improvement of blood glucose control using continuous glucose monitoring (CGM) in dialysis patients with diabetes.

**Methods:** All patients aged above 18 years, with diabetes mellitus and more than 3 months on hemodialysis or peritoneal dialysis were included from November 2021 to January 2022 in Eulji Medical Center. Patients underwent 2 times CGM during study period. Patients were monitored with self-monitoring blood glucose at least 3 times per day during CGM period. Based on results of baseline study, a dialysis physician modified treatment strategy such as insulin or medication dose and taking time. After 12 weeks, follow-up study was conducted with same protocol of baseline study.

**Results:** Twenty patients who entered the study had a male/female ratio 15/5 and mean age 61.7 ± 10.5 years. Only one patient had type 1 diabetes. Mean diabetes duration was 22.3 ± 7.4 years, and eleven patients (55%) were on insulin therapy such as multiple daily injection or premix insulin or basal insulin plus oral hypoglycemic agents. Patients had a hemodialysis/peritoneal dialysis ratio 18/2 and mean dialysis duration 4.9 ± 3.5 years. Mean blood glucose level were 164.5 ± 36.4 mg/dL at baseline and 150.3 ± 31.9 mg/dL at follow-up study (*p* = 0.026). Mean HbA1c were 7.4 ± 1.3 % at baseline and 6.9 ± 1.1 % at follow-up study (*p* = 0.023). In CGM profile, mean time of target in range (TIR) were 10 hour 57 min ± 6 hour 38 min and 29.2 ± 8.3 (%) at baseline and 14 hour 34 min ± 4 hour 31 min (*p* = 0.009). Glucose area under curve (AUC) over 180 mg/dL were 29.9 ± 25.9 mg/dL/day at baseline and 12.7 ± 10.1 mg/dL/day at follow-up study (*p* = 0.001) without change glucose AUC under 60 mg/dL.

**Conclusions:** In dialysis patients with diabetes, CGM can be useful assessment tool for better glucose control and helpful for improvement of blood glucose level and achievement of blood glucose stability.

PUB114

**Gender Type and Age Are Associated With Urinary Neutrophil Gelatinase-Associated Lipocalin (NGAL) in CKD Naïve Individuals**  
*Swasti Tiwari, Sukhanshi Khandpur, Mansi Bhardwaj, Shafaque Asif. Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

**Background:** Urinary tubular injury markers, kidney injury molecule-1 (KIM-1), and neutrophil gelatinase-associated lipocalin (NGAL), may help in predicting a decline in renal function in individuals with diabetes. However, the role of gender and age in defining urinary KIM-1 and NGAL in individuals with diabetes is not well established

**Methods:** A total of 545 individuals between 18-60 years were enrolled in the study. Urine KIM-1, NGAL, and albumin concentrations were estimated using sandwich ELISA. Urine creatinine was estimated by autoanalyzer (XL-640, Erba Mannheim, Germany), and blood glucose was measured using a handheld glucometer (Blood Glucose and Blood b- KetoneTesting Kit, Abbott Health Pvt. Ltd., India). Diabetes was defined using the International Diabetes Federation guideline. Urinary albumin, KIM-1, and NGAL were normalized with urine creatinine. Albuminuria was defined as urine albumin to creatinine ratio (ACR) ≥30 mg/g.

**Results:** The total cohort included 272(49.9%) males and 273(50.1%) females. Albuminuria was absent in the enrolled subjects. However, 66% of the individuals were found to have diabetes. Although within normal range, ACR was significantly higher in females (Median (IQR):2.04mg/g (1.11-3.97)) when compared to males (Median (IQR): 1.66mg/g (0.62-3.49)) in normoglycemic individuals. Further, urine NGAL (ng/mg creatinine) was also significantly higher in females compared to males. The Median (IQR) of urinary NGAL for individuals with diabetes were: 17.55 ng/mg (8.57) vs 11.37 ng/mg (4.78-26.15), *p*=0.04], and for those without diabetes: 11.93 ng/mg(6.06-29.90) vs 8.47 ng/mg (4.26-18.32), *p*<0.01. Significantly higher levels of NGAL were observed in individuals of age≥45 years (median (IQR): 11.35 ng/mg (5.74-28.77)) when compared to those below 45 years (median (IQR): 9.68 ng/mg (4.26-21.90)) (*p*=0.02). We observed no difference in KIM-1 levels by gender or age in individuals with or without diabetes.

**Conclusions:** Females and individuals older than 45 years had higher urine NGAL levels. Age and gender type need to be considered while establishing the clinical utility of urine NGAL. Funded by Indian Council of Medical Research (ICMR).

**Funding:** Government Support - Non-U.S.

PUB115

**Silent Kidney Disease in a Young Diabetic Woman**  
*Julio C. Nieto, Pamela Prado, Karina Chimbo Lituma, Pedro Morales Molina, Juan D. Diaz Garcia, Ydris Z. Rosillo-Salgado, Francisco Velasco Garcia Lascurain, Mario Alamilla Sanchez, Julio Manuel Flores Garnica. Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Mexico City, Mexico.*

**Introduction:** Chronic Kidney Disease (CKD) and Diabetes Mellitus (DM) are two non-communicable diseases of global significance. Although, DM is the main cause of CKD worldwide, not all cases of CKD are a direct consequence of DM. Other glomerular diseases such as IgA Nephropathy, Focal Segmental Glomerulosclerosis, Minimal Change Disease and Infection-Related Glomerulonephritis are important causes of nondiabetic renal disease (NDRD) in diabetic patients. Highlighting the importance of kidney biopsy in these patients.

**Case Description:** A 29 year-old woman with a history significant for DM2 of 5 years, in treatment with insulin; Hypertension of 1 year, in treatment with Losartan BID and Nifedipine TID, and Obesity class II; was sent to Nephrology consultation after presenting symmetric pitting edema of the lower limbs and uncontrolled hypertension. Laboratory findings: Hemoglobin: 12.2 gr/dL, Leukocytes: 10.72 x 10 <sup>9</sup> /L, Creatinine: 1.26 mg/dL, Blood Urea Nitrogen: 25 mg/dL, Triglycerides: 185 mg/dL, Cholesterol: 150 mg/dL, Albumin: 3.9 gr/dL, HbA1C: 6%. A 24 hour urine sample with 3.6 grams of proteins, normal complement levels, positive antinuclear antibodies (ANA) with a fine speckled pattern 3+ and negative extractable nuclear antigens were obtained. Kidney

biopsy was performed with histological finding of focal and segmental glomerulosclerosis tip lesion variant plus acute interstitial nephritis with eosinophil infiltrate and grade 2 interstitial fibrosis.

**Discussion:** NDRD ranges from 33% to 72.5% among patients with DM and It should be suspected in a diabetic patient with persistent decrease in glomerular filtration rate (GFR), markers of kidney injury such as proteinuria and a relatively recent diagnosis of DM without evidence of microvascular damage. The presence of Nephrotic Syndrome, glomerular hematuria and a decrease in GFR > 5 ml / min / 1.73 m2 per year, are among the indications to perform a kidney biopsy in diabetic patients. Allowing us to unmask a silent kidney disease.

PUB116

**Diabetic Kidney Disease Progression Risks in US Veterans**  
*Kibum Kim,<sup>1,2</sup> Heather A. Nyman,<sup>3,4</sup> Jacob L. Crook,<sup>2,5</sup> Chao-Chin Lu,<sup>2,5</sup> Richard E. Nelson,<sup>2,5</sup> Joanne LaFleur,<sup>6,7</sup> DeCIPHER <sup>1</sup>University of Illinois at Chicago College of Pharmacy, Department of Pharmacy Systems, Outcomes and Policy, Chicago, IL; <sup>2</sup>VA Salt Lake City Health Care System, Salt Lake City, UT; <sup>3</sup>University of Utah College of Pharmacy, Department of Pharmacotherapy, Salt Lake City, UT; <sup>4</sup>University of Utah Hospitals and Clinics, Department of Pharmacy, Salt Lake City, UT; <sup>5</sup>University of Utah School of Medicine, Division of Epidemiology, Salt Lake City, UT; <sup>6</sup>University of Utah Department of Pharmacotherapy, Salt Lake City, UT; <sup>7</sup>COIN Informatics Decision-Enhancement and Analytic Sciences Center, Salt Lake City, UT.*

**Background:** In the Veteran's Health Administration (VHA), patients at high risk of diabetic kidney disease (DKD) require interventions to delay progression to end-stage disease. We examined progression rates for DKD stages 3-5 in US veterans.

**Methods:** We identified veterans with type 2 diabetes (T2D) and DKD using diagnosis codes, prescription records, problem lists, and lab test results from October 2015 through 2021. Prevalent and incident DKD stages were characterized using KDIGO definitions. We used descriptive statistics to characterize the cohort and DKD stage prevalence and incidence rates.

**Results:** Out of 2.1 million US veterans with T2D, most (1.5 million [75.1%]) had reduced renal function (<90 mL/min/1.73m<sup>2</sup>). The mean age was 67.9, and most were male (95.3%) and White (72.4%), Black (19.0%) or Asian American (2.2%). Prevalent and incident DKD stage findings are in the Table. At baseline, 37.6% of T2D veterans with below-normal renal function had DKD. Over a mean follow-up time of 3.3 years, their annual risk of progressing to stages 3-5 was 10.8%. For veterans with prevalent DKD stages 3-4, annual risks of progressing were 26.5%, 16.1%, and 24.5% for stages 3a, 3b, and 4, respectively.

**Conclusions:** Only 4.6% of the VHA's large T2D population had DKD stages 4-5. Another 58% had filtration rates <90, with about 47.9% of these progressing to higher stages annually (121,000 veterans). These findings suggest that interventions are needed to slow DKD progression at early stages, minimizing the burden of DKD in this population.

**Funding:** Commercial Support - Renalytix

*Table. Prevalent DKD stage (according to eGFR and UACR/PCR laboratory results) and incidence rates for first stage progression in US veterans with DKD*

Prevalent stage	Prevalence Frequency (%)	Incidence per 1000 PY (95% CI)
Any	753,933 (100.0)	116.8 (116.4, 117.2)
Stage 1	58,107 (7.7)	888.4 (885.7, 891.1)
Stage 2	59,192 (7.9)	174.6 (172.7, 176.6)
Stage 3a	517,001 (68.6)	129.2 (128.3, 129.4)
Stage 3b	84,606 (11.2)	153.6 (152.1, 155.2)
Stage 4	23,725 (3.1)	251.2 (247.3, 255.2)
Stage 5	11,302 (1.5)	-

*Abbreviations: DKD, diabetic kidney disease; eGFR, estimated glomerular filtration rate; UACR, urinary albumin-creatinine ratio; PCR, protein-creatinine ratio; PY, person years; eGFR, estimated glomerular filtration rate; CI, confidence interval*

The prescribed average dialysate flow rate was 686ml/min pre-intervention and 620ml/min post-intervention ( $p = 0.000002$ ). Despite this, there was no statistically significant difference in measured URR ( $p = 0.19$ ). The average used dialysate volume per session decreased from 138L to 130L ( $p = 0.04$ ).

**Conclusions:** Decreasing the standard dialysate flow rate for acute inpatients had no impact on measured URR. While this confers modest dialysate concentrate and water savings per patient, the net effect of multiple daily sessions over a prolonged period of time offers important conservation benefits to any dialysis unit.

### Hyperkalemia Prevalence, Practice Pattern, and Mortality in Chinese Hemodialysis Patients: Visualize-HD Study

Xinju Zhao,<sup>1</sup> Jianwei Ren,<sup>2</sup> Yan Xu,<sup>3</sup> Yingchun Ma,<sup>4</sup> Haidan Zhao,<sup>5</sup> Jinghong Lei,<sup>6</sup> Li Zuo.<sup>1</sup> <sup>1</sup>Department of Nephrology, Peking University People's Hospital, Beijing, China; <sup>2</sup>Department of Nephrology, Aviation General Hospital, Beijing, China; <sup>3</sup>Department of Nephrology, Emergency General Hospital, Beijing, China; <sup>4</sup>Department of Nephrology, Beijing Boai Hospital, China Rehabilitation Research Center, Captain Medical University, Rehabilitation Medical College, Beijing, China; <sup>5</sup>Department of Nephrology, Peking University Shougang Hospital, Beijing, China; <sup>6</sup>Department of Nephrology, Beijing Aerospace General Hospital, Beijing, China.

**Background:** Hyperkalemia (HK) is a potentially life-threatening disorder in maintenance hemodialysis (MHD) patients associated with ventricular arrhythmias and sudden cardiac arrest. However, studies on the descriptive epidemiology of HK in China and management of potassium and crude mortality are scarce. The aim of this study was to examine HK prevalence, associated practice patterns and mortality in HD patients in China.

**Methods:** This is a multicenter, observational study. Data about serum potassium (sK), patient characteristics, practice patterns, and death records were collected. Continuous and categorical variables were summarized by descriptive statistics and frequency (percentages) respectively.

**Results:** In total, 1096 patients (61% Male) from 6HD centers having age distribution as 18-44(yrs) 11.8%, 45-64(yrs) 43.3%, 65-74(yrs) 27.6%,  $\geq 75$ (yrs) 17.3% were enrolled. The dialysis vintage distribution of  $<5$ yrs; 5-10yrs;  $\geq 10$ yrs was 56%, 32% and 12%, respectively. Nearly 30% patients were using renin angiotensin aldosterone system inhibitors. Nearly 20% patients were using K<sup>+</sup>-lowering drugs. 2.0mmol/L was the most common dialysate K<sup>+</sup> concentration (utilization rate 70%). There were 91% of patients on regular dialysis thrice a week. Most patients (94%) tested sK once every month. The prevalence of HK (sK $>5.0$ mmol/L) in Beijing HD patients was 44%. The proportion of sK $>5.5$  mmol/L, $>6.0$  mmol/L, $>6.5$  mmol/L was 20%, 7%, and 3%, respectively. The 3-year cumulative mortality of HD patients was 25% and 37% patients had HK on the last sK test before death. HK or acute cardiovascular events accounted for 22% of death causes.

**Conclusions:** High HK prevalence is evident in Chinese HD patients and HK management is paramount as it is an important component for the death in HD patients.

Clinical outcome of HK in Chinese HD patients

## PUB122

### Giant Mesenteric Cyst in a Patient Who Had Peritoneal Dialysis for 10 Years

Clementina Elizabeth Calderon Garcia,<sup>1,2</sup> Guillermo Navarro Blackaller,<sup>1,2</sup> Jonathan Chavez,<sup>1,2</sup> Ana E. Oliva,<sup>1,2</sup> Frida Margarita de la Vega Méndez,<sup>1,2</sup> Alexia Romero,<sup>1,2</sup> <sup>1</sup>Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico; <sup>2</sup>Universidad de Guadalajara Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico.

**Introduction:** We present the case of a 30-year-old man with a history of chronic kidney disease of 11 years of diagnosis, a based on peritoneal dialysis for 10 years, during this period he presented peritonitis refractory, and suspected sclerosing peritonitis was made, and he was transferred a hemodialysis.

**Case Description:** The patient presented with a progressive and painful increase in the abdominal perimeter that did not decrease with ultrafiltrate in hemodialysis sessions. An abdominal CT scan showed a giant mesenteric cyst measuring approximately 22 x 17 x

22 cm with a volume of 4,344 cubic centimeters, that was drained percutaneously through a multipurpose catheter without microbiological isolation and negative for malignancy.

**Discussion:** Mesenteric cysts are uncommon abdominal tumors, with an incidence ranging from 1 per 100,000 in adults, with varied symptomatology from asymptomatic to acute or chronic vague abdominal pain, increased abdominal perimeter. In 2010 a similar case was reported in the journal Nephrology Dialysis Transplantation of the University of Oxford, where a 55 years old woman on hemodialysis but previously on peritoneal dialysis and with a history of recurrent peritonitis and suspected sclerosing peritonitis with a giant mesenteric cyst. Giant mesenteric cysts are rare abdominal tumors. In the literature there are few cases where this tumor is related to peritonitis secondary to peritoneal dialysis catheter. The treatment of choice is complete excision of the cyst, in our case, it was treated with prolonged percutaneous drainage, so far without recurrence.

## PUB123

### Dialysis Patients' Preferences for Pain Management at End of Life: A Discrete Choice Experiment

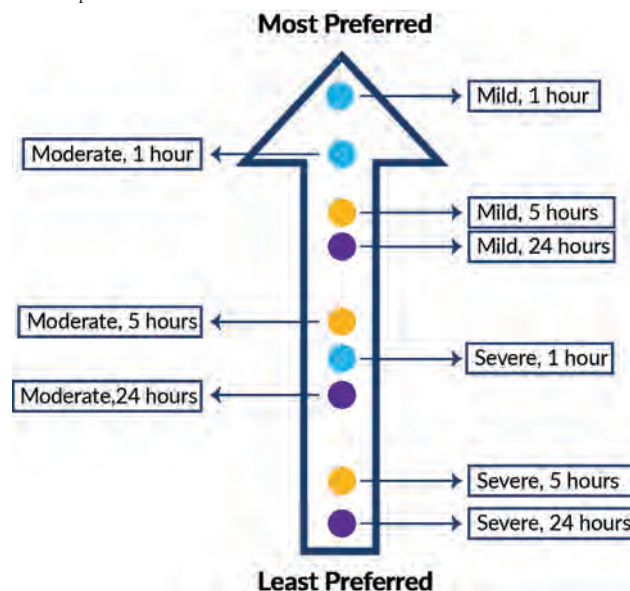

Ania Filus,<sup>1</sup> David A. Roer,<sup>2</sup> Steven M. Brunelli,<sup>1</sup> Francesca Tentori.<sup>1</sup> <sup>1</sup>Davita Clinical Research, Minneapolis, MN; <sup>2</sup>DaVita Inc, Denver, CO.

**Background:** Quality of care at the end of life (EoL) is an important topic for ESKD patients. Previous results indicate that the level of pain management is the most important attribute of care among dialysis patients at the end of life. We conducted a discrete choice experiment to evaluate patients' preferences for aspects of pain management.

**Methods:** An online survey conducted in February-March 2022 collected data from 233 in-center and 98 home dialysis patients and tested the relative importance of two aspects related to daily pain management: (i) the intensity of pain (mild, moderate, severe) and (ii) the duration of pain (1 hour, 5 hours, 24 hours). We utilized a block fraction factorial design with 3 blocks and 3 questions within each block.

**Results:** Results of this study indicate that pain intensity and duration were important attributes of pain management at the end of life. Patients ranked pain intensity from most preferred to least preferred as mild, moderate, severe. Results were similar with regards to pain duration; patients preferred 1 hour over 5 hours or 24 hours. Additionally, results indicate that patient preference for pain management at the end of life is an interaction of both pain intensity and duration, and depends on the initial level of pain intensity and duration a patient is experiencing. For example, a patient who is in severe 24 hour pain daily will find it more attractive to reduce their pain intensity from severe to mild than to reduce daily pain duration from 24 hours to 5 hours (Figure 1).

**Conclusions:** Pain management with respect to intensity and duration are both significant aspects of quality of care at the end of life among ESKD patients. Results from this study can help inform dialysis clinics' approach towards discussing pain management at EoL and palliative care.

## PUB124

### Halving Sodium Heparin While Maintaining Dialytic Clearances During Hemodiafiltration With an Asymmetric Cellulose Triacetate Membrane

Antonino Sidoti,<sup>1,2</sup> Beatrice Braccagni,<sup>1,2</sup> Marina Biagioli.<sup>1,2</sup> Nephrology unit Poggibonsi-Siena Italy <sup>1</sup>Nefrologia Valdelsa, Poggibonsi, Italy; <sup>2</sup>USLSUDEST, Poggibonsi, Italy.

**Background:** Computed tomography studies showed no significant filter coagulation while reducing by 50-75% heparin sodium (Hep) in extracorporeal circuit during in vitro hemodiafiltration (HDF) with an asymmetric cellulose triacetate filter. We checked if a 50% Hep reduction affects dialytic clearance (KD) during high volumes HDF.

**Methods:** Six patients (Pts) more than a year on hemodialysis with no residual kidney function participated. They had a two weeks HDF course, on a count of 3 sessions every week, using a Solacea 21H Nipro filter. 1st week (1stW) had same Hep dose of previous dialysis treatments, second week (2ndW) had an average of 54.7% Hep reduction. Treatments lasted 240', 2 Pts out of six at 210'. Hep was given as a bolus at start and as continuous infusion afterward, stopping Hep pump 15' before HDF end. aPTT was performed at 0', 30', 60', 120', 180', HDF end, at 1stW and 2ndW start. KD was acquired from the dialysis machine at 30', 120' and HDF end, Pts used always same machine (Baxter, Nipro, Medtronic) during 1stW and 2ndW. Ultrafiltration (UF), liters of blood treated (LTr), infused (Linf) were recorded for each HDF. Comparison of 1stW and 2ndW averages were made by paired t Student test, statistical significance set at  $p < 0.05$ .

**Results:** KD 1stW and 2ndW (table 1) pNS, average 239 1stW vs 236 ml/min<sup>2</sup> 2ndW; being UF 1stW 3.088, 2ndW 2.88 pNS, LTr 1stW 75.5 2ndW 77 pNS; Linf 1stW 20.54, 2ndW 21.63 pNS (Table 2); pNS for aPTT comparing 120' 180' and HDF end to aPTT basal level. Tiny signs of coagulation at venous drip chamber in two dialysis session 2ndW for pts 4 and 6.

**Conclusions:** KD doesn't change during high volume HDF even with an aPTT near to basal level, as seen in the second half of dialysis. Solacea filters can be used with minimal Hep doses without affecting dialysis adequacy.

**Funding:** Government Support - Non-U.S.

### Two Cases of Tandem Therapy With New Sell Adsorption Type Blood Purification Device Rheocarna™ and Online Hemodiafiltration for Hemodialysis Patients With Arteriosclerosis Obliterans

Toshihide Naganuma, Kentaro Shin, Yoshiaki Takemoto, Junji Uchida. *Osaka Kofutsu Daigaku, Osaka, Japan.*

**Introduction:** In Japan, new sell Adsorption Type Blood Purification Device Rheocarna™ (KANEKA CORPORATION) has been available for patients with the most severe form of arteriosclerosis obliterans (ASO). However, there is a disadvantage in performing the treatment on non-dialysis days or after the completion of dialysis, as the patient is restrained for long periods of time. Therefore, we report on an opportunity to use Rheocarna™ in tandem with online hemodiafiltration (OHDF) to reduce patient restraint time.

**Case Description:** Two hemodialysis patients with diabetic nephropathy as etiology and with Fontain classification IV ASO were included in the study. The patients were placed on Rheocarna™ due to worsening leg ulcers. Rheocarna™ was connected in parallel series to OHDF, and each monitoring value and blood pressure were measured every 30 minutes. The tandem therapy was performed in two ways: arterial (A-side) and venous (V-side) connection. Case 1 was connected 9 times on the A side and 13 times on the V side. Case 2 had 3 A-side connections and 6 V-side connections. The pressure in the circuit was significantly higher for the A-side connection. Systolic blood pressure remained stable during treatment (Figure 1).

**Discussion:** Although the tandem therapy is a complicated procedure and requires higher alarm settings than usual because the pressure is higher than when performed alone, the combination therapy of Rheocarna™ and OHDF was considered to reduce the patient's restraint time. In addition, both the A-side and V-side connections were considered to provide functionally stable treatment. In particular, the V-side connection is considered to provide more functionally stable treatment because the intra-circuit pressure remains low and the hypotension remains high, reducing the effect of pressure. In conclusion, we experienced two cases in which combination therapy of Rheocarna™ and OHDF was safely administered without trouble.

## PUB126

### Frequent Circuit Clotting in a COVID-19 Patient on ECMO and CRRT

Bijin Thajudeen. *Banner University Medical Center Tucson, Tucson, AZ.*

**Introduction:** A striking feature of COVID-19 is the high frequency of thrombosis, particularly in patients who require admission to the intensive care unit because of respiratory complications (pneumonia/adult respiratory distress syndrome). The spectrum of thrombotic events is broad, including in situ pulmonary thrombosis, deep-vein thrombosis, associated pulmonary embolism, and arterial thrombotic events. We report a case of frequent filter clotting secondary to heparin.

**Case Description:** A 37-year-old Hispanic male patient was admitted to the hospital with complaints of fatigue, cough, and shortness of breath. After his positive PCR result, he was diagnosed with SARS-CoV2 infection. He was transferred to the intensive care unit due to worsening hypoxia with subsequent intubation and mechanical ventilation. Due to persistent hypoxia, extracorporeal membrane oxygenation was started along with heparin anticoagulation. Around this time, he also had a drop in urine output due to acute kidney injury. With the initiation of ECMO, CRRT was started for volume and electrolyte management. Two days after the start of ECMO and CRRT, frequent clotting of the CRRT filter and the ECMO circuit was noticed. There was a simultaneous drop in platelet count as well. The reduction in platelet count and regular filter clotting was initially attributed to covid 19. But with increasing frequency of clotting episodes, we performed anti-PF4/Heparin antibody test, which was positive, confirming heparin-induced thrombocytopenia. Given HIT, anticoagulation was transitioned to argatroban, which resulted in the resolution of frequent clotting of both CRRT and ECMO circuits. Thrombocytopenia also resolved.

**Discussion:** This case highlights the importance of considering HIT as one of the reasons for hypercoagulability in patients with covid 19. There is an increased risk of HIT in patients with covid 19.

## PUB127

### Risk Factors for Admission Among Dialysis Patients in Southeast North Carolina

Andrew Lee, Hsiao L. Lai. *East Carolina University, Greenville, NC.*

**Background:** Hospitalizations account for nearly a third of cost of care for hemodialysis patients. There are many reasons for admission in this population. The purpose of this quality improvement project is to determine the common admission diagnoses for hemodialysis patients in southeast North Carolina and identify modifiable risk factors.

**Methods:** The hospital medical record for Vidant Medical Center, the largest hospital serving southeast North Carolina was reviewed from 1/1/2021 to 1/1/2022 for admissions from the local outpatient dialysis unit. Admission diagnoses included access related admissions, infection, anemia, acute coronary syndrome, cerebral vascular accident, and missed dialysis.

**Results:** Out of 135 patients, there were 250 admissions over a period of 1 year among 91 patients. 44 patients (~33%) had no admissions over this time. Admissions related to access issues or dialysis-treatment issues accounted for the top 2 reasons for admission at 26% each. Most access related issues were for creation or revision with 7 admissions for infected vascular access. Half of all dialysis-related admissions were due to shortness of breath. Non-access related infections accounted for a total of 59 admissions. Anemia and gastrointestinal bleeding accounted for 16 admissions.

**Conclusions:** Dialysis access management which vascular access centers help control admission rates with only two admissions for perm cath placement. Missed dialysis resulting in volume overload, hyperkalemia and hypertensive emergency occurs frequently. Much attention is paid in the outpatient setting to volume management, but patient compliance can be difficult to manage. Infections accounted for almost a quarter of admissions. A high prevalence of risk factors such as: diabetes, hypertension, cardiovascular disease and a high prevalence of protein malnutrition in this population are likely contributors. Anemia admissions accounting for 5% of the total, were mostly secondary to gastrointestinal bleeding rather than due to anemia of chronic disease. The average number of admissions per patient was 1.85 per year. If we exclude the 44 patients who did not get admitted the average number of admissions was 2.7 per year. Of the remaining 91 patient's requiring hospitalization, 21 of these patient's had more than 3 admissions.

## PUB128

**Anti-Depressing Intradialytic Blood Pressure**Antonio Corona. *Northwell Health, New Hyde Park, NY.*

**Introduction:** Intradialytic hypotension (IDH) is a frequently encountered complication of hemodialysis, with a prevalence of more than 10% of treatments. It causes debilitating symptoms, access thrombosis and under-dialysis. Furthermore, it is associated with poor outcomes, correlating negatively with cardiovascular and all-cause mortality. Interventions such as sodium modeling, cooled dialysate and vasopressors have been used to mitigate IDH, but despite these, refractory IDH cases remain difficult to manage. The following case describes a lesser known therapeutic option: Sertraline.

**Case Description:** A 66 y.o. M was referred to our Palliative Nephrology service for symptom management. His medical history included for end stage kidney disease on hemodialysis, coronary artery disease, heart failure, and peripheral vascular disease (PVD). His primary complaint was uncontrolled pain in his legs consistent with neuropathy due to PVD. His hemodialysis was complicated by IDH, with systolic blood pressures (SBP) of 80-90 mm Hg, despite midodrine. His low SBP limited the patient's ultrafiltration (1.2L on average that month), and furthermore, precluded his use of opioid analgesics, often leading to acute pain crises. Sertraline was started for his neuropathic pain and for his IDH. The initial dose was 50mg and then uptitrated to 100mg after two weeks. After an 8 week follow-up, his SBP improved to a range of 84 to 96 mm Hg with an increase in average volume removal of 1.5L. He reported improved subjective pain scores as well.

**Discussion:** Sertraline is a selective serotonin reuptake inhibitor anti-depressant medication. Although there are studies of its use in the hemodialysis population, the sample sizes are usually small and not placebo-controlled. Regardless, it has been described as having a positive effect on IDH by an average of 8.7mmHg in some case series. The mechanism is not well understood but the theory is that it can have vasodilatory and vasoconstrictive effects in different vascular beds in the circulatory system, mediated by pre-junctional S1 receptors and S2 receptors on smooth muscle. It has also been used as first-line for neuropathic pain, by acting on serotonin-mediated analgesic pathways. It is a well-tolerated drug for patients with kidney insufficiency with no dose adjustments necessary based on clearance. Sertraline can serve as an available, safe, therapeutic option for dialysis patients with IDH.

## PUB129

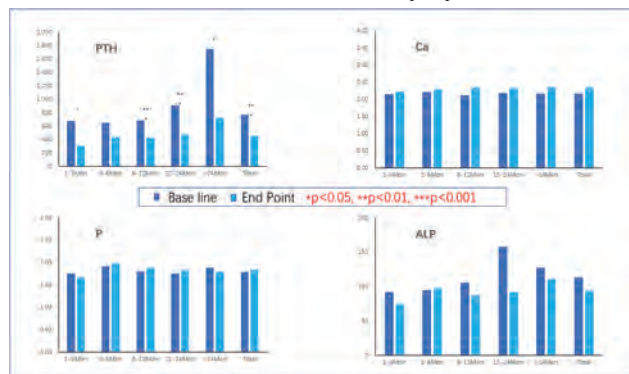

**Efficacy of Paricalcitol in the Treatment of Secondary Hyperparathyroidism in Maintenance Hemodialysis Patients**Santao Ou. *The Affiliated Hospital of Southwest Medical University, Luzhou, China.*

**Background:** To investigate the efficacy of paricalcitol on maintenance hemodialysis (MHD) patients with secondary hyperparathyroidism (SHPT).

**Methods:** Using the self-control method, 101 patients undergoing MHD with SHPT in the Affiliated Hospital of Southwest Medical University from September 2019 to December 2021 were retrospectively collected. The patients were treated with paricalcitol, and the serum parathyroid hormone (PTH), calcium, phosphorus, and alkaline phosphatase (ALP) were measured before and after treatment, respectively, and the dosage was adjusted according to the changes of the indexes in the monthly review. Statistical analysis was performed using SPSS 26.0 software.

**Results:** The PTH of all patients after treatment was lower than that before treatment ( $P < 0.001$ ), the overall compliance rate was 66.3%, and the average compliance time was 4.6 months; the average PTH change was  $(-414.3 \pm 465.9)$  pg/ml. (1) According to the follow-up time, the patients were divided into 5 groups (1-3 months, 3-6 months, 6-12 months, 12-24 months, >24 months) ( $n=15$ ;  $n=14$ ;  $n=31$ ;  $n=10$ ), each The end point of the follow-up time in the two groups was lower than the baseline PTH level. Except for the 3-6 month group, there was no significant difference before and after PTH ( $P=0.074$ ), and the differences between the other groups were statistically significant ( $P=0.001$ ,  $<0.001$ ,  $<0.001$ ,  $0.01$ ). (2) The blood calcium level was higher than that before treatment ( $P < 0.001$ ), and the differences in the baseline and end-point calcium levels in each group were statistically significant ( $P < 0.01$ ,  $0.02$ ,  $<0.01$ ,  $<0.01$ ,  $0.03$ ). There was no significant difference in serum phosphorus levels in each group before and after treatment ( $P > 0.05$ ). ALP levels in each group had no significant differences ( $P > 0.05$ ), while 6-12 months, 12-24 months and overall differences were statistically significant ( $P < 0.05$ ).

**Conclusions:** Paricalcitol can effectively reduce the levels of PTH and ALP in MHD patients with SHPT, and has little effect on calcium and phosphorus levels.

## PUB130

**Ocular Disequilibrium Syndrome as a Cause of Dialysis Noncompliance**Martin Sedlacek. *Icahn School of Medicine at Mount Sinai, New York, NY.*

**Introduction:** Non-compliance with dialysis treatments is a frequent problem in the ESRD population that is associated with increased morbidity, mortality and health care cost. Clinical assessment can often reveal an underlying cause to non-compliance with treatment. Here we present the case of a patient who experienced severe headaches that developed within the first hour of dialysis treatment.

**Case Description:** A 64 y/o man with ESRD, type 1 diabetes mellitus, HFpEF, PVD and proliferative retinopathy was seen during his third hospitalization for volume overload in three months since he started hemodialysis treatment. The patient had missed multiple treatments and shorted dialysis treatments, often to one hour or less. He was aware of the risks of missing dialysis but could not bear the intense frontal retroocular headaches that appeared during the first hour of dialysis and usually were accompanied by very high BP over 200mmHg. He previously was followed by ophthalmology for severe diabetic retinopathy with neovascularization glaucoma and open angle glaucoma but did not have follow up since two years with the pandemic and had run out of eye drops. Ophthalmology was consulted and restarted his treatment for glaucoma. His intraocular pressure (IOP) was 19/25 mmHg (normal <21mmHg), measurements during the dialysis procedure could not be obtained. The patient's headaches improved and he was able to tolerate full treatments. The patient was seen again 6 months later when he came to the ED for a vasovagal syncope. He had been hospitalized for uncontrolled HTN once in the interim but did not miss dialysis treatments. He did not have the recommended ophthalmology follow up but was taking his eye drops religiously and experienced headaches only on rare occasions.

**Discussion:** The rapid decrease of plasma osmolality at the beginning of hemodialysis can acutely increase IOP which may be symptomatic in the susceptible patient. This syndrome has been called ocular dialysis disequilibrium syndrome and occurs mainly in patients with glaucoma or a predisposition to glaucoma. Ocular dialysis disequilibrium is described only rarely which may be related to a lack of familiarity of nephrologists with ophthalmology and vice versa. This case illustrates how ocular dialysis disequilibrium syndrome can impact dialysis treatment and the importance of communication and clinical assessment in patients with non-compliance to dialysis.

## PUB131

**Home Hemodialysis (HHD) in a Critically Ill Patient With Sepsis**Artur Q. Silva,<sup>1</sup> Joao Braz Bezerra,<sup>2</sup> Nefron Group <sup>1</sup>Universidade Federal do Rio Grande do Norte, Natal, Brazil; <sup>2</sup>Americas Servicos Medicos, Rio de Janeiro, Brazil.

**Introduction:** HHD has been available as a modality of renal replacement therapy (RRT) since the 1960s for stable patients but not for critically ill patients. This study aims to present an experience in performing HHD in an elderly patient with multiple comorbidities and AKI due to sepsis.

**Case Description:** A 93-year-old man with several chronic diseases (CPOD, atrial fibrillation, dementia, stroke), had sepsis due to cholecystitis, which required percutaneous drainage and broad-spectrum antibiotic therapy (BSAT) for 10 days. After hospital discharge, the patient developed new sepsis due to pneumonia with MODS, and a new BSAT was initiated. The patient presented with gastrointestinal tract symptoms. Oral anticoagulant was discontinued, and total parenteral nutrition was started. All complementary examinations were performed at the patient's home (laboratory tests, ultrasonography, and transthoracic echocardiography). The patient's family refused a hospital regimen. A room in the patient's apartment was structured as an intensive care environment. He developed AKI with AKIN 3, RRT was indicated, an HD catheter was implanted, and HHD was initiated. The patient underwent nine sessions of HHD in 2 weeks, with hypervolemia reduction, interruption of the infusion of norepinephrine, improved level of consciousness, conclusion of the antibiotic therapy regimen, and replacement of continuous positive airway pressure with low-flow nasal cannulas. After >3 days, the patient died. Cardiopulmonary resuscitation maneuvers were not performed, as agreed with the family. No conflicts occurred with the patient's family at any time.

**Discussion:** HHD is indicated for stable patients and is possible in palliative care scenario. In our case, HHD was needed for end-of-life symptom management, and the physician board reflected that maintenance dialysis was palliative. All HD sessions (sustained low efficiency dialysis) were maintained full time by a nephrologist and nephrologist nurse in an apartment room structured as an intensive care unit, ensuring patient safety. HHD in critically ill patients is possible in selected cases, especially in a favorable risk-benefit ratio, and attempts to provide a last chance for patient recovery and time for the family to prepare for potential death. To the best of our knowledge, this is the first case of HHD in a critically ill patient in Brazil. HHD should not be used as a dysthanasia therapy.

## PUB132

**Unilateral Transudative Pleural Effusion in a Peritoneal Dialysis (PD) Patient**Violeta Alvarez Retamales, Hafiz Sarfraz A. Khan, Ronald L. Mars. *University of Florida College of Medicine, Jacksonville, FL.*

**Introduction:** A massive pleural effusion is a rare complication seen in patients on PD. Determining the etiology can be challenging. A pleuroperitoneal leak should be considered in order to prevent recurrent hospitalizations and/or inappropriate changes in therapy with no improvement in symptoms.

**Case Description:** 65 Y/O female with ESRD began PD one year prior to admission (PTA). One week PTA her PD effluent volume dropped significantly & she developed dyspnea. An abdominal KUB showed stool burden and a CXR showed a large sized(R) pleural effusion. Four days later, laxatives had improved her retained stool burden, her PD effluent returned to her normal baseline state, and her respiratory distress improved. Yet a repeat CXR confirmed a larger(R) pleural effusion. A thoracentesis produced 1200 mL of clear yellow transudate (pH 8.0, LD 20 IU/L, protein < 0.2g/L, glucose 387 mg/dl). Simultaneous serum studies showed LD 230 IU/L, total protein 6.2 g/L & glucose 238 mg/dl. PD was stopped and she was transitioned to hemodialysis with subsequent resolution of pleural effusion.

**Discussion:** A pleuroperitoneal leak is an unusual complication of PD, but the common denominator reflects a communication between these two cavities. A high glucose concentration in the pleural fluid is pathognomonic for this condition, as no other cause of pleural effusion has a marked elevation of glucose compared with serum levels. Etiologies may include trauma, sudden increasing intra-abdominal pressure or peritoneopleural fistula. Diagnosis may require scintigraphy, CT peritoneography or MRI to localize the leak. Therapeutic approaches with resolution may include discontinuing PD for 3-6 months, surgical patch grafting of the diaphragmatic leak, tetracycline instillation in the pleural space, or video-assisted talc pleurodesis.

CXR revealing a large sized (R) pleural effusion

PUB133

**Patients’ Preferences of Dialysis Modalities: Experiences From a Tertiary Level Military Hospital in the Philippines**  
Cernan C. Oliveros, Rafael Montepio. *Armed Forces of the Philippines Medical Center, Quezon City, Philippines.*

**Background:** There are two modalities of renal replacement therapy available in our country ; Hemodialysis and Continuous Ambulatory Peritoneal Dialysis. Usually renal replacement therapy is initiated when patients present with emergency indications. There are institutions that are only capable of emergency hemodialysis and many patients with emergency indications are put on it as default. The goal of this study is to educate chronic kidney disease patients about the attributes of the two modalities and find out their preference ahead of initiation of dialysis.

**Methods:** The study is prospective and observational, using a survey tool with to quantify preferences between two dialysis treatment attributes (Hemodialysis And Continuous Ambulatory Peritoneal Dialysis). The attributes include (1) Access site (2) Dialysis Frequency (3) Dialysis Participation (4) Dialysis Place (5) Travel Considerations (6) Fluid Intake (7) Diet Considerations (8) Activity Planning (9) Symptom Fluctuation (10) Activity Restrictions (11) Troubleshooting. After choosing their favored attributes between the two, patients will be asked the final choice of their preferred dialysis modality.

**Results:** The study has 95 respondents. Attributes of Continuous Ambulatory Peritoneal Dialysis that are favored over Hemodialysis are Fluid Intake, Symptom Fluctuation, Diet Considerations, Activity Planning, Activity Restrictions, Travel, Dialysis Place, and Dialysis Access, Hemodialysis attributes favored over Continuous Ambulatory Peritoneal Dialysis are Troubleshooting, Dialysis Participation and Dialysis Schedule. Majority of the patients prefers Continuous Ambulatory Peritoneal Dialysis (N=64, 67.37%) over Hemodialysis (N=31, 32.63%).

**Conclusions:** After giving predialysis education, majority of the patients chose Continuous Ambulatory Peritoneal Dialysis because it has many favored attributes than Hemodialysis.

Dialysis Characteristics	Hemodialysis	%	Continuous Ambulatory Peritoneal Dialysis	%
1. Dialysis Access Site	44	46.32%	51	53.68%
2. Dialysis Schedule	56	58.95%	39	41.05%
3. Dialysis Participation	61	64.21%	34	35.79%
4. Dialysis Place	36	37.89%	59	62.11%
5. Travel	34	35.79%	61	64.21%
6. Fluid Intake	0	0%	95	100%
7. Diet Considerations	7	7.37%	88	92.63%
8. Activity Planning	14	14.74%	81	85.26%
9. Symptom Fluctuation	0	0%	95	100%
10. Activity Restrictions	33	34.74%	62	65.26%
11. Troubleshooting	76	80%	19	20%

PUB134

**Relationship Between Dialysate Conductivity and Intraperitoneal Volume During Peritoneal Dialysis Treatment**  
Fansan Zhu,<sup>1</sup> Laura Rosales,<sup>1</sup> Lela Tisdale,<sup>1</sup> Maricar Villarama,<sup>3</sup> Peter Kotanko.<sup>1,2</sup> *<sup>1</sup>Renal Research Institute, New York, NY; <sup>2</sup>Icahn School of Medicine at Mount Sinai, New York, NY; <sup>3</sup>Mount Sinai Hospital Mount Sinai Heart, New York, NY.*

**Background:** Dialysate ionic conductivity (Cd) has been considered as a useful method to provide information about the peritoneal membrane transport (La Milia *et al.*, NDT, 2015). However, it is not clear whether the Cd is correlated with a change in intraperitoneal volume (IPV). The aim of the study was to evaluate the relationship between IPV on Cd during PD dwell.

**Methods:** Seven peritoneal dialysis (PD) patients (2 females; age 58.7±10.2 years, weight 87.9±23.2 kg) underwent a standard 4-hours peritoneal equilibration test (PET) using 2 L of 2.5% glucose dialysate. Dialysate Cd was measured hourly during dwell (conductivity meter CDH-280, Omega, CT). Segmental bioimpedance analysis (SBIA) using the Hydra 4200 device was performed during PD treatment (Zhu *et al.*; ASN, 2019). Ratio of IPV to 5 kHz resistance (R5) was calibrated by the known volume of fresh dialysate (2 L). IPV was calculated from continuous SBIA measurement of R5 during dwell. Ultrafiltration volume (UFV) was defined as the weight difference drained minus filled dialysate.

**Results:** One SBIA measurement was unavailable for technical reasons. Mean UFV was 0.40±0.35 L. Cd increased from pre to post PET from 11.25±0.18 to 12.61±0.46 mS/cm (p<0.0001). UFV was not associated with the change in Cd during the dwell (R<sup>2</sup>=0.34; p=0.17). Cd did not correlate with IPV. R5 correlated with IPV in all patients (Fig.1). Cd in individual patients was unrelated to membrane transport characteristics as measured by PET.

**Conclusions:** While IPV was correlated significantly with the resistance at 5 kHz (R5), Cd did not correlate with IPV (Fig.1). Our preliminary results show that R5 is mainly influenced by IPV changes rather than by changes in dialysate conductivity. This insight is relevant for the interpretation of R5 measurements.

Fig.1

## PUB135

**Association of Primary Care Provider (PCP) Use With Mortality and Hospitalization Among Older Home Dialysis Patients**

Rohanit Singh,<sup>1</sup> Raquel C. Greer,<sup>1</sup> Laura Plantinga,<sup>2</sup> Sandeep S. Soman,<sup>3</sup> Michael J. Choi,<sup>4</sup> Mara McAdams-DeMarco,<sup>1</sup> Bernard G. Jaar.<sup>1</sup> National Kidney Foundation Education Committee <sup>1</sup>*Johns Hopkins University, Baltimore, MD*; <sup>2</sup>*Emory University, Atlanta, GA*; <sup>3</sup>*Henry Ford Hospital, Detroit, MI*; <sup>4</sup>*MedStar Georgetown University Hospital, Washington, DC*.

**Background:** The impact of PCP services on outcomes for home dialysis patients is not well established. This study assesses the association of PCP services before and after dialysis start with mortality and hospitalization.

**Methods:** Using data from the USRDS, we assembled a cohort of 9854 incident (2008-2014) older (age  $\geq 67$  years) U.S. home dialysis patients. PCP use was measured for 2 years (1 year before and 1 year after dialysis start). PCP use was defined as “never used” if there was no PCP use during study period, “discontinued” for PCP use before but not after dialysis start, “initiated” for no PCP use before but PCP use after dialysis start, and “continued” for PCP use before and after dialysis start. We used Cox proportional hazards models to assess all-cause mortality and first all-cause hospitalization within the first year after starting dialysis. Inverse probability weighting was used to adjust for confounding.

**Results:** Overall, 21% never used PCP, 11% discontinued PCP use, 9% initiated PCP use, and 59% continued PCP use after starting dialysis. Compared to never using PCP services, discontinuing or continuing PCP services were associated with 11% and 9% adjusted lower risk of mortality, respectively. Initiating PCP use after home dialysis start was associated with 13% greater risk of first all-cause hospitalization (Table).

**Conclusions:** PCP use prior to starting home dialysis has a beneficial impact on mortality, even a legacy effect on patients who discontinued PCP use. Higher risk of hospitalization for initiating PCP use may reflect confounding by indication. Further research assessing the beneficial components of primary care use in the context of home dialysis is needed.

**Funding:** Private Foundation Support

Adjusted Hazard Ratios (95% CIs) for All-Cause Mortality and First All-Cause Hospitalization

**Severe Metabolic Acidosis due to Sodium Thiosulfate in Peritoneal Dialysis**

Mal P. Homan, Mykel G. Tadros, Joseph C. Guzzo. *Lehigh Valley Health Network, Allentown, PA*.

**Introduction:** Calcific Uremic Arteriopathy (CUA), known as calciphylaxis, is a disease process resulting in painful lesions due to necrosis and skin ischemia. It is usually seen in patients with End-Stage Kidney Disease (ESKD) with risk factors including secondary hyperparathyroidism, warfarin use, and longstanding renal replacement therapy. Sodium thiosulfate (STS) is used in treatment, which has demonstrated clinical improvement of calciphylaxis.<sup>5</sup> Typical dosing is thrice weekly on hemodialysis, though there are reports of intra-peritoneal administration.<sup>3</sup> One complication potentially limiting the use of STS is severe metabolic acidosis.<sup>1</sup>

**Case Description:** A 49-year-old female with ESKD on PD, Protein C deficiency, and DVT on warfarin presented to the hospital with multiple painful lesions; CUA was diagnosed. Warfarin and calcitriol were discontinued, and she was transitioned to apixaban. The patient remained on peritoneal dialysis as vascular access was complicated given history of recurrent DVT surrounding dialysis catheter placement. She was started on STS 25g thrice weekly through Hickman catheter. She presented two months later with worsening, severe pain. Her labs revealed elevated anion gap of 47 with a serum bicarbonate of 14 mmol/L. Venous blood gas revealed pH 7.21. Urinalysis negative for ketones, blood glucose was 94, mg/dL, and lactate was 1.2 mmol/L. She was started on bicarbonate therapy, PD was restarted, and further STS was held. Bicarbonate improved to 17-19 mmol/L the following day, and her anion gap improved down to 11 nine days later. Ultimately, STS was discontinued. Unfortunately, the patient's severe pain persisted despite escalation of analgesic therapy prompting consideration of hospice.

**Discussion:** This case highlights the potential effect of high anion gap metabolic acidosis attributed to STS therapy in a PD patient. Severity ranges from mild and asymptomatic to severe life-threatening metabolic acidosis.<sup>4</sup> The mechanism is unknown although several theories have been postulated, including hydrogen sulfide as a metabolite of STS inhibiting mitochondrial electron transport chain shunting ATP production towards lactate production, as well as formation of thiosulphuric acid in vivo and oxidative stress from sulfide-containing compounds. Better understanding of the use of STS, including its metabolism and side effects is needed, especially in PD patients.<sup>2</sup>

## PUB137

**Evolution of Peritoneal Functions in Patients Receiving Long Term Peritoneal Dialysis**

Cheng-Hsu Chen,<sup>1,2</sup> Jie-Wei Chiu,<sup>3</sup> Shangfeng Tsai,<sup>2</sup> Yu-Chen Tsai,<sup>3</sup> Ren-Shiang Chen.<sup>3</sup> <sup>1</sup>*National Chung Hsing University, Taichung, Taiwan*; <sup>2</sup>*Division of Nephrology, Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan*; <sup>3</sup>*Tungshai University, Taichung, Taiwan*.

**Background:** Long-term peritoneal dialysis (PD) results in structural and functional changes in peritoneum. The peritoneal equilibration test (PET) is a semi-quantitative measurement that characterizes the rate of transfer of solutes and the water transfer rate across the peritoneum in patients treated with PD. This study was to prospectively evaluate patients' survival in different peritoneal transport status as well as the potential correlations with disease categories.

**Methods:** The data were retrieved from the Taiwan Society of Nephrology Data Platform (TSN-KiDiT) with 268 patients in Taichung Veterans General Hospital (VGHTC) started chronic PD between 2014 to 2019. The longitudinal evolution of peritoneal function was analyzed by their alternative change of PET by the time. Patients were categorized into four groups based on their first PET D/P ratio at month 3 for each PD patients, and their trajectories were analyzed until the end of the study or time before drop-out PD. The data was analyzed their risk of their original disease entities, at the meanwhile, technique survival and patient survival were analyzed by their PET.

**Results:** Trajectories over time for high and low PET groups were evolved toward the high average (HA) or low average (LA) PET within four years. Patients with different PET groups in the first year of PD had significant difference in the technique survival ( $P = 0.006$ ), but not in patient survival ( $P = 0.151$ ). According to the risk factors of technique survival within 6 years of PD, we found patients with chronic glomerulonephritis (CGN) with different PET groups had significantly different in the technique survival ( $P = 0.012$ ), however, we could not demonstrate PET affected their survival in hypertension and diabetes patients.

**Conclusions:** We concluded that trajectories of four PET groups were evolved toward the average peritoneal function over the time. Though, solution type, using biocompatible solutions and duration of vintage of PD might affect peritoneal function, their entities of underlying disease might also play important role for their technique survival.

## PUB138

**Global Clinician Perceptions on the Priorities for Exercise Programming in People Receiving Peritoneal Dialysis**

Oksana Harasemiw,<sup>1,2</sup> Emilie Ford,<sup>1,2</sup> Iwona Gabrys,<sup>5</sup> Ruth Getachew,<sup>1</sup> Paul N. Bennett,<sup>3,4</sup> Clara Bohm.<sup>1,2</sup> Global Renal Exercise Network (GREX) <sup>1</sup>*Seven Oaks Chronic Disease Innovation Centre, Winnipeg, MB, Canada*; <sup>2</sup>*University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada*; <sup>3</sup>*University of South Australia, Adelaide, SA, Australia*; <sup>4</sup>*Satellite Healthcare, San Jose, CA*; <sup>5</sup>*Alberta Health Services, Edmonton, AB, Canada*.

**Background:** Although exercise and physical activity have been shown to improve physical function among people receiving Peritoneal Dialysis (PD), little is known about PD clinicians' perceptions and practices regarding exercise prescription and promotion.

**Methods:** A cross-sectional online questionnaire was developed through expert and patient consensus, and distributed to PD clinicians from 100 PD prevalent countries between July and December 2021 through social media and professional nephrology societies. As part of this survey, participants were asked the question “What are the most important aspects you would like to see incorporated in an exercise program for PD patients?” Responses were coded using Summative Content Analysis and grouped into themes by two analysts.

**Results:** 610 respondents (74% females; 37% nephrologists, 49% nurses, and 14% allied health professionals; 0.7% were from Africa, 25% Asia, 16.6% Australia/New Zealand, 22.1% Europe, 10% South America, 1.8% Middle East, 24% North America) provided 1076 unique perspectives that were included in the analysis. The overarching theme identified was the need for individualized and accessible programming. Under this umbrella, the four main themes identified were: promotion of specific exercise activities, overcoming common barriers to exercise for patients and PD programs, perceived cornerstones of exercise prescribing, and program design to address important outcomes for patients.

**Conclusions:** Overall, PD clinicians believe that PD does not preclude exercise participation and recognize the benefits for improving physical, mental, and social well-being. The involvement of exercise professionals is valued in clinical programs, however additional education for practitioners and patients regarding safety and the benefits of exercise is required.

## PUB139

**A Case of Calciphylaxis in a Patient on Apixaban**

Louis Damian, Asha J. Chemmalakuzhy. *Baylor Scott & White Health, Dallas, TX.*

**Introduction:** Calciphylaxis is a rare but serious condition that is mainly seen in chronic kidney failure patients treated with dialysis. While Warfarin has been demonstrated in many studies to be associated with increased vascular calcification due to inhibition of vitamin-K-dependent carboxylation of Matrix gla protein (MGP), Direct Oral Anticoagulants (DOACs) can prevent the progression of vascular calcification. Nevertheless, Calciphylaxis is reported among people who take apixaban

**Case Description:** 69 years-old, female with a past medical history of end-stage renal disease on CCPD, atrial fibrillation, hypertension, moderate aortic stenosis, and type 2 diabetes mellitus, presented to the hospital with several weeks of bilateral lower extremities pain. There are no specific aggravating or alleviating factors. She reported skin nodules in her bilateral lower extremities which she noticed around the same time. The patient was on Apixaban for atrial fibrillation for more than 12 months. She was on calcitriol for secondary hyperparathyroidism and Sevelamer for hyperphosphatemia. On physical exam, multiple tender subcutaneous nodules were noted on bilateral lower extremities without ulcerations or signs of infection. Laboratory findings were significant for Corrected calcium 8.0 mg/dL, Phosphorus 11.7 mg/dL, Intact PTH 286 pg/mL. A Punch biopsy was performed on the skin of the left thigh, it showed morphologic features consistent with calciphylaxis. Calcitriol was discontinued, patient switched to hemodialysis and was treated with sodium thiosulfate

**Discussion:** Calciphylaxis is a result of progressive arteriolar thrombosis. While Direct Oral Anticoagulants (DOACs) can prevent the progression of vascular calcification by direct inhibition of factor X which can create vascular smooth muscle migration and proliferation, which is a key step in atherosclerosis, In phase IV clinical study of FDA data, 18,315 people reported side effects when taking Eliquis. Among them, 6 people (0.01%) have Calciphylaxis. Further trails needed to investigate this association

## PUB140

**Challenges of Treating Stenotrophomonas maltophilia Peritonitis in a Peritoneal Dialysis Patient With Suprapubic Catheter**

Krishnakumar D. Hongalgi, Sidrah Abid, Kelly H. Beers, Swati Mehta. *Albany Medical Center, Albany, NY.*

**Introduction:** Peritoneal dialysis (PD) is a preferred home modality of treatment for end stage kidney disease (ESKD). Peritonitis is the most feared complication associated with long term PD and is associated with increased morbidity and mortality. We report a rare case of stenotrophomonas maltophilia peritonitis in a patient with chronic suprapubic catheter.

**Case Description:** 59-year-old male with ESKD with history of suprapubic catheter had beta hemolytic strep peritonitis followed by another episode of coagulase negative staph peritonitis which were treated outpatient with intraperitoneal (IP) antibiotics. He was admitted to the hospital later with another episode of abdominal pain and cloudy peritoneal effluent. He was hemodynamically stable, afebrile and had mild leukocytosis without left shift. Empiric treatment with IP vancomycin and ceftazidime was started. Peritoneal culture grew >100,000 colonies of stenotrophomonas maltophilia resistant to ceftazidime, sensitive to levofloxacin and trimethoprim/sulfamethoxazole. Ceftazidime was discontinued and patient was started on oral levofloxacin and trimethoprim/sulfamethoxazole with plan for 21 days of treatment. PD catheter was left in-situ and PD was continued without interruption. Patient improved clinically and was discharged with outpatient follow up. Levofloxacin was eventually discontinued after 2 weeks due to prolonged QT interval.

**Discussion:** PD has been established as a safe modality of kidney replacement therapy empowering patients in selfcare. PD catheter associated peritonitis is common cause of treatment failure as it can result in loss of PD catheter. Stenotrophomonas maltophilia is a rare cause of peritonitis with reported loss of PD catheter in over half of cases. Treating peritonitis in a patient with suprapubic catheters is challenging. Our patient was successfully treated with levofloxacin and trimethoprim/sulfamethoxazole without necessitating the removal of his PD catheter.

## PUB141

**Patients With Refractory Heart Failure and Diuretic Resistance: Is Peritoneal Dialysis a Good Therapeutic Option?**

Gonçalo Ávila, Patrícia Matias, Rita Calça, Patrícia Q. Branco. *Centro Hospitalar de Lisboa Ocidental EPE Hospital de Santa Cruz, Carnaxide, Portugal.*

**Background:** Patients with refractory heart failure (HF) and resistance to diuretics despite optimal medical treatment require frequent hospitalization and/or outpatient intravenous diuretic therapy. Peritoneal dialysis (PD) can be used as an alternative treatment to promote ultrafiltration and control fluid overload in these patients. The aim of this study was to assess PD efficacy in reducing hospitalization rate and congestion markers, technique complications, and survival in a group of patients with HF.

**Methods:** We performed a single-center, retrospective study, from 2014 to 2022, which included patients with New York Heart Association (NYHA) class IV HF despite optimal medical treatment, with resistance to diuretics, and estimated glomerular filtration rate (eGFR) > 15 mL/min/1.73m<sup>2</sup> according to the 2021 CKD-EPI equation. Clinical and laboratorial parameters were collected before and after PD initiation.

**Results:** Eleven patients were included, with mean age of 63.7 ± 14.4 years, and 72.7% males. Seven patients (63.3%) were diabetic. Most patients had reduced left-ventricular ejection fraction (81.8%) and two patients had congestive right-side HF. The most common HF etiology was ischemic (72.7%). Median follow-up was 18 months (IQR 12 - 33). Median eGFR at the time of PD start was 19 mL/min/1.73m<sup>2</sup> (IQR 16 - 21). The median hospitalization days due to fluid overload in the 12 months before starting PD was 18 days (IQR 1 - 37), and significantly decreased to 0 days (IQR 0 - 4) in the 12 months after (p=0.012). The median value of N-terminal prohormone of brain natriuretic peptide (NT-pro-BNP) in the 12 months prior to the beginning of PD was 8014 pg/mL (IQR 4038 - 30523), which declined to 5156 pg/mL (IQR 2885 - 8618) in the 12 months after (p=0.022). Complications included 8 episodes of peritonitis. Four patients dropped out of the technique after a median of 38.5 months, due to ultrafiltration failure (n=3) and refractory tunnel infection (n=1). Survival rate was 90.9% at 12 months and 63.6% at 24 months. Eighty percent of deaths were due to cardiovascular events.

**Conclusions:** In this group of patients, PD was a safe and effective therapeutic option for the treatment of refractory HF, leading to improved management of congestion and decreasing hospitalization days.

## PUB142

**Percutaneous Peritoneal Dialysis Catheter Insertion in an Office-Based Lab: A Retrospective Study**

Mohamed A. Sheta. *Global Vascular Access Center, Houston, TX.*

**Background:** Peritoneal Dialysis Catheter (PDC) can be inserted by one of three methods: Surgical, Laparoscopic and Percutaneous. The first two typically require inpatient settings. In this unique study we explore multiple aspects of percutaneous peritoneal dialysis catheter (pPDC) insertion in our office based lab (OBL).

**Methods:** This is retrospective study in our OBL reviewing the patient data in one year. This include patients demographics, number of previous abdominal surgeries, complications, sedation, one month patency, and causes of failure. We inserted all our pPDC under ultrasound and fluoroscopic guidance using Seldinger technique.

**Results:** From May 2021 to April 2022, we inserted 36 pPDCs in 36 patients. Average BMI was 32 (22.9-53.5). Two of our patients have colostomies and another two with moderate ascites. Only one patient was done under local anesthesia and rest were done under moderate sedation. Patients were not required to stop antiplatelet therapy or anticoagulation. No cardiac clearance was required. Success rate was 94% (34/36). Operating room time ranged from 15 minutes to 35 minutes. There was no reported intraoperative complications including bowel injury or major bleeding. No peri-catheter leak. Three patients prescribed narcotics for post-operative pain. Out of the 34 patients that got their pPDC successfully inserted, 31 had functional catheter at one month (91%).

**Conclusions:** Percutaneous peritoneal dialysis catheter insertion in OBL is a cost effective, safe procedure with very high patency rate.

## PUB143

**Mortality and Demographics Associated With Fungal Peritonitis in Patients on Peritoneal Dialysis in a Regional Hospital in Mexico**

Manuel A. Marquez, Jorge A. Gómez, Oscar Ollarvide. *Instituto Mexicano del Seguro Social, Jalisco, Mexico.*

**Background:** Peritonitis is one of the most frequent complications of peritoneal dialysis, and between 1% - 15% of these episodes are caused by fungal infections. The mortality rate of fungal peritonitis varies in different studies, with percentages from 5% to 53%. Despite the availability of newer antifungal drugs, catheter removal remains the cornerstone of managing fungal peritonitis. Some studies report mortality from 50% to 91% among patients without catheter removal. Courses of antibiotics precede most fungal peritonitis episodes. Other risk factors that may account for the risk of development of fungal peritonitis are low educational status and unhygienic conditions. Candida species cause most of these infections. Candida albicans and Candida parapsilosis are the most common pathogens, although the frequency of the latter is reported to exceed that of C. albicans species. One of the difficulties of fungal peritonitis is the failure to resume PD after a temporal transfer to hemodialysis, which occurs in up to 40% of patients.

**Methods:** We conducted a retrospective cohort study including all confirmed or suspected fungal peritonitis episodes among peritoneal dialysis patients followed in our institution between January 2020 and February 2022. We collected demographic characteristics, laboratory and clinical findings, management, and outcome from medical records.

**Results:** 13 cases were obtained from the database, 3 men and 10 women, with a mean age of 45 years, 38% with a history of diabetes mellitus, 61.5% of the patients had a history of peritonitis in the previous 6 months, and 46% with a history of peritonitis in the last month, the most frequently isolated microorganism was Candida in 76.9%, Candida parapsilosis complex was isolated in 61% (8 cases), Candida tropicalis in one case, Candida guilliermondii in one case and 23% (three patients) there was no absolute isolation. Of the 13 cases, 38.4% (5 cases) died during hospitalization, and one died after 6 months of follow-up.

**Conclusions:** Fungal peritonitis is a complication with a high mortality rate, with a mortality of 38% in our center, unlike what was reported by other centers. Candida parapsilosis complex was the fungus that was isolated most frequently; the history of peritonitis in the previous months forces us to focus on prevention.

## PUB144

**In-Center Hemodialysis vs. Home Dialysis: Comparison of Choice of Dialysis Modality**

Isabella L. Melena, Frank J. O'Brien, Lisa A. Koester. *Washington University in St Louis School of Medicine, St Louis, MO.*

**Background:** Both in-center hemodialysis (IHD) and home methods, peritoneal dialysis (PD) and home hemodialysis (HHD), have their advantages and disadvantages, but IHD continues to be the most common form of dialysis therapy even with similar mortality rates between the modalities and several studies showing a patient preference for home dialysis. Reasons for choosing a certain dialysis modality and continuing with the modality are varied and include factors of the patients, their caregivers, the healthcare monitoring system, and dialysis approach. Identifying factors a patient uses to choose a modality is important to increase the availability and utilization of the increasingly preferred and beneficial home modalities.

**Methods:** Participants on IHD and home methods, PD and HHD, were surveyed at the Washington University in St Louis School of Medicine dialysis clinics. Survey questions included questions on deciding factors for the chosen dialysis modality and education on other modalities.

**Results:** We enrolled 120 participants (n=90 on in-center hemodialysis and n=30 on home dialysis, 43% female, age [mean±SD] 59±14 years). Top factors for choosing in-center hemodialysis included perceived safety, convenience, or doctor choice. For home dialysis, the factors mentioned most included convenience, independence, and doctor recommendation. 69% of participants on in-center dialysis received education of other modalities, compared to 100% of participants on home dialysis.

**Conclusions:** Our data reaffirm that modality selection is a complex process and highlight potential areas for intervention and education to increase the utilization of home dialysis.

## PUB145

**Acute PD in ESKD Jehovah's Witness Patient With Severe Anemia and Uremic Bleeding**

Lakshmi Ganesan, Amir Abdi Pour, Sergio Infante. *Loma Linda University School of Medicine, Loma Linda, CA.*

**Introduction:** Due to high mortality associated with severe anemia and hemodialysis, anemia is aggressively managed with iron and ESA therapy in chronic HD patients. Severe anemia is generally managed first with transfusion. In patients who refuse transfusion, anemia management can pose a challenge. We present a case of changing modality to PD in Jehovah's Witness patient to allow for improvement of uremic bleeding, and stabilization of hemoglobin without transfusion.

**Case Description:** 39 yo M Jehovah's Witness with ESRD 2/2 DM2 on HD, PAD on DAPT (and h/o BLE angioplasty) admitted with LLE necrotizing fasciitis. Admission hemoglobin was 9.2g/dL. He received 5 HD treatments before his BKA on day 9. Due to symptomatic post-op anemia (5g/dL, nadir 4.2g/dL), he was too unstable for HD. Pt had ongoing bleeding attributed to blood thinners, surgery and uremic platelet dysfunction. Patient's volume status and mentation worsened. On day 17, Quinton catheter was placed and CCPD started. BUN was at 167mg/dL at start of PD. Due to bleeding from prior Veress access site, patient had two revisions before PD was successful. On day 21, pt completed full PD. He tolerated 6 days of 24hr/day of PD, 11 cycles, fill volume 500mL, increased to 1000mL. Repeat labs showed BUN 110mg/dL and Hgb 9.6g/dL. Anemia was managed with aggressive ESA dosing - Epogen 40K units qHS, started day 16. Respiratory status and mentation improved. He was transitioned back to HD on day 27 at patient's behest due to ongoing scrotal edema and hydrocele. He tolerated resuming HD, though Hgb was 7-8g/dL on HD even with higher dose ESA. He was discharged from hospital to resume outpatient HD.

**Discussion:** To date, there is no reported case of converting dialysis modality for anemia in Jehovah's Witness patients who are too unstable for HD. There is a reported case of using acute PD post-laparotomy. They do not cite anemia or ongoing bleeding as an indication in this case, but rather related to patient's advanced directive against autologous procedures. They acknowledge peritoneal dialysis superiority where cardiovascular instability and bleeding risk are concerned. While our patient experienced further bleeding after catheter placement, he still had improvement in his hemoglobin over one week of PD. This supports using acute PD when ESRD patients may be too unstable for HD due to severe anemia.

## PUB146

**Percutaneous Single Stitch Peritoneal Dialysis Catheter Insertion Using the Seldinger Technique: Boost for Interventions by Nephrologist**

Jitendra Goswami. *Soni Manipal Hospital, Jaipur, India.*

**Background:** Peritoneal dialysis (PD) catheter implantation is one of the effective treatments for patients with end-stage renal disease (ESRD). This study aimed to evaluate the safety and efficacy of percutaneous single stitch PD catheter insertion technique and its associated short-term postoperative outcomes.

**Methods:** In this study, ESRD patients who underwent peritoneal catheter insertion were enrolled retrospectively during September 2017- April 2019. All patients were evaluated for demographic and clinical characteristics, operative parameters and postoperative complications.

**Results:** A total of 43 patients were enrolled. The mean age of the patients was 61.90 years. Type 2 diabetes was the most common cause of ESRD. The median operative time was 12.00 min and the incision length were <1cm. the operative cost was 12000 per

patients and the median length of the hospital stay was 4 days. Three (6.97%) patients showed bloody dialysis. The number of patients using analgesic within 24 hrs and 48 hrs was 2.00 (4.65%) and 1.00 (2.32%), respectively.

**Conclusions:** This technique has the benefits of reduced surgical trauma, a shorter operative time, faster postsurgical recovery, less postoperative complications and may improve the patient's survival and decrease the morbidity.

## PUB147

**Lost Dwell Time and Cycler Alarms in Inpatient Automated Peritoneal Dialysis**

Nasha Elavia, Adrienne E. Flowers, Ami M. Patel. *University of Maryland School of Medicine, Baltimore, MD.*

**Background:** Automated peritoneal dialysis (APD) has multiple advantages over continuous ambulatory peritoneal dialysis in the hospital setting including lower risk of peritonitis from fewer connections, increased treatment options, reduced nursing time, and preferred modality for patients with higher membrane transport characteristics. To date, there are no previous studies investigating the loss of dwell time and cycler alarms using APD in the hospital setting.

**Methods:** We conducted a retrospective study of all inpatient APD treatments using the Amia Automated Peritoneal Dialysis System in a tertiary-care hospital from December 1, 2021 to May 30, 2022. The differences between prescribed and actual dwell times and the frequency of different cycler alarms were recorded.

**Results:** In the past 6 months, 13 patients underwent APD treatments at our hospital. Three patients were excluded due to incorrect orders or missing flowsheets. The remaining 10 patients completed 62 treatments. Approximately 31% of treatments had lost dwell time exceeding 30 minutes per treatment. Table 1 shows the frequency of the most common alarms.

**Conclusions:** There was significant lost dwell time and inadequate drain volume with inpatient APD. This can impact solute clearance and ultrafiltration. Future studies are required to investigate measures to minimize lost dwell time, reduce slow drain and improve drain volume in the hospital setting.

Table 1. Frequency of common alarms

Alarm	Frequency (%)
All slow drain	60
Slow drain requiring intervention	40
Inadequate drain volume	23
Patient line occlusion	10

## PUB148

**Tenckhoff Catheter Placement in Heart Failure With Refractory Ascites**

María Guadalupe C. Núñez,<sup>1</sup> Lillana Pacchiano,<sup>2</sup> Gabriela Leal,<sup>3</sup> Bernardo Moguel,<sup>3</sup> Karla B. Cano Escobar.<sup>3</sup> <sup>1</sup>*Hospital General de Zona #32, Instituto Mexicano del Seguro Social, Mexico City, Mexico city, Mexico;* <sup>2</sup>*Instituto Nacional de Enfermedades Respiratorias, Mexico city, Mexico;* <sup>3</sup>*Instituto Nacional de Cardiología Ignacio Chavez, Mexico city, Mexico.*

**Background:** Bening refractory ascites due to heart failure (HF) represents 5%, with a poor life expectancy. For treatment, instead of paracentesis, peritoneal dialysis catheter placement has been utilized. We describe our experience using Tenckhoff catheter in this patients.

**Methods:** Retrospective cohort study in a single third level center, from January 2015 to August 2021. Patients with benign refractory ascites due to HF with or without hepatic insufficiency were included. A Tenckhoff (TNK) catheter was placed. Follow-up was made a month after insertion and until outcomes (end stage renal disease (ESRD) or death) occurred.

**Results:** 16 patients were included. Patient characteristics are shown in Table 1. Weight fell from 69 to 62.2 Kg after TNK placement (p 0.017). Improvement of HF functional class was noticed, NYHA I/II changed from 12.5 to 66.7% and NYHA III/IV from 87.5% to 33.3% (p 0.034). Tricuspid insufficiency was improvement from 68.7% to 47.3% (p 0.041). There were no significant change in LVEF, sPAP or pericardial effusion. Emergency visits and hospitalizations were not changed significantly. eGFR and urinary volume improved from 28 to 35 ml/min/1.73 m<sup>2</sup> (p 0.025) and 1200 to 1483 cc (0.052), respectively (Figure 1). 81.25% developed AKI, requiring RRT in 38.4%. Complications: hematic fluid (25%), leakage (12.5%), accidental catheter displacement (6.2%). Peritonitis rate was 1 episode per-19 patient-months and 0.62 episodes per patient year. TNK was removed in 37.5% of cases. Death occurred in 25% and ESRD in 25%.

**Conclusions:** TKN placement is viable and safe in the management of refractory ascites in HF. However, it is important to select properly the patient in order to reduce the peritonitis events.

### Clinical Observation of Safflower Wine Wet Dressing to Improve the Function of Autogenous Arteriovenous Fistula in Hemodialysis Patients

Renhong Kang, Weijian Xiong. Chongqing Traditional Chinese Medicine Hospita, Chongqing, China.

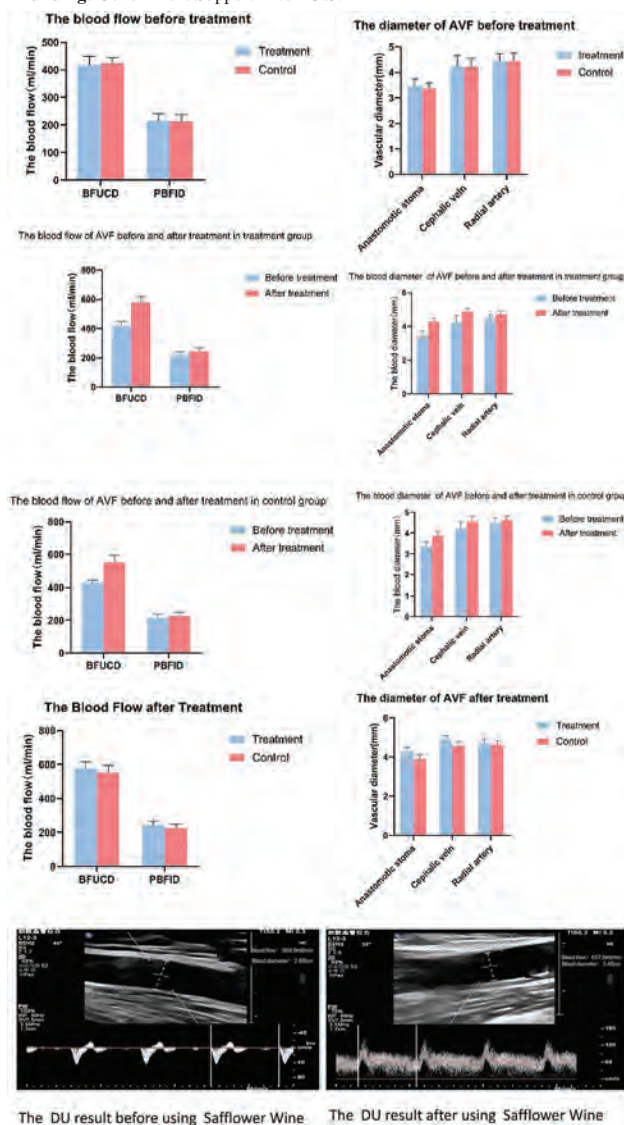

**Background:** Autogenous arteriovenous fistula (AVF), as the first choice of long-term vascular access, is an important lifeline for maintenance hemodialysis (MHD) patients, most patients will have AVF dysfunction in the course of MHD treatment, which will eventually lead to the loss of AVF function. This clinical observation found that safflower wine wet dressing can effectively increase the blood flow of AVF and enlarge the diameter of AVF. Therefore, the function of AVF can be improved and the service life of AVF can be prolonged.

**Methods:** Patients undergoing maintenance hemodialysis using AVF were selected from the blood purification center of Chongqing Traditional Chinese hospital from November to December 2021, the patients were divided into control group (34 cases) and treatment group (34 cases). The treatment group was treated with self-made safflower wine and the control group was treated with Mucopolysaccharide polysulfate (MPS). After 2 months of treatment, the Pump-controlled Blood Flow in Dialysis(PBFID), the diameter of AVF and Blood Flow under Color Doppler (BFUCD) were observed and recorded.

**Results:** There was no significant difference in PBFID, the diameter of AVF and BFUCD between the control and treatment groups before treatment. After 2 months treatment, both the control group and the treatment group were able to increase PBFID, BFUCD and expand AVF tube diameter, the effect of the treatment group significantly better than the control group.

**Conclusions:** Using the safflower wine wet dressing can effectively enhance the blood flow of AVF and enlarge the vascular diameter of AVF.

**Funding:** Government Support - Non-U.S.

## PUB150

**Effects of Monitoring and Surveillance in Assessing Vascular Access Complications in Patients on Hemodialysis**

Vinant Bhargava, Aditi Pandey, Anil Bhalla, Ashwani Gupta, Manish Malik, Anurag Gupta, Vaibhav Tiwari, Shiv Chadha, Devinder S. Rana. *Sir Gangaram Hospital, New Delhi, India.*

**Background:** Vascular Access forms the backbone and ensuring longevity of access directly correlates with longevity of hemodialysis.

**Methods:** Study Center: Sir Ganga Ram Hospital, New Delhi. Duration: 13th September 2020 to 13th March 2021. Population: chronic kidney disease patients undergoing hemodialysis through upper extremity vascular access. Design: Randomised controlled study. Inclusion Criteria: 1) Adult population between 18-65 years with end stage renal disease undergoing hemodialysis. 2) Patient undergoing at least 2 sessions per week with an upper extremity VA (AV fistula/AVG) created at least one month before inclusion in the study. 3) Patients with radiocephalic, brachiocephalic AV fistula and with basilic vein transposition.

**Results:** There were 32 males and 18 females and 28 males and 22 females among cases and controls. The mean age of the study population and controls were 51.61 years with a standard deviation of 9.9 years and 50.06 years with a standard deviation of 10.26 yrs respectively. Vascular access monitoring by physical examination was done in all patients in both groups. Vascular access surveillance by ultrasound doppler was done in all cases and 29 controls. On the basis of outcome, thrombosis (26%) and infection (22%) of the vascular access were the most common complications in the study population overall followed by stenosis (19%), aneurysm (8%) and ischemia of limb bearing the AV access (3%). Among the cases, the complications of vascular access reported were thrombosis in 19 (38%), infection in 12 (24%), stenosis in 11 (22%), aneurysm in 5 (10%) and ischemia of limb in 2 (4%) cases. Among the controls, the outcomes reported were infection in 10 (20%), thrombosis in 7 (14%), stenosis in 8 (16%), aneurysm in 3 (6%) and ischemia of the limb bearing the AV access in 1 (2%). Considering the cases and controls individually, overall complications were reported in 35 cases (70%) and 29 controls (56%) on vascular access monitoring and surveillance.

**Conclusions:** The association between vascular access surveillance and detection of vascular access complications was not significant as compared to vascular access monitoring alone. Outcomes were statistically comparable in both groups. Hence hemodialysis vascular access surveillance despite being widely used is still an area of ongoing controversy.

## PUB151

**Tunneled Dialysis Catheter Exchange in the Hands of the Interventional Nephrologist: The Fulquet Technique**

Irati Tapia, Diana Oleas. *Consorci Sanitari de Terrassa, Terrassa, Spain.*

**Background:** The high rate of complications related tunneled dialysis catheters (TDC) is widely known. Often, the malfunction of the TDC requires its exchange or replacement, generally performed by interventional radiologists. In our unit, the exchange procedure is performed by the interventional nephrology team. We use a guide wire through the old catheter lumen using the same venotomy site to place the new TDC, avoiding a new puncture. Objective: To describe our novel TDC exchange technique over guide wire ("Fulquet technique") as well as to analyze the main characteristics and complications derived from its implementation in our unit over the past 9 years.

**Methods:** A retrospective review from January 2012 to December 2021 of TDC exchange using the "Fulquet technique" performed by interventional nephrologists. The main demographic data, comorbidities, causes for TDC exchange, and major complications related to the procedure were analyzed.

**Results:** In terms of demographic data 58% of the patients were women. As cardiovascular risk factors 93% percent had a history of hypertension and 51.6% of diabetes. Nephroangiosclerosis was the predominant etiology of chronic kidney disease in the studied patients. Two hundred and sixty TDC were inserted during the reviewed period. Thirty-one TDC exchanges were performed representing an 11.9%. Ninety six percent of TDC exchanged were iSPLIT CATH@III type. The average time of TDC use was 307.7±401.9 days. The jugular vein was the most used with a 93.5% and 100% were located on the right site. Catheter malfunction was observed in 55.2% and cuff extrusion in 44.8%. These were the main indications for exchange. No exchange was performed due to TDC infection. We only observed one major complication (1/260, 0.003%) due to loss of the distal end of the TDC that required a surgical rescue.

**Conclusions:** In our experience, TDC exchange over guide wire ("Fulquet technique") can be performed by interventional nephrologist safely and effectively. Additionally, the development of novel techniques in vascular access provides nephrologists greater autonomy and a wider range of capabilities in terms of training. Based on these results we will continue using this technique in our unit.

## PUB152

**Removal of "Stuck Tunneled Hemodialysis Catheter" by Hong's Technique**

Ajay Jaryal,<sup>1</sup> Kunal Mahajan,<sup>2</sup> Sanjay Vikrant,<sup>1</sup> Dheeraj Sharma,<sup>2</sup> Praveen Dhaulta,<sup>2</sup> Ram Singh.<sup>2</sup> *<sup>1</sup>All India Institute of Medical Sciences - Bilaspur, Bilaspur, India; <sup>2</sup>Indira Gandhi Medical College, Shimla, India.*

**Introduction:** Sometimes tunneled catheters (TC) are the only means of long-term vascular access for hemodialysis (HD). They can be safely removed, but very rarely they may get stuck. Herein we report such a scenario where stuck TC was successfully removed by endoluminal dilation or "Hong's technique".

**Case Description:** A 21-year-old male, on maintenance HD, arrived in our hospital with a thrombosed brachiocephalic arteriovenous fistula (AVF). With no suitable veins for AVF, and refusal of the patient for peritoneal dialysis or AV graft, a TC was inserted, through which he received HD uneventfully for the next one and a half years until the TC, developed a crack and there was no way to salvage it. So, we went ahead to remove it but failed, as it was stuck. We asked for cardiology and vascular surgery consultation, who were equally unfamiliar. We discussed Hong's technique with them, and a team led by an interventional cardiologist decided to attempt it. In the cardiac catheterization laboratory, a guidewire was passed inside the lumen of TC over which endoluminal dilation of the TC was done with a 6.0 x 40 mm balloon (Figure 1) following which the TC was successfully removed (Video <https://www.kapwing.com/videos/628e597d96c0a100a2191963>).

**Discussion:** A stuck TC is one, which cannot be removed from its location i.e., central vein or right atrium by conventional technique. It usually happens due to the formation of fibrin sheath. Forceful removal can lead to life-threatening complications like catheter fragmentation or injury to large blood vessels. Then surgery is the only option. However, a novel procedure of endoluminal dilation pioneered by Hong can be lifesaving. As in the words of the pioneer, "the endoluminal balloon dilation of the HD catheter not only separates the stuck catheter from the adherent vein but also expands the vein simultaneously, thus enabling easy removal of the stuck catheter".

Balloon dilatation in the lumen of tunneled catheter.

## PUB153

**Nursing Care of Allergic Dermatitis for a Maintenance Hemodialysis Patient With a Tunneled Cuffed Catheter**

Liang Chen, Wu L. Li. *Chongqing City Hospital of Traditional Chinese Medicine, Chongqing, China.*

**Introduction:** Allergic dermatitis caused by disinfectant iodophor is known by nurse staffs. What make us confused in this case was regularly used iodophor to disinfect the catheter inlet before, but the patient suddenly allergy to it. It tricked us for a long time. It is not easy to disclose the real reasons at the first time.

**Case Description:** An 81-year-old male patient, dialysis for 1 year, underwent tunneled cuffed catheter (TCC) vascular access, no history of food and drug allergies, and self-care ability score: 70 points. Diagnosis: Chronic kidney disease stage 5, renal anemia, hyperphosphatemia. On May 19, 2021, TCC was intubated. On January 3, 2022, the skin around the catheter inlet appears red and desquamated, accompanied by an itching symptom.

**Discussion:** The key point for this case is that the patient has TCC implanted since May 2021, but the patient suffered redness, scaling, and itching after 8 months. No systemic symptoms, no allergic history. Even consulted by a dermatologist, the patient's skin symptom did not relief. We need to distinguish the possibility of catheter inlet infection. Raising the level of nursing is essential, we set up a treatment special group to deal with this problem. At the same time of confirming the diagnosis, we should deal with the local symptoms, or there would raise the risk of catheter infection for repeated scratching caused by itching. All the special group staffs agree that the symptoms were caused by local irritating. we changed all the nurse procedure but disinfectant iodophor, and the region of skin lesions is consistent with the region of iodophor disinfection. We used hydrogen peroxide instead of iodophor to disinfect the catheter inlet. The local skin symptoms gradually relieved, and get healed finally. From this case, we know that beside the conventional procedure to deal with the problems, we should change our mind because change will occur to some constant matters.

## The process of the skin symptoms nursing care

## PUB154

### Outcomes of Tunneled Venous Catheters for Chronic Hemodialysis in a Tertiary Care Centre

Kudithi Soundarya, Manjusha Yadla. *Gandhi Hospital, Secunderabad, India.*

**Background:** Vascular access is an important aspect of hemodialysis treatments and determinant of patient outcomes. AV fistula is preferred mode of vascular access but has many limitations including challenges in fistula creation, shortage of vascular surgeons, failure rates. Tunneled catheters are progressively more commonly used vascular access now a days.

**Methods:** Aim of the study is to determine the Outcomes of Tunneled venous catheters for chronic hemodialysis in tertiary care hospital. Study design is prospective observational study patients who underwent tunneled catheterization in Gandhi hospital during from January 2021 to March 2022 were analyzed. Outcomes assessed were demographics, etiology of ESRD, catheter outcomes, complications and patient outcomes.

**Results:** Total no of patients were 148, out of which 3 patients were HBV positive, 3 patients were HCV positive, one patient was HIV positive. Right IJV tunneled catheterization done in 144 patients, Left IJV tunneled catheterization done in 2 patients, femoral catheterization done in 2 patients. Mean age of patients was 52+/-12 years. Male to female ratio was 2:1. Out of 148 patients, 132 were hypertensive and 34 were Diabetic. Average duration of catheter survival in patients were 98+/-22 days. Average time to complications were 56 +/- 16 days. Immediate complications (9 patients) include exit site ooze in 5 patients, flow related problems in 2 patients, arrhythmias in 1 patient, seizures in 1 patient. Late Complications were seen in 23 patients (12 patients has CRBSI, 6 patients - blockage of catheter, 4 patients - catheter dislodgement, 1 patient had haemothorax during left IJV catheterization). On follow up, 28 patients expired, 40 patients alive with functional catheters, 66 patients converted to AV fistula, 1 patient converted to CAPD, and in 96 patients catheter removed, 14 patients lost to followup.

**Conclusions:** Percentage of tunneled catheter usage was 6% in our center. Average survival of catheter in patients was 98 +/- 22 days Percentage of complications was seen in 21 % of patients. Most common complication in our study was CRBSI (8%). Assisted survival of catheter was 62 %. Mortality of patients of chronic haemodialysis in our study was 20 %. Rate of conversion to AV fistula was around 49 %. Most common cause of catheter removal was conversion to permanent access (68%) followed by death (29%)

## PUB155

### Long-Term Conditions and Health Inequalities: Kidney Care for All, in Support of World Kidney Day (2022)

Shahid N. Muhammad. *Coventry University, Coventry, United Kingdom.*

**Background:** In the UK, unfortunately, one of the main issues surrounding healthcare is that patients with chronic illnesses like Chronic Kidney Disease (CKD) are restricted to NHS healthcare services and approaching healthcare provider. Further complications can arise especially for those who have healthcare challenges and where misinformation can lead to fragility and health inequalities. Patient and Public Involvement (PPI) can help bridge issues surrounding health inequalities. **Aims:** To identify 1) whether patients with CKD would like to approach health professionals and patients through online consultations and educational support, thus prompting collaborative efforts and 2) understand if/ whether CKD patients would welcome more integrative support from healthcare professionals through social media, wherein patients and professionals can bridge gaps across health inequalities.

**Methods:** In support of World Kidney Day (2022), this article seeks to highlight how health inequality can be bridged through online spaces and integrative practices between patients and health professionals.

**Results:** Patients are the intermediaries between primary and secondary healthcare services. CKD patients now have more opportunities to share lived experiences owing to the nature and implementation of social media platforms, like the Renal Patient Support Group (RPSG) and the Kidney Disease and Renal Support Group (KDARs) for Kids.

**Conclusions:** In addition to sharing experiences, this prompts patients to be more than mere recipients of healthcare; CKD patients become more empowered so that more informed decisions can be made. Educational intercessions are required generally to offset issues where there are inequalities but also to ensure excellence in health practice.

## PUB156

### Patient Perspective on Home Dialysis Access for Latinx Patients With Kidney Failure

Katherine M. Rizzolo, Rebeca Gonzalez Jauregui, Lilia Cervantes. *University of Colorado, Denver, CO.*

**Background:** Latinx people experience a 1.3 times greater incidence rate of kidney failure compared to non-Latinx White individuals, but are less likely to utilize home dialysis therapies. The motivation and mitigating factors allowing for Latinx individuals with kidney failure to pursue home therapies has not been elicited. In this study, we aim to better understand the patient experience as a Latinx-identifying patient with kidney failure treated with home dialysis.

**Methods:** Participants include patients over 18 years old identifying as Latinx receiving home dialysis in two home dialysis clinics in the Denver Metro area. 30-60 minute semi-structured phone interviews were conducted, transcribed and de-identified for thematic analysis.

**Results:** At the time of this abstract submission, 9 patients had been enrolled, though it is expected a maximum of 20 participants may be enrolled or until thematic saturation is reached. Full enrollment is expected by August 2022. The main reported reasons for pursuing home dialysis included independence, quality of life, and flexibility. A major driver towards success with home was self-advocacy, many participants reported they educated themselves on home dialysis modalities. Favorable characteristics of the home dialysis clinic included approachable staff and individualized education and training. Participants noted the need for widespread language and culture concordant home dialysis modality education. Major themes with illustrative quotes are noted in Table 1.

**Conclusions:** In our study, self-advocacy and individualized education was noted by almost all participants. Future directions with these findings may be interventions focusing on culture and language concordant modality education for the Latinx community with kidney failure.

#### Funding: NIDDK Support

Theme	Subtheme	Illustrative quote
<b>Theme 1</b> Reasons for pursuing home dialysis	Independence	I have to do eight hours of treatment. And so within that time period, most of the time I'm sleeping, but it doesn't impede me from doing what I need to do in my house.
	Quality of Life	Just being able to be myself and be able to continue my lifestyle as I currently live it. I didn't want any restrictions to inhibit my ability to, you know, really work on my health really work on my being available to my husband and my two children. You know, just not losing myself if that makes sense.
	Flexibility	They told me home dialysis or I go to a place. but for me, it was better to be at home it'd be more comfortable for me. Because you know, I can do it on my time. And that was very important to me.
<b>Theme 2</b> Reasons for success with home dialysis	Self-advocacy	The education at all was so minimal. The only option there was the blood one. And I said, "Hold it on, I'm going to do my research. And you guys can just say that I can do it."
	Individualized training	I really want to stress for families, it's, you know, the hands-on training is really, really important... I think that all people have, you know, different ways of learning. And so the more multifaceted the way that the teaching is, the better it is for everyone. Whoever really goes into this type of, you know, clinical treatment.
	Approachable clinic staff	The first few days was a lot of learning, but I always had access to a technician or a nurse to help me answer my questions.
<b>Theme 3</b> Ways to improve home dialysis access for the Latinx community	Improved dialysis education for the Latinx community	I think that there's a lot of unknowns for our community. I think people who do get on dialysis really don't know a lot about it. I know for a fact that I didn't know anything about it prior to getting on.
	Improved kidney education for families of patients	About a month ago I went to Mexico for two days to visit my relatives, and automatically, as soon as you arrive, it's nice, but it's sad. The first thing they say to you: Oh, how are you, keep fighting and so on... I mean, they think that because I'm on dialysis, I'm already ah, I'm already sad, I'm dying, this and that.
	Language concordance	There's not a lot of information in Spanish. So, that's why a lot of people, I think they're not choosing the PD catheter.

Table 1. Major themes and illustrative quotes

**Examining Renal Concerns in Ethics Consults**

Julie Steinberg,<sup>1</sup> Lauren Sparber,<sup>2</sup> <sup>1</sup>*Cohen Children's Medical Center, Queens, NY;* <sup>2</sup>*Northwell Health, New Hyde Park, NY.*

**Background:** Few published studies focus on the effects of collaboration between nephrology and ethics. It is widely accepted by nephrologists that there are ethical concerns which arise in daily practice. In addition to the impact on the individual, societal concerns include equitable access to care for kidney disease. The American Society of Nephrology, with the European Renal Association-European Dialysis and Transplant Association and International Society of Nephrology Joint Working Group released ten topics, which should serve as an ethical priority (2020). These include: Equity in access to integrated kidney failure care; Setting priorities in kidney disease prevention and care; Supporting shared decision making about kidney failure care; Avoiding futile or overly burdensome dialysis treatment; Reducing the cost of dialysis care without compromising quality; Preventing organ trafficking and transplant tourism; Evaluating the risks and outcomes of living kidney donation; Addressing the ethical implications of genetic kidney disease; Managing conflicts of interest in nephrology; Advocating responsibly for kidney health. Yet, there is no clear guidance on how to manage these concerns. Additionally, training does not focus on this in a standardized manner. This pilot study sought to describe the ethical framework necessary towards improving overall outcomes.

**Methods:** IRB approval was obtained to perform a retrospective chart review of bioethics consults for renal patients treated in a tertiary medical system in New York State. This included pediatric and adult patients. The authors reviewed the consults. Reasons for consult were extracted and categorized based on the priorities set forth in 2020. This included: organ transplantation; genetic kidney disease; avoidance of futile/overly burdensome dialysis; shared decision-making.

**Results:** Population-level concerns did not emerge in consults. More than one reason for consult could be identified, as well as a "none of the above" category. Continued analysis is on-going.

**Conclusions:** It is likely that the concurrent COVID-19 global pandemic and its effect on renal health and resource allotment heavily impacted these results. However, it is apparent that there is a large focus on the burden of dialysis, suggesting that these should be more clear approaches to these concerns, used by practicing nephrologists. Additional studies are required to further evaluate this initiative.

## PUB158

**Improving Transition of Care From Hospital to Clinic**

Vishnupriyadevi Parvathareddy. *Baylor College of Medicine, Houston, TX.*

**Introduction:** Patients evaluated by inpatient nephrology consult service often require outpatient follow up. Our SMART aim was to ensure follow up after hospitalization in clinic upon discharge in a previously fragmented system for requesting and scheduling appointments with a significant obstacle of having two separate EMR systems for inpatient and outpatient care.

**Case Description:** A hospital discharge follow up order was created in inpatient EMR which would be received by referral team and clinic requests were scheduled directly by contacting patients. In order to implement this change, educational handout was created for fellow/faculty and dot phrases were created to standardize information input. Both outcome measures (percentage of requested appointments completed) and process measures, (percentage of requested appointments scheduled and percentage of requests that prompted a scheduling attempt) were measured and followed on for a year. Baseline data and data after intervention were compared and early results showed a trend towards improvement in capture rate of patients scheduled and scheduling attempts.

**Discussion:** Pre- intervention scheduling process was quite fragmented and varied and there was no way to determine the outcome of the scheduling attempt. The new process of having a referral team which uses EMR to make and track appointments helped immensely with data gathering and detect any failures in the process. The newly designed process allows for collection of detailed data on the outcomes of scheduling requests which can help identify additional targets for improvement. Future PDSA cycles will focus on ways to target patients not captured in order to improve follow up rates. few things we will be adding would be screening for insurance compatibility prior to discharge, adding hospital follow up schedule slots each week to accommodate requests, monitoring data for no-shows to identify areas of improvement and sending a confirmation of scheduled appointment to requesting provider via EMR.

## PUB159

**Failure of Social Work, Education, and Environmental Improvements in the Evolution of Cardiovascular and Renal Risk Factors in an Ethnic Minority**

Maria Eugenia V. Bianchi,<sup>1</sup> Velasco Gustavo,<sup>2</sup> Daniel Forlino,<sup>1</sup> Ana M. Cusumano,<sup>3</sup> National Northeast University <sup>1</sup>*National Northeast University, Corrientes, Argentina;* <sup>2</sup>*Universidad Tecnológica Nacional, Buenos Aires, Argentina;* <sup>3</sup>*Centro de Educacion Medica e Investigaciones Clinicas Norberto Quirno, Buenos Aires, Argentina.*

**Background:** For 15 years (from 2003 to 2018), diverse Organizations including the Governments advocated to give consciousness and work together to stop or unless slow down the evolution of cardiovascular and renal risk factors in a minority ethnic group in Resistencia, Chaco Argentina. the poorest region. No improvements were seen during 15 years in their contribution to the nationwide IBP (almost 1,3%). This work aims to

show the results of the evolution of cardiovascular and renal risk factors(CVRRF) in two measurements (2003-2018) in the same cohort of Qom borignes.

**Methods:** Since 2003 a program has been designed and evaluated by the National Northeast University for early Detection of Cardiovascular and renal risk factors, (CVRRF). There were actions with population meetings. Governments during this year constructed houses, install water in each house and made sewers. Schools and Health Care centers were inaugurated for every 4000 persons approximately. A survey for those inhabitants was made to ask about Health accessibility.

**Results:** Obesity was the CVRF that has impressively grown over 15 years, with an increase in DM and GFR. GFR showed a RR factor for Mortality. Causes for Mortality changed from 2007 to 2018 with a 50% of TBC caused to be Cancer especially in females of gynecologic origin. Cardiovascular causes of dead increased too. The survey showed that they had no problems with the Health system, especially at the community level, but was afraid to go to the Hospital.

**Conclusions:** At a rhetorical level the population has recognized these actions studied, Although this Community received particular attention, other strategies should be thought. Or perhaps if the IBP does not grow in the province of Chaco, these actions are not sufficient.

**Funding:** Government Support - Non-U.S.

## PUB160

**Educational Support Surrounding CKD: A Qualitative Enquiry**

Shahid N. Muhammad,<sup>1,2</sup> <sup>1</sup>*The University of the West of England, Bristol, United Kingdom;* <sup>2</sup>*Coventry University, Coventry, United Kingdom.*

**Background:** An estimated 15 million patients in England have at least one Long-Term Conditions with the prevalence of Chronic Kidney Disease (CKD) rising. Understanding educational support can help navigate between health sectors. **Research Question:** This UK study seeks to understand Educational Support surrounding CKD. **Ethics:** This research was approved by Greater Manchester South Research Ethics Committee (Project ID: 19/NW/0282).

**Methods:** This research used Qualitative Methodology, and an Inductive Content Analysis (ICA) approach which is particularly effective in linking theory, or framework. **Patient and Public Involvement (PPI):** Two workshops took place in May and June (2019) wherein topic tagging activities were co-developed between the Renal Patient Support Group (RPSG) and the Kidney Disease and Renal Support Groups (KDARs) for Kids platforms. **Sampling and Recruitment:** 19 participants between 4 cohorts, that included 6 General Practitioner (GPs), 4 Healthcare Scientists (HS), 3 Nephrologists/Clinicians (N/Cs), and 6 CKD Patients (CKDPs) were recruited and participated in telephone interviews.

**Results: Data Collection:** Topic guides were developed for participant cohorts with several themes to collect data through one-to-one telephone interviews **Analysis:** NVivo-12 software provided opportunity to code and glean insight to develop overall conclusions. **Results:** Nine (9) main themes and several sub-themes were identified when coding for Health Professionals (HPs), and Nine (9) main themes and several sub-themes identified when coding qualitative data for Chronic Kidney Disease Patients (CKDPs).

**Conclusions:** There needs to be a coordinated effort between patients and professionals, to understand how CKD education should be more integrated at point of care, and in line with public health. Keywords: Nephrology, Education, Qualitative Research, PPI.

## PUB161

**Validating a Novel Framework to Classify Inpatient Nephrology Consultation Requests**

Larissa Kruger Gomes, Rushad Patell, Jeffrey H. William. *Beth Israel Deaconess Medical Center, Boston, MA.*

**Background:** Consistent classification of consult requests may lead to more productive, efficient, and collegial conversations about patient care which can facilitate improved work satisfaction and an enhanced learning environment. We propose a framework of 7 consultation types: ideal (I), obligatory(O), procedural, S.O.S., confirmatory(C), inappropriate, and curbside. We aimed to obtain validity evidence for this rubric to consistently classify consultation requests in an academic setting.

**Methods:** A random sample of 100 de-identified nephrology consultation requests from a single academic center were selected and independently coded as 1 of the 7

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

consultation types by 3 nephrologists and 3 hospitalists. Total (same consult assignment by 6/6 coders) and partial (same consult assignment by >4/6 coders) concordance was calculated. Total and partial (>2/3 coders) inter-rater concordance based on consult and provider types was calculated.

**Results:** Of the 100 consults, perfect concordance was 55%, and partial was 36%. Amongst nephrologists total concordance (agreement in 3/3) was 61% and 78% for hospitalists. In cases where there was not perfect concordance (n=45), nephrologists completely agreed with each other 13.3% of the time, and partially agreed 68% of the time, while hospitalists completely agreed with each other 51% of the time and partially agreed 37.8%. Of the consults that at least 4 coders classified in the same way, nephrologists were less likely to have perfect concordance for I (68% vs 83%, respectively;  $P=0.028$ ), similarly for SOS (32% vs 72%  $P<0.001$ ), hospitalists had a lower concordance rate for O (82% vs 94%  $P=0.27$ ). Nephrologists and hospitalists were similarly likely to consider a consult to be I (53 vs 54%  $p=0.4$ ), SOS (28% vs 24%  $p=0.12$ ) or C (1.7% vs 3%  $p=0.15$ ). There was no significant difference in word count of the requests that were concordant ( $65\pm44$ ), partially concordant ( $59\pm40$ ) and discordant ( $77\pm31$   $p=0.51$ ).

**Conclusions:** Nephrology consult requests can be classified into a rubric of 7 subtypes. Perfect concordance between hospitalists and specialists was 55% and reached 91% if partial and complete concordance are combined. Nephrologists and hospitalists were as likely to classify consults as SOS or I consults. Opportunities exist to utilize the rubric to improve communication between providers and to improve the medical education of trainees.

## PUB162

**The Path to a Nephrology-Critical Care Medicine Career and Outcomes**  
Isaac Pak, Michelle Kirk, George N. Coritsidis. *Westchester Medical Center, Valhalla, NY.*

**Background:** The interest in this dual specialty eligibility has recently been on the rise since our program at Mount Sinai - Elmhurst Hospital was initiated over 15 years ago. Understandably so, since hemodynamic knowledge, electrolyte understanding, and volume status are key pathophysiological concepts necessary in both nephrology and critical care. It is an exciting and quickly evolving field that is drawing the attention of physicians-in-training. However, there is little data on the path and aftermath of those interested in Nephrology/Critical Care (NCC). This makes it difficult for those interested to accurately gauge the compatibility between their personal goals and outcomes pursuing this field. Our goal was to create a current and updated snapshot of this cohort and to explore existing opportunities and challenges as well as future prospects of this unique field.

**Methods:** In 2 different surveys, 1) we contacted applicants for the NCC program at Elmhurst Hospital Center-Mount Sinai in New York between 2014-2019, and 2) surveyed physicians identified as NCC from present CMS lists regarding: programs trained, practice status and satisfaction with NCC decision.

**Results:** Of the 25 applicants, 20 were contacted. 4 were initially interested in pulmonary critical care before applying to NCC, 10 did not pursue NCC after doing nephrology due to family/personal reasons, 2 did neither, and 8 (40%) completed NCC. Of the 50 currently practicing NCC physicians, 40 were successfully contacted, with 11 responses. Of the respondents, 8 were foreign medical school graduates. None of the respondents completed a combined 3-year fellowship, but stated that they would have preferred a combined fellowship. 3 were practicing both equally, 5 primarily nephrology, and 3 primarily critical care. 3 of the 8 who were primarily practicing one specialty were moonlighting in the opposite specialty. 8 were affiliated with an academic institution. When asked about the benefits of their training, all were satisfied and believed their training in both specialties positively affected their ability to practice the other.

**Conclusions:** Over half of applicants do not complete the dual training, often due to personal reasons, remained in nephrology. Of the responding NCC physicians, 6 of 11 were practicing both specialties. 9 of 11 were satisfied with their choice and would choose the same dual-specialty training.

## PUB163

**Comparison of Self-Reported Medical History and ICD Codes for Diagnosis of CKD, Hypertension, and Diabetes Mellitus**

Aparna Saha,<sup>1,2</sup> Cristina M. Liriano Cepin,<sup>2</sup> Ron Do,<sup>3,2</sup> Girish N. Nadkarni,<sup>1,2</sup> Lili Chan.<sup>1,2</sup> BPC <sup>1</sup>Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY; <sup>2</sup>The Charles Bronfman Institute for Personalized Medicine, New York, NY; <sup>3</sup>Icahn School of Medicine at Mount Sinai Department of Genetics and Genomic Sciences, New York, NY.

**Background:** Patient medical history obtained from electronic health records (EHR) or patient self-report are important features used in clinical research. However, EHR data may be incomplete and patients may not be aware of their medical diagnoses. We aimed to evaluate the concordance between EHR and self-report to assess their reliability and validity for chronic kidney disease (CKD), hypertension (HTN) and diabetes mellitus (DM).

**Methods:** We utilized data collected as part of the BioMe Phenomics Center (BPC) from 2018-2021. Medical surveys were administered at enrollment and yearly thereafter. Patient diagnosis of CKD, HTN, and DM were extracted from the problem list using ICD codes from EHR and surveys. We compared EHR and survey diagnosis with our ground truth diagnosis as: 1. CKD if the patient had 2 values of eGFR <60 mL/min/1.73m<sup>2</sup>, 2. DM if they had a HbA1c >6.5% or DM medication and 3. HTN if patients had 2 values of either a systolic blood pressure >130 mmHg or diastolic blood pressure >80 mmHg or HTN medication. Comparison testing used chi-square test and agreement assessed using Cohen's  $\kappa$ .

**Results:** 154 subjects participated in our research study. The mean age was 56 years with 70% female, 32% black, 54% white and 7% hispanic. 22% of subjects had CKD by eGFR criteria and 13% had ICD code for CKD and reported CKD on the survey (Fig

1a). However, there was moderate agreement between eGFR and ICD codes ( $\kappa=0.4$ ) and surveys ( $\kappa=0.6$ ). For DM, while there were significant differences between HgbA1c/medication diagnosis and survey and ICD codes, there was substantial agreement between the HgbA1c/medication diagnosis and ICD codes ( $\kappa=0.7$ ) and perfect agreement with surveys ( $\kappa=0.9$ ). ICD codes and surveys found significantly less HTN compared to blood pressure/medication diagnosis. However, there was fair agreement between the blood pressure/medication diagnosis and ICD ( $\kappa=0.3$ ) and surveys ( $\kappa=0.2$ ). Discrepancies were noted in the use of medications on survey at baseline and follow-up compared to EHR (Fig 1b).

**Conclusions:** Survey data was better at identifying patients with DM and HTN and was similar to ICD codes for CKD. A combination of ICD and survey data should be used when available.

## PUB164

**Nephrologists Frustrated With FDA Decisions on Roxadustat, Vadadustat, and Tenapanor**

Jennifer Robinson, Chris Dudzenski, Denise Foy. *Spherix Global Insights, Exton, PA.*

**Background:** The FDA has had recent controversial decisions, notably, the approval of Aduhelm (aducanumab) in Alzheimer's Disease in 2021 despite the Advisory Committee's vote against recommendation. Over the past year, the renal community has seen multiple Complete Response Letters (CRL) for drugs in development including vadadustat, roxadustat, and tenapanor. We sought to understand how these regulatory decisions were being perceived by clinicians.

**Methods:** 252 specialty physicians participated in an online survey in July 2021. Follow-up studies were conducted in August 2021 and March 2022 with nephrologists (n=105 each).

**Results:** Nearly half of physicians surveyed in July 2021 indicated their confidence in the FDA eroded in some degree in recent years, most notably a staggering 84% of neurologists (Figure 1). Among leading health organizations, 48% indicated high confidence in the Centers for Disease Control, compared to only 37% in the Food and Drug Administration and 26% in the American Medical Association. Comparatively, confidence in professional organizations such as American Society of Nephrology, American College of Gastroenterology, American College of Rheumatology, American Academy of Dermatology, and American Academy of Neurology were significantly higher. Among nephrologists surveyed in August 2021, 71% disagreed with the FDA's decision not to approve roxadustat, which was approved for use in the EU shortly after. March 2022 feedback after the vadadustat CRL was similar. Nephrologists were even more frustrated by the lack of approval for tenapanor with only 20% of nephrologists supporting the FDA's decision not to approve.

**Conclusions:** The majority of nephrologists, 74%, agree there is a high unmet need for an alternative to ESAs. Despite this, half of the surveyed nephrologists from March 2022 feel the recent FDA decisions are stifling innovation within the renal field.

## PUB165

**Pilot Study of Leadership Lecture Series in Nephrology Fellow Education**

Lakshmi Ganesan, Loma Linda University School of Medicine, Loma Linda, CA.

**Background:** ACGME identifies six core competencies required in trainees - patient care, medical knowledge, practice-based learning and improvement, interpersonal and communication skills, professionalism, and systems-based practice. Notably, three of the six directly correlate to leadership skills such as emotional intelligence, communication, conflict management, advocacy and advancement. While some argue these skills are partly inherent, there is still a teachable component. Here we have taken the approach of introducing these skills during fellowship.

**Methods:** We introduced a lecture series, integrated into fellows' education, over the course of two year fellowship. Topics varied from communication, financial literacy to conflict management, diversity and inclusion, mindfulness/self-care, and business of medicine, advancement and early career transitions. Though these may be part of many curricula in other programs, we formalized the curriculum to include guest speakers as well to enhance networking opportunities.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Results:** Based on internal survey data, recent and past Nephrology graduates and current faculty, these topics were selected as vital to education. After one year of insinuating this curriculum, our trainees report feeling more prepared for the transition to attendinghood. All four fellows report they were very likely to use these skills in the future. They also report being able to use the skills learned in leadership series during their time as a trainee as well.

**Conclusions:** Physicians are often thrust into leadership roles. Whether that is managing a multi-disciplinary team of nurses, social workers, dietitians or more, or in more traditional administrative roles. We are also gaining recognition of leadership skills in patient-centered care with conflict resolution, communication skills and emotional intelligence. These skills emphasize and enrich the clinical education we receive by allowing us to implement our medical knowledge as effective healthcare leaders.

## PUB166

### Denosumab in Immobilization-Induced Hypercalcemia

Jugal Thaker, Abdallah Sassine Geara. *University of Pennsylvania, Philadelphia, PA.*

**Introduction:** Critically-ill patients with prolonged immobility are at risk of hypercalcemia. In ESRD patients with hypercalcemia therapeutic options are limited: Hydration may cause volume overload, loop diuretics are not effective and bisphosphonates may cause over suppression of bone turnover. This case series presents two patients with immobilization-induced hypercalcemia successfully treated with denosumab

**Case Description:** Case 1: a 51 y/o male s/p bilateral lung transplant who developed chronic respiratory failure due to COVID-19. Case 2: a 54 y/o male initially admitted with COVID-19 requiring b/l lung transplant. Both patients developed AKI that progressed to ESRD and were bed bound. Evaluation for the hypercalcemia was compatible with immobilization-induced hypercalcemia: low iPTH, normal 1,25-VitD levels, negative multiple myeloma workup and mildly elevated PTH-rp (due to accumulation of the carboxy-terminal fragments). We eliminated calcium in the enteral feeds, used low calcium dialysis bath without success. Both patients received denosumab 60mg S/c once with improvement of the hypercalcemia. They developed asymptomatic hypocalcemia treated with resumption of calcium in the diet and using a 2.5Ca dialysis bath.

**Discussion:** Denosumab is monoclonal antibody to the RANKL that inhibits osteoclast formation. It is currently used in osteoporosis therapy and cancer-induced hypercalcemia. In ESRD patients with immobilization-related hypercalcemia, denosumab offers the advantage of no renal dose adjustment necessary, rapid onset of action and longer therapeutic duration. Patient should be monitored for hypocalcemia, rebound hypercalcemia and risk of over suppression of bone remodeling.

Case 1

Case 2

## PUB167

### Not Your Typical Heart Failure: A Rare Case of Adult-Onset Bartter Syndrome

Hanah L. Williams,<sup>1,2</sup> Andrew T. Ho,<sup>2</sup> Joseph Ahoulim,<sup>3,2</sup> Andrew Y. Kim,<sup>3,2</sup> Ellika Salari,<sup>3,2</sup> Sheldon J. Myers.<sup>1,2</sup> *<sup>1</sup>Western University of Health Sciences, Pomona, CA; <sup>2</sup>Temecula Valley Hospital, Temecula, CA; <sup>3</sup>UHS Southern California Medical Education Consortium, Temecula, CA, USA, Temecula, CA.*

**Introduction:** Bartter Syndrome (BS) is a renal tubulopathy characterized by hypokalemia, hypochloremia, metabolic alkalosis, hyperreninemia, and hyperaldosteronism. It causes a mutation in the loop of Henle's thick ascending limb's Na-K-Cl (NKCC) cotransporter. This gives BS a characteristic mechanism mimicking the loop diuretic, furosemide. Understandably, this complicates the treatment of comorbid conditions, specifically heart failure (HF). In HF, if potassium (K+) falls below 3.5 mmol/L (4-5 mmol/L) in the setting of aggressive replenishment, an alternative diagnosis should be considered. Furthermore, if an electrolyte imbalance cannot be explained, tubulopathies should be on the differential. The complexity of HF and renal response can be exacerbated by BS, thus playing a role in overall management.

**Case Description:** We report an unusual case of a 55-year-old female with a history of HF with reduced ejection fraction (HFrEF) and chronic hypotension, who presented with HFrEF (EF 10%) exacerbation. Her course was complicated by metabolic alkalosis and severe hypokalemia (as low as 1.8 mmol/L) refractory to aggressive potassium repletion protocols. Serum renin, serum chloride (Cl-), urine Cl-, and urine K+ levels were 32,092 ng/ml/hr (<5.82 ng/ml/hr), 81 mmol/L (96-106 mmol/L), 87 mmol/L (<40 mmol/L), and 108 mmol/L (<62 mmol/L), respectively. These findings are consistent with BS. Ultimately, she required ICU monitoring and emergent airway protection. The patient developed recurrent ventricular arrhythmias and passed from cardiac arrest.

**Discussion:** In the setting of BS, a HFrEF patient's survival is futile if not caught early. Both HF and hypokalemia carry a risk of sudden cardiac death as a single entity, so when seen concurrently, treatment becomes complicated. While BS is underrepresented in adults, early recognition and understanding of this tubulopathies' effects on heart failure management could reduce mortality and morbidity in this complicated patient population.

KCl Response in Patient with BS

## PUB168

### A Case of Hyperkalemia and Hypocalcemia With IV Magnesium Administration in Preeclampsia

Anne Brooker, Ira S. Meisels, Martine Pollack-Zollman. *Mount Sinai Morningside Hospital, New York, NY.*

**Introduction:** Magnesium (Mg) is used to decrease neuromuscular excitability in cases of preeclampsia/eclampsia. High serum levels are needed to achieve this. Although usually safe, there are reports of maternal hyperkalemia (hyperK) and hypocalcemia (hypoCa). We describe one such case.

**Case Description:** A 44 year old woman was admitted for preeclampsia due to intrauterine growth restriction and HTN. IV Mg was started. Mild hyperK developed, which resolved once IV Mg was stopped. When IV Mg was restarted, she developed severe hyperK and hypoCa that correlated with hyperMg (Graph 1). HyperK was medically treated and AKI was not present. Work up for hyperK included PAC (2.5 ng/dL, range 0.0-30.0 ng/dL) and PRA (0.925 ng/mL/hr, range 0.167-5.380 ng/mL/hr). HyperK and HypoCa improved with resolution of hyperMg.

**Discussion:** HypoK is resistant to correction if hypoMg is present. Rodan et al presents evidence of Mg inhibition of ROMK channels (via effects on membrane potential) and suggests that hypoMg fails to inhibit ROMK causing increased urinary K excretion. It is possible that the opposite is true: hyperMg may inhibit ROMK to the point of hyperK. A review of the literature revealed 3 cases of hyperK with the use of IV Mg in preeclampsia; we present the 4th case. Our literature search did not reveal cases of hyperMg causing hyperK in non-pregnant women. Possibly, the combination of hyperMg with the relatively low renin/aldo state of preeclampsia is needed to provoke hyperK. The patient did receive labetalol, ketorolac and heparin, which may cause hyperK. While calcium (Ca) is the main mediator of PTH secretion, hyperMg can directly suppress the release of PTH from the parathyroid gland, blunt PTH's actions peripherally and compete with Ca for reabsorption leading to increased urinary Ca losses. This case highlights

the importance of careful electrolyte monitoring in pregnant patients with preeclampsia on IV Mg. Further studies are needed to elucidate the physiologic mechanism of these electrolyte derangements.

## PUB169

### Laboratory Findings in Fatal Ingestion of Hand Sanitizer

Kaitlyn E. Spinella,<sup>1</sup> Jared Yeggy,<sup>1</sup> Judy Sakya,<sup>1</sup> Kirtan Patel,<sup>1</sup> Nathan Dang,<sup>1</sup> Shahzad Safdar,<sup>1,2</sup> <sup>1</sup>The Christ Hospital Health Network, Cincinnati, OH; <sup>2</sup> Mt Auburn Nephrology, Cincinnati, OH.

**Introduction:** Alcohol-based hand sanitizer is typically composed of ethanol or 2-propanol, as recommended by the Center for Disease Control and Prevention. However, since the start of the SARS-CoV-2 pandemic, the demand has increased exponentially, leading to the increased circulation of products that do not meet regulatory standards. This case describes a patient who ingested hand sanitizer; however, based on the laboratory findings, it likely contained more toxic alcohols than ethanol.

**Case Description:** A 53-year-old male presented to the emergency department (ED) via emergency medical services (EMS). Patient reportedly had ingested hand sanitizer and become unresponsive. EMS found him pulseless upon arrival, and advanced cardiac life support (ACLS) was initiated, resulting in return of spontaneous circulation (ROSC). He arrested again in the ED and ACLS was initiated, resulting in ROSC again. No family was present, but per chart review, patient had a history of a seizure disorder, polysubstance abuse, and cirrhosis. Patient was admitted to the intensive care unit for further management. Labs indicated an anion gap metabolic acidosis, significant for anion gap of 48 mmol/L, sodium 151 mmol/L, potassium 5.7 mmol/L, bicarbonate 8 mmol/L, creatinine 4.96 mg/dL, blood urea nitrogen (BUN) 74 mg/dL, glucose 196 mg/dL, and lactate 30.48 mmol/L. Serum osmolality was measured at 407 mOsm/kg with a calculated osmolality of 389 mOsm/L (including ethanol level of 216 mg/dL). Venous blood gas showed a pH of 6.86 on admission. Upon discussion with Poison Control, fomepizole or ethanol treatment was not recommended, as hand sanitizers are typically made from ethanol and his level was not severely elevated, so only supportive care was necessary. Continuous renal replacement therapy (CRRT) was initiated. However, he began to demonstrate decorticate posturing. Following discussion of prognosis with family, they decided to pursue comfort care.

**Discussion:** Since the beginning of the SARS-CoV-2 pandemic, hand sanitizer production has increased, with some being manufactured outside of typical regulatory standards. As indicated by the osmolar gap and severe anion gap metabolic acidosis, the hand sanitizer ingested in this case may have contained methanol or ethylene glycol. Consequently, it is essential to have a high index of suspicion for alcohols other than ethanol in hand sanitizer ingestion.

## PUB170

### Transtubular Potassium Gradient in Hypertensive Emergency

Jia Wei Tan, Kwabena S. Nketiah Sarpong, Sun-Joo Jang, Samdesh Sethi, Lakshmi D. Polisetty, Arjun Gogna. *Bridgeport Hospital, Bridgeport, CT.*

**Background:** Transtubular potassium gradient (TTKG) indirectly evaluates the potassium secretion at the site of cortical collecting duct and serves as a surrogate marker for mineralocorticoid activity. In hypokalemic hypertensive emergency (HE) patients, TTKG is a useful test in the workup for secondary cause of hypertension.

**Methods:** We conducted a retrospective study on HE patients admitted under the Yale New Haven Health (YNHH) system from 2016 to 2021. We selected patients with International Classification of Diseases, Tenth Edition (ICD-10) diagnosis of HE (I16.1) and at least 1 additional diagnosis for concurrent end organ damage. We excluded patient with urine sodium less than 25 mEq/L and patients who have a urine osmolality that is less than plasma osmolality.

**Results:** Among the hypokalemic patients, the median TTKG is 10.21 (IQR: 8.88-12.45). Among the normokalemic patients, the median TTKG is 4.35 (IQR: 3.33-6.49). Among the hyperkalemic patients, the median TTKG is 2.29 (IQR: 1.80-2.77). The TTKG is significantly different among the 3 groups ( $p < 0.01$ ). There is no significant difference of serum creatinine, systolic blood pressure (SBP) and urine potassium/urine creatinine ratio (uK/uCr) across the three potassium groups.

**Conclusions:** The high TTKG in hypokalemic HE patients reflects an underlying renal potassium wasting disorder. We suggest to trend the values of TTKG during treatment course of HE. If the abnormal TTKG returned to normal with reduction in blood pressure, the potassium wasting state is likely secondary to pressure natriuresis from accelerated hypertension, and further diagnostic tests should be ordered with discretion. If the TTKG is persistently high, evaluation of a mineralocorticoid excess state should be pursued in the inpatient setting.

Post-hoc analyses were performed with pairwise Wilcoxon ranksum test (\*\*\*)  $P < 0.01$ , \*\*  $P < 0.05$ .

## PUB171

### Nephrogenic Diabetes Insipidus Secondary to Foscarnet

Wadhah M. Bin Homam, Joseph H. Holthoff, Umair Ali, Yazan A. Bashtawi. UAMS Internal Medicine/Nephrology *University of Arkansas for Medical Sciences, Little Rock, AR.*

**Introduction:** Foscarnet is a pyrophosphate analog. It binds reversibly near the pyrophosphate-binding site of DNA polymerase and selectively inhibits viral polymerase. Foscarnet is used in the treatment of CMV infection in immunocompromised patients. We are presenting a case report of a patient with lambda light chain myeloma post SCT who developed nephrogenic diabetes insipidus secondary to foscarnet for the treatment of CMV viremia.

**Case Description:** A 71-year-old lady was diagnosed with lambda light chain myeloma in 9/2021 when she presented with nose bleeds, headaches, loss of appetite, and was found to have pancytopenia. The patient underwent autologous SCT. The patient was readmitted due to worsening nausea and vomiting, underwent upper GI endoscopy with a biopsy suggestive of chemical gastritis. The patient was found to have CMV/HHV6 viremia for which ganciclovir was started. Due to worsening pancytopenia, ganciclovir was shifted to foscarnet (80 mg/kg, 6 g iv daily). 3 days after initiation of foscarnet, the patient developed hypernatremia with serum sodium increased to 147 mmol/L. Other investigations showed a serum creatinine of 1 mg/dL, BUN of 5 mg/dL, serum albumin of 2.2 mg/dL, serum calcium of 7.5 mg/dL, corrected serum calcium of 8.9 mg/dL and a serum potassium of 3.3 mmol/L. Initially, hypernatremia was believed to be secondary to volume depletion in the setting of vomiting and poor oral intake. Despite isotonic fluid replacement, serum sodium continued to increase, reaching 164 mmol/L and the patient became confused. The patient was polyuric with a maximum urine output of 9L/d. The plasma osmolality was 311 mmol/kg, and the urine osmolality was 191 mmol/kg. Having the patient's general condition, the water deprivation test wasn't done. Nephrogenic diabetes insipidus secondary to foscarnet was highly suspected. IV chlorthalidone 500 mg/day was started and foscarnet was discontinued, 10 days after its initiation. Upon foscarnet's withdrawal and along with hypotonic fluids infusions, hypernatremia started to gradually improve, and serum Na<sup>+</sup> reached the normal levels 5 days after.

**Discussion:** Nephrogenic diabetes insipidus is a rare side effect of foscarnet use. A search of the World Health Organization's adverse effect database revealed 359 reports of drug-induced diabetes insipidus. Lithium was the most common cause (159 reports) followed by foscarnet (15) and clozapine (10).

## PUB172

**A Prospective, Real-World Evidence Study of Hyperkalemia Management Decision Making: Design of the TRACK Study**

Judith Hsia,<sup>1</sup> Nitin Shivappa,<sup>2</sup> Ameet Bakhai,<sup>3</sup> Jordi Bover,<sup>4</sup> Javed Butler,<sup>5,6</sup> Pietro Manuel Ferraro,<sup>7,8</sup> Linda F. **Background:** Prospective data on healthcare professionals' (HCP) decision making and patient management related to hyperkalemia (HK) are scarce. The TRACK study will collect data on HCP objectives and decision-making behaviors when encountering patients with HK in real-world practice, as well as patient perceptions of HK and its treatment.

**Methods:** TRACK is a multinational, prospective, observational, longitudinal cohort study within the US and Europe. We plan to enroll approximately 1250 patients with established HK. During the 12-month follow-up, data will be collected from health records and HCPs using an electronic case report form at 3-month intervals. Patient-reported outcomes will also be collected. The primary objective is to describe HK management decisions, their rationale, and expectations at baseline, and their association with treatment response indicators (correction of HK; target doses of renin-angiotensin-aldosterone system inhibitors [RAASi]; healthcare resource utilization) (Figure). The secondary objective is to describe patients' clinical parameters during follow-up. Exploratory objectives include patient awareness and satisfaction with HK management.

**Results:** Anticipated study completion is 2024.

**Conclusions:** This non-interventional, real-world study will gather insights into HCP approaches to implementing HK management. TRACK will characterize the use of HCP decision making on HK recurrence, inform the use of guideline-directed therapies related to RAASi use, and address knowledge gaps regarding HCP and patient perspectives on HK management.

TRACK Study Design Concept

## PUB173

**Management of Severe Hyponatremia With Modified Continuous Venovenous Hemodiafiltration (CVVHDF) Solutions**

Stephanie M. Sanders, Matthew Kaptein. *Loma Linda University, Loma Linda, CA.*

**Introduction:** Hyponatremia is common in patients with cirrhosis. Guidelines suggest limiting the rate of serum sodium concentration (S[Na]) correction of chronic hyponatremia to reduce complications, including osmotic demyelination syndrome (ODS). Standard solutions used in continuous venovenous hemodiafiltration (CVVHDF) have [Na] 140mEq/L. In patients with severe hyponatremia requiring CVVHDF, it is difficult to prevent rapid correction of S[Na].

**Case Description:** We present a 40 yo woman in ICU with decompensated cirrhosis. On admission, she had serum Cr 1.0mg/dL and S[Na] 134mEq/L. S[Na] decreased by 18mEq/L roughly linearly over 16 days to a nadir of 116mEq/L despite free H<sub>2</sub>O restriction <1L/day. CVVHDF was started overnight 2h later with standard [Na] 140mEq/L solutions. 12h later, S[Na] increased to 125mEq/L. The CVVHDF order was modified to target [Na] 125mEq/L in pre-filter fluid, dialysate, and post-filter fluid. H<sub>2</sub>O was added to each dialysate bag using the principle Concentration1(140mEq/L)\*Volume1(5L)=Concentration2(125mEq/L)\*Volume2(5.6L), yielding 600mL sterile H<sub>2</sub>O added to each 5L bag. S[Na] was 124mEq/L by CVVHDF day 2. That day [Na] in dialysate was kept constant because of a transient S[Na] increase the day prior. CVVHDF day 3, H<sub>2</sub>O added to dialysate was reduced to target dialysate [Na] 130mEq/L, and on CVVHDF day 4 was reduced again to target [Na] 135mEq/L. CVVHDF days 5+, standard dialysate with [Na] 140mEq/L was used. S[Na] increased to 128mEq/L 24h after S[Na] 116mEq/L, likely due to administration of hypertonic saline. 18h later, after about 30h CVVHDF, 12h with [Na] 140mEq/L bath, 18h with [Na] 125mEq/L bath, S[Na] was 124mEq/L.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

S[Na] increased roughly linearly to 136mEq/L 5 days after measurement of S[Na] 116mEq/L. After correction of 12mEq/L in the first 24h with concurrent hypertonic saline administration, rate of correction never exceeded 7mEq/L/day. The patient was discharged without liver transplant, on HD, and showed no signs of ODS.

**Discussion:** Changing the target [Na] in CVVHDF solutions is a more precise method for gradually increasing S[Na] than administering D5W intravenously at high rate during CVVHDF, and adjusting D5W rate according to frequent S[Na] measurements. Adding more than 600mL sterile H<sub>2</sub>O to each 5L bag was not attempted. The maximum amount of H<sub>2</sub>O that can be added is unknown.

## PUB174

**Immobilization Related Hypercalcemia in ESRD: Is Denosumab a Viable Treatment Option?**

Abhinava Sridhar,<sup>1</sup> Sanjeev Gupta,<sup>1,2</sup> Savneek S. Chugh,<sup>1,2</sup> Amol Mittal,<sup>1,2</sup> Uzma Malik.<sup>1,2</sup> *<sup>1</sup>Westchester Medical Center, Valhalla, NY; <sup>2</sup>New York Medical College, Valhalla, NY.*

**Introduction:** The most common abnormality of mineral bone disease seen in ESRD is renal osteodystrophy. However, persistent parathyroid hormone (PTH) independent hypercalcemia raises the possibility of immobilization or malignancy. Denosumab is a potential treatment option but its efficacy and safety in ESRD remains poorly studied. We describe 2 ESRD patients with immobilization related hypercalcemia that was successfully treated with denosumab.

**Case Description:** Case 1: 54 year old man with well controlled diabetes and Chronic Kidney Disease (CKD), started on hemodialysis (HD) after cardiac arrest with poor neurological recovery. Case 2: 57 year old man with laparoscopic gastric sleeve complicated by hemorrhagic shock and Acute Kidney Injury (AKI) needing HD. Course of hypercalcemia described in table. Neither patients experienced hypocalcemia as a side effect.

**Discussion:** Immobilization related hypercalcemia occurs when osteoclastic bone resorption exceeds osteoblastic bone formation causing an imbalance in the bone remodeling process. Denosumab is a monoclonal antibody that binds and inhibits RANKL reducing osteoclast maturation and bone resorption. Both our patients were not on any drugs that could cause hypercalcemia and had no evidence of underlying granulomatous disease. Although PTHrP was mildly elevated in both patients, it was attributed to ESRD itself and we hypothesize that hypercalcemia was due to prolonged immobilization. Intravenous hydration is an unsafe option in ESRD. HD using low Ca dialysate is an option, but both patients were resistant to this. Both patients had improvement in Ca levels with denosumab and neither experienced hypocalcemia as a side effect probably due to ongoing hemodialysis. Case reports describe patients with ESRD and hypercalcemia who were successfully treated with denosumab. It offers advantages compared to bisphosphonates with its rapid onset, longer action and no dose adjustment for kidney function. **Learning objectives:** Denosumab is a potential treatment option for immobilization or malignancy related hypercalcemia in ESRD. Hypocalcemia which is a common side effect of denosumab could be averted in ESRD patients due to ongoing HD.

Course of Hypercalcemia during hospital stay

Weeks 6-14	Calcium (Ca) levels between 11.1-11.3 mg/dL. Initial testing revealed PTH 92 pg/mL and Vitamin D 19 ng/mL. Patient was started on Vitamin D supplementation and low Ca dialysate bath was used.
Week 15	Worsening Hypercalcemia peaking at 12mg/dL. Repeat testing revealed Vitamin D 34 ng/mL, PTH 19 pg/mL, and PTHrP 34 pg/mL. Vitamin D was discontinued in setting of suppressed PTH. Given ESRD, pamidronate was contraindicated and patient received one dose of subcutaneous (SQ) Denosumab 60mg.
Weeks 16-19	Ca levels between 9.6-10.6 mg/dL.
Week 20	Worsening Hypercalcemia peaking at 12.3 mg/dL. Patient received another dose of Denosumab 60mg SQ.
Weeks 21-22	Ca levels between 9.6-10 mg/dL. Patient ultimately underwent palliative exsufflation given poor neurological status and worsening sepsis.
Week 1	Initiated Vitamin D supplementation for Vitamin D level 15.7 ng/mL.
Week 10	Initial work up notable for PTH 16 pg/mL, Vitamin D 20 ng/mL, and PTHrP 39 pg/mL. Vitamin D supplementation was decreased and low Ca dialysate bath was used.
Week 11	Persistent hypercalcemia peaking at 11.8 mg/dL. 1 dose of calcitonin 544 units SQ given.
Week 13	Continued on Calcitonin 400 units Intramuscular q12. Ca levels 12.3-12.9 mg/dL.
Weeks 14-18	Worsening Hypercalcemia peaking at 13 mg/dL. Received Denosumab 120mg SQ. Ca levels 8.8-9.5 mg/dL. Discharged with outpatient follow up.

PTHrP-PTH related peptide

## PUB175

**β-Blockers (BB) and Serum Potassium (K) Levels in Hemodialysis (HD) Patients**

Sally Chau,<sup>1</sup> Vinod K. Valluri,<sup>1</sup> Garrett Yu,<sup>1</sup> Masoud Haghi,<sup>1</sup> Kulwant S. Bath,<sup>1</sup> Golriz Jafari,<sup>1</sup> Anita Kamarzarian,<sup>1</sup> Susana M. Mendoza,<sup>1</sup> Phuong-Thu T. Pham,<sup>2</sup> Phuong-Chi T. Pham.<sup>1</sup> *<sup>1</sup>UCLA Medical Center Olive View, Sylmar, CA; <sup>2</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

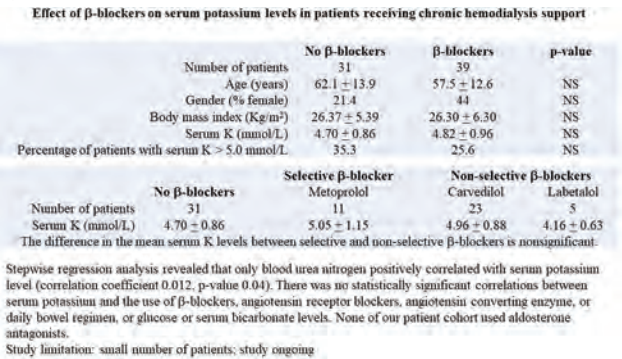

**Background:** Chronic hemodialysis patients commonly require the use of multiple antihypertensive or cardiovascular protective agents including BB. As BB may cause hyperkalemia via blocking renin secretion (β1) and Na-K-ATPase (β2), we aimed to investigate whether the use of BB, in particular, nonselective vs. selective BB, is associated with increased serum K levels and hyperkalemia in patients receiving chronic HD therapy.

**Methods:** Inclusion: Chronic HD patients admitted to Olive View-UCLA Medical Center Exclusion: Patients admitted for missed dialysis treatments, vascular access repair, rhabdomyolysis or cell death (e.g., hemolysis, elevated lactate dehydrogenase levels) Data collected: Age, gender, comorbidities (diabetes mellitus, hypertension, heart disease); Factors that could contribute to hyperkalemia (glycemia control, use of

inhibitors of the renin angiotensin aldosterone system, acidemia (serum bicarbonate), bowel regimen); The use of nonselective versus selective BB Analysis: Average values of all lab values collected will be compared among the 3 groups: 1. No beta-blockers, 2. Any form of BB, 3. Nonselective BB (carvedilol, labetalol), and 3. Cardioselective beta-blockers (metoprolol). Stepwise regression was also performed for factors that could affect potassium levels.

**Results:** Results are summarized in Figure.  
**Conclusions:** To date, our data suggest: 1. BB users do not have higher serum K level compared with non-BB users 2. Non-selective BB (carvedilol and labetalol) is not associated with greater K levels compared to selective BB. 3. Blood urea significantly correlates with serum K. The use of angiotensin converting enzyme inhibitors or angiotensin receptor blockers does not correlate with serum K. Limitations: Ongoing study, small dataset

PUB176

A Case of Medullary Sponge Kidney Presented With Persistent Hypokalemia

Rui Song,<sup>1</sup> Sunita Lakhani,<sup>1</sup> Syeda Hassan,<sup>1</sup> Raja N. Kyriakos,<sup>1</sup> Lawrence Freitas,<sup>1,2</sup> <sup>1</sup>Abington Memorial Hospital, Abington, PA; <sup>2</sup>Hypertension Nephrology Associates, Willow Grove, PA.

**Introduction:** Medullary sponge kidney (MSK) is a rare and benign congenital abnormality of renal tubules characterized by cystic dilation of the renal medullary collecting ducts. We present a case who was found to have MSK during hypokalemia workup.

**Case Description:** A 33-year-old female with well-controlled HIV on Biktarvy (HIV-1 RNA < 20 copies/ml) presented with palpitations and tingling in the arms and legs for one day. She was found to have a serum potassium of 2.8mmol/L, magnesium of 1.6mEq/L, normal anion gap metabolic acidosis (NAGMA), creatinine of 0.8mg/dL, calcium of 9mg/dL and phosphorus of 3mg/dL. She is normotensive. She denies diuretic/laxative use, eating disorder, hypothyroidism, polyuria or diarrhea. She had chronic persistent hypokalemia (2.7-3.3mmol/L) and one episode of pyelonephritis 7 years ago. Family history includes ESRD of her grandmother. Her urine tests showed a urine potassium of 22 mmol/L, urine sodium of 64 mmol/L, urine anion gap of 13, urine PH of 7.5 with no proteinuria or hematuria. The urine drug screen was negative. Nephrology was consulted and further workup showed normal serum cortisol level, TSH and aldosterone/renin ratio, vitamin D deficiency (25-OH vitamin D 16.4ng/mL) with secondary hyperparathyroidism (PTH 252 pg/mL). A urine diuretic screening test was sent. Renal ultrasound (US) showed bilateral diffuse echogenic renal medullary pyramids, no hydronephrosis, mass or stone. The cause of the hypokalemia was thought to be MSK complicated by incomplete distal renal tubular acidosis (RTA). Potassium citrate was started but she was lost to follow-up.

**Discussion:** Incomplete distal RTA is common in MSK and is often asymptomatic. The patient was detected with mild hypokalemia, NAGMA and a urine pH of 7 since 7 years ago when having pyelonephritis, indicating distal RTA. Her distal RTA could be multifactorial. Vitamin D deficiency might be a factor but her normal serum calcium level does not support it. Her HIV and Biktarvy (has Tenofovir) usage are unlikely the main contributors as her hypokalemia happened much earlier than the HIV history. Her kidneys from the CT scan 7 years ago did not show calcification or increased density of the pyramids but now she has a typical US finding of MSK. This case highlights that hypokalemia and distal RTA might be the first sign of MSK while structural changes were not prominent in the imaging.

PUB177

Lithium Induced Partial Nephrogenic Diabetes Insipidus: An Unusual Presentation

Jesus D. Vega-Colon, Maria E. Rivera, Alexis Rivera Gonzalez, Hillarie A. Rios Torres, Cristina M. Casas Loyola, Carlos G. Rivera-Bermudez, Krystahl Z. Andujar-Rivera, Ileana E. Ocasio Melendez. University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico.

**Introduction:** Nephrogenic Diabetes Insipidus (NDI) is described as a reduction in urinary concentrating ability caused by a resistance of vasopressin. It is characterized by hypotonic polyuria, polydipsia, and hypernatremia. Hereditary causes or acquisition from drugs like lithium and amphotericin B most be considered as potential triggers.

Fluid deprivation with subsequent urine osmolality (Uosm) measurement can help us classify this disorder into partial (Uosm: 250-750 mOsm/Kg) or complete NDI (Uosm <250 mOsm/Kg). Few cases describe the occurrence of partial NDI in a Hispanic male with history of lithium use.

**Case Description:** We report a 47-year-old Puerto Rican male with Bipolar disorder and Epilepsy brought to our institution due to general weakness, lethargy and decrease appetite in the past 7 days. Caretaker reported use of lithium carbonate 300 mg twice a day for the past 12 years. During hospital stay nephrology service was consulted due to hypernatremia of 155 meq/L and lithium toxicity (1.97 mg/dl). Urine output showed evidence of persistent polyuria of 4.5 liters in 24 hours. Upon further evaluation urine osmolality was obtained showing results of 358 mOsm/Kg. Decision was made to stop lithium and perform fluid deprivation achieving minimal increase in urine osmolality to 391 mOsm/kg. As part of treatment, low dose thiazide diuretic was started with goal of impairing free water excretion. Resolution of hypernatremia to 143 meq/L and adequate uresis of 1.4 liters in 24 hrs was acquired following 72 hours. Based on the association of hypernatremia, polyuria with initial Uosm greater than 250 mOsm/Kg, history of Lithium use and minimal increase in Uosm following fluid deprivation, the diagnosis of partial NDI was recognized.

**Discussion:** This case exemplifies an uncommon type of NDI that should be involved on the differential diagnosis. A thorough history is essential as it can help unravel the offending agent. Increased awareness of lithium toxicity side effects will help clinicians prevent life-threatening electrolyte disorders. The uniqueness of our case lies on the rarity of this type of NDI reported on literature. Our patient successfully responded to low dose thiazide diuretic correcting dysnatremia and archiving satisfactory uresis.

PUB178

Persistent Normo-Osmolar Hyponatremia in an Ex-Alcoholic  
Tushar Bajaj, L. Tammy Ho. University of Chicago Pritzker School of Medicine, Chicago, IL.

**Introduction:** Dysnatremia is common in patients with chronic-alcohol use disorder. Differential includes beer portomania which is a vasopressin-independent mechanism in which patients drink large quantities of beer and have inadequate food intake. This leads to low excretion of urinary solute and limited excretion of renal water. We present an interesting case of a previous alcoholic with normo-osmolar hyponatremia; however, despite abstaining from drinking. She continued to have normoosmolar hyponatremia which questions true abstinence versus resetting of the osmostat.

**Case Description:** Patient is a 66 YO Female with goblet cell carcinoid s/p right hemicolectomy, left ovarian mucinous cystadenoma s/p TAH/BSO, HTN, GERD, HLD, Knee OA, PTSD, normocytic anemia who has had persistent hyponatremia. This was noted 2 years prior to initial evaluation with a hospital admission for generalized weakness, nausea, slurred speech, alcohol abuse. She was found to have hypovolemic hyponatremia and starvation ketoacidosis. She had multiple ED visits for generalized weakness and fatigue. There were multiple reports of alcohol abuse in the past but she reported quitting 1 year prior to evaluation. Patient was started initially on salt tablets but this was later discontinued. Whole blood sodium confirmed true disorder with value of 125mmol/L. Refer to Table 1 for timeline of events.

**Discussion:** Etiology of normo-osmolar hyponatremia in patient remains uncertain. The patient has had persistent polyclonal gammopathy with elevated kappa free light chains but this predates the hyponatremia onset. Patient had normal triglyceride levels and slightly elevated total cholesterol. There was no evidence of a serum osmolar gap, measured at 288, calculated at 286-294. Measurements of ETOH level could not explain normal osm in setting of low sodium. On several non-related lab draws, ETOH levels were consistent with her history of abstinence and documented to be zero. We recommended the patient to stop salt tablets and continue to monitor off medications. Persistent normoosmolar hyponatremia suggests possibility of reset osmostat.

Timeline

	Month 1	Month 2	Month 12	Month 22	Month 22
Serum Sodium	121	134	130	123	124
Serum Osmolality	259	348	293	293	288
Urine Sodium	31		20		
Urine Osmolality	223		127	160	202
Serum Ethanol	20			140	

PUB179

A Rare Case of Aspirin-Induced Symptomatic Hyponatremia  
Madeline S. Chung, Amy Yau. The Ohio State University Wexner Medical Center, Columbus, OH.

**Introduction:** Prostaglandins in the kidney act to attenuate the actions of antidiuretic hormone (ADH). Non-steroidal anti-inflammatory drugs (NSAIDs) inhibit the synthesis of prostaglandins resulting in an increased response to ADH in the kidney leading to free water retention and hyponatremia, especially under conditions which also promote hyponatremia.

**Case Description:** We present a 61-year-old man with past medical history significant for hypertension and basal and squamous cell skin carcinomas who presented complaining of excessive urination and generalized weakness for 3 days and altered mentation. Blood pressure was 153/76 mmHg and other vitals unremarkable. He was lethargic with delayed response to questions and euvoletic on exam. Medications included losartan 50mg daily with no diuretics. Admission labs were significant for a serum sodium of 111 mEq/dL, urine sodium of 135 mmol/L, urine osmolality of 542 mOsm/L, TSH 1.633  $\mu$ U/mL and cortisol 53.52  $\mu$ g/mL. Two weeks prior, his serum sodium level was 138 mEq/dL. CT

head and chest X-ray were negative for any acute pathologies. He was started on 3% saline with improvement in symptoms but 24 hours later developed a brisk water diuresis. Labs were significant for a serum sodium of 122 mEq/dL, urine sodium of 12 mmol/L, and urine osmolality of 98 mOsm/L. Further history revealed a high water intake based on advice from his physician and new intake of aspirin 325mg three times a day due to shoulder pain. His hyponatremia was managed with DDAVP, free water, and saline. It remained normal prior to discharge without any additional intervention. Pan-CT and MRI brain were obtained and negative.

**Discussion:** SIADH attributable to NSAIDs is a rare occurrence, especially since prostaglandins present in the kidneys inhibit the actions of ADH while prostaglandins present in the central nervous system stimulate the secretion of ADH. But NSAID use can lead to an effect similar to SIADH in the setting of other situations which also promote ADH secretion such as pain and/or nausea. In our case, there were multiple factors that likely contributed to hyponatremia including pain, increased free water intake, and new NSAID use. The half-life of aspirin increases with higher plasma concentrations and is anywhere from 3-10 hours. Clinicians should be careful about encouraging excessive water intake especially in the setting of other risk factors for hyponatremia to include NSAID use.

PUB180

Executive Summary of the Korean Society of Nephrology 2022 Recommendations on Controversial Issues in the Diagnosis and Management of Hyponatremia

**Background:** Hyponatremia, defined as serum sodium concentration <135 mmol/L, is the most frequent body fluid and electrolyte balance disturbance encountered in clinical practice. Although several international guidelines for hyponatremia have been available, the differential diagnosis of hyponatremia is frequently challenging in patients with complex clinical settings and varying treatment.

**Methods:** A multidisciplinary guideline development committee representing specialists with a genuine interest in hyponatremia was convened by the Korean Society for Electrolyte and Blood Pressure Research in collaboration with the Korean Society of Nephrology (KSN), clinical practice guideline (CPG) committee. The committee has developed the CPG and applied strict management strategies to minimize potential bias. The committee prioritized clinical questions and outcomes according to their importance for clinicians and patients. The committee used the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach, including GRADE Evidence-to-Decision frameworks, to assess evidence and make recommendations.

**Results:** This CPG consists of 12 recommendations (2 in diagnosis, 8 in treatment, and 2 in special situations of hyponatremia). Each begins with statements graded by the strength of recommendations and the quality of the evidence. Each statement is followed by rationales supporting the recommendations.

**Conclusions:** We were keen to ensure that the document represents recommended approaches for multiple etiologies of hyponatremia based on both consensus of experts in hyponatremia and the most recent published data in this field. We hope this CPG will be meaningful as a recommendation in practice, providing clinical decision support to improve patient outcomes.

Table 1. Recommendations

Topic	Recommendation	Recommendation Strength	Quality of Evidence
Differential diagnosis of hyponatremia	1. For patients with hyponatremia, we consider it reasonable that additional measurement of fractional urea acid excretion (FUEA) may be recommended to differentiate likely causes of hyponatremia, such as syndrome of inappropriate antidiuresis (SIAD) or diuretic-induced hyponatremia.	Expert consensus	
	2. There are insufficient data to make a recommendation for using the copegatin to urine sodium (CUNa) ratio to differentiate patient's volume status.	Inconclusive (I)	Very low
Treatment of severe hyponatremia	3. We suggest rapid intravenous bolus administration of hypertonic saline in patients with symptomatic severe (Na <125 mmol/L) hyponatremia.	Conditional recommendation (II)	Low
Management for mild hyponatremia	4-1. We consider it reasonable to rigorously evaluate the causes of mild hyponatremia and to manage causative diseases to improve the clinical outcomes.	Expert consensus	
	4-2. There are insufficient data to make a recommendation for treating mild hyponatremia with hypertonic saline or oral sodium chloride solely to increase the serum sodium (SNa) concentration.		
Treatment of hypervolemic hyponatremia	5-1. We suggest vasopressin receptor antagonists (vaptans) use in heart failure with hypervolemic hyponatremia in terms of rapid sodium correction.	Conditional recommendation (II)	Moderate
	5-2. We do not recommend vaptans in liver cirrhosis with hypervolemic hyponatremia.	Expert consensus	
SIAD	6. We suggest the treatment of vaptans in SIAD patients with moderate to severe hyponatremia.	Conditional recommendation (II)	Low
Prevention of overcorrection in hyponatremia	7. We suggest that desmopressin should be applied individually according to risk factors affecting overcorrection, therapeutic regimen of hypertonic saline and whether or not glucose solution is administered during overcorrection in patients with hyponatremia.	Conditional recommendation (II)	Very low
Special issues (1) Hyponatremia in patients with cerebral diseases	8. We consider it reasonable that the treatment with hypertonic or isotonic saline infusion, oral sodium chloride, or fluid restriction for the correction of hyponatremia should be individualized among patients with cerebral diseases.	Expert consensus	
Special issues (2) Prevention of hyponatremia in pediatric patients under the age of 18 years	9-1. We recommend the administration of isotonic fluids as maintenance fluid therapy in hospitalized pediatric patients over 1 month and under the age of 18 years.	Strong recommendation (A)	High
	9-2. There are insufficient data to make a recommendation for administering isotonic fluids as maintenance fluid therapy in neonates, because of risk of the development of hyponatremia.	Inconclusive (I)	Moderate

PUB181

Ethylene Glycol Toxicity: Usual Presentation With Uncommon Clinical Course

Asma Rashid,<sup>1</sup> Sangeetha Murugapandian,<sup>2</sup> <sup>1</sup>*Banner University Medical Center Tucson, Tucson, AZ;* <sup>2</sup>*Banner University Medical Center Tucson, Tucson, AZ.*

**Introduction:** Ethylene Glycol a toxic alcohol found in many household and industrial products, is an odorless, colorless, and sweet tasting liquid. It can be taken as a substitute for alcohol, swallowed accidentally or deliberately in a suicidal attempt. Fomepizole, which inhibits the formation of toxic metabolites, has become the mainstay in the treatment preventing the need for hemodialysis. We describe a case of ethylene glycol poisoning, treated early with fomepizole, with improvement in acidosis but subsequently developed worsening kidney function and required dialysis.

**Case Description:** 63-year-old male with history of hypertension, diabetes mellitus type II, hyperlipidemia, peripheral vascular disease, and depression, presented to hospital following ingestion of 24 Oz of antifreeze in a suicidal attempt. He was hemodynamically stable. Ethanol level was negative. He had anion gap of 21, osmolar gap of 88, pH of 7.29 and lactate of 10 mMol/L. Given clear history of ethylene glycol ingestion patient was started on fomepizole along with thiamine, folic acid and pyridoxine. His anion gap and osmolar gap started to improve however after 48 hours they started to increase again along with new onset AKI and development of calcium oxalate crystals requiring hemodialysis. Following two hemodialysis sessions, his ethylene glycol level was less than 10. He did not require any more hemodialysis sessions.

**Discussion:** Ethylene glycol, after ingestion is quickly absorbed from gastrointestinal tract and rapidly redistributed throughout the body. Oxidative reactions convert ethylene glycol to glycolaldehyde and glycolic acid responsible for metabolic acidosis and lactic acidosis. The glycolic acid is then converted to glyoxylic acid, oxalic acid and glycine. Oxalic acid is deposited as calcium oxalate crystals and contributes to renal failure and hypocalcemia. Fomepizole prevents formation of ethylene glycol toxic metabolites thus preclude hemodialysis need. In our case, patient presented with normal kidney function, but with elevated anion gap and osmolar gap which resolved with fomepizole. Although fomepizole prevents further formation of toxic metabolites, the already formed toxic metabolites along with high osmolality and direct effects of ethylene glycol on renal tubules, induced acute kidney injury, with subsequent development of oxalate crystals, necessitating hemodialysis.

Hiding in Plain Sight: Licorice, the Culprit of Severe Hypokalemia

Srikanth Thiruvurudsothy,<sup>1</sup> Theesitha Srikanth,<sup>2</sup> Arsitha Jeyarajasingam.<sup>3</sup> <sup>1</sup>*Virtua Health, Marlton, NJ;* <sup>2</sup>*Sichuan University West China Hospital, Chengdu, China;* <sup>3</sup>*University of Sri Jayawardanapura Department of Medical Education and Health Sciences, Nugegoda, Sri Lanka.*

**Introduction:** Chronic ingestion of licorice is well known to cause findings similar to those with the syndrome of apparent mineral corticoid excess (AME), which can result in hypertension, hypokalemia, and metabolic alkalosis. Here we present an interesting case of a woman with persistent hypokalemia.

**Case Description:** Patient is a 70-year-old Caucasian woman referred to nephrology for persistent hypokalemia. She has a history of hospitalizations in the past for hypokalemia and hypomagnesemia. The patient has had a history of hypertension for approximately 10 years and had been on Losartan and Verapamil. She also has a history of Gastroesophageal reflux disease and was on Pantoprazole. During a recent hospitalization for hypokalemia and hypomagnesemia, pantoprazole was switched to famotidine and was started on magnesium and potassium supplementation. She has no history of diuretic use or alcohol abuse. No diarrhea. She was eating a balanced diet. At a follow-up visit, the patient revealed that she consumed licorice, at least once daily. She was asked to stay away from licorice. We subsequently held potassium and magnesium supplementation,

and followed up with repeat labs in a few weeks. Testing including renin, aldosterone, and urine electrolytes were unremarkable. Renal ultrasound with doppler showed normal-sized kidneys and no evidence of renal artery stenosis. Subsequent blood work showed stable potassium levels without supplementation. She has had elevated serum bicarbonate levels which also seem to have improved since then. Interestingly, her blood pressure readings are also improved.

**Discussion:** Persistent hypokalemia, metabolic alkalosis and HTN should trigger a variety of differential diagnoses. In our patient’s case, chronic proton pump inhibitor use was a confounding factor for low magnesium and potassium. A thorough history is essential to differentiate diagnoses such as AME and chronic licorice ingestion. Licorice ingestion is well known to cause hypertension and hypokalemia. Our case demonstrates, how the cessation of licorice consumption has improved the patient’s quality of life, decreased pill-burden, and prevented recurrent hospitalizations, for severe hypokalemia.

PUB183

**Severe Hyponatremia due to Dehydration Causing AKI Requiring Dialysis: A Case Report**  
Sini Bijoy,<sup>1</sup> Muhammad Khalid Tahir,<sup>1</sup> Angela Grigos,<sup>1</sup> Farhang Ebrahimi,<sup>1</sup> Muhammad Durrani,<sup>2</sup> Nusayba Ahmed.<sup>2</sup> <sup>1</sup>Richmond University Medical Center, Staten Island, NY; <sup>2</sup>American University of Antigua College of Medicine, Saint Johns, Antigua and Barbuda.

**Background:** Hyponatremia is an electrolyte derangement defined as a serum sodium value exceeding 145 mmol/L. It is primarily caused by unreplaced water loss due to impaired thirst or inaccessibility to water. The latter explains why hyponatremia is often seen in the elderly population who are mentally and/or physically impaired and often present with a concomitant infection. Hyponatremia can also be caused by the excess consumption of salt without the addition of water or iatrogenically caused by the administration of hypertonic solutions.

**Methods:** We report a case of an 81 year old male from a nursing home, who, at baseline, is alert and communicative, but presented with markedly diminished mental status and lethargy. Routine admission labs showed a critical serum sodium level of 187 mmol/L and a marked leukocytosis which was later explained by a left sided pneumonia and a urinary tract infection. The patient was admitted to the intensive care unit for closer monitoring and management.

**Results:** On admission, physical examination revealed severe dehydration with dry mucous membranes, severely contracted upper and lower extremities, marked lethargy and an almost negligible response to noxious stimulation. A 24 hour T-max of 100.6F, blood pressure of 156/90, and saturating adequately on nasal cannula. Further lab-work showed serum osmolality of 386 mosm/kg, a creatinine of 2.6 mg/dL, and glucose level of 166. Hypotonic saline was started with supplemental free water administration and frequent assessment of volume status and a sodium correction goal between 6-8 mmol per 24 hours. After 36 days of hospitalization, intensive care unit monitoring, intermittent dialysis, and treatment of urinary tract infection and left sided pneumonia, the patient was discharged to back to home facility with a serum sodium of 131 mmol/L and a creatinine of 0.3 mg/dL, at baseline mental status.

**Conclusions:** Careful administration of hypotonic fluids over multiple days to avoid over correction and intermittent hemodialysis, resulted in normalization of sodium levels, improved urine out, stabilizing of renal function, and improvement in overall hemodynamics.

**Diagnosing Cerebral Salt Wasting: Are We Swimming Against the Current?**  
Cyndia Rodriguez Negrón, Carlos Cortes, Herminio Garcia-Estrada, Luis A. Diaz Cruz. VA Caribbean Healthcare System VA Caribbean Healthcare System, San Juan, Puerto Rico.

**Introduction:** Syndrome of Inappropriate Antidiuretic Hormone (SIADH) after brain injury is characterized by euvolemic hyponatremia, concentrated urine & increased natriuresis. Cerebral Salt Wasting (CSW) also presents with concentrated urine & increased natriuresis, but patients are hypovolemic. Some authorities argue that CSW does not exist & it is simply SIADH with increased natriuresis due to iatrogenic volume expansion or reduced venous capacitance caused by catecholamine-induced vasoconstriction. We herein present a case of moderate hypovolemic hyponatremia after cerebral manipulation.

**Case Description:** 47 y/o man admitted to ICU due to moderate hyponatremia & altered mental status with sepsis due to meningitis. Had a recent left frontotemporal craniotomy & lobectomy for glioblastoma multiforme. Slow mentation, dry oral mucosa & decreased skin turgor present upon examination. Urine output >4 L in <24 hours. Serum: Na: 123mEq/L Cr: 0.5mg/dL BUN: 7.3mg/dL K:4.0mEq/L HCO<sub>3</sub>: 18mEq/L Cl: 97mEq/L Glu: 158mg/dL Urine Na: 223mEq/L K: 37mEq/L Cr: 42.7 Spec. Gravity: 1.014. Cortisol: 13.36ug/dL TSH: 1.690. Was not taking diuretics, SSRIs nor other medications associated with SIADH. 3% Saline had to be provided x2 & mostly had to be kept on 0.9%NSS & fludrocortisone up to 0.3mg BID to maintain normal Na levels. Urine became dilute after 0.9%NSS. He was later transferred to another institution for neurosurgical care.

**Discussion:** CSW is extremely rare & not universally contemplated in differential diagnoses. SIADH is more common, but polyuria & hypovolemia are not present. While 0.9%NSS would worsen serum Na in SIADH, in CSW it should remove the ADH stimulus, cause dilute urine & thus correction of Na, as was in our case. Some authors believe that SIADH & CSW are one entity, but this case clearly presents marked differences in diagnosis & treatment as previously described. Recognition is of importance as some therapies used in SIADH like fluid restriction, vaptans & oral urea powder would be harmful in CSW. It is imperative for physicians to detect CSW early, this will allow for proper management & thus avoiding consequences of worsening hyponatremia & hypovolemia.

PUB185

**Partial Nephrogenic Diabetes Insipidus Secondary to Lithium Use**  
Sameh Nassar,<sup>1</sup> Simon A. Kashfi,<sup>2</sup> Maria C. Sanchez,<sup>1</sup> Bessy Suyin Flores Chang,<sup>1</sup> Jamil Ibrahim.<sup>1</sup> <sup>1</sup>St. Barnabas Hospital, Bronx, NY; <sup>2</sup>The City College of New York CUNY School of Medicine, New York, NY.

**Introduction:** Nephrogenic diabetes insipidus (NDI) is caused by reduced renal response to vasopressin. NDI affects up to 40% of patients on lithium. We present a case of partial NDI secondary to lithium use.

**Case Description:** A 66 year old male with bipolar disorder on lithium presented with shortness of breath, chest tightness and cough. On exam he was cachectic, lethargic, tremulous with decreased skin turgor and dry mucous membranes found to have COVID-19 with initial unremarkable blood work. Received treatment for COVID and subsequently developed worsening encephalopathy, follow up blood work revealed elevated serum sodium of 168 mg/dL, with urine osmolality of 382 and lithium level was elevated at 1.6 mEq/L. He received adequate IV fluid hydration with hypotonic fluids and free water. Serum sodium remained elevated with polyuria. Follow up labs showed urine osmolality decrease to 94 mosm/L therefore nephrogenic diabetes insipidus was suspected. A desmopressin stimulation test was performed and hourly urine osmolality was obtained [Table 1] confirming the diagnosis of nephrogenic diabetes insipidus with a partial response to desmopressin compatible with lithium-induced partial diabetes insipidus. Treatment was started initially with chlorthalidone with inappropriate response, then dose increased to 100mg daily with further addition of amiloride 10mg twice daily with subsequent response and decrease of sodium level from 167 to 147 mEq/L.

**Discussion:** Lithium-induced NDI is explained by downregulation of aquaporin 2 channel expression in the principal cells due to accumulation of toxic concentrations of lithium and reduction of the kidneys’ ability to preserve water in response to vasopressin. NDI usually presents with polyuria, polydipsia, severe dehydration, and electrolyte imbalance. A less than 50% increase in urine osmolality following desmopressin administration proves NDI. Treatment options include high doses of desmopressin, low sodium diet, thiazide diuretics, amiloride, and NSAIDs.

**Clinical and Laboratory Profile of Patients With Autosomal Dominant Polycystic Kidney Disease (ADPKD)**  
Vasiliki Gkika, Michaela Louka, Eirini Tigka, Myrto Kostopoulou, George I. Tsiarpanlis. General hospital of Athens “G. Gennimatas”, Athens, Greece.

**Background:** Recent advances in the treatment of ADPKD highlight the interplay between the clinical and laboratory profile of the disease. This study aims to present the baseline characteristics of patients followed in a large ADPKD cohort from a single center and explore possible associations between demographic, clinical, and laboratory parameters.

**Methods:** This study enrolled patients who were being followed in a specialized outpatient ADPKD clinic from December 2018 to December 2021. At enrollment, demographics, medical and family history, and laboratory data were recorded using a standardized form. Estimated glomerular filtration rate (eGFR) was calculated and Magnetic Resonance Imaging for total kidney volume (TKV) measurement was performed.

**Results:** Three hundred (162 females and 138 males) ADPKD patients at a mean age±SD of 40.87±12.9 years were enrolled in the study. Overall, 67.3% of them were classified as Chronic Kidney Disease, (CKD) stage 1 and 2. The ADPKD was diagnosed at a mean age±SD of 27.2± 11.65 years. Twenty-six percent of 300 patients were diagnosed before the age of 20. A positive family history was present in 89.75% of patients. In this subgroup, the mean age of the affected parent who reached end stage renal disease (ESRD) was 55 (range 28-87) years. Hypertension was diagnosed in 88% of the patients at a mean± SD age of 35.89 ± 11 years. Hepatic cysts were present in 78% of them, urinary tract infections, nephrolithiasis, macroscopic hematuria, and pain in 44.87%, 43%, 24.71% and 54.23% respectively. In 31% of the cases, there was a family history of intracranial bleeding. In multivariable analysis, lower eGFR was associated with older age (p< 0.001), younger age at the time of ADPKD diagnosis (p < 0.012) and greater values of the height-adjusted TKV (p < 0.001) and Body Mass Index (BMI) (p = 0.11).

**Conclusions:** In this study, patients with ADPKD were diagnosed at a young age and hypertension developed in the majority of them early in the course of the disease. Renal function was influenced by age, height-adjusted cyst-renal volume, early diagnosis of ADPKD, and BMI.

## PUB187

### Machine Learning Techniques for Automated Segmentation of Kidneys and Cysts in Autosomal Dominant Polycystic Kidney Disease: A Systematic Review

Hyun Bae Jang,<sup>1</sup> Ahsan Alam,<sup>2</sup> <sup>1</sup>*McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada;* <sup>2</sup>*McGill University Health Centre, Montreal, QC, Canada.*

**Background:** Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most common hereditary kidney disease. Total kidney volume (TKV) is used clinically as a prognostic biomarker, so its accurate determination is critical to determine treatment eligibility or inclusion into clinical studies. Recently, machine learning techniques have been applied to ADPKD to better segment kidneys or cysts. We performed a systematic review of machine learning models applied to ADPKD kidney and cyst segmentation.

**Methods:** We conducted a literature search using relevant search terms including ADPKD, imaging, kidney or cyst segmentation, and machine learning techniques. The last search date was May 12, 2022. Studies were screened for relevance prior to inclusion in the systematic review. We identified seventeen studies. Two were excluded as they involved mouse models. We examined the patient and disease characteristics included in these studies, as well as the machine learning technique employed, and whether any external validation was performed.

**Results:** Of the fifteen human studies eligible for inclusion (n=5243 kidney images[SJ1]), one used 3D ultrasound (n=66), three used CT images (n=502), and the remaining 11 used MR images (n=4675). The study sizes ranged from 11 up to 1445 patients, with 13 to 2400 scans. Four studies used axial cuts and 11 studies used coronal cuts to develop their model. The majority of models employed an artificial neural network approach; however, some studies utilized and compared the performance of different machine learning techniques. Only one study developed a model to segment kidney cysts. All models achieved high dice coefficient, sensitivity, specificity or recall when comparing with manual segmentation. Only one study performed external validation using a different cohort.

**Conclusions:** Various machine learning techniques can accurately automate kidney segmentation in patients with ADPKD. Most studies relied on a small sample size and only one performed external validation. Whether these automated segmentation models can be deployed in a clinical environment or can outperform estimated TKV remains to be determined.

## PUB188

### A Mutation in the GANAB Gene as a Cause of Bilateral Renal Cysts

Jean H. Ancion, Dina R. Al-Tuhafy, Katerina Hysi, Saira Sajid, James Drakakis. *NYU Langone Hospital - Long Island, Mineola, NY.*

**Introduction:** Polycystic kidney disease can cause of chronic renal failure in children and adults. The disease is inherited by an autosomal dominant trait (ADPKD) or an autosomal recessive trait (ARPKD). ADPKD commonly results from a mutation in the PKD1 (80-85%) and PKD2 (15-20%) genes, which code for polycystin-1 (PC1) and polycystin-2 (PC2), respectively. These are a significant cause of end stage renal disease due to renal cell dysplasia. There is another, lesser known form of ADPKD known as polycystic kidney disease-3 (PKD3). This results from mutations in glucosidase II alpha subunit (GANAB) gene and present in mid- and late adulthood. As such, there is a third source of genetic renal cyst formation, albeit not as commonly encountered or described.

**Case Description:** 61 year old male with past medical history of hypertension was referred after an in office urologic ultrasound noted bilateral cysts (quite large on the left). Complete abdominal sonogram showed R kidney 13.5 cm + L kidney 17.1 cm with L sided cysts including --5 x 4.5 cm cyst upper pole, 13.4 x 10.8 cm cyst lower pole, 3.7 x 1.7 cm hypochoic nodule adj to upper pole cyst. CT scan followed for better characterization and revealed several L kidney cysts; Bosniak class I cysts upper/lower pole and also Bosniak class II cyst in upper pole on L (3.3 x 2.4 cm). Plus several subcentimeter cortical R kidney cysts. The patient's father was noted to have been on dialysis (cause unknown). Due to the extensive nature of the cysts and family history, genetic testing was undertaken. This revealed heterozygous likely pathogenic variant in the GANAB gene.

**Discussion:** Until recently, mutations in the genes coding for PC1 and PC2 were believed to be the only ones implicated in genetic cystic kidney disease. In 2016, mutations in GANAB, encoding the glucosidase IIa subunit were reported to cause ADPKD (0.3%) and this was called PKD3. The phenotype is one of mild to very mild cystogenic effects in the kidneys. This case illustrates the importance of genetic testing in the workup of otherwise incidentally noted large bilateral renal cysts. The identification of GANAB mutation offers possible further gene targeted therapeutics and potentially better insight into the management of ADPKD. Furthermore, it helps us better understand the spectrum of such disorders.

## PUB189

### Complicated Retroperitoneal Hemorrhage in Autosomal Dominant Polycystic Kidney Disease: A Case Report

Yeshwanter Radhakrishnan,<sup>1</sup> Parikshit Duriseti,<sup>1</sup> Maroun Chedid,<sup>1</sup> Fouad T. Chebib,<sup>2</sup> <sup>1</sup>*Mayo Clinic Minnesota, Rochester, MN;* <sup>2</sup>*Mayo Clinic in Florida, Jacksonville, FL.*

**Introduction:** Autosomal dominant polycystic kidney disease (ADPKD) is the leading genetic cause and the 4th most common cause of end-stage kidney disease worldwide. Cyst bleeding is not uncommon, however rarely, ruptured cysts may present with life-threatening retroperitoneal hemorrhage requiring prompt management. We report a case of a patient with ADPKD who presented with hemorrhagic shock in setting of cyst rupture and severe retroperitoneal hemorrhage.

**Case Description:** A 60-year-old male with chronic kidney disease of unknown stage secondary to ADPKD presented to the hospital with chief complaints of lethargy, chest pain, and altered mental status. His initial labs were significant for hemoglobin (Hb) 4.7 g/dL, high anion gap metabolic acidosis with serum bicarbonate 5 mmol/L, serum lactate 3.3 mmol/L, blood urea nitrogen 217 mg/dL, and serum creatinine 17.1 mg/dL with an unclear baseline. Abdominal imaging revealed enlarged polycystic kidneys bilaterally with soft tissue masses concerning for retroperitoneal hematoma (RPH) from a ruptured renal cyst. He was noted to have bleeding from left L3 lumbar artery that was embolized by Interventional Radiology (IR). He was admitted to the ICU for hemorrhagic shock and was initiated on Hemodialysis (HD) and massive transfusion protocol. The Hb continued to trend down despite transfusions and repeat imaging demonstrated expanding RPH. He underwent repeat IR guided embolization of the left L1, L3, L4 lumbar arteries and left renal capsular artery. The Hb transiently stabilized for next 3 days, however it continued to trend down. Oral tranexamic acid (TA) 1300mg once daily for 9 days was trialed due to continued bleeding. The patient's Hb stabilized around 8.5 g/dL after TA and he did not require any further transfusions. He remained HD dependent at the time of discharge.

**Discussion:** Life-threatening spontaneous RPH following cyst rupture in the absence of major trauma or use of anti-coagulants, is a rare complication in ADPKD. Treatment involves blood transfusions, management of shock, IR guided embolization. TA can be considered when the above measures fail for cyst bleeding. Urgent nephrectomy might be considered for refractory bleeding.

## PUB190

### ARPKD Diagnosed in an Adult Without Kidney Manifestations

Benjamin R. Wagner. *Dignity Health Medical Group Dominican, Santa Cruz, CA.*

**Introduction:** Autosomal recessive polycystic kidney disease (ARPKD) is largely a condition of infancy or childhood. Its prevalence among adults is low and incident diagnosis during adulthood is exceedingly rare. Here, a case is presented of compound heterozygosity with two different mutant alleles in PKHD1 in a young adult with advanced cirrhosis, though no kidney disease.

**Case Description:** A 30-year-old woman presented with jaundice, easy bruising, and hemolytic anemia. Abdominal imaging revealed stigmata of cirrhosis with massive hepatosplenomegaly. Liver biopsy was performed and a diagnosis of cirrhosis was confirmed. This was initially attributed to alcohol use, as she had consumed 2-5 drinks daily between March and November 2020 – early in the COVID-19 pandemic. Testing for autoimmune etiologies, alpha-1 antitrypsin deficiency, hemochromatosis, and Wilson's disease was negative. Genetic testing was ultimately obtained and revealed two variants in the PKHD1 gene (c.1018 G>A p.[G340R], c.983 G>A p.[R328Q]), raising the possibility of ARPKD. Kidneys were unremarkable on imaging, being normal in size and without cysts. Creatinine remained stable at ~0.8-0.9 mg/dL. Urinalysis was bland. Family history is notable for cirrhosis in her father and possible cholangiocarcinoma in a maternal aunt. The patient's mother has tested positive for one mutant allele.

**Discussion:** Our knowledge of the manifestations of ARPKD in adulthood is scarce, based largely on small case series and case reports. Its phenotypic presentation in adults has proven to be highly variable, though most often with strong hepatobiliary sequelae. A presentation with a complete lack of kidney manifestations – as seen in this case – should now be recognized.

## PUB191

### Macronutrient Composition and Protein Intake of a Plant-Focused, Kidney-Safe Ketogenic Approach for Individuals With Autosomal Dominant Polycystic Kidney Disease

Jessianna Saville,<sup>1,4</sup> Clarissa S. Paimanta,<sup>1,4</sup> Diana Bruen,<sup>1,4</sup> Jacob A. Torres,<sup>2,3</sup> Thomas Weimbs,<sup>2,3</sup> <sup>1</sup>*RenAlign, Titusville, FL;* <sup>2</sup>*Santa Barbara Nutrients, Santa Barbara, CA;* <sup>3</sup>*Department of Molecular, Cellular, and Developmental Biology and Neuroscience Research Institute, University of California Santa Barbara, Santa Barbara, CA;* <sup>4</sup>*Kidney Nutrition Institute, Titusville, FL.*

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited cause of renal failure and has limited pharmacological treatment options. Recent research has uncovered that cyst cells in ADPKD depend on glucose for energy and are unable to metabolize fatty acids and ketones. As such, the ketogenic diet may be a viable nutrition intervention to slow or prevent ADPKD progression and improve health outcomes. However, most clinically used ketogenic or low-carbohydrate diets are either normoproteic or hyperproteic, while for ADPKD, lowering protein intake and promoting intake of plant protein are recommended to prevent further renal injury and

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

slow disease progression. This study assesses the macronutrient composition of the plant-focused ketogenic diet (PFKD) as implemented in the Ren.Nu program, a breakthrough dietitian-led program to teach individuals with ADPKD the implementation of the kidney-safe PFKD.

**Methods:** Nutrient intake of 7 participants enrolled in the Ren.Nu program who had consistent daily food logs were analyzed for macronutrient composition. Nutrient analysis was based on approximately 1-week of food logs marked as complete days, extracted from week 10 out of 12 weeks of the Ren.Nu program.

**Results:** The daily intake in a PFKD averages to 82.6 g of total carbohydrates, 30.7 g of fiber, 131.1 g of total fat, and 46.7 g of protein intake, which ranges between 0.63 to 0.83 g of protein/kg of body weight/day. The macronutrient breakdown in percentage of daily energy intake was 20.2% for total carbohydrates, 72.1% for total fat, and 11.4% for protein. The Atwater general factors were used for energy calculations based on grams of each macronutrient consumed.

**Conclusions:** This study indicates that the PFKD approach for ADPKD as taught in the Ren.Nu program successfully sustained a macronutrient composition to achieve ketosis, while keeping protein levels within the appropriate recommendations to avoid renal stressors and slow or prevent disease progression. The Ren.Nu program is now publicly available for individuals with ADPKD.

## PUB192

### SGLT-2 Inhibitors Are Well Tolerated in Patients With Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD)

Anthony J. Bleyer,<sup>1,2</sup> Kendrah O. Kidd,<sup>1</sup> Victoria C. Robins,<sup>1</sup> Alice Kim,<sup>1</sup> Martina Zivna,<sup>2</sup> Stanislav Kmoch,<sup>2,1</sup> <sup>1</sup>Wake Forest University School of Medicine, Winston-Salem, NC; <sup>2</sup>Univerzita Karlova, Praha, Czechia.

**Background:** SGLT-2 inhibitors (SGLT2i) are effective in chronic kidney disease but have not been studied in ADTKD. There are currently no treatments available for ADTKD. We performed a prospective observational study to determine if SGLT2i are safe in ADTKD patients.

**Methods:** Patients in the Wake Forest ADTKD prospective cohort study were asked to alert us if started on SGLT2i (either empagliflozin or dapagliflozin). Baseline laboratory studies were obtained with sample storage for biomarker measurement at baseline and 1 month. Patients were followed with serum creatinine measurements at least quarterly.

**Results:** The baseline characteristics of participants included: mean age 44±16 y, 53% ADTKD-*MUC1*, 47% ADTKD-*UMOD*, 53% male, mean baseline eGFR 37±11 ml/min/1.73m<sup>2</sup>, with 5 with eGFR <30 ml/min/1.73m<sup>2</sup> (21,21,25,26, and 26 ml/min/1.73m<sup>2</sup>) and the remaining participants with eGFR between 30 and 57 ml/min/1.73m<sup>2</sup>. Eight participants stopped SGLT2i: 1 due to pregnancy, 1 due to anxiety, and 6 due to early eGFR decline that concerned the patient or doctor. For the 6 who stopped due to eGFR concerns, the mean time of discontinuation was 2 months, with a mean decline in eGFR of 6 ml/min/1.73m<sup>2</sup> (2-11 ml/min/1.73m<sup>2</sup>). The eGFR returned to prior values after stopping medication. For patients who did not stop, the mean decline in eGFR at two months was 3.5 ml/min/1.73m<sup>2</sup>. Urinary KIM-1 levels were measured in 10 individuals and increased from a mean baseline of 644±671 pg/mg creatinine to 5152±9062 and at 6 month follow up decreased to 1671±2390 in 6 patients. Change in KIM1 did not correlate with eGFR change. The mean change in eGFR over the course of the study is shown in the figure with comparison to DAPA CKD results. One patient started SGLT2i with an eGFR of 21 ml/min/1.73m<sup>2</sup>, which has remained stable for 16 months.

**Conclusions:** SGLT2i were well tolerated and patient outcomes were similar to DAPA-CKD.

**Funding:** Private Foundation Support

## PUB193

### An Unusual Presentation of Fabry Disease in an Elderly Female

Justin Ilagan,<sup>1</sup> Yihan Wang,<sup>2</sup> Christin M. Giordano McAuliffe,<sup>3</sup> <sup>1</sup>Jersey Shore University Medical Center, Neptune City, NJ; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN; <sup>3</sup>Nephrology Associates, Murfreesboro, TN.

**Introduction:** Fabry disease is an X-linked lysosomal storage disease that causes an accumulation of globotriaosylceramide within lysosomes due to a lack of alpha-galactosidase. While a typical patient is a white male in their second decade of life, atypical presentations can be seen in up to 1 in 40,000 females [1,2]. We present an unusual clinical presentation of an elderly female patient found to have a positive alpha-galactosidase (GLA), Glu398Lys subtype, mutation identified following presentation with uremic symptoms.

**Case Description:** A 71 year old female with a past medical history significant for chronic kidney disease (CKD) stage 3, atrial fibrillation, and hypertension who presented in the hospital for altered mental status. Physical examination was unremarkable. Initial labs were notable for a bicarbonate of 11 mmol/L (normal 24-31 mmol/L), blood urea nitrogen of 113 mg/dL (normal 5-25 mg/dL), creatinine of 3.4 mg/dL (normal 0.61-1.24 mg/dL), and an albumin of 2.4 g/dL (normal 3.5-5 g/dL). Initially, the C3 and C4 complement levels were undetectable, but later improved. Renal ultrasound was notable for a 10.1 cm left kidney and 4.5 cm right kidney with normal dopplers. Due to concern for uremia, she underwent hemodialysis (HD) after which her altered mental status resolved. A renal biopsy was performed with findings notable for myelin bodies on electron microscopy. Prior to discharge, renal function improved and HD was stopped. Due to her age, the possibility of drug-induced Fabry disease was explored and genetic testing was performed.

**Discussion:** FD is considered the second most common lysosomal storage disease, leading to acroparesthesias, angiokeratomas, proteinuria, and cardiac manifestations. In our case, we suspect that she had underlying CKD due to FD leading to her presentation. Her atrial fibrillation may also be a manifestation of FD. Due to the infrequency of reported cases, there should be increased awareness of manifestations of the disease to identify appropriate patients for genetic testing, so treatment is prompt. Family members should also be genetically tested to treat and avoid complications later in life. Additionally, drugs, most notably hydroxychloroquine, are also known to cause FD and should be considered when there is an unusual presentation.

## PUB194

### The Novel MYH9 Variant, c.1270C>G, p.Arg424Gly, May Primarily Cause Hepato-Renal Disease

Tilman Jobst-Schwan,<sup>1,2</sup> Antje Wiesener,<sup>3</sup> Florian J. Wopperer,<sup>1,2</sup> Mario Schiffer,<sup>1</sup> Michael S. Wiesener,<sup>1</sup> <sup>1</sup>Universitätsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany; <sup>2</sup>RECORD – Research Center On Rare Kidney Diseases, Erlangen, Germany; <sup>3</sup>Universitätsklinikum Erlangen Institut für Humangenetik, Erlangen, Germany.

**Background:** The gene *MYH9* encodes for the heavy chain of non-muscular myosin IIA. Mutations in *MYH9* cause a very rare autosomal-dominant monogenic disorder that may include macrothrombocytopenia, proteinuric kidney disease, cataract, sensorineural deafness and elevated liver enzymes. The full set of symptoms is defined as Epstein-Fechter syndrome.

**Methods:** Whole exome sequencing was performed in a patient with ESRD and unclear elevated liver enzymes. Segregation analysis in affected and unaffected family members was performed by Sanger sequencing. Biopsies of kidney and liver as well as skin fibroblasts were investigated. Blood smears were inspected by light microscopy for Döhle like bodies in granulocytes, and stained for Myosin IIA.

**Results:** We identified the putative deleterious *MYH9* variant c.1270C>G, p.Arg424Gly (ACMG class 4, CADD score 22, evolutionary highly conserved), heterozygously in 4 affected members of a non-consanguineous family of Albanian descent (Fig. 1A). The variant affects the  $\alpha$ -helix of the motor domain according to *in silico* analysis (Fig. 1B). Granulocytes in the blood smears presented neither Döhle like bodies nor Myosin IIA positive conglomerates, the typical findings of *MYH9* related disease. However, all 4 patients presented with proteinuria, elevated liver enzymes and intermittent thrombocytopenia. The 3 adult patients developed sensorineural hearing impairments, both patients of the parental generation cataracts in addition.

**Conclusions:** We identified a novel variant in the gene *MYH9* in a family with a hepato-renal disease as the major phenotype of the intrafamilial syndrome. Despite the segregation and the matching clinical pattern in all 4 affected family members, the typical microscopic phenotypes of granulocytes (Döhle like bodies, Myosin IIA conglomerates) were not detected. However, *MYH9* variants affecting the motor domain have a high risk for manifestations in adulthood as shown before by Pecci et al. (*Hum Mutat* 29:409, 2008), supporting the pathogenicity of the *MYH9* variant c.1270C>G, p.Arg424Gly.

Fig. 1: *MYH9* variant c.1270C>G, p.Arg424Gly affects the motor domain. (A) All 4 affected family members carry the variant in a heterozygous state. (B) The variant is located in the exon sequence coding the motor domain (orange bar) of Myosin IIA (NP\_002464.1).

## PUB195

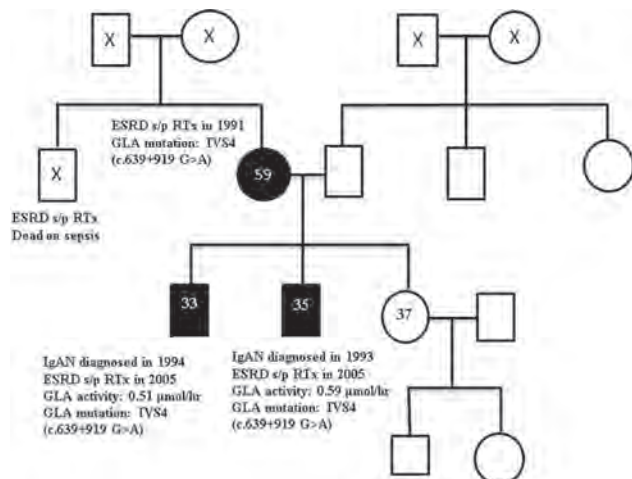

## Family Cluster of IgA Nephropathy Combined With Fabry Disease and Alport Syndrome

Chia-Yu Shih,<sup>1</sup> Cheng-Hsu Chen,<sup>1,2</sup> Shangfeng Tsai.<sup>1,1</sup> *Taichung Veterans General Hospital, Taichung, Taiwan; <sup>2</sup>Department of Post-Baccalaureate Medicine, College of Medicine, National Chung Hsing University, Taichung, Taiwan.*

**Introduction:** IgA nephropathy (IgAN) was the leading cause of chronic nephritic syndrome, acute nephritic syndrome, and persistent hematuria, accounting for 55.2%, 36.7%, and 76.7% in Taiwan, respectively. Fabry disease and Alport syndrome are inherited as an X-linked disorder caused by mutation of GLA gene and COL4A5 gene, and these diseases are rare in Taiwan. Thus, most clinical practice might neglected the combination of rare disease. Here, we reported a family cluster of IgA nephropathy by clinical manifestations, laboratory and pathology examinations, and simultaneous diagnosis of Alport syndrome and Fabry disease through our precision medicine screening.

**Case Description:** The indicated brothers were diagnosed as IgAN by renal biopsy at their age 8 and 10 with hematuria and proteinuria. Light microscopy and immunofluorescence showed that IgA was deposited in the mesangium. They received kidney transplantation with triple therapy for more than 15 years. The precision medicine project screening the Fabry disease found they are GLA gene mutant c.639+919 G>A (IVS4+919G>A), the whole exome sequencing (WES) demonstrated COL4A5 c.2917+1 del confirmed with Alport syndrome. Their mother was also KTx recipients concomitantly diagnosed Fabry disease IVS4 and carrier of COL4A5 c.2917+1 del. The findings in our case emphasize the importance of renal biopsy and gene detection in hereditary kidney disease, especially for Fabry disease and its rare coexistence with Alport syndrome.

**Discussion:** In general, the biopsy-proven IgAN is major cause of GN in the world, however, we should still keep in mind that persistent nephritis or nephrotic syndrome without complement consumption might also include with variants in Alport syndrome. Thanks to Fabry disease screening, we found this family cluster of concomitant of IgAN, Alport syndrome and Fabry disease IVS4, through the enzyme supplement therapy to preserve their heart function.

## PUB196

## Partial Results of a Brazilian Study Evaluating an Alternative Method for Fabry Disease Screening in Women

Ribeiro,<sup>17</sup> Luis Gustavo Modelli de Andrade.<sup>1</sup> *<sup>1</sup>Universidade Estadual Paulista Julio de Mesquita Filho, Botucatu, Brazil; <sup>2</sup>Universidade Federal do Paraná, Curitiba, Brazil; <sup>3</sup>Universidade de São Paulo Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto, Brazil; <sup>4</sup>Santa Casa de Misericórdia de Itabuna, Itabuna, Brazil; <sup>5</sup>Universidade Federal de Goiás, Goiânia, Brazil; <sup>6</sup>Fundacao Pro-Rim, Joinville, Brazil; <sup>7</sup>Serviço de Terapia Renal de Ourinhos, Ourinhos, Brazil; <sup>8</sup>Metta Saúde Clínica do Rim, Foz do Iguaçu, Brazil; <sup>9</sup>Santa Casa de Maringá, Maringá, Brazil; <sup>10</sup>Universidade Federal do Amazonas, Manaus, Brazil; <sup>11</sup>Instituto de Medicina Integral Professor Fernando Figueira, Recife, Brazil; <sup>12</sup>Universidade Federal do Rio Grande do Norte, Natal, Brazil; <sup>13</sup>Centro de Nefrologia de Nova Friburgo, Nova Friburgo, Brazil; <sup>14</sup>Sanofi, São Paulo, Brazil; <sup>15</sup>Grupo Instituto do Rim do Paraná, Curitiba, Brazil; <sup>16</sup>Clirelan, Caratinga, Brazil; <sup>17</sup>DLE, Rio de Janeiro, Brazil.*

**Background:** Fabry disease (FD) is a rare X-linked lysosomal storage disorder that may affect multiple organs, including the kidneys. The main objective of this study was to evaluate the effectiveness of combining  $\alpha$ -GAL enzyme activity and plasma levels of lyso-GL3 for screening FD in females with chronic kidney disease (CKD).

**Methods:** Female with CKD, stages 3 to 5, under regular nephrology follow up were selected from renal centers of all regions of Brazil. Exclusion criteria: under 18 years old and a known diagnosis of FD. Patients underwent biochemical analysis of  $\alpha$ -GAL enzyme activity and plasma levels of lyso-GL3. GLA gene sequencing was performed if  $\alpha$ -GAL enzyme activity was below and/or the lyso-GL3 levels were above the reference range. Sensitivity and specificity analyses were performed to assess the performance of the combined biochemical approach for the diagnosis of FD.

**Results:** From October 2020 to December 2021, 1163 patients were included. Low  $\alpha$ -GAL activity was found in 36 (3.1%) patients and increased lyso-GL3 levels were found in 95 (8.2%) patients. The median age was 52 [42–63] years. Genetic analysis of the patients who presented low  $\alpha$ -GAL and/or increased lyso-GL3 detected the same genetic variant of unknown significance in the GLA gene, R118C, in 3 unrelated patients. The sensitivity and specificity of  $\alpha$ -GAL reduction for the detection of FD was 97% and 66%, respectively. Whereas for high plasma levels of lyso-GL3, they were 91% and 33%, respectively. No cases presented concomitantly increased lyso-GL3 and reduced enzyme activity.

**Conclusions:** Preliminary results suggest that combining  $\alpha$ -GAL enzymatic activity with lyso-GL3 dosage may be a good alternative for screening FD in females with CKD. A thorough medical evaluation is required to determine the pathogenicity of R118C in our patients.

## PUB197

## Are Kidney Cysts More Frequent in Individuals With COL4A3-COL4A4 Pathogenic Variants?

Melissa Pilco Teran,<sup>1,2</sup> Monica Furlano,<sup>1,2</sup> Víctor Martínez Jimenez,<sup>4</sup> Marc Pybus,<sup>1,2</sup> María vanessa Pérez gómez,<sup>3</sup> Asunción Rius Peris,<sup>5</sup> Leonor Fayos de Arizón,<sup>1,2</sup> Gerson Berná,<sup>1,2</sup> Jonathan Hernandez Mancera,<sup>1,2</sup> Hugo Vergara Pérez,<sup>5</sup> Elisabet Ars,<sup>1,2</sup> Roser Torra.<sup>1,2</sup> *<sup>1</sup>Fundacio Puigvert, Barcelona, Spain; <sup>2</sup>Hospital de la Santa Creu i Sant Pau Institut de Recerca, Barcelona, Spain; <sup>3</sup>Hospital Universitario Fundacion Jimenez Diaz, Madrid, Spain; <sup>4</sup>Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain; <sup>5</sup>Hospital General Universitari de Castello, Castellon de la Plana, Spain.*

**Background:** Individuals carrying heterozygous DNA pathogenic variants in *COL4A3* and *COL4A4* have a wide spectrum of disease and constitute the most underdiagnosed genetic kidney condition. Recent data suggested that up to 1/106 individuals may harbor a pathogenic variant in *COL4A3* or *COL4A4* although all published series are biased towards more affected individuals. Some reports suggest a high prevalence of kidney cysts in these persons. We analyzed the possibility of cystic phenotype related to this condition.

**Methods:** Clinical, radiological (ultrasound) and laboratory data from patients with heterozygous pathogenic variants in *COL4A3* and *COL4A4* were retrospectively analyzed.

**Results:** Our cohort include 178 patients (mean age 43 years (SD 14.6)) with a pathogenic variant in *COL4A3* or *COL4A4*. Age and eGFR were related to the presence of kidney cysts ( $p < 0.001$ ). Kidney cysts were more frequent in patients older than 50 years (59%), but in patients from 30-50 years the incidence was 41%. Patients with kidney cysts had a mean age of 53 years and a mean eGFR (CKD-EPI) of 58ml/min/1.73m<sup>2</sup> (SD 32). We found a positive correlation between presence of proteinuria and kidney cysts: 59% of patients with proteinuria developed cysts compared to 28% in patients without albuminuria or proteinuria. As proteinuria increased, the presence of cysts did so, however, only 40% (2/5) with nephrotic range proteinuria showed cysts. Prevalence of cysts was not affected by the mutated gene (47.7% in *COL4A3* patients vs 43.1% in *COL4A4*) neither severity of mutation. Seven patients from this cohort showed nephromegaly.

**Conclusions:** The presence of kidney cysts in individuals with a pathogenic variant in *COL4A3* or *COL4A4* is mostly associated with age, eGFR and proteinuria but not with genotype and has no clinical consequences. Due to the high prevalence of both ADPKD and pathogenic variants in *COL4A3* or *COL4A4* it is expected that both conditions coexist in a number of patients.

## PUB198

## Crescentic Alport Syndrome: A Rare Clinical Entity

Chintav Shah,<sup>1</sup> Casey N. Gashti. *Rush University Medical Center, Chicago, IL.*

**Introduction:** Alport's syndrome is an X-linked disorder caused by mutations in alpha 3, 4 or 5 collagen IV chains resulting in defective assembly of glomerular basement membrane (GBM) heterotrimer. It typically presents in 2<sup>nd</sup> to 4<sup>th</sup> decade with the triad of CKD with hematuria and proteinuria, sensorineural deafness and anterior lenticonus. It is histologically characterised by thinning of GBM early followed by thin and thick basket weave appearance on EM, lack of immune complex on IF and abnormal collagen type IV staining with eventual glomerular sclerosis and ESKD. Rare cases of crescentic glomerular lesions have been reported.

**Case Description:** A 23-y/o woman with a history of microscopic hematuria since age 2 presented with fatigue and a serum creatinine (SCr) of 2.5 mg/dl from a normal baseline a few months prior. Father has hx of gross hematuria and one atrophic kidney, sister with visual problems, but no Hx of ESKD or deafness. Urinalysis was significant for 2+ protein, 2+ blood, 3-10 RBC/HPF and Urine protein/Cr ratio of 1.9 g/g. An autoimmune, serologic and infectious workup was negative. A renal ultrasound was normal. A renal biopsy demonstrated focally active pauci-immune crescentic glomerulonephritis with thin GBM (213 nm). Genetic testing demonstrated a heterozygous mutation in *COL4A5* gene, confirming the diagnosis of X-linked Alport's. Due to the clinical presentation of rapidly progressive glomerulonephritis, we opted to treat her with prednisone and Rituximab in addition to RAAS blockade. Her serum Cr improved to 1.7 mg/dl and has remained stable in 1 year of follow up.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Discussion:** Alport's syndrome, while typically X-linked, has a variable phenotype in women although crescents are rare in any gender. The presence of crescents suggests a faster progression and poorer prognosis. It is hypothesized that high intraglomerular capillary pressure and defective synthesis of collagen IV leads to loss of structural integrity of the GBM, leading to rupture of capillary loops and formation of crescents. Although no definitive treatment is presently available for this disease, our case demonstrates that immunosuppressive therapy can be used to treat the inflammatory component of crescentic Alport's and preserve renal function.

## PUB199

### Mysteries of Alport Syndrome

Muhammad F. Habib, Sharmil Suma Kumaran, Michael Lioudis. *SUNY Upstate Medical University, Syracuse, NY.*

**Introduction:** Thin basement membrane nephropathy (TBMN) occurs in approx. 5-9% of the population, but <1% get diagnosed. TBMN when associated with COL4A3/COL4A4 variants is often referred to as autosomal dominant Alport syndrome.

**Case Description:** A 56-year-old female with a 30-pack year smoking history presented with microscopic hematuria and proteinuria for the last 20 and 14 years respectively. She was normotensive and work up in the past was unrevealing. Initial labs showed a creatinine of 0.69 mg/dl with urinalysis showing 100 mg/dl proteins as well as 19/HPF RBCs. Her urine protein/creatinine ratio was 1.13 mg/mg. CTA/P was benign and nephritic/nephrotic syndrome testing were negative. Family history revealed microscopic hematuria in her siblings, mother, and maternal grandmother. There was no family history of deafness, ocular abnormalities, or renal failure. She underwent a renal biopsy showing segmental thinning of glomerular basement membrane (GBM), hypertensive nephrosclerosis, 30% global glomerulosclerosis, and 20% interstitial fibrosis and tubular atrophy (IFTA). Her genetic testing was positive for heterozygous variant of COL4A4. Patient was treated with angiotensin II receptor blockers.

**Discussion:** Alport syndrome can be inherited in an autosomal dominant/recessive and X-linked pattern. Autosomal dominant disease is also called TBMN (20-30% of Alport syndrome). It differs from X-linked form in the manner of inheritance, lack of COL4A5 variant, severity of disease and histological features. Microscopic hematuria is the main feature of TBMN with no family history of renal failure, ocular or hearing abnormalities. COL4A3/COL4A4 variants along with an autosomal dominant inheritance pattern is required for diagnosis. Patients with proteinuria who undergo a renal biopsy show diffuse thinning of the GBM (<250 - <265 nm-WHO criteria) on electron microscopy. However, as seen in our patient's biopsy, a mix of thin and lamellated GBM can also be seen. Our patient had all the clinical features, as well as the inheritance pattern to suggest an autosomal dominant Alport syndrome. However, the diagnosis was missed for decades. We believe at the onset of hematuria/proteinuria, a thorough history followed by a renal biopsy could have led to an early diagnosis and initiation of therapy leading to a reduction in morbidity. Therefore, providing appropriate genetic counseling/family screening for the patient and her family.

## PUB200

### Sarcopenia, Nutritional Status, and Mortality Risk Assessed Using Bioimpedance Spectroscopy in the Elderly Living in a Long-Term Care Facility

Hyokyong Yu, Young Eun Kwon, Song in Baeg, Hye Min Choi, Dong-jin Oh. *Myongji Hospital, Hanyang University College of Medicine, Goyang-si, Gyeonggi-do, Republic of Korea.*

**Background:** This study was aimed to clarify the impact of sarcopenia and on mortality risks.

**Methods:** This prospective cohort study enrolled the elderly residents who were living in nine long-term care facilities. We collected participants' data such as body mass index (BMI), comorbidities, and laboratory data from September to October in 2017 and mortality data until October 2019. Nutritional status was evaluated using mini nutritional assessment (MNA) score and multi-frequency bioimpedance spectroscopy was used to check body composition. Appendicular skeletal muscle mass was calculated using the equation according to the article of Lin T-Y et al (Clinical Nutrition, 40(5), 3288-3295, 2021). Sarcopenia was diagnosed by European Working Group on Sarcopenia in Older People (EWGSOP2) definition (sarcopenia vs. normal group). In addition to the comparison between the two groups, and multivariate regression analyses were performed to verify the association with mortality risks according to sarcopenia group.

**Results:** A total number of 279 elderly participants were enrolled, and 238 seniors were diagnosed with sarcopenia according to the EWGSOP2 guideline. Median age was 83 years old and median BMI was 20.4 kg/m<sup>2</sup>. Sarcopenia group was older than normal group, showed lower BMI and had lower MNA score. Muscle mass was positively correlated with BMI, MNA score, hand grip strength and albumin level. In univariate Cox regression analysis, hazard ratio (HR) of sarcopenia was 4.541 (95% confidence interval

(CI) 1.429–14.429, P=0.010). Sarcopenia was associated with higher mortality risk after adjusting age, gender and diabetes mellitus (HR 3.744, 95% CI 1.155–12.134, P=0.028).

**Conclusions:** Sarcopenia was very prevalent in the elderly of long-term facility care. Sarcopenia group were significantly associated with higher mortality risks.

**Funding:** Government Support - Non-U.S.

## PUB201

### Palliative Goals of Care With Conservative Treatment of CKD 5 Prolonged Life Up to 24 Months in an Elderly Patient

Jasjot K. Bhullar. *Spartanburg Regional Healthcare System, Spartanburg, SC.*

**Introduction:** One-fifth of patients on dialysis in the USA and Australia are ≥75 years old, and this segment of the population constitutes the fastest growing dialysis age-group. While there is a paucity of data surrounding mortality in elderly patients treated with conservative measures, it is understood that elderly patients are more likely to have greater morbidity, increased frailty, and decreased functional status. For these patients and others, a conservative approach may be optimal.

**Case Description:** 82-year-old female presented to the emergency room in September 2019 with the chief complaint of chest pain. She was found to have CKD stage IV with a serum creatinine of 3.7 at that time. Due to changes on chest Xray and presumed Acute Kidney Injury she underwent aggressive diuresis. Unfortunately, her creatinine worsened. A renal ultrasound at that time showed bilateral atrophy. She was discharged home once stable with outpatient nephrology follow up. Due to weakness and hypertensive urgency, she was rehospitalized in December 2019. By that time, she had progressed to ESRD. The patient and family were hesitant to pursue dialysis and her creatinine and symptoms stabilized, so the decision was made to pursue conservative management of CKD 5. Assessment and plan as follows: 1. Hyperkalemia—Lokelma 2. Constipation- Milk of magnesium 3. Pain- low dose gabapentin + opioids per pain management 4. Fatigue- 5. Swelling- Torsemide increased to 40mg daily (Oct 2021), then to 40mg bid (Nov 2021) 6. Hyperphosphatemia- Phoslo 667mg tid 7. HTN- Torsemide, Norvasc 8. Vit D deficiency- vit D supplement Despite multiple kidney-related symptoms for which she is being treated, she has been able to maintain autonomy, quality of life and increased independence due to successful conservative medical management of her ESRD for over 2 years.

**Discussion:** Symptoms and medical management of CKD 5 is a two pronged approach which can help ease the burden of the nephrology team and the palliative care team while achieving patient oriented outcomes of prolonged and improved quality of life. Palliative Management Plan: 1. Pain 2. Fatigue 3. Anorexia 4. Nausea and vomiting 5. Pruritis and Restless Leg Syndrome 6. Advanced Care Planning CKD Medical Management Plan: 1. Volume status 2. Hyperkalemia 3. Metabolic acidosis 4. Anemia of CKD 5. weight loss 6. Hyperphosphatemia and secondary hyperparathyroidism 7. Hypertension

## PUB202

### Lupus-Like Glomerulonephritis as the First Presentation of AIDS

Stefan C. Hemmings, Maxine C. Seales Kasangana. *Baptist Health, North Little Rock, AR.*

**Introduction:** Crescentic Glomerulonephritis (GN) with Full House Immune Complex staining is typical of lupus nephritis and is an uncommon presentation of AIDS in the HAART era.

**Case Description:** A 21 yo Black man presented to hospital with chest pain and feeling generally unwell. One month earlier he presented to another hospital with abdominal pain and PR bleed. A CT abdomen was unremarkable and his creatinine was 1.0mg/dL then. On exam he had normal blood pressure and a mild fever (Temp 100.1F). He was slim built with shotty cervical and axillary lymph nodes, without edema. Labs showed mild anemia, Hb 10.9g/dL and creatinine 1.9mg/dL. On day 2 his creatinine was 1.96mg/dL. On urinalysis: 3+ blood and 3+ protein, UPCR 1.6g/g and albumin of 2.8. His CRP 3.4 and ESR >140mm/hr were elevated. With a presumed GN diagnosis and suspicion for lupus, pulse methylprednisolone 1g daily x 3 doses was started. A renal biopsy performed on Day 4 revealed: "Focal Necrotizing and Crescentic GN with Full House Immune Complex staining". Serology was negative for ANA, dsDNA and ANCA. Complements were normal. At follow up, review of his sexual history was significant for unprotected MSM starting only the year prior. Additional serology was significant for positive HIV antibodies and syphilis (1:64 titer). A CD4 count of 158 met AIDS criteria, with a viral load of 59,000 copies. Oral steroids were continued with a 4 month taper along with MMF. Biktarvy was initiated within 2 weeks of his HIV diagnosis. His creatinine normalized within 1 month (1.19mg/dL) and within 2 months his UA and UPCR (0.1g/g) were unremarkable. He had a normal CD4 count >400 and an undetectable viral load within 6 months.

**Discussion:** HIV-associated lupus-like GN is rare but well described in HIV positive individuals. HAART with steroids +/- MMF therapy early in disease can stabilize renal function. HIV testing should be performed more frequently in patients presenting with acute GNs.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

## PUB203

### Profound Proteinuria and Pathology Pearls: A Case of Secondary Focal Segmental Glomerulosclerosis

Sruthi Sundaram,<sup>1</sup> Joseph Doan,<sup>2,1</sup> <sup>1</sup>University of Nevada Reno School of Medicine, Reno, NV; <sup>2</sup>Sierra Nevada Nephrology, Reno, NV.

**Introduction:** A 68-year-old male presented with several months of worsening lower extremity edema. Pertinent history included type 2 diabetes, obesity, and hypertension.

**Case Description:** The patient's initial labs demonstrated albumin 3.5 with 24-hour urine showing isolated nephrotic-range proteinuria at 5.4g/24hr without hematuria. Chemistries were normal without evidence of declining renal function. Workup for autoimmune diseases and light chain gammopathy was negative as were imaging studies for malignancy. Kidney biopsy showed severe arterial intimal fibrosis without arteriolar hyalinosis, two globally sclerosed glomeruli, and one segmental sclerosed glomerulus. Clinicopathologic findings were most consistent with secondary focal segmental glomerulosclerosis (FSGS). There was no evidence of immune-complex or paraprotein-related disease. Patient was initiated on ACE-inhibitor therapy and started a weight-loss program, with subsequent improvement in quantitative proteinuria. The patient's mildly low serum albumin also normalized, and his lower extremity edema improved.

**Discussion:** Secondary FSGS is diagnosed with kidney biopsy. Light microscopy, immunofluorescence, and electron microscopy assess for structural capillary, tubular, and glomerular abnormalities, and investigate immune-complex or paraprotein-related disease. In this case, identification of nephrotic-range proteinuria led to early diagnosis and intervention to slow progression prior to development of advanced kidney disease. Additional pathology findings of severe arterial intimal fibrosis without diffuse foot process effacement to suggest a primary process, confirmed secondary FSGS attributed to obesity and hypertension. This case is unique due to the patient presenting with symptoms of proteinuria despite the absence of significant hypoalbuminemia, that led to diagnosis of obesity-related glomerulopathy to advanced kidney disease. An increase in incidence of obesity-related FSGS has been shown in studies over the past few decades, highlighting the importance of appropriate screening and monitoring in patients with obesity.

## PUB204

### Glomerulonephritis in Sickle Cell Disease

Hanna T. Webb, Katherine J. Kelly, Carrie L. Phillips. *Indiana University School of Medicine, Indianapolis, IN.*

**Introduction:** Sickle cell nephropathy is varied, related to chronic ischemic changes, TMA, papillary necrosis, glomerulonephritis. Nephrotic syndrome in sickle cell anemia: - FSGS - MPGN - TMA - Hyperfiltration

**Case Description:** 43 yr old PMH sickle cell anemia with dyspnea. Edema for one year but recently worse. One week of pleuritic chest pain. Anasarca, crackles at right lung base. Urinalysis: 2 RBCs, neg WBC 24-hr urine protein 6.2 g CT chest: right lower lobe consolidation, loculated pleural effusion Renal ultrasound: echogenic parenchyma, right 12 cm and left 11 cm Kidney biopsy: Immune complex GN (diffuse proliferative glomerulonephritis with focal crescents and segmental membranous glomerulopathy) Completed 14 days prednisone for pneumonia, persistent proteinuria and edema. Initiated mycophenolate 1000mg BID and prednisone 60mg for lupus nephritis class IV/V. Urine protein-creat ratio 10->6 after one month of MMF. In interim with acute heart failure and an ejection fraction of 30%. Planning endomyocardial biopsy for lupus myocarditis and added hydroxychloroquine.

**Discussion:** We decided to pursue biopsy for broad differential of nephrotic syndrome in sickle cell disease and pneumonia. This case highlights unrelated conditions that occurred concurrently, with variable presentations.

### IgM Nephropathy, a Rare Variant of Minimal Change Disease: A Case Report

Dominic D. Archer,<sup>1</sup> Frederick Smith,<sup>2</sup> Monique N. Pratt,<sup>1</sup> <sup>1</sup>Rand Memorial Hospital, Freeport, Bahamas; <sup>2</sup>Princess Margaret Hospital, Nassau, Bahamas.

**Introduction:** Immunoglobulin M (IgM) Nephropathy is a rare presentation of nephrotic syndrome. IgM Nephropathy is an autoimmune disease and is immune complex mediated with deposition in the mesangium of the kidneys. The presentation is similar to minimal-change disease, and can present as acute renal failure in both children and adults. The objective of this clinical case is to highlight a successful treatment response of a patient with IgM Nephropathy with rituximab.

**Case Description:** A 28-year-old female diagnosed with minimal change disease in childhood who was maintained on steroids since childhood, had worsening proteinuria on 24-hour urine collection despite receiving higher doses of oral steroids in May 2019. A kidney biopsy was performed on July 2019, which revealed IgM 1+ segmental granular staining on immunofluorescent histology, and diffuse visceral epithelial cell foot processes effacement on electron microscopy. The patient was diagnosed with IgM nephropathy, a variant of minimal change disease. The patient was managed on prednisone 40mg po od and mycophenolate mofetil 1g po bd. On 24<sup>th</sup> February 2020 the patient had 7906.8mg/24-hr of proteinuria. In July 2020 the patient had 2362mg/24-hr urine collection. The patient had some reduction in proteinuria, but the response was inadequate and remained steroid dependent. The patient was given one dose of rituximab 1-gram intravenous infusion, and a repeat 24-hour urine collection showed 803mg/24-hr in August 2020. Prednisone and mycophenolate mofetil were discontinued. The patient then received a second dose of rituximab 1-gram intravenous infusion in November 2020, and a repeat 24-hr urine collection showed 450mg. On subsequent visit the patient was noted to have normal levels of proteinuria of 140mg/24-hr in February 2021. The patient is no longer steroid dependent and is maintaining normal levels of proteinuria.

**Discussion:** The use of rituximab in patients with inadequate response to steroids, cyclophosphamide and mycophenolate mofetil may be beneficial.

## PUB206

# Systemic Lupus Erythematosus and Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis Overlap Syndrome vs. Drug-Induced Autoimmune Disease: A Diagnostic Challenge

Lindsay Richels, Dorothy Thomas. *University of Saskatchewan, Regina, SK, Canada.*

**Introduction:** Autoimmune conditions with renal involvement often have a wide range of clinical symptoms and laboratory findings suggestive of more than one autoimmune disease. Therefore, antibodies and clinical features play a significant role in guiding the initial treatment choices of clinicians, especially when patients present acutely.

**Case Description:** A 79-year-old female presented to the emergency department with worsening shortness of breath and fatigue. Laboratory results showed a serum creatinine of 213 umol/L (baseline 90 umol/L). Urine analysis showed 3+ blood and +2 protein. ANA was positive with a titre of 1:2560, C3 was low at 0.52, C4 was low at 0.13, anti-double-stranded DNA (dsDNA) was positive 48.2. Further autoimmune workup revealed positive anti-SSA and anti-SSB, positive ANCA with a perinuclear pattern and elevated anti-MPO antibody (>200); Histone Ab was elevated with a ratio of 1.2. Bronchoscopy showed diffuse alveolar hemorrhage. Past medical history included resistant hypertension, and, two years prior, the patient had been started on hydralazine with increasing doses. The patient denied any history of rashes, arthritis, myalgias or family history of autoimmune disease. Hydralazine was discontinued and the patient was pulsed with corticosteroids. She was then transitioned to oral prednisone and mycophenolate mofetil with improvements in renal function. Hydroxychloroquine was later added and the patient's urine analysis normalized.

**Discussion:** Hydralazine-induced ANCA vasculitis is reported in the literature and can be associated with elevated ANCA MPO-antibodies and positive dsDNA, ANA and anti-histone antibodies. We present a patient of advanced age who was thought to have lupus nephritis as an initial presentation of systemic lupus erythematosus or SLE/AAV overlap syndrome. Still, given her advanced age, clinical presentation, positive antibodies, and recent hydralazine use, the diagnosis of hydralazine-induced ANCA vasculitis was also considered a likely diagnosis. Without renal biopsy it is difficult to say with complete certainty the exact renal pathology however, treatment response with immunosuppression was achieved and despite using less aggressive treatments the patient expired secondary to infectious complications.

## PUB207

# It's Probably the Lupus: A Case of Secondary Thrombotic Microangiopathy

Victor D. Hoang, David N. Dado. *Keesler Air Force Base, Keesler AFB, MS.*

**Introduction:** Thrombotic microangiopathy (TMA) is a group of rare disorders characterized by thrombocytopenia, hemolytic anemia, and microvascular thrombi leading to end-organ damage. Secondary TMA occurs in response to an underlying trigger such as infection, connective tissue disease, or medications. Most secondary cases occur via unclear mechanisms, however kidney biopsy can assist in diagnosis.

**Case Description:** A 28-year-old female with history of systemic lupus erythematosus with class V lupus nephritis presented with a 2 month history of worsening bilateral lower extremity weakness. She had unremarkable brain and whole spine imaging. The patient was hemodynamically stable, with no focal neurologic deficits on exam. Her labs were notable for Cr 1.8, Hgb/Hct 7.1/22.8, and Plt 9. Her peripheral blood smear was notable for a significant number of schistocytes per high-power field. An apheresis catheter was urgently placed for plasma exchange, and the patient was scheduled to receive methylprednisolone daily. Additional labs were ordered to include ADAMTS13 level, HIV, hepatitis panel, coagulation factors, and urine pregnancy test. Initial labs resulted: C3 50, C4 3, ESR 13, CRP 0.2, haptoglobin <10, LDH 2286, dsDNA 1, INR 0.8, fibrinogen 212, and reticulocyte index 11.9%. The patient received empiric plasma exchange and IV steroids due to concern for thrombotic thrombocytopenic purpura. Her platelet count increased daily and peaked at 177. On hospital day 5, ADAMTS13 activity level resulted 19% and was inhibitor negative. This prompted additional workup with atypical hemolytic uremic syndrome genetic panel and renal biopsy. Preliminary renal biopsy demonstrated class V lupus nephritis with mild class III features, and evidence of thrombotic microangiopathy. After discussion with Rheumatology, Hematology, and Nephrology, the patient was diagnosed with secondary TMA from lupus flare. She was discharged to complete rituximab infusions weekly for 4 weeks.

**Discussion:** This case demonstrates the difficulty in distinguishing between primary and secondary TMA syndromes, and the urgency required to manage these patients. In this case, kidney biopsy was critical in determining the management plan for this patient, confirming secondary TMA.

## PUB208

# A Case of Crescentic C3 Glomerulonephritis in a 24-Year-Old Male: A Rare Entity

Venkata Kishore R. Mukku, Tina Kochar, Shancy Jacob, Syed A. Hussain. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

**Introduction:** C3 glomerulopathy (C3G) is a clinicopathologic entity secondary to dysregulation of alternative complement pathway in plasma and glomerular microenvironment. C3 glomerulopathies are uncommon forms of glomerulonephritis (GN) characterized by substantial risk of progression to end stage renal disease.

**Case Description:** 24-year-old male with history of hypothyroidism presented to clinic with throat infection and was treated with amoxicillin. Lab work showed worsening renal function and admitted for further work-up which showed negative serologies for Hepatitis B, C, HIV, ANA, ANCA, Anti-ds DNA, cryoglobulin, anti-GBM antibody and complements. Urinalysis revealed microscopic hematuria and random urine protein was 1.3g/g. Patient was initiated on dialysis for worsening renal function and oliguria. He was started on solumedrol and underwent renal biopsy which showed diffuse crescentic glomerulonephritis (GN) on light microscopy. There were 28 glomeruli, 7 of which were globally sclerotic. 15 glomeruli show cellular crescents, 3 of which showed fibrinoid necrosis. There was mild interstitial fibrosis and tubular atrophy. Mesangial and rare subepithelial electron dense deposits were seen on electron microscopy. Immunofluorescence revealed, 1-2 + granular mesangial end glomerular capillary wall positivity for C3 with trace IgM and C4d. These findings are consistent with crescentic C3 GN in the absence of bacterial infection. Patient was started on mycophenolate, steroids and was referred for out-patient genetic testing.

**Discussion:** The spectrum of clinical manifestations in C3G is wide, from incidental asymptomatic microscopic hematuria to rapidly progressive forms leading to kidney failure. However, most common presentation in clinical setting is proteinuria with preserved kidney function. When the disease is diagnosed in adults, presence of monoclonal gammopathy must be ruled out. Serum C3 hypocomplementemia is a characteristic feature of C3G, although not strictly necessary for the diagnosis. The clinical manifestations of C3G may be preceded by an infection. Hence, a differential diagnosis considering postinfectious GN is mandatory. The therapeutic alternatives available at present can be classified as supportive therapy with angiotensin converting enzyme inhibitors, immunosuppression with steroids, mycophenolate, and anticomplement therapy with eculizumab.

## PUB209

# Lupus Nephritis With Thrombotic Microangiopathy Resistant to Immunosuppression

Frida Margarita de la Vega Méndez,<sup>1,2</sup> Ana E. Oliva,<sup>1,2</sup> Clementina Elizabeth Calderon Garcia,<sup>1,2</sup> Alexa N. Oseguera Gonzalez,<sup>1,2</sup> Miguel Ángel P. Venegas,<sup>1,2</sup> Jonathan Chavez,<sup>1,2</sup> Maria de la luz Alcantar Vallin,<sup>1,2</sup> Ramon Medina.<sup>1,2</sup> <sup>1</sup>*Universidad de Guadalajara, Guadalajara, Mexico;* <sup>2</sup>*Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico.*

**Introduction:** LN can be complicated by vascular conditions and hematological disorders patients with thrombotic microangiopathy show a greater severity and worse prognosis

**Case Description:** A 16-year-old woman with SLE treated with a 6 monthly cycles of cyclophosphamide prednisone and chloroquine At the onset of SLE she presented serum creatinine levels of 0.8 She was admitted into our emergency unit due to nausea In her clinical examination she was found 152/98 mmHg, HR of 90 RR of 18 generalized pallor facial and limb edema hemoglobin 4.9 g/dl leukocytes 9.24 thrombocytopenia of 73.25 urea 205.8 mg/dl creatinine 12.39 phosphate 11.4 mg/dl calcium 8 mg/dl potassium 6.4 mmol/l sodium 134 mmol/l LDH 826 U/L 24-hour urine protein 1.87 grams complement test for HBsAg positive serum smear with schistocytes 3 per field haptoglobin 10.1 and a negative ADAMTS13 and shiga toxin test Hemodialysis was started as well as bolus of methylprednisolone for 3 days renal biopsy was performed which showed diffuse LN IV and the presence of thrombi The patient presented a partial clinical improvement however bicytopenia worsens and mycophenolic acid was started with any hematological improvement and persistent schistocytes so we decided to restart methylprednisolone Due to the presence of hepatitis B and TMA not responding to the initial immunotherapy it was decided to start prophylaxis with tenofovir/emtricitabine and an initial dose of rituximab This revealed clinical and hematological improvement

**Discussion:** This case represented a clinical challenge because the patient presented resistance to the initial treatment A treatment with rituximab was considered however the patient became diagnosed with chronic hepatitis B which made it even more difficult to decide the treatment since the risk of reactivation is high using monoclonal antibodies It was also difficult to determine if the affection to the kidney was due mainly to LN or to the presence of TMA or to know whether renal functions could be recovered with immunosuppressive treatment In those patients with LN and TMA the treatment is not clearly defined patients with TMA and LN have a worse renal prognosis than those with only LN Thus determining which would be the best treatment for them is highly relevant

## PUB210

# High Chronicity Index of the Modified National Institutes of Health Scoring System of Lupus Nephritis Is Associated With Increased Risk of ESKD: A Retrospective Single-Center Study

Shiori Nakagawa, Yasunori Iwata, Tadashi Toyama, Megumi Oshima, Hisayuki Ogura, Taro Miyagawa, Shinji Kitajima, Akinori Hara, Norihiko Sakai, Miho Shimizu, Takashi Wada. *Kanazawa University Hospital, Department of nephrology Kanazawa Daigaku, Kanazawa, Japan.*

**Background:** Lupus nephritis (LN) is a major manifestation which develops in more than 50% of patients with systemic lupus erythematosus, and is also a risk factor for morbidity and mortality in these patients. The revision of International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification for LN was suggested by a working group, who recommended a modified National Institute of Health (NIH) activity and chronicity scoring system to evaluate active and chronic LN lesions. However, whether this approach was useful for estimating prognosis for LN patients is unclear.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Methods:** We conducted a retrospective cohort study in Japanese subjects with biopsy-proven LN, between 1977 and 2022. Pathologic lesions were evaluated based on ISN/RPS 2003 classification and the modified NIH scoring system. Patients were grouped by activity index (low, 0–5; moderate, 6–11; high, 12–24), and chronicity index (low, 0–2; moderate, 3–5; high, 6–12). The primary outcome was a composite of end-stage kidney disease (ESKD) or all-cause death, and the secondary outcome was ESKD.

**Results:** Seventy subjects with a median age of 31 years were included. Median follow-up period was 11.3 years. For the activity index, Kaplan–Meier analysis showed that the survival rate of the primary outcome decreased with a higher activity index (log-rank trend  $p = 0.026$ ). Multivariable analysis, adjusted by age and serum creatinine, did not show any significant relationship to the activity index. For the chronicity index, Kaplan–Meier analysis showed that the survival rate of the primary outcome decreased with a higher chronicity index (log-rank trend  $p < 0.001$ ). Multivariable analysis revealed that moderate (HR 6.18, 95% CI 1.15 to 33.3;  $p = 0.034$ ) and high chronicity indices (HR 20.33, 95% CI 1.14 to 360.50;  $p = 0.04$ ) were significant risk factors for the primary outcome. Consistent results with the primary outcome were determined by Kaplan–Meier and univariable analysis for the secondary outcome.

**Conclusions:** Moderate and high chronicity indices were associated with an increased ESKD risk for LN. This modified NIH scoring system may help physicians predict long-term prognosis for patients with LN.

## PUB211

### Concurrent Anti-Neutrophil Cytoplasmic Antibody Associated Vasculitis and Anti-Glomerular Basement Membrane Disease

Emma Greear,<sup>1,2</sup> Jahanzeb Saeed,<sup>1,2</sup> Justin A. Amato,<sup>1,2</sup> Jeff S. Croteau,<sup>1,2</sup> Carl S. Henderson,<sup>1,2</sup> Adegbeniga Bankole,<sup>1,2</sup> <sup>1</sup>Carilion Clinic, Roanoke, VA; <sup>2</sup>Virginia Tech Carilion School of Medicine, Roanoke, VA.

**Introduction:** Many diseases, infections and medications plague the kidneys. However, the likelihood of having two uncommon disease processes simultaneously affecting the kidneys is quite rare.

**Case Description:** A 79-year-old woman with upper airway limited anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV) noted worsening fatigue. Laboratory testing revealed a new increase in serum creatinine, elevated inflammatory markers, and proteinuria. The patient had historically been on Rituximab for maintenance AAV therapy but developed an allergy. The patient was then placed on methotrexate, but this was stopped due to postoperative wound healing complications following an abdominal surgery. She had been off all AAV therapies for 1 year when her renal function began to decline. She was admitted to the hospital due to acute renal failure and concern for relapse of AAV. While hospitalized the patient was treated with intra-venous pulse dose methylprednisolone, Plasma Exchange (PE), and cyclophosphamide. Serum anti-glomerular basement membrane (anti-GBM) antibody and proteinase 3 (PR3) antibody testing was positive. A renal biopsy confirmed anti-GBM and PR3 ANCA associated crescentic glomerulonephritis. Despite aggressive treatment the patient's renal function did not recover and hemodialysis was initiated.

**Discussion:** Guidelines created by the American College of Rheumatology (ACR) and Kidney Disease Improving Global Outcomes (KDIGO) discuss treatment of AAV and anti-GBM disease. The AAV guideline created by ACR recommends against the use of PE in patients with AAV with one caveat. The role of PE is still recognized by the ACR in those patients with both diseases. KDIGO also recommends PE in this patient population. No direct statements are made to guide the initial therapy beyond PE in this group of patients. Therefore, the treatment of this patient subgroup must be individualized and based upon evidence used to guide the treatment of the two distinct diseases. Here in this case, we will explore the management of this unique subgroup of patients.

## PUB212

### Cannabinoids May Be a Trigger or a Stop of Glomerular and Podocyte Injury From Parvovirus B-19 Infection

Hussein A. Hussein, CLS Nephrology CLS Health, Webster, TX.

**Introduction:** Cannabinoids are widely distributed recreational substances and young patients with chronic epilepsy tend to use the substance even though harmful side effects such as acute tubular necrosis (ATN) and acute interstitial nephritis (AIN) have been reported. This is a rare case of glomerulopodocytopathy that might be triggered by Cannabinoids to raise awareness among clinicians and to emphasize on the need for patient education concerning the deleterious side effect of these substances.

**Case Description:** A 21 years-old African American male was brought to the emergency room with seizure disorder and hypertension. Initial lab results showed a creatinine kinase of 233, serum creatinine of 1.13 mg/dL, it peaked at 7.6 in 72 hours.

Upon nephrology consultation, obstructive nephropathy was ruled out. His renal ultrasound showed severe echogenicity. Urine microscopy showed granular cast with no WBC or RBC casts. His urine protein creatinine ratio was 1.3 gm. A physical examination showed mild lower extremity edema, he denies NSAIDs use. Serology was negative for ANA, Anti dsDNA, Anti Smith Ab, ANCA, COVID-19, HIV, HCV. Serology for Parvovirus B-19 (IgG) was positive while IgM was negative, APOL1 gene wasn't done due to lost follow up. 3 months earlier creatinine was 0.9 mg/dL, at time he was admitted for respiratory illness treated with steroid and antibiotics. Pathology revealed collapsing glomerulopathy in 4/22 glomeruli, no interstitial fibrosis and tubular atrophy and mild arterio- and arteriolosclerosis. His renal function responded well to pulsed steroids, He was maintained on 1 mg/kg daily prednisone taper, and his creatinine started trending down, while the edema resolved and the blood pressure normalized. The patient was discharged with nearly normal creatinine and a urine protein to creatinine ratio of 0.3.

**Discussion:** Cannabinoids induced AKI with ATN or AIN are common. The renal injury related to delta-9-tetrahydrocannabinol (active ingredient in marijuana). The cannabinoid might trigger glomerulopathy and podocytopathy due to underlying viral illness could need further investigations, or it can be a protective substance for the glomerulus. Being vigilant with a high index of suspicions to any rapid progression of GN with a decline of renal functions, in order to take immediate actions with a diagnostic biopsy; prompting treatment to reverse salvaged renal functions.

## PUB213

### IgA Nephropathy as a Potential Complication of SARS-CoV-2 Vaccination

Olusola Sogbein, Tina Kochar. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

**Introduction:** Vaccination against COVID-19 is essential, however an immunological flare is a potential rare complication resulting in glomerulonephritis with IgA deposits in the mesangium. We present a case of a patient who developed IgA nephropathy post-vaccination.

**Case Description:** 48-year-old woman with a past medical history of Leukocytoclastic vasculitis and hypertension presented to the Emergency Department with fatigue, nausea, epigastric pain, foamy urine and a diffuse erythematous purpuric rash within days of receiving the SARS CoV-2 vaccination. Her creatinine was 1.92 mg/dL and urinalysis showed 3+ blood and 30 mg/dL of protein. COVID-19 testing was negative. Protein/creatinine ratio was 2.1 g/g and urine microscopy showed dysmorphic red blood cells. Serologies for HIV, Hepatitis B and C were negative. Further testing revealed negative ANA, normal ASO titer, absent cryoglobulins, rheumatoid factor < 20, C3 158 (nl) and C4 35 (nl). However, IgA level was elevated at 462 mg/dL (reference 70-312 mg/dL). Patient was started on prednisone at a dose of 1mg/kg with a presumptive diagnosis of IgA vasculitis/HSP. Subsequent skin biopsy was consistent with leukocytoclastic vasculitis while kidney biopsy showed glomerular deposition of IgA and endocapillary hypercellularity. At one month follow-up with nephrology, prednisone taper was started because of good clinical response and partial remission with UPCR reduction to 1 g/g. Prednisone was gradually tapered over the next 2 months. At her 3 month follow-up she was found to be in complete remission with a UPCR 0.2 g/g and her creatinine was 0.83 mg/dL.

**Discussion:** We present a case of IgA nephropathy post-SARS CoV-2 mRNA vaccination. It has been speculated that the mRNA lipid nanoparticle-encapsulated platform contained within the mRNA vaccine produces such a robust CD4 and CD8 T-cell response that pro-inflammatory cytokines activate this immune complex associated glomerular disease. In conclusion, SARS CoV-2 vaccination may potentially trigger IgA nephropathy in predisposed patients. Steroid therapy may be efficacious in managing this rare complication.

## PUB214

### Progression of Proteinuria and Renal Insufficiency in Two Patients With Inflammatory Bowel Disease: Does Fecal Microbiota Transplantation Matter?

Ping Wen, Jie Zhang, Jining Wu, Yi Fang, Weichun He, Junwei Yang. *Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

**Introduction:** Inflammatory bowel disease (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), is a chronic, immune-related, progressive disease. Numerous extraintestinal manifestations occur in IBD, including lesions of the skin, hepatobiliary and renal complications. Proteinuria and/or hematuria is the main manifestation of kidney injury.

**Case Description:** Patient A: A 46-year-old Asia male with history of CD (6 years) presented with proteinuria, hematuria, and elevated serum creatinine. After several flares of CD, the patient received fecal microbiota transplantation (FMT). The patient developed proteinuria (2.3g/d), hematuria and renal insufficiency (eGFR 56.4ml/min/1.73m2) 5 years after the CD. The pathological diagnosis is IgA nephropathy (IgAN), mild to moderate mesangial proliferation with global abandon (9/27), segmental abandon (4/27) and crescent formation (3/27). Patient B: A 46-year-old Asia male with history of CD (7 years) presented with proteinuria and hematuria. Different from patient A, patient B manifested proteinuria and hematuria at the onset of CD but the kidney function was normal. The patient also received FMT for several times. In emergency department, he was dyspnea and chest tightness. Lab was notable for anemia, renal insufficiency, heart failure, and hyperkalemia. Hemodialysis was performed to improve heart failure, acidosis, and hyperkalemia. Because of the poor heart function, kidney biopsy was not performed.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

**Discussion:** The common features of two patients were proteinuria, hematuria, and renal insufficiency. However, the appearances of kidney injury were at different stages of CD. The pathological feature of kidney was IgAN, indicating IgA may play a crucial role. Increased small intestinal mucosal permeability during disease progression has been demonstrated in IgAN, and the intestinal mucosa is one possible source of IgA in IgAN. Another common point of two patients was fecal bacteria transplantation. Whether fecal microbiota can act as an antigen to trigger immune response is unknown. Previous studies have demonstrated peptides from bacteria can activate CD4+ T cells or B cells to produce autoantibodies. Different flora may play opposite effects in gut immune, therefore induce kidney injury.

## PUB215

### A Case of Renal Amyloidosis (AD) Presented as Orthostatic Hypotension Rula A. Abdulrahman, Stony Brook University, Stony Brook, NY.

**Introduction:** Neurogenic hypotension can happen in the context of immunoglobulin light chain AD. The most serious feature is autonomic nervous system impairment, mainly characterized by severe refractory orthostatic hypotension. Amyloid deposition may be found in many organs and the patient can presents with cardiac, gastrointestinal, renal, and neurological symptoms, but rarely hypotension only. Here we describing a patient who presented with severe orthostatic hypotension, found to have renal AD.

**Case Description:** 67 year old male with past medical history of type 2 diabetes, chronic kidney disease, coronary artery disease, colon cancer, and history of COVID-19 infection who presents to nephrology clinic after being referred by primary care provider for elevated Creatinine to 2.5 mg/dl (baseline around 1.2 mg/dl). on clinic visit found to have severe orthostatic hypotension. blood pressure (BP) supine 121/80 mmHg, heart rate (HR) 87 beat per minute (BPM) ; sitting 106/70 mmHg, HR-92 BPM; standing: 92/59 mmHg, HR-100 BPM, no other abnormalities on physical examination. and was admitted to the hospital for evaluation. upon admission to the hospital, pateint received IV fluid, found to have 11 gram protein on 24 hour urine collection laboratory work up showed positive ANA, immunofixation was positive for lambda chain. Fat pad biopsy without signs of AD. Bone marrow biopsy results were inconclusive. Renal biopsy was performed, findings consistent with AL AD. pateint to start treatment with hematolgy

**Discussion:** The amyloidoses are a group of disorders in which soluble proteins deposit extracellularly in tissues as insoluble fibrils, causing organ dysfunction that is usually progressive. Renal amyloid is a major source of morbidity in affected individuals. When the kidney is involved, renal insufficiency is common, accounting for 47% of cases in a study. Proteinuria has been reported with full nephrotic syndrome in 25–68%. it usually progress to end stage renal disease if left untreated. in our case we are describing an unusual presentation of renal AD, in which the symptoms were orthostatic hypotension. renal function was below baseline but was improving with volume replacement, pateint was felt to have prerenal acute kidney injury. the significant amount of proteinuria prompted further testing. We feel that nephrotic syndrome from amyloid should be considered when patient presented with orthostatic hypotension.

## PUB216

### A Rare Case of Class 4 Lupus Nephritis Presenting With Type 4 RTA Tram Dao, Shubha Ananthakrishnan, Niti Madan. University of California Davis Department of Internal Medicine, Sacramento, CA.

**Introduction:** Renal tubular acidosis is sometimes seen in patients with lupus nephritis. A recent study of a large systemic lupus erythematosus patient population demonstrates that about 16% of the group had RTA. The most common type seen is type 1 RTA. However, there have been less than 10 cases reported of type 4 RTA associated with lupus nephritis. It is thought that type 4 RTA is an indication for a more aggressive form of SLE, with wider tubular damage caused by severe lupus nephritis.

**Case Description:** We present a 30 year old female with history of cutaneous systemic lupus erythematosus who presented to the emergency department for abnormal lab values. She was found have nephrotic range proteinuria and acute kidney injury. Patient only reports acute periorbital swelling and ongoing hair thinning. Admission labs were notable for potassium 6.8 mmol/L, carbon dioxide 21 mmol/L, anion gap of 5 mEq/L, urea nitrogen 17 mg/dL, and creatinine 1.55 mg/dL. Urine studies shows a spot protein to creatinine ratio of 4,444 mg/g. Urine microscopy showed numerous white blood cells, white blood cell clumps, and scattered renal tubular epithelial cells; no red blood cells were noted. Urine anion gap was positive at 47 mEq/L. Renal biopsy showed diffuse class 4 lupus nephritis with moderate activity and no significant chronicity, membranous class 5 lupus nephritis, and moderate interstitial inflammation. Type 4 RTA was also diagnosed and confirmed with renin level < 0.1 ng/mL/hr, and aldosterone level < 3 ng/dL. Patient was started on steroids and mycophenolate for her lupus nephritis. The patient's renal function then improved with improvement of hyperkalemia, she was then transitioned off of sodium zirconium cyclosilicate.

**Discussion:** It's important for providers to keep type 4 RTA in mind when hyperkalemia is detected in their SLE patients. Often times, the use of ACE inhibitors can mask the RTA association and delay diagnosis. Treatment includes addressing the underlying autoimmune disease with steroids, immunosuppressive therapy, as well as loop diuretics and fludrocortisone to address the RTA.

## PUB217

### Myeloperoxidase-ANCA-Positive Granulomatosis with Polyangiitis with Severe Renal Dysfunction: A Case Report

Brian Bustos, Soo H. Kae, Pooja Shekar, Eduardo M. Padrao. University of Connecticut School of Medicine, Farmington, CT.

**Introduction:** Granulomatosis with polyangiitis (GPA) is associated with antineutrophil cytoplasmic antibody (ANCA) and rarely, myeloperoxidase (MPO). In previous studies, MPO-ANCA-positive GPA frequently has had limited disease without severe organ involvement and less of a need for aggressive immunosuppressive therapy.

**Case Description:** 59-year-old male with a history of hypertension presented to the hospital due to 10 days of nausea and vomiting. Two months prior, he developed fatigue, malaise, and ear pain. Outpatient lab work at the time was unremarkable. In the emergency department, lab work was significant for creatinine of 20.0 mg/dL (baseline 0.86 mg/dL one month prior), BUN 224 mg/dL, erythrocyte sedimentation rate of greater than 129 mm/h, c-reactive protein of 15.86 mg/L, and ferritin of 3,388 ng/mL. A foley catheter was placed and the patient produced only about 40 cc of urine. Urinalysis demonstrated moderate protein and 3 red blood cells per high-power field. Ultrasound and computed tomography of the abdomen showed no obstructive renal pathology, however noted increased parenchymal echogenicity. A dialysis catheter was placed and he underwent hemodialysis. Further lab work was notable for positive double-stranded DNA, p-ANCA, and MPO, however a negative PR3 antibody. Renal biopsy revealed focal necrotizing and crescentic glomerulonephritis, granulomatous interstitial inflammation, and multifocal necrotizing arteritis and arteriolitis. He was diagnosed with acute oliguric renal failure secondary to MPO-ANCA-positive GPA. He underwent five sessions of plasmapheresis, managed with steroids, and was subsequently started on Cyclophosphamide following improvement in renal function.

**Discussion:** GPA may have renal involvement, and glomerulonephritis has been seen to develop in 77-85 percent of patients. MPO-ANCA-positive GPA is rare, and MPO positivity is usually associated with microscopic polyangiitis (MPA). Additionally, in previous studies, it was seen that MPO-ANCA-positive GPA frequently had limited disease without severe organ involvement and also a lesser need for aggressive immunosuppressive therapy. This particular case is unique such that our patient was MPO-ANCA positive, while developing severe renal involvement. Moreover, he eventually required immunosuppressive therapy with steroids and cyclophosphamide.

## PUB218

### Focal Proliferative Glomerulonephritis, IgA and C3 Predominant

Marwa Alithawi,<sup>1</sup> Tina Sharma,<sup>1,3</sup> Bassam Alkamachi.<sup>2</sup> <sup>1</sup>Pontiac General Hospital, Pontiac, MI; <sup>2</sup>Henry Ford Hospital, Detroit, MI; <sup>3</sup>St. Martinus University Faculty of Medicine, Willemstad, Curaçao.

**Introduction:** Glomerulonephritis (GN) is classified into five groups: immune complex-mediated GN, antineutrophil cytoplasmic antibody-associated GN, anti-glomerular basement membrane GN, monoclonal immunoglobulin-mediated GN and C3 glomerulopathy[1,2]. Distinguishing between the subtypes is based on factors such as the clinical presentation, comorbidities, labs and the histopathology of the renal biopsy.

**Case Description:** A 66-year-old male with a past medical history of Chronic Obstructive Pulmonary Disease, hyperlipidemia, Diabetes mellitus type II and schizoaffective disorder was found to have abnormal kidney function, hematuria and proteinuria. He presented with a new onset cough, shortness of breath, diarrhea and vomiting. For the past 25 years, he smoked 10 cigarettes a day and denied recreational drug use. Physical examination revealed reduced air entry and coarse crackles in the right middle and lower lobes of the lung. Labs showed a serum Creatinine of 8.1 mg/dL and an estimated glomerular filtration rate (eGFR) of 7 mL/min. Chest X-Ray showed streaky densities in the right middle and lower lobes of the lung. Retroperitoneal ultrasound of the kidneys showed normal kidney size bilaterally and the CT scan of the abdomen and pelvis was within normal limits. Further workup ruled out paraproteinemias, systemic lupus erythematosus, vasculitis, pauci-immune disorders and Goodpasture syndrome. The kidney biopsy revealed focal proliferative glomerulonephritis with IgA, C3 and lambda chain deposition within the glomerulus. If IgA nephropathy, then it would correspond to Oxford classification of M1 E1 S1 T1 C1 – one small cellular crescent.

**Discussion:** Extensive workup failed to identify the cause of the acute deterioration in kidney function. The clinical course did not align with histopathology leading to the management and prognosis to be challenging. Though no official diagnosis was made, a thorough review was done of the differentials: Rapidly Progressive GN, Primary versus Secondary IgA Nephropathy, and Postinfectious GN. The most plausible diagnosis is IgA-Dominant or codominant postinfectious GN. It is important to know the details and the difference between the subtypes of glomerulonephritis to manage the various aspects of the patient's health such as assessing risk factors, associated comorbidities, clinical management, medication adjustments, follow up work up, complications and prognosis.

## PUB219

### Floats Like a Butterfly, Stings Like a Bee: Lupus Nephritis

Krystahl Z. Andujar-Rivera,<sup>1,2</sup> Ileana E. Ocasio Melendez,<sup>1</sup> Jesus D. Vega-Colon,<sup>1</sup> Maria E. Rivera,<sup>1</sup> Alexis Rivera Gonzalez,<sup>1</sup> Jose D. Ortiz Rosario.<sup>2</sup> <sup>1</sup>Universidad de Puerto Rico Recinto de Ciencias Medicas, San Juan, Puerto Rico; <sup>2</sup>Doctors' Hospital of San Fernando de la Carolina, Carolina, Puerto Rico.

**Introduction:** Lupus nephritis (LN) is a severe complication of Systemic Lupus Erythematosus (SLE) that has a broad spectrum of clinical and pathologic features with various prognoses according to its stage. A kidney biopsy contributes in terms of diagnosis, prognosis and management.

**Case Description:** A 28-year-old woman with SLE presents to the emergency department due to progressive swelling of lower extremities associated with facial swelling and periorbital edema. She was on therapy with mycophenolate mofetil, hydroxychloroquine and prednisone 60 mg/day. Physical examination was notable for lower extremity pitting edema up to thighs and decreased breath sounds. Found to have oliguric AKI with SCr of 3.0 mg/dL (baseline Cr 0.6 mg/dL), low C3/C4 levels, elevated anti-dsDNA antibodies. Hepatitis B, Hepatitis C and HIV serologies were negative. UPCR revealed 13,000 mg/g of proteinuria (1,400 mg/g 2 months prior). Urine sediment was active with evidence of acanthocytes. A kidney biopsy was performed which revealed lupus nephritis class IV and V. Intravenous pulse methylprednisolone was initiated 1,000 mg for 3 days and IV cyclophosphamide as recommended by rheumatology specialist. Mycophenolate mofetil was continued. Despite aggressive immunosuppressive treatment, kidney function continued to deteriorate, and she was started on kidney replacement therapy.

**Discussion:** Treatment of lupus nephritis is as multisystemic and complex as the disease itself. Class V lupus can occur in combination with class III or IV, as in our patient. In some studies, patients with combined diffuse LN and lupus membranous nephropathy have worse outcomes than those with diffuse disease only. In a review, it was documented that the risk of ESKD in lupus nephritis increased in the late 2000s after a decrease in the 1970s and mid-1990s. Recently, new research has demonstrated improved outcomes in lupus nephritis with novel therapy like Belimumab and Voclosporin. Development of novel therapies is exciting however given the risk for kidney loss and increased risk for ESKD, it is imperative that treatments for lupus nephritis be both accessible and effective for our patients.

## PUB220

### Simultaneous Presentation of ANCA-Associated Pauci-Immune Crescentic Glomerulonephritis and Systemic Lupus Erythematosus

Manuel Arizaga Napoles, Guadalupe Montserrat Ochoa De Leon, Maria de la luz Alcantar Vallin, Ramon Medina, José David G. Barajas, Juan Gómez Fregoso, Jonathan Chavez. *Hospital Civil de Guadalajara, Guadalajara, Mexico.*

**Introduction:** The presence of vasculitis may be found in the course of Systemic lupus erythematosus (SLE) but rarely corresponds to an ANCA-associated vasculitis (AAV) furthermore antineutrophil cytoplasmic antibodies (ANCA) positivity can be present in patients with SLE and may be related with a poor prognosis however the clinical expression of an AAV is extremely uncommon. We report a case of a young man fulfilling the criteria for SLE who develop a Rapidly progressive glomerulonephritis (RPGN) and the findings on the kidney biopsy corresponds to a Pauci-immune crescentic glomerulonephritis (PICGN)

**Case Description:** Patient with history of hypertension diagnosed 1 year earlier and previous hospitalization six month ago for an episode of venous thrombosis. Begin oral anticoagulation and was discharged with an estimated glomerular filtration rate (eGFR) of 76ml/min/1.73m<sup>2</sup>. It was referred to our unit for a decline of 50% in eGFR and glomerular hematuria. In physical exam we found arthritis and peripheral edema. We approach this case by performing levels of complements both were found low. In the setting of RPGN and low complements. We order antinuclear antibodies that resulted positive 1:1,280 with a fine speckled pattern. By this point the patient fulfilled the ACR/EULAR 2019 criteria for SLE. We carry out a kidney biopsy that concluded necrotizing proliferative extracapillary pauciimmune glomerulonephritis, with granulomas without eosinophilic infiltration. Tubulointerstitial nephritis and arteriolar fibrosis were also found. Due to this findings ANCA were perform anti-myeloperoxidase antibody was found positive 1:10 2+ on immunofluorescence and 1.35 in enzyme-linked immunoassay. The patient receive an induction therapy with methylprednisolone and cyclophosphamide. We achieve no progression in the necessity of renal replacement therapy but the eGFR remains on 35ml/min/1.73m<sup>2</sup> after induction therapy

**Discussion:** This case demonstrates that the presence of overlap between SLE and AAV is a rare but feasible entity. Although ANCA may be present in SLE they are typically not related with a clinical expression of the disease. As the seen in this case where the kidney biopsy findings are strongly associated with AAV

## PUB221

### A Case of ANCA Vasculitis and IgA Nephropathy in a Patient With Hematuria

Leanne Brown, Aditi Singh, Nickolas Coombs. *UConn Health, Farmington, CT.*

**Introduction:** Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) represents a group of autoimmune small vessel diseases with a broad array of clinical manifestations. The pathologic hallmark of AAV glomerulonephritis (GN) is necrotizing and/or crescentic lesions without significant immune complex deposition. Co-existent IgA nephropathy and ANCA-associated crescentic glomerulonephritis represents the rare concurrence of two common forms of glomerulonephritis. We present a case of renal-limited antibody positive ANCA vasculitis with a background of IgA nephropathy.

**Case Description:** A 69 year-old-male with a history of chronic kidney disease, presented to the hospital for evaluation of painless hematuria and an acute kidney injury. Urinalysis was positive for proteinuria and hematuria with dysmorphic red cells seen on microscopy. He was subsequently found to have high titers of myeloperoxidase (MPO) positive ANCA antibodies and therefore started on empiric immunosuppressive therapy with high dose steroids. Renal biopsy demonstrated no crescentic lesions or fibrinoid changes to the glomeruli. Interestingly, IgA stain was positive with mesangial expansion without subendothelial or subepithelial deposits on electron microscopy. Due to worsening kidney function, and no response to steroid therapy, the patient was initiated

on vasculitis treatment protocol, with prednisone followed by cyclophosphamide. The result was improvement in serum creatinine and MPO-ANCA titers. He was continued on maintenance therapy with rituximab with clinical and biochemical remission achieved.

**Discussion:** Co-existent IgA nephropathy and ANCA-associated crescentic GN represents the rare concurrence of two common forms of GN with very few cases documented in literature. The pathogenesis, treatment and prognosis of this dual glomerulopathy is not well defined. However, as highlighted by this case, there is a favorable response to immunosuppressive therapy. Given the high mortality rate associated with AAV, prompt and adequate treatment is paramount. Adequate therapy requires an early diagnosis, but diagnosing AAV can be challenging, and is often made based on clinical features in combination with positive ANCA serology. Renal biopsy remains gold standard for diagnosis but should not delay initiating immunosuppressive therapy.

## PUB222

### Sudden Onset Hyperglycemic Hyperosmolar Syndrome due to Tacrolimus in a Patient With FSGS

Daniel J. Castro-Pereira. *Southwest Kidney Institute PLC, Tucson, AZ.*

**Introduction:** The initial treatment for primary focal segmental glomerulosclerosis (FSGS) includes glucocorticoids. Those with no reduction in proteinuria are considered glucocorticoid resistant and subsequent administration of another agent such as Tacrolimus is recommended. This is a case of sudden onset of hyperglycemic hyperosmolar syndrome (HHS) due to tacrolimus shortly after having started therapy.

**Case Description:** A 21-year-old Hispanic female was found to have hypertension and proteinuria. Work up revealed: total cholesterol 250 mg/dL, albumin 3.5 g/dL, creatinine (SCr) 0.9 mg/dL, hemoglobin A1c (HbA1c) 5.4% and urine protein/creatinine ratio 8,794 mg/g. Renal biopsy found FSGS, therefore the patient was initiated on prednisone. After 12 weeks of therapy and no reduction in proteinuria, the prednisone was tapered, and tacrolimus initiated. Within a few days the patient reported blurry vision and feeling dizzy. Blood tests revealed tacrolimus level of 2.3 ng/mL, glucose 493 mg/dL, SCr 1.99 mg/dL, carbon dioxide 20 mmol/L, triglycerides 2,866 mg/dL and HbA1c of 10.9%. She was admitted for treatment of HHS and Tacrolimus was stopped. Three months later her HbA1c was 5.4%.

**Discussion:** The risk of DM is well established with CNIs. Tacrolimus can reduce insulin secretion and contribute to insulin resistance. In the post-transplant population, Tacrolimus has been associated with a higher incidence of DM (16.6%) vs CSA (9.8%). In an analysis of the United States Renal Data System, data from primary renal transplant recipients who developed new onset DM following transplantation, found that over a 3-year posttransplant period, 58.3% developed at least one diabetic complication which included DKA in 8.1%, and HHS in 3.2%. There are multiple reports of patients who have developed DM due to the use of tacrolimus, when used as an immunosuppressant and preventative agent against organ rejection in patients that have presented with DKA or HHS. Although most of these cases have presented in patients with a kidney transplant, cases of liver, heart, lung, and bone marrow transplant have also been reported. There are also a small number of cases of sudden onset DKA in patients that have not received a solid organ nor a bone marrow transplant which is quite unusual. These cases include patients with polymyositis, interstitial pneumonia, aplastic anemia, lupus nephritis, FSGS and minimal change disease.

## PUB223

### Membranous Nephropathy Associated With Mantle Cell Lymphoma: A Case Report

Lauren Bernard,<sup>1,2</sup> Mohamed G. Atta,<sup>1</sup> John Sperati,<sup>1</sup> Celia P. Corona Villalobos,<sup>1</sup> Alan Y. Xu,<sup>1</sup> Avi Z. Rosenberg,<sup>1</sup> Steven Menez.<sup>1</sup> <sup>1</sup>*Johns Hopkins Medicine, Baltimore, MD;* <sup>2</sup>*Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

**Introduction:** The KDIGO 2021 Clinical Practice Guideline for the Management of Glomerular Diseases recommends age-appropriate cancer screening in patients with membranous nephropathy (MN). Computed tomography (CT) scanning of the chest, abdomen, and pelvis is typically not recommended in that screening paradigm. Here, we report a case of MN associated with mantle cell lymphoma diagnosed by pan-CT.

**Case Description:** A 63-year-old man with chronic untreated hepatitis B virus (HBV) developed fatigue, bilateral leg edema, nephrotic range proteinuria (15.8 g/24 hr), and microscopic hematuria (11-30 RBCs/hpf) over several weeks. Serological workup included normal or negative serum free light chain ratio, serum protein electrophoresis/immunofixation, C3/C4, ANA, ANCA, HIV, and HCV. Double-stranded DNA titer was borderline positive at 10 IU/mL (<10). HBV viral load was 37,000 copies/mL, and he was initiated on entecavir. Kidney biopsy was performed, with light microscopy showing mild focal mesangial hypercellularity. Immunofluorescence showed granular capillary wall and mesangial staining for IgG, IgA, IgM, C3, and C1q with ultrastructural confirmation of subepithelial electron dense deposits, consistent with MN. Staining was negative for PLA2R, NELL-1, and THSD7A. Age-appropriate screening for colon and prostate cancer was normal. A CT scan was then performed, revealing mediastinal, retroperitoneal, and superficial axillary lymphadenopathy. Lymph node biopsy established a diagnosis of mantle cell lymphoma. He was started on rituximab and bendamustine, achieving full remission. Proteinuria subsequently declined, with UPCR decreasing to 10.4, 4.6, and <1 g/g at 1, 3, and 6 months, respectively. While the patient received simultaneous treatment for his cancer and HBV, given his low-level viremia and PLA2R negativity, it was favored that his MN presentation was secondary to his lymphoma.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**Discussion:** The association of malignancy with MN is well-established. The optimal approach, however, to excluding malignancy in patients with MN remains incomplete. Mantle cell lymphoma is associated with a spectrum of immune complex mediated kidney disease, including MN. This case supports more aggressive cancer screening in the evaluation of patients with glomerular disease of unknown origin.

PUB224

Full-Blown Nephrotic Syndrome in a Fully Vaccinated Woman Following COVID-19 Infection

Alan Segal, Maine Medical Partners--Nephrology *MaineHealth, Portland, ME.*

**Introduction:** There have been a few cases of nephrotic syndrome reported after vaccination for COVID-19. When GFR is well-preserved, the majority of these patients have Minimal Change Disease (MCD). Here, we present a case of full-blown nephrotic syndrome in a fully vaccinated woman developing 6 weeks after she had a COVID-19 infection

**Case Description:** A 66-year-old woman with a 6 year history of well-controlled type 2 DM but no history of retinopathy, proteinuria, or kidney disease received the Pfizer-BioNTech vaccine x 2 in April 2021 and Pfizer booster in October 2021. She had an exuberant local reaction each time she had a vaccine. In January 2022, she suffered a COVID-19 infection and about 6 weeks later, she noted the onset of peri-orbital edema followed by progressive leg edema. At the time of evaluation 5 weeks later, she had pitting edema to the abdomen and sacral edema. Overall, she gained 30 pounds of edema. She had not used any new medications including NSAIDs. Labs showed serum [albumin] of 2.2 g/dL and serum [creatinine] of 0.92 mg/dL. A full serological work-up including serum free light chains and anti-PLA2R antibody was negative. Urine [albumin]:[creatinine] ratio increased from <30 mg/g in May 2021 to >22,000 mg/g in April 2022. A kidney biopsy was scheduled and the results are pending at the time of this writing.

**Discussion:** A number of glomerulopathies have been reported in vaccinated patients and those with COVID-19 infection. The majority of post-vaccination cases have been due to MCD, almost always developing within 10 days of receiving the vaccine. Although our patient had a severe local reaction to the 2 vaccines she received in April 2021, she did not have proteinuria in May 2021 and did not present with nephrotic syndrome until 6 weeks after a COVID-19 infection in January 2022. The kidney biopsy results are pending, but given her presentation and the few similar cases reported, it seems most likely she will have MCD triggered by immune dysfunction, dysregulation, or a circulating permeability factor affecting the podocytes. Of course, it is also possible that the development of her nephrotic syndrome was not related to her COVID vaccinations or infection.

PUB225

ANCA+ Glomerulonephritis: A Comparison of Epidemiology and Phenotype Before and After the COVID-19 Pandemic

Ian D. Brodka, Andrew Lee, Fatima Bawany, Ryan O'Connor, Tanzy Love, Hae Yoon Grace Choung, Catherine A. Moore. *University of Rochester, Rochester, NY.*

**Background:** ANCA-associated glomerulonephritis (ANCA-GN) is a complex disease with high risk of mortality and morbidity. Although the cause of disease is commonly not identified, infections and environmental exposures have been observed. The COVID-19 pandemic has increased concerns about immunologic risk, with post-vaccination diagnosis highlighted in several case reports. We aimed to evaluate the changes in incidence and clinical/histopathological profile of ANCA-GN over time, comparing a historical cohort to recent cases in the COVID era.

**Methods:** We conducted a retrospective review of patients with a pathologic diagnosis of ANCA-GN at the University of Rochester from 1/1/15 to 11/1/21. Data obtained included biopsy reports, laboratory findings, comorbidities, COVID vaccination status, and demographics. The 2015-2020 cohort was compared to the 2021 cohort.

**Results:** 65 subjects were included, including 54 from 2015-2020 and 11 from 2021, with a consistent incidence of 10-11 diagnoses per year. There was no significant difference in age, sex, race, or geographic region between cohorts, and no difference in histopathological findings. Clinical variables were similar between groups. Among the 11 subjects diagnosed in 2021, 6 received COVID vaccination before diagnosis, 2 were unvaccinated at diagnosis, and 3 were unknown. Two subjects received vaccination within 60 days of diagnosis and the remainder were >90 days from vaccination.

**Conclusions:** There was no significant difference in the incidence of ANCA-GN between the historical cohort of patients and those diagnosed in 2021. The histopathologic and biochemical profile did not differ significantly. There was no temporal relationship noted between vaccine timing and disease onset in the post-COVID cohort.

An Overlapping Case of Predominant Tubulointerstitial Lupus Nephritis and IgG4-Related Kidney Disease

Benjamin S. Horowitz, Lilian Saro-Nunez, Billie S. Fyfe-Kirschner, Jonathan Lebowitz. *Rutgers Robert Wood Johnson Medical School, Piscataway, NJ.*

**Introduction:** Lupus nephritis (LN) occurs in up to 50% of patients with systemic lupus erythematosus (SLE) and leads to significant morbidity and mortality, with up to 25% of proliferative LN patients having CKD-related mortality within 5 years. Occurring in two thirds of LN cases, Tubulointerstitial nephritis (TIN) is a key prognostic factor in LN and is associated with progression to ESRD, lower response to therapy, and development of hypertension. In LN, TIN rarely occurs in isolation, as it usually occurs with concurrent glomerulonephritis (GN). IgG4-Related Kidney Disease (IgG4-RKD) can also cause TIN and shares certain pathologic features with Lupus TIN. However, fewer than 5 cases of true overlap between these disorders have previously been reported.

**Case Description:** A 27-year-old man, without known medical history, presented with 3 months of fevers and arthralgias. Laboratory testing revealed a Creatinine (Cr) 7.2 mg/dl (unknown baseline), a positive ANA 1:1280, low C3 and C4, IgG4 215 mg/dl, and platelets 27. Urinalysis was significant for 55 RBCs/hpf and the urine protein to creatinine ratio was 1.396 mg/mg. Imaging revealed diffuse mediastinal and cervical lymphadenopathy. Renal biopsy showed TIN with dense lymphoplasmacytic infiltrate, storiform fibrosis, 14.3 IgG4-positive cells per high powered field, and “full house” immunoglobulin staining, with minimal mesangial hypercellularity and immune complex deposition. Kidney function improved with pulse dose methylprednisolone followed by a prednisone taper and mycophenolate mofetil, both of which were slowly tapered off by 18 months. However, the patient suffered a suspected relapse six months later, for which he received pulse dose methylprednisolone and was then restarted on prednisone and mycophenolate mofetil. Currently, the patient has stage 4 CKD, but is not on dialysis.

**Discussion:** The patient met both EULAR/ACR 2019 and SLICC 2012 criteria for SLE, as well as pathology consensus criteria and organ-specific criteria for IgG4-RKD. This case highlights that IgG4-RKD and LN can occur concurrently. Further research is needed to understand the pathogenesis and elucidate optimal treatment for such patients. This case highlights the need for research into the optimal treatment of LN patients with isolated or predominant TIN.

PUB227

Rituximab Dosing in Glomerular Diseases: A Narrative Review

Husam Alzayer,<sup>1,2</sup> Kuruvilla K. Sebastian,<sup>1</sup> Michelle M. O'Shaughnessy,<sup>1</sup> <sup>1</sup>Cork University Hospital, Cork, Ireland; <sup>2</sup>Saudi Arabia Ministry of Health, Arar, Saudi Arabia.

**Background:** Rituximab is increasingly prescribed for glomerular diseases. However, the recently published Kidney Disease Improving Global Outcomes (KDIGO) 2021 Clinical Practice Guideline for the Management of Glomerular Diseases lack details on recommended dosing regimens for most individual glomerular diseases. We performed this structured narrative review summarizing the evidence for rituximab dosing in glomerular disease to guide safe and effective prescribing in this setting.

**Methods:** The Pubmed search methodology was developed with a medical librarian and performed by the first, with review by a second, author. Randomized controlled trials (RCTs) and prospective cohort studies (PCSs) examining rituximab efficacy and/or safety

in ANCA associated vasculitis (AAV), membranous nephropathy (MN), lupus nephritis (LN), or podocytopathies (minimal change disease or FSGS) were included.

**Results:** Fifty-three studies (14 RCTs and 39 PCSSs) were included. We identified no fewer than 16 different rituximab dosing regimens studied as induction therapy for one or more of these five glomerular diseases (**Figure**). The most frequently studied rituximab induction regimens were 1,000mg as two doses two weeks apart (17 studies, 32%) and four doses of 375 mg/m<sup>2</sup>/week (18 studies, 33.9%). Twenty-six studies (49%) examined rituximab as monotherapy or in conjunction with steroids alone, while the remaining studies examined rituximab as part of combination immunosuppression.

**Conclusions:** Rituximab is a valuable treatment for glomerular disease. Adapting treatment to achieve B-cell depletion, with frequent evaluation of disease-specific biomarkers, might prove the optimal approach to achieving and maintaining remission.

Most frequently studied rituximab induction regimens, by number of studies

## PUB228

### Proteinuria Reduction in FSGS and IgAN: Are Nephrologists and Other Specialists Ready for a Change in Standard of Care?

Carole Drexel,<sup>1</sup> Emily Bixler,<sup>1</sup> Edgar V. Lerma,<sup>2</sup> Jai Radhakrishnan,<sup>3</sup> Rosanna Coppo,<sup>4</sup> Michael Cheung,<sup>5</sup> <sup>1</sup>PlatformQ Health, Needham, MA; <sup>2</sup>Associates in Nephrology, SC, Evergreen Park, IL; <sup>3</sup>Columbia University Medical Center, New York, NY; <sup>4</sup>Fondazione Ricerca Molinette, Torino, Italy; <sup>5</sup>KDIGO, Rego Park, NY.

**Background:** With the release of the 2021 KDIGO Practice Guidelines and a growing pipeline based on an improved understanding of disease progression and proteinuria regulation, the management of glomerular diseases (GD), such as focal segmental glomerulosclerosis (FSGS) and immunoglobulin A nephropathy (IgAN), is rapidly changing. Nephrologists (neph) and other providers (HCPs) have evolving roles, with an urgent need to recognize and treat patients early to reduce risk of transplantation.

**Methods:** Three 60-minute CME activities were held live from Feb to Dec 2021 and will remain on-demand for 1 year. Test questions were administered before and immediately after each activity. A follow-up survey on HCP behavior was sent to post-test respondents 2 months after completion. Responses were analyzed for engagement, lessons learned, and continuing gaps. Cohort analysis compared the performance of neph with the overall HCP population. Chi-square tests compared paired responses ( $P < 0.0001$ ; pre/post and pre/2 months).

**Results:** As of 5/3/2022, 4,835 HCPs (20% neph) had engaged. About 48% of neph said that 1%-15% of their patients had been newly diagnosed with GD. After participating in at least 1 activity, neph enhanced their knowledge and competence (pre- vs post-activity) regarding diagnosis (59% vs 91%), proteinuria regulation (47% vs 66%), KDIGO guidelines (43% vs 84%), and trial data on sparsentan (39% vs 82%). The performance of neph was higher than HCPs across all domains tested. On follow up, >90% of respondents said the education had a positive impact on their clinical practice and on patient experiences and outcomes.

**Conclusions:** Data support the positive impact of live and on-demand CME on ability of HCPs to adapt to the changing paradigm for proteinuria reduction in FSGS and IgAN management. Additional education is needed for neph on the dual roles of endothelin I and angiotensin II in kidney-function decline, and to reinforce KDIGO guidelines on goals of GD management and place of steroids in IgAN. Education for the larger group of HCPs can also enhance GD diagnoses, early recognition, and referrals.

**Funding:** Commercial Support - The CME was supported by Traveer Therapeutics.

## PUB229

### IgA Nephropathy With c-ANCA Positivity in a Patient With Crohn Disease

Kelly V. Liang, Kimberly P. Liang, Timothy A. Fields. *University of Kansas School of Medicine, Kansas City, KS.*

**Introduction:** IgA nephropathy (IgAN) is an immune complex glomerulonephritis (GN) characterized by glomerular deposition of IgA-dominant immune complexes, often accompanied by mesangial hypercellularity. Antineutrophil cytoplasmic antibodies (ANCAs) cause small-vessel vasculitis and pauci-immune crescentic GN. The coexistence

of ANCAs and IgAN is quite rare. ANCAs have been associated with inflammatory bowel disease (IBD) but are more prevalent in ulcerative colitis (~75%) than Crohn's disease (~17%). IBD-associated ANCAs are usually p-ANCA or atypical ANCA rather than c-ANCA. ANCA-associated vasculitis (AAV) can be associated with tumor necrosis factor-alpha inhibitors such as infliximab. We report a rare case of c-ANCA PR3-positive IgAN in a patient with IBD treated with infliximab who presented with proteinuria.

**Case Description:** A 27-year-old female with history of Crohn's disease since 2010 treated with infliximab, allergic rhinoconjunctivitis, mild asthma, erythema nodosum in June 2021 (resolved with prednisone), Charcot-Marie-Tooth disease, psoriasis, and COVID-19 disease in Oct 2021, was found to have positive c-ANCA (1:160) and PR3 (5.0 AI, reference <1.0) in Dec 2021, raising question of vasculitis. Her rhinosinusitis was well controlled with allergy medications without oral steroids. She was referred to Nephrology for proteinuria with urinalysis (UA) in April 2022 showing 2+ protein, 3+ blood, 2-10 WBC, 20-50 RBC. Urine protein/creatinine ratio was 1.9. She had foamy urine but no gross hematuria. She previously had UA with packed RBC in June 2021. Urogram showed non-specific bladder wall thickening. Cystourethroscopy was negative. In April 2022, her BP was 97/66 and she had no edema. A renal biopsy in May 2022 revealed IgAN (M0 E1 S1 T0 C0). She was started on lisinopril and fish oil.

**Discussion:** This is a very rare case of c-ANCA PR3-positive IgAN in IBD treated with infliximab. The patient's history of sinusitis along with c-ANCA PR3 antibody positivity suggested possibly an AAV associated with infliximab, which has been reported rarely in IBD. Her proteinuria of 1.9 g/day raised concern for GN due to pauci-immune AAV. However, renal biopsy showed IgAN rather than AAV. This case highlights the importance of renal biopsy in establishing a definitive diagnosis of glomerular disorders in patients with ANCA positivity, as serum ANCAs do not necessarily represent pauci-immune GN.

## PUB230

### Recovery of Infective Endocarditis-Associated Glomerulonephritis in a Pediatric Patient After Orthotopic Pulmonary Valve Replacement

Dalia Zubidat, Efrén Bernal, Lihong Bu, Cheryl L. Tran, Christian Hanna. *Mayo Clinic Minnesota, Rochester, MN.*

**Introduction:** Infective endocarditis (IE) associated glomerulonephritis (GN) is caused by immune-mediated glomerular injury, and treatment is mainly focused on eliminating the source of infection. Here, we describe a case of *Aggregatibacter actinomycetemcomitans* IE associated GN in a pediatric patient with congenital heart disease.

**Case Description:** An 8-year-old boy with Tetralogy of Fallot underwent a right ventricular outflow tract augmentation and new pulmonary artery valve creation. Six months after, he presented with *Aggregatibacter actinomycetemcomitans* endocarditis affecting mainly the pulmonary valve, non-oliguric acute kidney injury, hypertension, hematuria, and nephrotic range proteinuria. Immunological workup showed low complement proteins C3 and C4, elevated ANCA titers (1:320), negative MPO, PR3, anti-GBM antibody, ANA, anti-DNAse B, and ASO. A percutaneous native kidney biopsy was performed and showed proliferative GN suggestive of IE-induced GN (Figure 1). Due to failure of medical therapy, including a prolonged IV antibiotic course, and ongoing active glomerular disease, he underwent an orthotopic pulmonary valve replacement 4 months after his IE presentation resulting in a rapid improvement in his glomerular disease and near-complete recovery on follow up 4 months after valve replacement, except mild microscopic hematuria and proteinuria (Table 1).

**Discussion:** Surgical intervention can be considered an effective treatment in patients with IE-associated GN in cases refractory to medical therapy.

Figure 1.

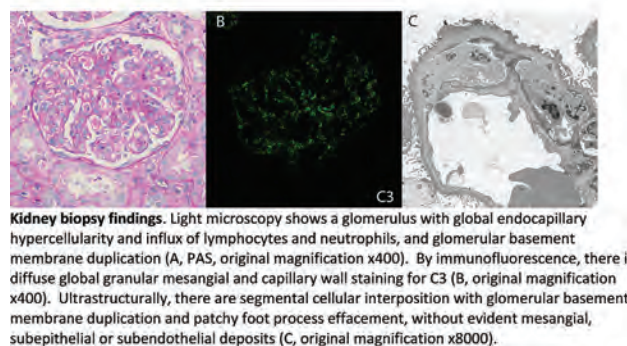

Figure.1

Table 1.

Laboratory studies	At kidney biopsy	Prior to valve replacement	2 weeks post-replacement	4 months post-replacement	Reference Range

**Renal IgA Deposits in Cirrhosis, Innocent Bystander to Rapidly Progressive GN: A Case Report**

Nitpriya Paliwal, Christopher Canfield, Sandeep Aggarwal. *University of Pennsylvania, Philadelphia, PA.*

**Introduction:** Cirrhosis is associated with renal mesangial IgA deposits thought to be due to reduced immune complex hepatic clearance but associated rapidly proliferative Glomerulonephritis (RPGN) is uncommon. We present a case of IgA predominant RPGN in a cirrhotic patient.

**Case Description:** 36 y/o M with PMHx of psoriasis, ETOH cirrhosis, strong family h/o FSGS presented with AKI along with nephrotic syndrome & microscopic hematuria. Labs: Serum cr: 4.3 mg/dl, UPCR -13 gm/gm, Una <10, Ucr: 153, CK - 409, INR - 1.2, WBC - 6200/ cum, hb - 6.8 gm/dl, Sr albumin -1.7 gm/dl Urine microscopy: Multiple dysmorphic rbcs & RBC casts Imaging: Renal US without hydronephrosis, TTE revealed no obvious valvular abnormalities or no intra-cardiac vegetations or thrombus. Significant serologies: negative for HIV, viral hepatitis panel, SPEP with immunofixation, Anti-gbm ANA, Anti-ds dna, anca, ASLO and RF, quantiferon gold, covid-19, INR -1.2 cryocrit negative. Low complement c4 (17mg/dl) with c3 (94mg/dl). Clinical course: Given Cirrhosis & low urine Na; albumin based volume resuscitation & HRS protocol was attempted with no improvement. Urine microscopy findings prompted us to do renal biopsy. Biopsy: LM, 12 glomeruli, 3 globally sclerosed: Diffuse, global endocapillary and mesangial hypercellularity. No crescents or microthrombi Glomerular capillary walls with double contours and fuchsinophilic material within mesangial, subendothelial and epimembranous areas. IF: capillary wall and mesangial immunostaining: Ig-A 3+, IgG: 1+, IgM: 1+, C3: 3+, C1q: trace, kappa: 2+, lambda: 3 + EM: 1 glomerulus: Extensive subendothelial expansion + subendothelial/mesangial immune-type deposits & associated cellular interposition. Intramembranous/subepithelial hump-like deposits. No tubuloreticular inclusions. 70% podocyte foot process effacement. Patient diagnosed with Ig A predominant MPGN & was treated with solumedrol x 3 and started on steroid taper along with celcept and discharged home with improvement in creatinine and proteinuria.

**Discussion:** Immune complex glomerular disease in cirrhotic patients can be of varied etiology. Although common, renal IgA deposition in cirrhotic patients are of unclear clinical significance. Larger scale clinicopathological studies are needed to understand the risk factors for development of clinically significant glomerulonephritis in cirrhosis.

## PUB232

**IgA-Dominant Postinfectious Glomerulonephritis, the Other Side of the Coin: Case Report**

Rodolfo A. Moreno,<sup>1,2</sup> Guillermo Navarro Blackaller,<sup>5,3</sup> Kevin A. Solis,<sup>4</sup> Werner De León,<sup>4</sup> Jorge A. Hernández,<sup>1,2</sup> Jonathan Chavez,<sup>5,3</sup> <sup>1</sup>Centro Medico Militar, Guatemala, Guatemala; <sup>2</sup>Universidad Mariano Galvez de Guatemala Facultad de Ciencias Medicas y de la Salud, Guatemala, Guatemala; <sup>3</sup>Universidad de Guadalajara, Guadalajara, Mexico; <sup>4</sup>Universidad de San Carlos de Guatemala Facultad de Ciencias Medicas, Guatemala, Guatemala; <sup>5</sup>Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico.

**Introduction:** Postinfectious glomerulonephritis (PIGN) is a disease presented as nephritic syndrome with hypocomplementemia usually secondary to a skin or throat infection by B-hemolytic Streptococcus and with biopsy findings of endocapillary proliferation, C3 deposits along the capillary wall and mesangium, subepithelial immune complex deposits and IF positive for IgG. There are other unusual presentations of PIGN with IgA dominance or C3-IgA codominance.

**Case Description:** A 58-year-old Guatemalan male with history of consumption of 10 beers/month for 40 years. No other medical history. During hospitalization for diagnosis of cholangitis presented a lower-limb cellulitis, for which clindamycin was started. Blood cultures were taken and were positive for *S. epidermidis* and AKI (Cr 2.84mg/dl) was observed, associated with de novo appearance of hematuria (80% acanthocytes), proteinuria (580mg/day) and hypertension. Diagnostic approach for nephritic syndrome was performed obtaining: low C3 0.592, ANA, ANCA, HIV-HCV-HBV negative, total cholesterol 184mg/dl, albumin 2.78g/dl. Renal biopsy was performed and reported: PIGN with IgA dominance with extra capillary proliferation. Reason why pulses of methylprednisolone were given for 3 days and then oral prednisone (1mg/kg/day), tapered until suspended. The soft tissue infection resolved and was discharged. At 1-month follow-up evaluation was evidence of a 50% decrease in proteinuria compared to baseline, disappearance of hematuria but with persistence of high SCr (2.09mg/dl).

**Discussion:** IgA-dominant PIGN is characterized by usually presenting in patients >60 years with DM, alcohol consumption and staphylococcal skin infections. It can present low complement and biopsy findings are characterized by IgA dominance over C3 and no IgG in IF. Elevated serum IgA levels may be involved in the pathogenesis. Treatment is based on eradication of the infection with antibiotics and in some cases the use of steroids is suggested depending on the aggressiveness of the lesion and the presence of crescents in the renal biopsy. It has worse prognosis than the traditional PIGN.

## PUB233

**Kidney Biopsies During the COVID-19 Outbreak: A Series of Cases**

Eliana Dina-Battle,<sup>1,2</sup> Hector A. Pantaleon,<sup>1</sup> Nicole M. Suárez,<sup>1</sup> Cindy S. Valera Saleta,<sup>1</sup> Eliana Bencosme,<sup>1</sup> <sup>1</sup>Hospital Metropolitano de Santiago, Santiago De Los Caballeros, Dominican Republic; <sup>2</sup>Pontificia Universidad Catolica Madre y Maestra, Santiago de los Caballeros, Dominican Republic.

**Background:** Kidney disease due to COVID-19 has been described with several presentations, both in acute phase and in posterior timing of the infection, and kidney biopsy is important for an ideal management. But the process of adequately perform a biopsy during the pandemic entails risks, as being the exposed and infected by the SARS-CoV-2. Besides of the usual potential complications, such as post-biopsy hemorrhage, that may require admission in an already crowded medical structure. For these reasons, attainment of kidney biopsies was limited to those who without an adequate histopathological diagnosis, were at higher risk of inappropriate management, as well as a pathology secondary to the SARS-CoV-2 could be ignored. The aim of this study is to perform a description of the cases biopsied during the SARS-CoV-2 pandemic, being emphasized those whose indication emerged because of the viral infection.

**Methods:** Descriptive study of the clinical presentation in addition to histopathological findings of cases requiring kidney biopsy during the period of March 2020 - July 2021.

**Results:** A total of 37 cases were collected, with a median age of 40 years (range: 60), 51% males and 73% with known history of hypertension. A 35% of the cases presented nephrotic syndrome; with average proteinuria of 4189.5mg/24h. The most frequent histopathological diagnosis was focal segmental glomerulosclerosis (FSGS), accounting for 40% of the cases. 4 patients required biopsy after COVID-19. One of them presented with Acute Kidney Injury (AKI) during the acute phase of the SARS-CoV-2 infection with prolonged hemodialysis requirement; presenting histopathological diagnosis of global and segmental glomerulosclerosis. Another case of AKI during the acute phase of infection and subsequent proteinuria presented global and segmental glomerulosclerosis with collapsing characteristics; while 2 cases due to nephrotic syndrome post-infection, presented histological data of minimal change disease and FSGS with acute tubular injury.

**Conclusions:** Regardless of the appearance of a new pathology that affects the kidneys, the incidence of entities such as FSGS persists with greater frequency. However, that does not diminish the importance of performing renal biopsies, since this is an essential tool for management in cases where there is overlap of specific glomerular diseases with COVID-19.

## PUB234

**FSGS Recurrence: Status Report on a New International Collaborative**

Eloise Salmon,<sup>1</sup> Abhijit S. Naik,<sup>1</sup> Alessia Fornoni,<sup>2</sup> Hailey Desmond,<sup>1</sup> Rasheed A. Gbadegesin,<sup>3</sup> Matthias Kretzler,<sup>1</sup> Leonardo V. Riella,<sup>4</sup> Howard Trachtman,<sup>1</sup> Debbie Gipson,<sup>1</sup> <sup>1</sup>University of Michigan Michigan Medicine, Ann Arbor, MI; <sup>2</sup>University of Miami, Coral Gables, FL; <sup>3</sup>Duke University School of Medicine, Durham, NC; <sup>4</sup>Massachusetts General Hospital, Boston, MA.

**Background:** Recurrent FSGS post-kidney transplantation occurs in nearly 20-60% of patients with devastating effects on graft and patient survival. The risk of recurrence increases with each subsequent transplant procedure. This phenomenon represents a scientific and therapeutic challenge because it is an unexpected complication and occurs in a setting in which clinical research is difficult to implement. In order to improve our understanding of FSGS recurrence, a multidisciplinary conference was organized to explore the pathogenesis, current treatment, and potential therapeutic options for this serious condition.

**Methods:** A two-day virtual meeting was convened in December 2021. The participants included clinicians, basic scientists, epidemiologists, bioinformaticians, patients, and patient advocacy group representatives. The conference was divided into the following thematic areas: (1) the state of the problem; (2) use of genetics as a research accelerator; (3) identifying disease pathways: podocyte and beyond; (4) identifying disease pathways and modifiers; (5) exploring disease mechanisms: methodology; and (6) therapy development & rare disease trial design.

**Results:** The session format was split to allow presentation followed by moderated discussion. Each session in the symposium included 3-4 presentations by experts in the field that highlighted the scope of the problem existing knowledge, key gaps, and future opportunities.

**Conclusions:** The FSGS Recurrence Collaborative represents an important effort to gather the intellectual and practical knowledge and experience that will be needed to improve our understanding of this severe complication of kidney transplantation. It is hoped that bringing this interdisciplinary expertise in glomerular disease together will stimulate innovative ideas and original approaches to treatment of FSGS recurrence.

## PUB235

**Clinical-Pathological Features of Repeat Renal Biopsies in Patients With Refractory Nephrotic Syndrome**

Xinyuan Cui,<sup>1,2</sup> Shuguang Yuan,<sup>1</sup> Xuejing Zhu,<sup>1</sup> Yifu Li,<sup>1,2</sup> <sup>1</sup>The Second Xiangya Hospital of Central South University Department of Nephrology, Changsha, China; <sup>2</sup>Renal Research Institute of Central South University, Changsha, China.

**Background:** Refractory nephrotic syndrome is a subset of nephrotic syndrome with pathological conditions resistant to the treatment using corticosteroids and other immunosuppressives for six months or more. Patients who had these underlying

conditions had poor clinical outcomes in general. In addition, the pathological changes associated with the progress of the disease were not fully understood.

**Methods:** This retrospective study was on patients with refractory nephrotic syndrome undergoing repeat renal biopsies between August 2011 and June 2021 from a single center in Changsha, China. Relevant clinical and histological records of patients with repeat renal biopsies were documented. In addition, a comparison of data from the first and second renal biopsies was performed.

**Results:** This study included ten cases with complete clinical and histological records. Each case had a poor response to corticosteroids and other immunosuppressive agents and poor clinical outcomes for at least six months. The ages of the first and second renal biopsies were  $28.9 \pm 13.1$  and  $31.5 \pm 13.6$  years, and the mean biopsy interval was  $2.6 \pm 2.4$  years. The first pathological diagnosis included: three cases of membranoproliferative glomerulonephritis, two cases of crescentic glomerulonephritis and minimal change glomerulonephritis, and one case of IgA nephropathy, Henoch-Schönlein purpura nephritis, and Idiopathic nodular glomerulosclerosis. After comparing the data at the first and second renal biopsies, the results showed that: (1) The renal function had worsened compared with the baseline at the first renal biopsy; serum creatinine increased significantly ( $234.5 \pm 183.3$  vs.  $411.9 \pm 364.3$  mmol/L,  $p < 0.05$ ). (2) Major pathological features had not changed significantly, and only one case had changed the diagnosis from minimal change glomerulonephritis to focal segmental glomerulosclerosis. (3) An increasing percentage of global glomerulosclerosis and segmental sclerosis had been found compared to the first renal biopsy ( $19.0 \pm 24.3$  vs.  $42.2 \pm 28.9\%$ ,  $p < 0.05$ ). (4) Other immunofluorescences staining for IgG, IgA, IgM, Fibrin, C1q, and C3 had no significant changes.

**Conclusions:** The disease progresses of refractory nephrotic syndrome is associated with the severity of glomerular sclerosis. Therefore, the value of repeat renal biopsies for refractory nephrotic syndrome may be limited.

## PUB236

### Desires and Needs of Dutch Atypical Hemolytic Uremic Syndrome Patients and Relatives

Romy N. Bouwmeester, Nicole Van De Kar. In collaboration with the Dutch Kidney Patient Association *Radboud UMC, Nijmegen, Netherlands*.

**Background:** Atypical hemolytic uremic syndrome (aHUS) is a rare and severe form of a thrombotic microangiopathy (TMA). Our knowledge in the biochemical and genetic mechanisms of aHUS is continuously increasing, resulting in the development of targeted treatments such as eculizumab. The improved outcome perspectives and switch to a restrictive eculizumab treatment strategy could be considered life changing for aHUS patients. However, little is known on individual experiences, needs and desires of atypical HUS patients and their relatives.

**Methods:** This is a nationwide, exploratory, qualitative interview study with a direct content analysis approach. In-depth interviews and a six-week evaluation were audio-recorded and semi-structured. A topic guide included the Institute for Positive Health (IPH) model, which contains six domains of health on a subjective scale.

**Results:** Thirteen interviews with five aHUS patients and fourteen relatives were conducted after which data saturation was obtained. Long-term disease symptoms (e.g. fatigue) are present in the majority of patients and negatively influence bodily and daily functioning. The resilience of both patients and relatives is remarkable. However, despite a high rate of acceptance, among others the (potentially traumatic) acute phase of aHUS and the unpredictable possibility of disease recurrence have a lasting impact on mental well-being. Support is essential yet to be improved by increasing the accessibility of psychological support in aHUS healthcare and the availability of more comprehensible information.

**Conclusions:** A new era should begin, as we strive to further optimize health care for aHUS patients while focusing on the person and not only the disease. These insights in the actual needs and desires of Dutch aHUS patients and their relatives will help optimize and personalize aHUS health care. In addition, this study can be an example of a more personalized approach in both research and health care of other rare kidney diseases.

## PUB237

### Adult Primary Podocytopathy in Southeast Asia: Clinicopathological Characteristics, Treatment-Associated Toxicities, and Outcomes

Ru Sin Lim,<sup>1</sup> Chye Chung Gan,<sup>2</sup> Geraldine Boh,<sup>1</sup> Soo Ying Yew,<sup>2</sup> Shok H. Ooi,<sup>2</sup> Soo Kun Lim,<sup>2</sup> See Cheng Yeo.<sup>1</sup> <sup>1</sup>Tan Tock Seng Hospital, Singapore, Singapore; <sup>2</sup>University of Malaya Medical Centre, Kuala Lumpur, Malaysia.

**Background:** Glucocorticoid remains the treatment of choice in adult primary podocytopathy (Minimal Change Disease, MCD and Focal Segmental Glomerulosclerosis, FSGS). The use of steroid-minimization strategy to minimize toxicity has not been well studied. We aim to study the efficacy and safety of glucocorticoid minimization (IV Methylprednisolone 500mg daily for 3 days followed by Prednisolone 0.5-0.7mg/kg/day) versus high dose glucocorticoid (Prednisolone 1mg/kg/day) regimen for the treatment of newly diagnosed adult primary podocytopathy in Singapore (Tan Tock Seng Hospital, TTSH) and Malaysia (University Malaya Medical Center, UMMC).

**Methods:** Patients with newly-diagnosed renal biopsy proven MCD and FSGS at TTSH and UMMC from 01/01/2011 till 31/12/2021 were included in this study. Exclusion criteria include that of age  $< 18$  years old, follow up duration of  $< 3$  months, or development of End Stage Kidney Disease (ESKD) which precludes the use of immunosuppressants. The remission rate and treatment-related toxicities between the 2 cohorts will be compared and analyzed.

**Results:** A total of 58 (36 MCD, 22 FSGS) and 34 (30 MCD, 4 FSGS) patients were included from TTSH and UMMC respectively. Compared to UMMC cohort, TTSH cohort is older (mean age in years  $\pm$  standard deviation, SD is  $51.5 \pm 21.5$  vs  $32.5 \pm 16.6$ ,

$p < 0.001$ ), more patients present with edema 54 (93.1%) vs 26 (76.5%),  $p = 0.029$ , with heavier proteinuria (mean proteinuria  $11.2 \pm 5.8$  g/day vs  $5.9 \pm 3.9$  g/day,  $p < 0.001$ ), and better baseline renal function mean eGFR ( $81.5 \pm 36.8$  ml/min per  $1.73 \text{ m}^2$  vs  $97.7 \pm 35.0$  ml/min per  $1.73 \text{ m}^2$ ,  $p = 0.041$ ). The starting prednisolone dose is higher for TTSH in relation to UMMC cohort (mean dose  $\pm$  SD is  $62.0 \pm 11.0$  mg/day vs  $39.1 \pm 9.8$  mg/day,  $p < 0.001$ ). There is no difference in terms of complete remission (60.4% vs 70.6%), partial remission (24.1% vs 14.7%) and steroid resistance (15.5% vs 14.7%),  $p = 0.602$  in TTSH and UMMC cohorts respectively. No difference was observed with regards to median days (interquartile range, IQR) to achieve remission, 41 (25.5-94.5) days in TTSH vs 56 (27-84) days in UMMC,  $p = 0.452$ . There is no significant treatment-related toxicity difference observed in the 2 cohorts.

**Conclusions:** Glucocorticoid minimization strategy appear to be efficacious and safe in adult primary podocytopathy.

## PUB238

### CT-Guided Kidney Biopsy by Interventional Nephrologists

Mohamed A. Rahil, Jean Michel Marc, Carole Deprele, Ophélie Baudoin, Agnes Delay, Eric Legrand. *Centre hospitalier d Ardeche Nord, Annonay, France*.

**Background:** Histopathology of renal parenchyma is the key diagnostic for kidney disease treatment. Generally, the act is simple under US guidance, but when the kidney size is small or for obese patients, this act could be a real challenge with more risk of complications. In Annonay Hospital (France) all renal biopsies are done by a CT guidance. We report a retrospective study of 123 patients who have had a CT guided kidney biopsies by interventional nephrologists.

**Methods:** Between January 2016 and June 2020, 123 CT guided kidney biopsies were performed at Annonay hospital in France. 77 man, and 46 women. The mean age was 64 years, the mean BMI was 26.54. The patient was installed in prone position. Preliminary CT images at 5-mm axial slices covering the entire length of the kidney are obtained. A metallic mark is placed at the right side of the back to localize the entrance skin site. A local anesthetic agent is then injected. A 16-gauge core biopsy is introduced following exactly the calculating depth. Once two samples are acquired, postprocedure images are obtained to assess major complications.

**Results:** Renal parenchyma is obtained in all patients (100%), over 123 biopsies, 121 presented between 1 to 48 glomerulus (98.37%), 2 biopsies presented a medulla tissue (1.62%), 97 patients (78%) presented a perinephric hemorrhage more than 1 cm in postprocedure images. 15 patients presented a macroscopic hematuria (12.19%). One patient required renal embolization for an expansive perinephric hemorrhage.

**Conclusions:** The CT guided renal biopsy is a precise and rapid technic to have a renal parenchyma with a failure rate bordering 0%, but the cost and the radiations rate should be compared with the other methods.

## PUB239

### Clinical Study on the Therapeutic Effect of Englitazone on Urinary Protein in Patients With IgA Nephropathy

Qin Y. Du, Sheng Xiao, Fei F. Jiang, Fei Deng. *Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China*.

**Background:** In this study, irbesartan and englitazone were used in IgA nephropathy patients with urinary protein, and comparing the therapeutic effect of englitazone with irbesartan, on IgA nephropathy urinary protein. The adverse reactions of IgA nephropathy patients were recorded during the treatment, so as to bring new therapeutic strategies for IgA nephropathy.

**Methods:** 1. From January 2020 to January 2022, 40 patients with proteinuria more than 300mg/24h were confirmed as primary IgA nephropathy according to Oxford classification have been done the underwent renal biopsy in Sichuan Provincial People's Hospital or Jinniu District People's Hospital. They were the research subjects, and 20 patients were in each group. Group A (control group) : SGLT2 inhibitor (Englitazone, 10 mg/ tablet), one tablet daily after breakfast for 24 weeks; Group B (control group) : RAAS blocker (irbesartan), 150 mg/ tablet, one tablet daily after breakfast for 24 weeks. 2. Body temperature, pulse, respiration, systolic blood pressure, diastolic blood pressure, blood routine, urine routine, liver function, serum creatinine, urea nitrogen, urinary microalbumin to creatinine ratio,  $\beta_2$ -microglobulin, cystatin C, and hypoglycemic events were observed before treatment and at the week 8<sup>th</sup>, 12<sup>th</sup>, 24<sup>th</sup> after treatment.

**Results:** 1. There were no significant differences in general clinical data and observation indicators between the two groups at baseline ( $P < 0.05$ ). 2. There was statistically significant difference in proteinuria between 2 groups before and after treatment ( $P < 0.05$ ). 3. After treatment, there was statistically significant difference in urinary protein between group A and group B within 8<sup>th</sup> after the treatment ( $P < 0.05$ ),

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

but there was no difference within 12<sup>th</sup>, 24<sup>th</sup> after the treatment (P > 0.05). There were no statistically significant differences in blood routine, liver function, serum creatinine, urea nitrogen and β2-microglobulin between group A and group B after treatment (P > 0.05); there were statistically significant differences in blood pressure between group A and group B after treatment (P<0.05); there were no statistically significant differences in blood glucose between group A and group B after treatment (P<0.05).

**Conclusions:** Application of SGLT2 inhibitor in early IgA nephropathy can reduce urinary protein and stabilize renal function, and the safety is quite well.

PUB240

Complement Mediated Hemolytic Uremic Syndrome After an Egyptian Vacation

Evgueni M. Minev,<sup>1</sup> Jamey E. Eklund,<sup>2</sup> <sup>1</sup>Nephrology Associates Of Northern Illinois and Indiana, Mount Prospect, IL; <sup>2</sup>Medical College of Wisconsin, Milwaukee, WI.

**Introduction:** Thrombotic microangiopathy (TMA) is characterized by intravascular hemolysis, low platelets, CNS & renal pathology. TTP is caused by congenital or acquired ADAMTS-13 deficiency, resulting in large vWF multimers and creation of platelet-rich thrombi. Enterohemorrhagic colitis causes HUS via shiga toxin, while complement dysregulation is an increasingly recognized cause of hemolytic-uremic syndrome (cHUS).

**Case Description:** A 24 year-old previously-healthy man presented with 3 days' of bloody diarrhea, fever and abdominal cramps after returning from a 7-day trip to Egypt. He stayed in a hotel and ate meat in restaurants. He received ciprofloxacin but developed a rash, so he was then given IV Bactrim, Flagyl, and saline. Colonoscopy revealed presumed infectious pseudomembranous hemorrhagic colitis. On day 6 of symptoms, he developed AKI, thrombocytopenia, and anemia so nephrologist was consulted and TMA diagnosed. Labs listed below. Daily plasmapheresis with FFP replacement was started. Once ADAMTS13 resulted, PLEX was stopped. The patient suffered seizures and transient cortical blindness. Treatment with eculizumab was initiated with immediate symptom improvement, and complete recovery in 3 months. Genetic complement testing revealed one abnormal allele in exons 4 & 5 of CFHR5 gene. Eculizumab was successfully weaned after 6 months (monitoring by daily UA, weekly labs, CH50 monthly), and the patient remains in remission 3 years later.

**Discussion:** The majority of cHUS is mediated by abnormal regulatory factors (CFH, CFI, MCP); activation factors (C3 & CFB); and coagulation related factors (DGKE, THBD, PLG). Our patient had 2 abnormal alleles in the CFHR5, gene c622T>C, p.Cys208Arg in exon 5 and c480\_481insA located in exon 4. While these mutations are described as variants with unknown significance (VUS), carriers of the double-mutated CFHR5 alleles have lower CFHR-5 levels. It is likely that the initial hemorrhagic colitis inflammatory milieu overwhelmed and shifted the alternative complement pathway into activated mode, leading to severe HUS, which improved only after eculizumab therapy.

Labs

Serum	Stool	Complement
Platelets 19	(-) Shiga toxin PCR	C3 70
Creatinine 3	(-) Shigella	C4 8
(++) Schistosomites	(-) E Coli O157:H7	CH50 79
Haptoglobin <7.8		C5-9 524
LDH 796		CFH 19.6
ADAMTS13 activity 63%		

PUB241

The Gut: A Giant Nephron!

Jennifer Bergeron, Agnes B. Fogo, Julia Lewis. Vanderbilt University Medical Center, Nashville, TN.

**Introduction:** Anti-glomerular basement membrane (anti-GBM) disease is a rare pulmonary-renal syndrome in which α3(IV)NC1 autoantibodies bind to the GBM in the lung and kidneys to cause severe deterioration in renal function and life-threatening lung hemorrhage. Here we report an indolent form of anti-GBM disease causing a severely elevated creatinine.

**Case Description:** A 27-year-old Caucasian man with class II obesity and average muscle mass presented with 3 weeks of upper respiratory infection symptoms, 3 days of dyspnea, scant hemoptysis, peripheral edema, and progressive oliguria after having worked as a mechanic that day. Surprisingly, serum creatinine (SCr) was 36.3mg/dL with BUN 160mg/dL, potassium 6.8mg/dL, bicarbonate 11mg/dL, phosphorus 9.1mg/dL, albumin 2.6mg/dL, and hemoglobin 4.4mg/dL. Chest CT revealed diffuse ground glass opacities in both lungs with subpleural sparing consistent with pulmonary hemorrhage. Serologic work up included normal CPK, negative ANCA, and anti-GBM titer of 225. Kidney biopsy showed 3 of 26 glomeruli globally sclerosed and 16 with early fibrocellular crescents, 10-20% diffuse early interstitial fibrosis, and 3+ diffuse global linear staining along capillary loops for IgG by IF, diagnostic of anti-GBM mediated glomerulonephritis. He was treated with 3 days of IV steroids then a prednisone taper, plasmapheresis (14 days), and cyclophosphamide 0.8mg/kg/day. He required CRRT then HD before switching to PD, on which he remains. He has had no signs of renal recovery and his titers have been normal for 3 months.

**Discussion:** Patients with anti-GBM disease can present late in their disease course as they can be asymptomatic, or with symptoms related to anemia or a mild upper respiratory illness. SCr is a function of the generation of creatinine by muscle and its renal and extrarenal excretion. With an average creatinine generation of 20mg/kg/day, without renal excretion SCr will rise about 1mg/dL per day, suggesting that this patient had a prolonged time with a marked reduction in GFR before presentation. With severely

reduced GFR, nonrenal creatinine clearance by gut flora creatininases can account for 2-4ml/min, resulting in a maximum SCr of 35-40mg/dL in the average muscle massed human, as we saw in this patient's steady state SCr of 36 before dialysis. This patient has the highest creatinine reported in anti-GBM disease (previously SCr 21). As expected, such a high SCR predicted a poor renal prognosis.

PUB242

Outcome of Conservative Management Strategy for Fibrillary Glomerulonephritis

Saira Sajid, Katerina Hysi, Jean H. Ancion, Dina R. Al-Tuhafy, James Drakakis. NYU Langone Hospital - Long Island, Mineola, NY.

**Introduction:** Fibrillary glomerulonephritis (GN) is an immune complex GN with amyloid like fibrils (larger than those in amyloid) which are IgG positive and Congo red negative. It is a rare entity, diagnosed in 0.5-1.0% of native kidney biopsies. The usual presentation is proteinuria, hematuria and hypertension in middle aged to older adults. Frequently, there is an association with hepatitis C infection. DNAJB9 detection in biopsies has been reliable for the diagnosis. The outcome is poor with progression to ESRD occurring in 50% of patients within a few years of diagnosis. There are no well established treatment options, though there have been reports of Rituximab stabilizing disease progression.

**Case Description:** 88 year old female with hypertension who upon returning to the US after residing in Italy, was found to have 3+ protein on urinalysis (UA). Subsequent UA was consistent, despite being on Valsartan. Initial urine protein quantification 4.6 g/g. Serum albumin was relatively preserved and creatinine 1.4 - 1.5 mg/dL. Imaging revealed kidney size to be normal, with bilateral parapelvic cysts. Basic serologies were negative. Kidney biopsy was done revealing fibrillary glomerulonephritis, with mesangial proliferative features. Strongly positive glomerular staining for DNAJB9. There were no signs of endocapillary proliferation or cellular crescents. 50% tubular atrophy and interstitial fibrosis. Offered trial of immunosuppression (with Rituximab), which was declined. Over the next nearly 2 years, proteinuria remained nephrotic spectrum, but renal function held steady and without change.

**Discussion:** Most studies of fibrillary GN cite poor renal outcomes. Age, degree of proteinuria at the time of biopsy and amount of fibrosis have all been listed as negative predictors of renal outcomes. In some reports, Rituximab has been associated with non progressive chronic kidney disease, although literature overall suggests there is no clear benefit of immunosuppression. Our case is illustrative in that it outlines the course of an 88 year old female with fibrillary GN (not related to hepatitis C or monoclonal protein) treated conservatively. Over the span of 2 years from diagnosis, her proteinuria remains 4-5 g/g while Cr is unchanged at 1.4 - 1.6 mg/dL. More data need be gathered on which factors render the patient most likely benefit from immunosuppression.

PUB243

Anti-PLA2R Autoantibodies and Clinical Activity in Patients With Primary Membranous Nephropathy

Vinod Kumar,<sup>1</sup> Deeksha Pal,<sup>1</sup> Krishan Lal L. Gupta,<sup>1</sup> Vivekanand Jha,<sup>2</sup> Raja Ramachandran.<sup>1</sup> <sup>1</sup>Post Graduate Institute of Medical Education and Research, Chandigarh, India; <sup>2</sup>The George Institute for Global Health India, New Delhi, India.

**Background:** Two-thirds primary membranous nephropathy (PMN) patients have M-type Phospholipase A2 receptor autoantibodies (anti-PLA2R Abs). Change in circulating anti-PLA2R Abs can serve as a predictor of treatment response. We examined the temporal association of anti-PLA2R Abs with a clinical response among a cohort of patients with PMN

**Methods:** We enrolled consecutive treatment naïve or relapsing PMN patients who were treated with immunosuppressive therapy. Serum anti-PLA2R Abs were evaluated at baseline, 3, 6 & 12 months using a Euroimmune ELISA kit (Lübeck, Germany). Clinical response was defined as per the KDIGO2021 guidelines; complete remission(CR): proteinuria reduction to <0.3g/d, stable serum albumin and creatinine >3.5g/dl; Partial remission(PR): proteinuria reduction to 0.3-3.5g/d and a decrease of >50% from baseline. Patients were followed up for 18 months

**Results:** A total of 64 patients (44 males & 20 females) were enrolled in the study. The mean age, baseline proteinuria, serum albumin, creatinine, and anti-PLA2R Abs was 40±13.8 yrs, 8.63±5.17 g/day, 2.3±0.69 g/dl, 0.90±0.43 mg/dl, and 250.29±243.09 RU/ml, respectively. At the end of follow-up, 49 patients (76.5%) had achieved clinical remission (CR; n=14). Baseline anti-PLA2R Abs titers were 168.8(127.3,197.6), 204.7(64.8,332.2) and 370(129.2,481.1) RU/ml respectively in complete, partial or no response patients. There was 98% and 69% reduction in anti-PLA2R at 12 months as compared to baseline in CR/PR and resistant group, respectively (**Figure**). Patients with the resistant disease had a resurgence of antibodies at 12 months. Serological remission preceded clinical remission, and persistence or resurgence of antibodies at 12 months was associated with resistant disease.

**Conclusions:** Patients with PLA2R-associated PMN had a significant reduction in anti-PLA2R Abs with treatment which preceded clinical response. Persistence of anti-PLA2R Abs at 12 months is strongly associated with clinical activity.

## PUB244

**Atypical Presentation of Kidney Involvement in Sjögren Syndrome**

Karina Chimbo Lituma, Julio C. Nieto, Claudia B. López, Carolina Gonzalez-Fuentes, Guillermo E. Ramírez Garcia, Mario Alamilla Sanchez, Julio Manuel Flores Garnica, Faustino J. Silva Centeno, Regina C. Hernandez, Victor M. Ulloa Galvan. *Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Mexico City, Mexico.*

**Introduction:** Primary Sjögren's syndrome (pSS) is an autoimmune disorder that mainly affects the exocrine glands. Kidney involvement is manifest by proteinuria and defects in tubular function. Renal biopsy confirms the presence of tubulointerstitial nephritis, this is the most common presentation of kidney disease, glomerulonephritis is an infrequent presentation.

**Case Description:** 51-year-old female with pSS diagnosed 10 years ago by biopsy, with glandular manifestations. 1 month before admission, she presented a tumor at the level of the right submandibular region. She received treatment with clindamycin and NSAIDs, alongside drainage of the collection. She developed purpuric lesions in the pelvic limbs and presented intermittent fever accompanied by impaired renal function, glomerular hematuria, and decreased urine volumes. Hemoglobin 8.7 gr/dl, Hematocrit 27.7%, Creatinine 2.0 mg/dl, Albumin 2.1 gr/dl, viral panel no reactive, C3: 55.4 mg/dl, C4: 1.7 mg/dl, rheumatoid factor: 94.2 IU/ml, urine test: DU 1.018 Ph 5.0 Leuko 4 Proteins 500 Erythrocytes 250 Bacteria Moderate Proteinuria 1.7 g/24h, Albuminuria 1.1 g/24 h. Renal biopsy reporting a membranoproliferative, extracapillary glomerulonephritis, due to immune complex deposition. Tubulointerstitial nephritis rich in plasma cells, and intracapillary hyaline thrombi indicative cryoglobulins. Treatment with intravenous steroids was implemented with a satisfactory clinical response.

**Discussion:** PSS is an entity with infrequent kidney involvement. Renal tubular acidosis is described as the foremost clinical manifestation in pSS renal involvement and is associated with tubulointerstitial nephritis by histopathological findings, followed by membranous-like glomerular involvement reported in reviews. Treatment with glucocorticoids and other immunosuppressive agents appear to slow the progression of kidney disease.

## PUB245

**Adalimumab: A Case of Secondary Membranous Nephropathy**

Gina G. Suarez, Angel R. Castro, Pedro A. Canuelas. *Hospital de la Concepcion, San German, PR.*

**Introduction:** Membranous nephropathy (MN) is a cause of nephrotic syndrome characterized by a pattern of histologic change noted on light microscopy: glomerular basement membrane thickening with little or no cellular proliferation or infiltration. Around 75% of cases of MN in adults are primary or idiopathic, and the rest are attributed to an assortment of agents or conditions, mostly due to observational data that removing the inciting agent or treating the underlying condition resulted in improvement or overall termination of the nephrotic syndrome. Anti-TNF agents have been shown to be a secondary cause of MN, but there is limited documentation about this. We give you a case of secondary MN manifesting in a patient after starting treatment for inflammatory bowel disease with adalimumab. This adverse effect is a rare complication of treatment making this case relevant for clinicians to monitor and maintain a high level of suspicion.

**Case Description:** A 51-year-old female with severe Crohn's Disease, but controlled Type II Diabetes Mellitus, and Essential Hypertension presents with isolated, nephrotic-range proteinuria in routine lab work sent by her primary care physician after two months of initiating adalimumab for her Crohn's Disease (24-hour urine collection yielded 7.1 g of protein and urine spot yielded 6.9 g of protein). Age- and sex-based cancer screening, anti-double stranded DNA, antinuclear antibodies, and complement levels, Hepatitis Panel, HIV, and RPR were all negative. Renal biopsy demonstrated MN Stage I with deposits negative for phospholipase A2 receptor (PLA2R; a major antigen in human primary MN) antibodies plus mild acute tubular injury and arterio- and arteriolonephrosclerosis. Adalimumab was discontinued; the patient was started on infliximab and in follow-up the patient's proteinuria decreased significantly, supporting the theory of adalimumab having caused MN.

**Discussion:** In light of aforementioned workup being found negative, including imaging for hidden malignancy, tumor markers, SPEP/UPEP, adequate blood pressure and glycemic control, timeframe of proteinuria coinciding with the commencement of adalimumab and improvement of proteinuria after it was discontinued, the most likely explanation for this patient's nephrotic range proteinuria remains the usage of adalimumab. Biopsy confirms our hypothesis with presence of secondary MN supported by negative PLA2R antibodies.

## PUB246

**Predicting ESRD in Pauci-Immune Glomerulonephritis**

Saliha Yildirim, Emre Yasar, Betül Oğut, İpek Isik gonul, Galip Guz. *Gazi Üniversitesi Tıp Fakültesi, Ankara, Turkey.*

**Background:** Pauci-immune GN is a vasculitis presented with absence of immune deposits on kidney biopsy. Three different scoring systems have been proposed to predict renal disease prognosis; Berden classification (BC), Mayo Clinic/Renal Pathology Society Chronicity Score (MCS) and ANCA Renal Risk Score (ARRS). In this article we aimed to compare the predictiveness of scoring systems in terms of end-stage renal disease in pauci-immune GN.

**Methods:** Patients diagnosed with pauci-immune GN in our center were included. BC classes, MCS and ARRS of the patients were calculated. The patients were divided into two groups according to ANCA positivity and the relationship of the scoring groups with the development of end-stage renal disease (ESRD) was evaluated using appropriate statistical methods.

**Results:** A total of 42 patients were included in this study (Table 1). %25 of the ANCA positive group (ANCAP) and %16.7 of the ANCA negative pauci immune group (ANCAN) patients developed ESRD. When the ANCAP classified according to BC all of the sclerotic patients (p=0.011), according to MCS %50 of the patients with severe disease (p=0.652), according to ARRS %75 of the patients with high risk disease developed ESRD (p=0.017). When the ANCAN classified according to BC %20 of the sclerotic patients (p=0.026), according to MCS %33.3 of the patients with severe disease (p=0.770), according to ARRS %27.3 of the patients with medium risk disease developed ESRD (p=0.308).

**Conclusions:** In our study we found that regardless of ANCA, BC was a valuable method to predict ESRD. In ANCAP ARRS was also valuable for ESRD prediction. Our study is unique for including both ANCAN and ANCAP patients. Major limitations of our study were low number of patients and retrospective nature of the study. Further studies with more patients are needed for the evaluation of ESRD in this patient group.

## PUB247

**Autosomal Recessive Alport Syndrome With Pathogenic Variants**

Lakshmi Kannan, Rahul Mishra, UmmeRubab Syeda, Rishi Raj. *Pikeville Medical Center, Pikeville, KY.*

**Introduction:** Approximately 0.2% of adults and 3% of children in the United States with end-stage renal disease have Alport Syndrome (AS). The hallmark of AS is microscopic hematuria; cochlear and ocular manifestations can also occur. It is caused by genetic mutations affecting type IV collagen which consists of a heterotrimeric complex of  $\alpha 3$ ,  $\alpha 4$ , and  $\alpha 5$  chains encoded by COL4A3, COL4A4 (situated on chromosome 2), and COL4A5 (situated on X-chromosome).

**Case Description:** A 56-year-old female with a medical history significant for hypertension, hypothyroidism, and high-tone sensorineural hearing loss presented with hematuria, hypertension, and abnormal renal function. Family history revealed a sister with hearing loss and microscopic hematuria and a maternal grandmother with a progressive renal disease requiring dialysis at the age of 32 years. A recent eye exam revealed an immature cataract in the left eye. Renal biopsy revealed only revealed thin basement membrane but no specific diagnostic features. The biopsy was insufficient and given the finding of high-frequency hearing loss and hematuria suspicion of hereditary nephritis was high. DNA analysis was done which showed a novel pathogenic mutation of the COL4A3 gene (c.4981C>T (p.Arg1661Cys) and c.2048G>A (p.Gly683Glu) indicating a diagnosis of autosomal-recessive AS. The patient is on lisinopril for hypertension and has only microscopic hematuria and stable kidney function at present.

**Discussion:** When a diagnosis of AS from histological analysis of renal biopsy specimens becomes difficult, comprehensive genetic testing can provide a definitive means of making a diagnosis. Once a genetic diagnosis is established, screening of symptomatic, at-risk family members or prenatal testing for pregnancy and preimplantation genetic testing can obviate the need for a kidney biopsy. The rate of progression of kidney disease in patients with AS is highly variable; genetic analysis would provide additional prognostic information and it has been found that early stop codons, frameshift mutations, large deletions, and rearrangements are associated with early-onset renal failure and hearing loss than missense mutations. In individuals requiring a kidney transplant, there is a 3% chance of developing anti-glomerular basement membrane disease, possibly from more destructive genetic alterations.

## PUB248

**Elderly Age, Female Gender, and Prolonged Hemodialysis Stay Related With Pathological Body Composition Bioimpedance in Ecuadorian Hemodialysis Patients**

Juan C. Santacruz, Kevin G. Armijo, Nicole D. Noguera Barrera, Layla N. Baez, Veronica Gavilanes, Angel C. Santacruz. *Clínica de los Riñones Menydia, Quito, Ecuador.*

**Background:** Hemodialysis (HD) patients are exposed to nutritional and volume disturbances. Bioimpedance Spectroscopy (BIS) performs nutritional and hydration status analysis allowing nutritional diagnosis and dry-weight adjustment. Few is known in Ecuadorian HD population about BIS disturbances. The aim of this study was to evaluate nutritional and volume status by BIS in Ecuadorian chronic HD patients.

**Methods:** Observational, cross-sectional study, in Ecuadorian HD patients in “Clínica de los Riñones MENYDIAL”. Inclusion criteria: Age  $\geq 18$  years, HD for  $\geq 3$  months, non-prior hospitalization in last 3-month. Amputees and younger 18 years were excluded. BIS was performed prior HD session using Body Composition Monitor. Blood analysis of ferritin, transferrin, and cholesterol, were obtained.

**Results:** Totally 283 patients, 55% were male, age 56,5(±15,years), HD time 4,5(±3,6,years). BIS findings: decreased fat tissue mass 64% and sarcopenia 32%. Pathological phase angle ( $<4.6^\circ$ ): 57%, patients were older ( $p<0.001$ ), mainly female ( $p=0.003$ ) and longer HD stay ( $p=0.02$ ). Women were related with decreased lean tissue ( $p<0.001$ ) and transferrin ( $p=0.005$ ) higher adipose tissue ( $p=0.001$ ) ferritin ( $p<0.001$ ), and cholesterol ( $p=0.03$ ). BIS in water distribution revealed 73% overhydration ( $\pm 2,2L$ ), altered EC/IC water ratio ( $>1.1$ ) in 73% where patients were significantly older ( $p<0.001$ ). See image 1.

**Conclusions:** BIS offered accurate water distribution and body composition information which could help to identify earlier disturbances in elderly Ecuadorian HD patients with prolonged HD stays and women which were linked with protein-energy wasting syndrome findings and increased risk of mortality.

Associations Between Albuminuria and Mortality Among US Adults With and Without Comorbidities, 1999-2019

Yelena Drexler,<sup>1</sup> Julien Tremblay,<sup>1</sup> Robert Mesa,<sup>1</sup> Bailey Parsons,<sup>2</sup> Efren Chavez,<sup>1</sup> Gabriel Contreras,<sup>1</sup> Alessia Fornoni,<sup>1</sup> Leopoldo Raij,<sup>1</sup> Samuel L. Swift,<sup>3</sup> Tali Elfassy.<sup>1</sup> <sup>1</sup>University of Miami School of Medicine, Miami, FL; <sup>2</sup>University of Central Florida College of Medicine, Orlando, FL; <sup>3</sup>University of New Mexico Health Sciences Center, Albuquerque, NM.

**Background:** Albuminuria is a risk factor for all-cause mortality. It remains unclear whether the association between albuminuria and mortality differs based on demographic and comorbidity factors and which populations benefit most from identifying elevations in the urine albumin-to-creatinine ratio (ACR). We assessed whether albuminuria is differentially associated with mortality by demographic characteristics and co-morbid conditions.

**Methods:** This study included 49,955 adult participants from the nationally representative National Health and Nutrition Examination Survey (1999-2018) with mortality data through 2019 linked from the National Death Index. ACR was calculated using albumin (mg)/creatinine (g) from spot urine samples and classified as: ACR <10, ≥10 to <30, ≥30 to <300, or ≥300 mg/g. We used multivariable adjusted Poisson regression models to determine the incidence density ratio (IDR) for the association between ACR category with all-cause mortality. We tested for effect modification between ACR category with demographic characteristics and comorbidities.

**Results:** Over 9.86 years of follow-up, compared with ACR <10, greater ACR was associated with increased mortality risk of 39% at ACR 10–30 (IDR: 1.39, 95% CI: 1.29–1.50), 85% at ACR 30–300 (IDR: 1.85, 95% CI: 1.70–2.02), and 125% at ACR ≥300 (IDR: 2.25, 95% CI: 1.91–2.64) after adjusting for demographic, socioeconomic, behavioral, and clinical factors. Results differed by sex and presence of comorbidities (p for interactions <0.05). For example, compared with ACR <10, ACR ≥300 was associated with increased mortality risk of 148% among women (IDR 2.48, 95% CI: 2.01–3.07), 124% among men (IDR: 2.24, 95% CI: 1.84–2.72), 125% among individuals without hypertension or hypercholesterolemia (IDR: 2.25, 95% CI: 1.60–3.16), 128% among individuals with hypertension only (IDR: 2.28, 95% CI: 1.88–2.76), and 169% among individuals with both comorbidities (IDR: 2.69, 95% CI: 2.09–3.45).

**Conclusions:** Albuminuria ≥10 mg/g is associated with increased risk of all-cause mortality. The relative mortality risk is more pronounced among women than men, and among hypertensives with hypercholesterolemia. These findings highlight the importance of albuminuria for risk stratification among US adults.

PUB250

Heart Failure With Preserved Ejection Fraction (HFpEF): A Cardiologist Disorder or a Nephrologist Problem? Analysis From a Largely Hispanic Population

Rahul Patel,<sup>1</sup> Akash Sharma,<sup>2</sup> Roma N. Ahuja,<sup>2</sup> Nghia D. Tran,<sup>2</sup> Aliseiya J. Garza,<sup>1</sup> Shweta Bansal.<sup>1</sup> <sup>1</sup>The University of Texas Health Science Center at San Antonio, San Antonio, TX; <sup>2</sup>The University of Texas Health Science Center at San Antonio Joe R and Teresa Lozano Long School of Medicine, San Antonio, TX.

**Background:** Heart failure with preserved ejection fraction (HFpEF) has been recognized as a multisystem process and chronic kidney disease (CKD) plays a central role in this paradigm. However, racial/ethnic variability and prevalence of CKD are not well described.

**Methods:** Consecutive HFpEF patients (total n=204) were identified from a HF population screened for a clinical trial from 2019-2020 (n=188) and inpatients with HF exacerbation during 2021 (n=16) at University Hospital. HFpEF was defined as symptomatic HF with left ventricular ejection fraction (LVEF) >40% on Echo. Clinical and lab variables were collected ±1 year from Echo date. Race/ethnicity was self-reported. CKD was identified from the problem list. Rates were compared with EMEPROR-preserved trial's HFpEF population which was largely White.

**Results:** Of 204 HFpEF patients, 9 were Black, 14 were from other races, and due to small size were excluded from the analysis. Majority of the study population were Hispanics (130 of 181, 72%). LVEF was 40-50% in 31% of the study population. Table 1 demonstrates characteristics by EMPEROR population, and Hispanics and non-Hispanic Whites (NHW) in our analysis. Of significance, our population was younger, had DM2, CAD, CKD and obesity at higher rates, and AFib and BNP at lower rates as compared to EMPEROR population. The differences in Hispanics and NHW were unremarkable except more HTN and lower eGFR in Hispanics.

**Conclusions:** CKD and diabetes are highly prevalent in HFpEF patients in South Texas. In context of this observation and recent success of newer agents as empagliflozin, a multispecialty integrative approach is strongly warranted for management of HFpEF patient population.

Table 1: Baseline Characteristics of EMPEROR-Preserved and South Texas HFpEF Study Populations

Why Can Physical Activity Reduce ESRD or CKD? Exploring the Role of the “Heart Rate Paradox”

Chi pang Wen, Min Kuang Tsai. National Health Research Institutes, Zhunan, Taiwan.

**Background:** Physical activity has been shown to reduce chronic kidney disease/end-stage renal disease. Much of its mechanism was attributed to the reduction of risk factors associated with CKD. The role of “resting heart rate (RHR)” in its association with CKD/ESRD with physical activity involved has never been explored.

**Methods:** MJ cohort, N=543,667 adults, was recruited from participants from a private medical screening program across Taiwan (1996-2017). Each participant had data on physical activity (5 categories of MET-h/w), CKD (5 stages by eGFR and proteinuria) and RHR (10 beats/min increment from 40 based on EKD reading). Heart rate paradox connotes “rapid heart rate by vigorous exercise is required to achieve a healthier state of slower heart rate at rest”. Hazard ratios were calculated by Cox model. Some participants, active or inactive, made second visits offering data on changing RHR after engaging in physical activity.

**Results:** A 3-way associated risks were established among physical activity, RHR and CKD/ESRD on this cohort, indicating: (1) Active individuals had less CKD: 11%, 7% and 12% less for CKD, proteinuria and ESRD, respectively. (2) Faster RHR had more CKD/ESRD: Risk increased by 14% /10 beat/min increase and by 24% increase comparing ≥80/min with 60-69/min.(3) Active individuals had slower RHR: 6 beats/min difference with active and 14% less all-cause mortality. Becoming active at second visit 1-2 years later from initially inactive participants with RHR at 80-89/min (N=6269), 2/3 of them slowed RHR down to <80/min, lowered mortality, fewer CKD and gained 4 years in life expectancy.

**Conclusions:** We found slowing down RHR as an important mechanism for our observation of the ability of physical activity to reduce CKD/ESRD. CKD had faster RHR and, with vigorous exercise, “heart rate paradox” reduced CKD when RHR was reduced.

PUB252

Echocardiographic Findings in ESRD Patients in Hemodialytic Treatment

Ana E. Oliva, Frida Margarita de la Vega Méndez, Clementina Elizabeth Calderon Garcia. Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico.

**Background:** Chronic kidney disease is a worldwide health problem, representing approximately 15% of the population in the United States. Up to 60% of patients are in hemodialytic therapy and suffer hemodynamic, inflammatory and neurohumoral changes, associated with traditional factors such as diabetes mellitus, arterial hypertension, obesity and metabolic syndrome; which predispose more than 40% to cardiovascular diseases, leading to cardiac complications occupying the first cause of mortality worldwide in 2017. Screening and echocardiographic follow-up are of great importance to determine cardiovascular compromise and identify possible structural alterations that may develop cardiovascular diseases.

**Methods:** The present study was of an analytical retrospective, carried out in 55 chronic kidney patients undergoing hemodialysis treatment.

**Results:** The predominant gender was male 36% and the mean age was 65.5 years. The risk factors are arterial hypertension (94%) and type 2 diabetes mellitus (76.4%), which were statistically significantly related to the etiology of aortic stenosis (p = 0.005, OR: 0.52, CI: 0.130 to 2.080) and (p = 0.01, OR: 0.00, CI: 0.00 to 1.03) respectively. The prevalent echocardiographic findings were left ventricular hypertrophy (65.5%), mitral regurgitation (54.5%), aortic regurgitation (38.2%), left ventricular diastolic dysfunction (34.5%), and 80% had left ventricular ejection fraction normal.

**Conclusions:** The prevalent echocardiographic findings were left ventricular hypertrophy (65.5%), left ventricular systolic dysfunction (12.7%) and aortic insufficiency (38.2%). There was a statistically significant relationship in risk factors such as arterial hypertension and type 2 diabetes mellitus with the appearance of aortic stenosis.

Echocardiographic findings in End-stage Renal Disease Patients in Hemodialysis Treatment

Echocardiographic findings	%
Left ventricular hypertrophy	65.5
Left atrial enlargement	34.5
Left ventricular diastolic dysfunction	34.5
Left ventricular systolic dysfunction	12.7
Mitral stenosis	1.8
Mitral regurgitation	54.5
Aortic stenosis	3.6
Aortic insufficiency	38.2
Right ventricular systolic dysfunction	0

### Cardiorenal Units as a Strategy to Improve Outcomes in Cardiorenal Syndrome

Maria Marques Vidas, Marta Maria Cobo Marcos, Belen Garcia Magallon, Jorge Vázquez, Maria Luisa Serrano Salazar, Darío Janeiro, Jose M. Portoles. *Hopital Universitario Puerta de Hierro, Majadahonda, Spain.*

**Background:** Cardiorenal Syndrome (CRS), is often a challenging condition with paucity of evidence-based therapy. The increasing burden of this entity has prompted the creation of cardiorenal units (CRU) as integrating programs intended to provide a combined multidisciplinary approach to maximize all chances for organ and patient recovery. Here we describe the early results of the creation of one CRU

**Methods:** Observational study: all patients diagnosed with CRS, who have been seen in the cardiorenal day care unit, formed by specific trained nephrologist, cardiologist and nurses. Assessment of cardio-renal function and volume status was performed by conventional cardiac ultrasound plus V-Scan, GFR estimation by CKD EPI, NT-proBNP determination and bioelectrical impedance when indicated.

**Results:** Cardiorenal Unit of Puerta de Hierro University Hospital was created in Jan 2021. 68 patients have been evaluated with a mean follow up of 4 months (SD 3.2). Most frequent cardiologic diagnoses were 63.9% heart failure with reduced function (HFrF) and 37.1% Heart failure with preserved ejection fraction (HFpEF) and the presence on Pulmonary Hypertension or Tricuspid regurgitation was 29.4% and 50.9%. 51.6% patients showed diuretic resistance. Most frequent renal diagnosis were pure CRS 36.9%, and 27.7% and 24.6% CRS associated to diabetic kidney disease or nephroangiosclerosis, respectively. Mean FGe rate when patients were initially evaluated was 31.5 ml/min/1.73m2 (SD 11.0) with demonstration of albuminuria in 48.5% of patients. The integrated cardio-renal management of these patients included initiation or adjustment of specific cardio-nephro protective drugs (SGLT2 inhibitors (46.8%), ARNi (25.8%), aldosterone receptor antagonists (4.8%)) or diuretic regime adjustment including iv administration (54.8%). Peritoneal dialysis was indicated in 3 patients and hemodialysis in one. 13.2% patients suffer new episodes of heart failure that needed hospitalization or unexpected medical attention at the day-care clinic. One patient died during follow-up (1.5%).

**Conclusions:** We conclude that this coordinated cardio-nephro approach of CRS was useful to optimize drug therapy aimed to mid-long term goals of cardio-nephro protection and to implement advanced therapies for fluid management in patients with diuretic resistance.

## PUB254

### Effects of Uremic Toxins TMAO and PAGIn on In Vivo and Ex Vivo Vascular Function in Patients With ESRD

Samsul Arefin, Sam Hobson, Leah N. Hernandez, Peter Stenvinkel, Karolina Kublickiene. *Karolinska Institutet Institutionen for klinisk vetenskap intervention och teknik, Huddinge, Sweden.*

**Background:** Patients with end stage kidney disease (ESKD) are characterized by the aggregation of uremic toxins that have an extensive range of pathophysiological actions on organ systems. We focused on trimethylamine N-oxide (TMAO) and phenylacetyl glutamine (PAGIn) due to their proposed effects on vascular dysfunction, calcification with following increased risk for cardiovascular disease. We aimed to investigate if TMAO and PAGIn have any detrimental effects on peripheral microcirculation in ESKD patients.

**Methods:** Living-donor kidney transplantation patients were included, in which *in-vivo* endothelial function and soluble TMAO and PAGIn were assessed together with other functional and biochemical parameters. Reactive hyperemia index (RHI) and soluble TMAO and PAGIn were measured using EndoPAT and ELISA technique, respectively. For *ex-vivo* effects of TMAO and PAGIn we used organ bioassays with isolated small vessels from subcutaneous fat biopsies donated from non-CKD participants. Briefly, isolated arteries were cultured under controlled conditions with and without addition of 10µM TMAO or 100µM PAGIn. After 24 hours arteries were mounted on Myography system to assess of vascular function and structure.

**Results:** Circulating TMAO correlated with RHI in patients with ESKD ( $\rho=-0.255$ ,  $p<0.05$ ,  $n=64$ ). This correlation existed in males ( $\rho=-0.286$ ,  $p<0.05$ ,  $n=49$ ) but not in females ( $\rho=-0.157$ ,  $p>0.05$ ,  $n=15$ ). The arteries from ESKD patients with higher circulating PAGIn ( $>49.38\mu\text{g/mL}$ ) showed increased adrenergic tone ( $p<0.05$ ,  $n=17$ ) and reduced endothelium independent dilatation ( $p<0.05$ ,  $n=20$ ). Isolated artery bioassay with

TMAO showed preserved overall endothelial function, but contribution of endothelium-derived hyperpolarizing factor (EDHF) vs. nitric oxide (NO) was reduced ( $p<0.05$ ,  $n=8$ ). After PAGIn, the overall endothelium dependent dilatation was reduced and both EDHF & NO contribution impaired ( $p<0.05$ ,  $n=8$ ). No effects of TMAO and PAGIn were observed on contractile function or structure.

**Conclusions:** Uremic toxins such as TMAO and PAGIn are associated with adverse effects on peripheral microcirculation in patients with ESKD. Further studies are ongoing to assess how TMAO and PAGIn affects NO vs EDHF pathways.

## PUB255

### Does Gender Affect Electrophysiological Properties of Neurons With Axons From the Kidney?

Kristina Rodionova,<sup>1</sup> Tilmann Ditting,<sup>1,2</sup> Johannes Döllner,<sup>1</sup> Nada Cordasic,<sup>1</sup> Karl F. Hilgers,<sup>1</sup> Peter Linz,<sup>1</sup> Christian Ott,<sup>1,2</sup> Roland E. Schmieder,<sup>1</sup> Mario Schiffer,<sup>1</sup> Kerstin U. Amann,<sup>1</sup> Roland Veelken,<sup>1,2</sup> <sup>1</sup>*Friedrich-Alexander-Universität Erlangen-Nuremberg Medizinische Fakultät, Erlangen, Germany;* <sup>2</sup>*Paracelsus Private Medical University Nuremberg, Nuremberg, Germany.*

**Background:** Previously we reported on a complex composition of afferent nerves from the kidney comprising highly active tonic and less active phasic neurons. The portion of the latter is significantly increased in renal inflammation and hypertension likely impairing the sympathetic control by afferent renal nerves. Androgens were reported to act on sensitive afferent nerve structures. Hence we wanted to test the hypothesis that the function of neurons with renal afferents is subject to sexual dimorphism.

**Methods:** Three groups of SD rats (male, female and ovariectomized female) were investigated. Renal neurons were retrogradely labeled with DiI. In culture, labeled dorsal root ganglion neurons (DRG Th11-L2) with renal afferents were investigated electrophysiologically using current clamp mode to assess action potential generation during current injection (neurons were characterized as tonic highly active ( $>5$  action potentials, AP) and phasic less active neurons ( $\leq 5$  AP upon stimulation). Rats were matched for body weight and age.

**Results:** In neurons from male and female rats, the relation of tonic highly active neurons to less active phasic neurons did not differ significantly (82% tonic neurons in male vs. 79% in female, z-test). No significant differences in the firing pattern of renal neurons were also observed in ovariectomized females as compared to males and females that were not ovariectomized. Threshold of action potential generation and duration of action potentials did likewise not differ between the various groups investigated.

**Conclusions:** Although sexual dimorphism may occur in the nervous control of visceral organs like the kidney it proved to be not obvious with respect to the renal afferent innervation. In how far afferent renal nerve fibers from male and females may have a different influence on central sympathetic outflow remains to be determined.

## PUB256

### An Eye to the Future: Development of a Metabolic-Renal-Cardiac (MRC) Service

Saif Al-Chalabi,<sup>1,2</sup> Saira Nawaz,<sup>2</sup> Helen Alderson,<sup>1</sup> Philip A. Kalra,<sup>1</sup> Dimitrios J. Poulikakos,<sup>1</sup> James Ritchie,<sup>1</sup> Smeeta Sinha,<sup>1</sup> <sup>1</sup>*Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom;* <sup>2</sup>*The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom.*

**Background:** Diabetes mellitus (DM), chronic kidney disease (CKD), and cardiovascular diseases (CVD) share common risk factors, often co-exist together, and are associated with poor outcomes. With the emergence of cardio-renal-metabolic protective medications, it is time to manage these conditions as one entity: cardiorenal metabolic syndrome (CRS). Here we report on the development of our own MRC clinic and describe the MRC clinic cohort.

**Methods:** The clinic was designed to provide diabetology and cardiology input in addition to nephrology care for patients with CRS. The majority of referrals were patients with cardio-renal syndrome or advanced diabetic nephropathy. A retrospective analysis was done for all patients that attended the MRC clinic in the first 8 months since establishment (1/3/2021-1/11/2021). Demographic data as well as data on chronic kidney disease stage, metabolic and cardiovascular morbidity and medication uptake was collected.

**Results:** The MRC clinic was founded by a dedicated team of nephrologists with a special interest in CVD and DM. A total cohort of 209 patients were seen in the MRC clinic during the first 8 months with more than 450 patient visits. The median age was 71 years (IQR 59-78) with a predominance of males (56 %). Patients with CKD stage 3 or 4 accounted for 85% of patients and 73.2% had DM. Patients had a significant burden of CVD: 47.8% heart failure 50.2% hypertension, 34% ischemic heart disease. Use of key medications at MRC entry was sub-optimal with 59.8% receiving renin-angiotensin-aldosterone (RAAS) inhibitors, 22% sodium-glucose cotransporter 2 inhibitors, 23.9% mineralocorticoid antagonist (MRA), and 63.6% receiving beta-blockers. Potassium binders were prescribed for 24 patients (11.5%) to facilitate optimisation of RAAS inhibition and MRA use.

**Conclusions:** Optimisation of disease modifying medications was sub-optimal in the patients at referral into the MRC service. The MRC clinic provides an opportunity to improve medicines optimisation as well addressing risk factors for disease progression e.g. blood pressure and glycaemic control. An effective multi-morbidity service should also incorporate patient and clinician education with integrated care pathways and multi-disciplinary review, and these facets are being developed within our local service.

## PUB257

**Metabolic Cage Housing Alters Heart Rate Variability in Male Adrenal-Specific BMAL1 KO Mice**

Victor M. Mendez, Cheoting C. Maugans, Hannah M. Costello, G. R. Crislip, I. Jeanette Lynch, Kityan Cheng, Lauren G. Douma, Michelle L. Gumz. *University of Florida, Gainesville, FL.*

**Background:** The clock protein BMAL1 is a transcription factor that regulates many genes that set the physiological clock in motion, generating circadian rhythms in regulated variables including heart rate (HR). BMAL1 action is also important for the regulation of physiological functions independent of timing to maintain homeostasis. Previous work in the lab has shown altered HR rhythm in male adrenal-specific BMAL1 knockout (AS-BMAL1 KO) mice. Changes in HR may be associated with adverse cardiorenal outcomes. The time intervals between adjacent heart beats (RR intervals) can be studied to determine HR variability (HRV), which can provide insight into changes in HR and autonomic system balance. The goal of this study was to determine the role of adrenal BMAL1 in the regulation of HRV.

**Methods:** AS-BMAL1 KO and control male mice ( $n=5-6$ ) were implanted with telemeters. Mice then recovered for 10 days before 4 days of HR baseline measurements were made in home cages. Mice were then placed in metabolic cages and HR was collected over 5 days. HR was collected at 1000Hz for 2 mins every 3 hrs on the last day of home and metabolic cage recordings. Time- and frequency-domain analyses were performed using Kubios software with pre-determined high frequency (HF) and low frequency (LF). An index of parasympathetic and sympathetic nervous system (PNS and SNS) activity was also calculated.

**Results:** For AS-BMAL KO male mice and controls housed in home cages, changes in RR intervals, LF and HF variability, and LF/HF ratio were not apparent. Kubios-generated indexes of PNS and SNS activity showed no difference between KO mice and controls. When mice were placed in metabolic cages, HR increased and there was a significant genotype effect in LF/HF ratio (ANOVA genotype  $p=0.0232$ ). Additionally, time-dependent effects in LF and HF variability were also present (ANOVA time  $p=0.0356$  and  $p=0.0258$ , respectively). Differences in indexes of PNS and SNS activity were not apparent.

**Conclusions:** Adrenal BMAL1 influences LF/HF ratio only when mice were in metabolic cages, which acted as a stressor, but does not impact indexes of PNS and SNS activity. Future work will focus on understanding the mechanisms behind changes in HR in AS-BMAL1 KO mice and the role of adrenal BMAL1 on HR/HRV in females.

## PUB258

**Nephrology Chronicles: Stone Baby**

Muhammad F. Habib, Haris Mobeen. *SUNY Upstate Medical University, Syracuse, NY.*

**Introduction:** Lithopedion is an extrauterine pregnancy resulting from fetus death and calcification. It is extremely rare with an increased incidence in geographical areas with poor socio-economic conditions and lack of adequate medical care.

**Case Description:** A 50-year-old Congolese female refugee presented for hypertension (HTN) evaluation with an initial BP of 160/90 and labs showing CKD G2/ A1. In 2012, she had a 3<sup>rd</sup> trimester missed miscarriage secondary to an abdominal ectopic pregnancy. At the time, due to inadequate medical resources in Congo, she was unable to have products of conception removed and this was left unattended for 9 years. Upon her arrival to the U.S. in 2021, an USA/P with her PCP showed a calcified pregnancy. CT A/P revealed a 92 x 176 x 155 mm extrauterine lithopedion causing bowel obstruction, IVC compression with collaterals and significant compression of pelvic structures. Patient was worked up for secondary causes of HTN, which were normal. Renal doppler ultrasound was ordered, but patient missed her appointments. She was treated with ACE-inhibitors with relative normalization of blood pressures.

**Discussion:** Lithopedion is an extremely rare event with approximately 300 reported cases over 400 years of medical literature. It was 1<sup>st</sup> described by Albucasis in the 10<sup>th</sup> century and has been associated with hypertensive cerebrovascular events and bowel obstruction. In our patient, inadequate medical care led to lithopedion being unattended for over 9 years. The mechanism of HTN is unclear in these patients and the exact physiology can only be postulated. A myriad of physiological changes could have caused her HTN; sustained sympathetic activity with increased peripheral vascular resistance as well as persistence of gestational alterations of renin-angiotensin-aldosterone system with lithopedion can be one explanation. However, other mechanisms like compressive effect of lithopedion on the abdominal vasculature like aorta and renal arteries might have also led to our patient's HTN. A much simpler explanation such as essential HTN is always a possibility. The paucity of medical literature on the subject makes it difficult to understand the exact physiology of development of HTN in lithopedion patients. Hence, we present this case to the nephrology community to discuss and better understand the complex physiological interplay that could have happened in our patient with a lithopedion leading to HTN.

## PUB259

**Uremic Toxins Promote Early Vascular Ageing in CKD**

Sam Hobson, Samsul Arefin, Leah N. Hernandez, Chiara Leotta, Peter Stenvinkel, Karolina Kublickiene. *Karolinska Institutet, Stockholm, Sweden.*

**Background:** Chronic kidney disease (CKD) is a clinical model of premature ageing, a phenomenon described as a discrepancy between chronological and biological age. One system affected is the vasculature, termed early vascular ageing (EVA), characterized by endothelial dysfunction, arteriosclerosis, and vascular calcification. Multiple uremic toxins that accumulate as renal function declines have been independently associated with EVA, cardiovascular disease, and mortality in CKD patients. These compounds include indoxyl sulphate (IS), trimethylamine N-oxide (TMAO), and phenyl acetyl glutamine (PAG). In recent years, the pathogenic roles of distinct uremic toxins and how they contribute to progress CKD have been elucidated, however an exhaustive list of mechanisms that promote EVA are far from complete.

**Methods:** We aimed to better understand how the aforementioned toxins drive specific components of EVA using a combination of experimental techniques.

**Results:** Firstly, implementing an *in vitro* calcification assay using uremic serum from CKD G5 patients, we demonstrated uremic serum-induced calcification in aortic vascular smooth muscle cells (aVSMCs) was associated with reduced NRF2 expression, the master regulator of antioxidant genes, as well as downstream targets of NRF2. Next, to investigate the role of individual toxins, we found that TMAO, but not PAG, associated with coronary artery calcification (CAC) score in a binational CKD G4-5 cohort ( $n=388$ ), which further associated with oxidative stress/advanced glycosylated end-product generation. To adopt a translational approach, we found TMAO, but not PAG, promoted calcification in aVSMCs and vessel rings isolated from CKD G5 patients undergoing living donor-kidney transplantation (LD-KTx). Finally, in a separate study, we showed that IS, a protein-bound uremic toxin, negatively correlated with reactive hyperaemia index, an *in vivo* marker of endothelial dysfunction, at baseline and 2-years after LD-KTx. Preliminary wire myography experiments in resistance vessels suggest IS may affect endothelial function.

**Conclusions:** In summary, we have used a plethora of experimental techniques to give new insights into how uremic toxins detrimentally effect the vessel wall in uremic conditions. Further experiments are required determine whether use of therapeutics to target these pathways can delay the onset of EVA.

**Funding:** Private Foundation Support, Government Support - Non-U.S.

## PUB260

**Multiple Renal Cysts**

Roy Rajan,<sup>1,2</sup> Clay A. Block,<sup>1,2</sup> Thomas M. Kaneko,<sup>1,2</sup> Charles W. Hopley.<sup>1,2</sup> <sup>1</sup>Dartmouth-Hitchcock Health GraniteOne, Lebanon, NH; <sup>2</sup>Dartmouth College Geisel School of Medicine, Hanover, NH.

**Introduction:** Hyperaldosteronism can cause hypertension and hypokalemia. Chronic hypokalemia in turn can lead to renal scarring and cystogenesis in the kidneys.

**Case Description:** A 77-year-old man was referred for numerous bilateral kidney cysts up to 8.9 cm, identified on CT obtained to investigate for renal artery stenosis. He had been on antihypertensive medications for more than 25 years. Hypokalemia had been present for at least 10 years and had persisted even when diuretic therapy was discontinued. His medical history includes CKD stage 2-3a, prostate cancer in remission, GERD, and hypothyroidism. His medications were atenolol, amlodipine, losartan, potassium chloride 10mEq daily, and levothyroxine. There was no family history of kidney disease. The BP was 138/78 and the physical examination unremarkable. Morning plasma aldosterone-to-renin ratio was followed by salt-loading and measurement of 24-hr urine aldosterone were diagnostic of primary aldosteronism. Patient elected for medical therapy with a mineralocorticoid receptor blocker. His BP control improved and his potassium normalized.

**Discussion:** The differential diagnosis of bilateral kidney cysts includes genetic conditions (ADPKD) and acquired conditions like advanced CKD or ESKD and medications such as lithium. Less appreciated is the role of chronic hypokalemia in the induction of cyst formation. Hypokalemia induces intra-cellular acidosis by promoting K<sup>+</sup> efflux, which in turn promotes H<sup>+</sup> influx into cells causing intracellular acidosis. This has been proposed to increase ammonia genesis, which activates complements and causes tubular damage, causing cell growth and proliferation and alteration in cytokines leading to cyst formation. Cyst formation might be reversible if hypokalemia is corrected early in the course. Primary hyperaldosteronism may increase activity of Na<sup>+</sup> + K<sup>+</sup> + ATPase causing increased intra cellular K<sup>+</sup> contributing to its efflux. Our patient did not have a family history of renal disease and due to his advanced age with relatively normal kidney function, it is unlikely due to a genetic renal disease.

PUB261

**Type B Lactic Acidosis in a Patient With Metastatic Rectal Cancer**  
Supriya Gerardine,<sup>1</sup> Latoya N. Gayle,<sup>2</sup> Aisha Shaikh.<sup>1,2</sup> <sup>1</sup>Memorial Sloan Kettering Cancer Center, New York, NY; <sup>2</sup>Weill Cornell Medicine, New York, NY.

**Introduction:** Lactic acidosis in the absence of systemic hypoperfusion is due to type B lactic acidosis. Type B lactic acidosis has been observed in malignancies, but the underlying pathogenesis is poorly understood. Type B lactic acidosis is rare in cancer patients, but when it occurs, it is commonly observed in hematological malignancies and rarely with solid organ tumors. Here we describe a case of type B lactic acidosis in a patient with acute liver failure due to metastatic rectal cancer.

**Case Description:** A 50-year-old man with metastatic rectal cancer presented to the hospital with severe lower back pain due to a pathologic fracture of L3. He was normotensive, and his heart rate, temperature, and oxygen saturation were normal. Laboratory tests revealed high anion gap metabolic acidosis (31.5) due to severe lactic acidosis (> 11.9 mmol/L) (Table). Kidney function was normal; blood and urine cultures were negative, and there was no evidence of an underlying infection. CT scan showed complete replacement of the liver parenchyma due to numerous metastases. Over the next 48-hours, the patient developed acute liver failure and became encephalopathic. Due to extensive metastatic disease, the patient transitioned to palliative care and passed away.

**Discussion:** Type B lactic acidosis in malignancy can be caused by increased lactate production and decreased lactate clearance. The increase in lactate production can be due to hepatic glycolysis, anaerobic glycolysis in tumor cells (Warburg effect), paracrine actions of tumor necrosis factor- $\alpha$ , and vitamin deficiency. The decrease in lactate clearance occurs in severe liver disease. Treatment of type B lactic acidosis is directed toward treating the underlying malignancy. In this case, increased lactate production by tumor cells and decreased hepatic lactate clearance caused type B lactic acidosis. The decreased hepatic lactate clearance was due to metastatic liver disease. Type B lactic acidosis is rare and awareness of this entity can lead to prompt diagnosis and management of malignancy.

Laboratory test (reference range)	Day of admission	2-days after admission

**AKI due to Waldenström Macroglobulinaemia Manifesting as Acute Tubular Necrosis**

Michelle Madden,<sup>1</sup> Mairead Hamill,<sup>1</sup> Brendan Doyle,<sup>2</sup> Catherine M. Brown,<sup>1</sup> Sean F. Leavey.<sup>1</sup> <sup>1</sup>University Hospital Waterford, Waterford, Ireland; <sup>2</sup>Beaumont Hospital, Dublin, Ireland.

**Introduction:** A sixty-one year old man was referred with an elevated creatinine of 2.6mg/dL (eGFR 25ml/min) detected on a routine screening blood test. Creatinine had been 0.85mg/dL eight months previously.

**Case Description:** There was no relevant medical history and no regular medications. He described no systemic symptoms, no recent illness and no ingestion of new medications or toxins. Physical examination was unremarkable. Urinalysis showed trace blood, negative for protein, glucose and leukocyte esterase. The urine albumin/creatinine and protein/creatinine ratios were normal, but lambda light chains were detected in trace quantities on immunofixation. Blood tests showed a 12.5g/L IgM lambda monoclonal paraprotein. Bone marrow biopsy detected no excess plasma cells and only a mild increase in B cell lymphoid population to 10%. Ultrasound demonstrated normal size kidneys with no evidence of obstruction. A skeletal survey was negative for bony lesions. In the absence of a clear haematologic indication to commence treatment for monoclonal gammopathy, a kidney biopsy was performed. This showed acute tubular necrosis but there was no demonstrable evidence of cast nephropathy, lymphomatous infiltration, abnormal light chain or immunoglobulin accumulation/ deposition on immunofluorescence or on electron microscopy; thus not pathognomonic for paraprotein-mediated kidney injury. Plasma viscosity measured within the normal range. Kidney function was monitored closely for a few more weeks before a decision to proceed with clonally directed therapy. The patient's eGFR was in the 20-25 ml/min range for 8 weeks from initial diagnosis to initiation of therapy. He received six cycles of cyclophosphamide, rituximab and dexamethasone. Paraprotein reduced from 12.5g/L to 1.1g/L and creatinine reduced in tandem to 0.93mg/dL after three months of chemotherapy, remaining stable twelve months later.

**Discussion:** Paraproteins cause both glomerular and tubular patterns of injury, but acute tubular necrosis without demonstrable paraprotein or a cast nephropathy has been rarely described as a presentation in Waldenström macroglobulinemia. The acute kidney injury resolved with clonally directed therapy. This case highlights the importance of considering a monoclonal paraprotein as potentially pathogenic in otherwise unexplained presentations of acute tubular necrosis.

PUB263

**Carfilzomib-Associated Accelerated Hypertension**

Niloufarsadat Yarandi,<sup>1</sup> Nelson Leung.<sup>1,2</sup> <sup>1</sup>Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; <sup>2</sup>Mayo Clinic Division of Hematology, Rochester, MN.

**Introduction:** Carfilzomib is a highly selective irreversible second-generation proteasome inhibitor, currently used for relapsed refractory multiple myeloma (MM). Hypertension (HTN) is one of the most common cardiovascular adverse events (CVAEs) of carfilzomib which may lead to treatment interruption.

**Case Description:** 77-year-old female with history of marginal zone lymphoma and well-controlled HTN on hydrochlorothiazide 25 mg daily and spironolactone 25mg daily, was diagnosed with IgG lambda MM. Creatinine 0.8 mg/dL, Kappa free light chain (FLC) 0.26 mg/dL, Lambda FLC 25.2 mg/dL, kappa/lambda FLC 0.010, IgG 6060 mg/dL. The patient had multiple lines of therapy but due to either disease progression or drug intolerance was eventually transitioned to carfilzomib/dexamethasone(Kd) when her BP noted to increase. She did not tolerate amlodipine and nifedipine due to lower extremity edema and ultimately was maintained on benazepril 40 mg daily, carvedilol 12.5 mg twice daily and chlorthalidone 25 mg daily. The patient developed accelerated HTN after cycle 6 of carfilzomib with BP of 205/165 mmHg. There was no neurologic deficit or signs of volume overload. CT scan did not show any acute intracranial pathology. She was stabilized in the ICU and later downgraded to the floor. Isosorbide mononitrate 10 mg daily to antihypertensive regimen. Her creatinine increased to 1.13 mg/dL by day 2 of hospital stay. Upon discharge, her BP was 134/56 and was restarted on full-dose carfilzomib 2 days after. BP remained well-controlled.

**Discussion:** ENDEAVOR and ASPIRE showed improvements in progression-free survival (PFS) and overall survival with twice-weekly carfilzomib-based therapy. In ARROW, once-weekly Kd improved PFS and overall response rate compared to twice-weekly Kd. Older patients with lower kidney function experienced more adverse events. HTN is one of the most common CVAEs reported. Oxidative stress on cardiac myocytes, increase in vascular tone and reactivity, vascular dysfunction caused by endothelial effects of proteasome inhibition are proposed mechanisms for CVAE and HTN associated with Carfilzomib. Nifedipine and nitroglycerin can reduce spasmogenic effect of carfilzomib. Therefore, long-acting nitrates and dihydropyridine calcium channel blocker are preferred in treatment of carfilzomib-associated hypertension. Effective management of the adverse event allows patients to continue with their life-saving therapy.

## PUB264

# Incubation in Michel Transport Medium as a Diagnostic Tool to Differentiate Between Calcium Oxalate and 2,8-Dihydroxyadenine Tubular Crystals in a Kidney Biopsy

Dalia Y. Ibrahim, Laura Biederman, Tibor Nadasdy, Anjali A. Satoskar, Sergey V. Brodsky. *The Ohio State University, Columbus, OH.*

**Background:** Differential diagnosis of crystal deposition in the kidney is one of the challenging areas of renal pathology. Some crystals (such as calcium oxalate and 2,8-dihydroxyadenine (DHA)) show bright birefringence under the polarized light. We had earlier reported that calcium oxalate crystals dissolve in Michel transport medium (MTM).

**Methods:** To analyze the utility of MTM as a differential diagnostic tool between calcium oxalate and DHA crystals, we incubated kidney biopsy cores (3 patients with calcium oxalate nephropathy), not previously exposed to MTM, in MTM for 24h.

**Results:** A patient with end stage kidney disease secondary to DHA crystal deposition had early recurrence of the disease in a kidney allograft 4 weeks post-transplant. In a kidney allograft biopsy, brown, calcium oxalate-like, brightly birefringent crystals were noted in the tubules both in formalin fixed paraffin sections and in frozen sections cut from the snap frozen tissue (Figure 1 A, B). This tissue was exposed to MTM prior to freezing. To compare, 3 kidney biopsies with calcium oxalate tubular deposits where tissue was not exposed to MTM, were used. In fresh frozen tissue sections, numerous birefringent calcium oxalate crystals were seen (Figure 1, E). After 24-hour incubation of the biopsy cores in MTM, the birefringent calcium oxalate crystals disappeared in all 3 cases. Next, we incubated unstained sections of frozen tissue that was not exposed to MTM prior to freezing from cases with calcium oxalate crystals; as well as sections of frozen tissue from the case with DHA crystals for 2h, 8h and 24 hours. Incubation for 2 h, 8h and 24h resulted in dissolving of calcium oxalate crystals in all 3 biopsies (Figure 1, F) but not DHA crystals (Figure 1, C).

**Conclusions:** We suggest that exposure to MTM may be helpful in patients with birefringent crystal deposition in frozen tissue.

**Figure 1. Polarization of sections with tubular crystal deposits.** Sections of kidney biopsy with 2,8-dihydroxyadenine (A-C) or calcium oxalate (D-F) tubular deposits were analyzed under the polarized light. A, D – sections of paraffin-embedded tissue. B – sections of frozen tissue that was exposed to Michel transport medium (MTM) for 24 h as a biopsy core. C – slide with sections was exposed to MTM for 24 h. E – section of fresh frozen tissue prior to incubation in MTM. F – slide with sections was exposed to MTM for 2 h. Magnification 100x.

## PUB265

# How Can Hemolysis Affect a Urine Protein Electrophoresis Test? A Case of Proteinuria due to Postartemisinin Delayed Hemolysis

Christina L. Tamargo, Sandra I. Vazquez Salas, Jose M. Monroy-Trujillo. *Johns Hopkins Medicine, Baltimore, MD.*

**Introduction:** Proteinuria on urine dipstick typically reflects albumin, but it can reflect other proteins. Furthermore, hemolysis can affect proteinuria and urine protein analyses. Here we report a case of proteinuria due to hemolysis after malaria treatment with artemether/lumefantrine.

**Case Description:** A 22-year-old woman with no past medical history was referred to the emergency department because of lightheadedness and dyspnea in clinic. She had been discharged three days prior after a hospitalization for *Plasmodium falciparum* malaria; she completed a course of artemether/lumefantrine during that stay. On admission she was tachycardic and febrile, with labs notable for hemoglobin 6.5, platelets 339, Cr 0.7 mg/dL, AST 88, ALT 39, total bilirubin 3.5 mg/dL (direct 3.4), LDH 1680, haptoglobin <3 mg/dL, fibrinogen 214 mg/dL, and negative direct antiglobulin test. Urinalysis showed 2+ protein, large hemoglobin, and 2 RBC/hpf, with urine pH of 7.0. 24-hour urine protein electrophoresis (UPEP) later revealed 1440 mg protein/day (165 mg albumin, 108 mg alpha-1 globulin, 876 mg alpha-2 globulin, 108 mg beta globulin, 183 mg gamma globulin). Urine microalbumin-to-creatinine ratio was 124 mg albumin/g creatinine. Her proteinuria was deemed to be secondary to postartemisinin delayed hemolysis.

**Discussion:** The protein detected on urine dipstick is typically only albumin, though false positives can occur with hematuria and alkaline urine. In this case, while the patient had microalbuminuria, alpha-2-globulin was the most elevated component on her UPEP (Figure 1). Alpha-2-globulin is usually increased as an acute-phase reactant; however, it also contains haptoglobin. During hemolysis, hemoglobin-haptoglobin complexes can form and create a large band in the alpha-2-globulin region. Given the hemolysis confirmed on her other laboratory workup, this patient's proteinuria was likely due to formation of such complexes, with possible contribution from microalbuminuria and/or false positive urine dipstick. This case highlights the importance of 24-hour UPEP in the evaluation of proteinuria.

# A Retrospective Review of Kidney Biopsy: What's Time and Needle Got to Do With It?

Larab L. Giniyani,<sup>1,2</sup> Andrew A. Moses,<sup>1,2</sup> Maria V. DeVita,<sup>1,2</sup> Jordan L. Rosenstock.<sup>1,2</sup> <sup>1</sup>Lenox Hill Hospital, New York, NY; <sup>2</sup>Northwell Health, New Hyde Park, NY.

**Background:** The in-center observation time (OT) needed post-kidney biopsy is controversial. A recent review suggested 6-8 hours after biopsy because most complications have been detected by this time. At our institution we aimed to lower the OT after outpatient kidney biopsies. Initially, since 2015 we were monitoring for less than 6 hours and gradually began to decrease the OT over time. From 2020 we have adopted an OT of less than 4 hours. From 2018 onwards, we also began using a smaller gauge needle (18 gauge).

**Methods:** We reviewed all outpatient kidney biopsies performed by the nephrology division at our institution from 2015 until 2022.

**Results:** All patients had a hemoglobin checked after the biopsy and prior to discharge. There were 107 biopsies reviewed. 69 had OT of 4-6 hours and 38 had OT < 4 hours. There was a total of 4 complications (3.74%). Two complications, symptomatic retroperitoneal bleeds, were detected in less than 3 hours. The other 2 complications were seen at 9 hours (clot retention) and 72 hours (retroperitoneal bleed after anticoagulation restarted). Forty nine percent of the biopsies were done using 18-gauge needles with 1 complication in this group versus 3 in the 16 gauge group. All cases had adequate tissue for interpretation.

**Conclusions:** In summary, in an outpatient population, it does not appear that post biopsy OT between 3 and 8 hours is necessary to identify complications as complications developing during this time period are uncommon. Furthermore, an 18-gauge needle may lower the risk of complications and obtains adequate tissue.

## Major Complications of Kidney Biopsy from 2015 -2022

Each kidney represents a kidney biopsy. The complications are in different cases as registered in the legend. Retroperitoneal bleed within 48hrs as RPB.

# Light-Chain Amyloidosis With Concurrent Apolipoprotein A4 Amyloidosis in a Case of Autosomal Dominant Polycystic Kidney Disease

Atsuko Uehara,<sup>1</sup> Daisuke Ichikawa,<sup>1</sup> Tsutomu Sakurada,<sup>1</sup> Akira Shimizu,<sup>3</sup> Yugo Shibagaki,<sup>1</sup> Tomo Suzuki.<sup>1,2</sup> <sup>1</sup>Sei Marianna Ika Daigaku, Kawasaki, Japan; <sup>2</sup>Kameda Medical Center, Kamogawa, Japan; <sup>3</sup>Nihon Ika Daigaku Fuzoku Byoin, Bunkyo-ku, Japan.

**Introduction:** Most cases of amyloidosis are caused by the deposition of a single amyloid protein, and the deposition of two or more proteins is rare. We describe a case of autosomal dominant polycystic kidney disease (ADPKD) who developed progressing kidney disease due to concurrent immunoglobulin light chain (AL) and apolipoprotein A4 (ApoA4) amyloidosis.

**Case Description:** The patient was a 54-year-old man who was referred to our hospital because of chronic kidney disease (CKD) with serum creatinine (sCr) of 1.3 mg/dL. Based on the presence of multiple kidney cysts and family history with PKD2 mutation, he was diagnosed as CKD due to ADPKD. Since his sCr doubled within a year, he underwent kidney biopsy, which showed amorphous deposits localized in the interstitium stained positive with Congo red. The deposits were strongly positive for PAS staining, which was atypical of amyloidosis. Immunofluorescence revealed kappa restricted staining. Electron microscopy revealed the deposition of amyloid fibrils. With amyloid detected within his bone marrow, he was diagnosed as AL amyloidosis and underwent autologous hematopoietic stem cell transplantation. Later, laser microdissection-liquid chromatography-tandem mass spectrometry (LC-MS/MS) detected ApoA4 and kappa

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

in the kidney tissue. Immunohistochemistry stainings also revealed co-deposition of kappa and ApoA4. Therefore, we concluded that our case was concurrent AL and ApoA4 amyloidosis.

**Discussion:** This is the first case of concurrent AL and ApoA4 amyloidosis developed in a case with ADPKD. Concurrent AL amyloidosis might be different from single AL amyloidosis regarding symptoms and treatment responsiveness. Therefore, it is important to accurately diagnose amyloidosis using LC-MS/MS when kidney biopsy findings are atypical of AL amyloidosis.

Immunohistochemistry stainings of kidney tissue revealed similar distribution of kappa and ApoA4.

## PUB268

### Using miR21 as a Marker of AKI in Nephrolithiasis

Roma N. Ahuja, Sitai Liang, Ronald Rodriguez, Dean Bacich. *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

**Background:** Perturbation of miRNA expression regulates inflammation and fibrosis. In animal studies, sustained high grade renal obstruction results in miR-21 induction which then targets a series of genes resulting in increased collagen deposition and interstitial fibrosis. miR-21 is therefore predictive of later stage renal fibrosis, and its profile could be a promising biomarker for the acute renal injury. We sought to explore this relationship in human populations.

**Methods:** Blood samples from patients presenting to the emergency department for acute renal colic due to kidney stones were collected at the time of presentation and again one month after definitive treatment to serve as a baseline for miR-21 expression. They were compared against a control group with no history of nephrolithiasis. RT-PCR was used to quantify miR-21 expression.

**Results:** The relative fold change was calculated using the miR-21 expression levels at time of presentation and one month after completion of stone treatment and then compared against controls. The experimental group had a higher average upregulation than the non-stone patients, however this difference was not statistically significant (Figure 1).

**Conclusions:** Kidney damage is measured through serum BUN and Cr, however both markers are indicative of irreversible damage. miR-21 is unique as its elevation occurs during the reversible phase of injury, and therefore has the propensity to serve as a definitive marker of acute kidney injury. Animal studies found that expression levels rose in obstructive cases. We hypothesized expression levels of miR21 would be elevated at least two-fold in nephrolithiasis patients relative to normal controls. We performed a prospective non-randomized pilot study measuring miR-21 expression in urolithiasis patients presenting to the emergency department compared against non-stone controls. In this cohort, we were unable to demonstrate that miR-21 can be used as a marker of acute kidney injury.

Figure 1. Relative fold change of miR-21 from time of presentation to ED compared to baseline levels one month after resolution of stones.

## PUB269

### A Simple Method for the Bioinformatical Identification of ARMH4 and WIPF3 as Previously Uncharacterized Human Podocyte Proteins With Structural and Immunomodulatory Functions

Francesco De Luca,<sup>1</sup> Michelle Kha,<sup>1</sup> Karl Swärd,<sup>2</sup> Martin E. Johansson.<sup>1</sup>  
<sup>1</sup>Goteborgs universitet Sahlgrenska Akademien, Goteborg, Sweden; <sup>2</sup>Lunds universitet Medicinska fakulteten, Lund, Sweden.

**Background:** The podocytes are critically involved in maintaining the selective filtration barrier of the kidneys. They are target for a multitude of kidney diseases such as the glomerulonephritides and diseases causing nephrotic syndrome. Despite being in the focus of intense investigation, the transcriptome and proteome of human podocytes remain incompletely characterized.

**Methods:** We have analyzed publically available data sets of bulk RNA-Seq data from human kidneys (n=85, <https://gtexportal.org>) to computationally define potential novel podocyte markers. For confirmation we used an online histology resource ([www.proteinatlas.org](http://www.proteinatlas.org)) followed by in-house staining of human kidneys and glomerular isolation. We also cross referenced to GWAS findings with bearing on proteinuria. Putative functions of the novel factors were examined using viral overexpression in tubular epithelial cells and by changes in gene expression in differentiating podocytes.

**Results:** Several previously unrecognized gene products were identified that correlated to established podocyte markers on RNA level and could be histologically confirmed to localize to podocytes. *ARMH4* (a.k.a. UT2 or C14orf37) and *WIPF3* (a.k.a CR16) were among the hits. These were selected due to their connection to findings in GWAS studies. We show that these transcripts increase in response to overexpression of the podocyte transcription factor *LMX1B*. Moreover, overexpression of ARMH4 from low endogenous levels in primary kidney epithelial cells reduced release of the inflammatory mediators IL-1B and IL-8 (CXCL8), whereas WIPF3 stabilized N-WASP, which is known to be required for maintenance of podocyte foot processes.

**Conclusions:** ARMH4 and WIPF3 are proteins expressed by human podocytes. We suggest that they may modulate inflammatory insults by controlling release of cytokines and contribute to cytoskeletal structure, respectively.

## PUB270

### An Unusual Complication of a Kidney Biopsy

Abdullah Shahid, Joseph C. Parker. *East Carolina University, Greenville, NC.*

**Introduction:** Kidney biopsy is the gold standard procedure for the diagnosis of multiple kidney disorders. Various complications can occur during the procedure including bleeding due to puncture of an intra-renal vessel. Injury to the extra-renal vessels is rare. We present a case of a bleeding complication due to injury to the lumbar artery after a kidney biopsy.

**Case Description:** A 54-year-old female presented to the nephrology clinic for evaluation of proteinuria. She has had hypertension for about 8 years. Diabetes mellitus was recently diagnosed. Our workup showed proteinuria of 3 gm. Serum albumin level was 3.9 gm/dL and urinalysis was unremarkable. Serological workup for evaluation of proteinuria was negative. A decision was made to pursue a kidney biopsy. With the patient in the prone position, the left kidney was identified with an ultrasound. An 18-gauge spring loaded needle was used to obtain 2 cores of kidney tissue under ultrasound guidance. After the second pass the patient developed sudden pain at the biopsy site. A quick look with the ultrasound did not show any obvious hematoma but because of patient's discomfort, the procedure was abandoned. A CT scan of the abdomen showed a 14 cm perinephric hematoma. An immediate arteriogram showed bleeding from a pseudoaneurysm of a branch of the L1 lumbar artery which was stopped with micro-coil embolization. There was no evidence of bleeding from the intra-renal arteriogram.

**Discussion:** Bleeding is one of the common complications of a kidney biopsy. Most of the bleeding episodes occur due to an injury of an intra-renal vessel. Injury of a lumbar artery is rare, with only a few cases reported so far. Small branches of lumbar arteries may not be detectable on doppler ultrasound and are vulnerable to injury during a kidney biopsy. Injury of a lumbar artery should be considered in case of a negative renal arteriogram. Hence a kidney biopsy should only be performed at or near a center with angiographic and surgical support.

Lumbar artery angiogram, pre and post coil embolization

PUB271

Indications and Complications Associated With Centrifuge-Based Therapeutic Plasma Exchange

David M. Warner, Prakash S. Gudsoorkar, Manish Anand. University of Cincinnati, Cincinnati, OH.

**Background:** Therapeutic Plasma Exchange (TPE) is an extracorporeal treatment modality for management of certain diseases. To investigate the indications and safety of TPE, a retrospective review was conducted to identify the indications for TPE and the associated complications.

**Methods:** This is a single center retrospective review of centrifuge based TPE performed by the nephrology department at a tertiary care academic center between June 2018 to July 2019. Overall, 320 TPE treatments were performed on 44 patients.

**Results:** In total, there were fourteen diagnostic indications for TPE (Fig 1) along with their category of indication based on the American Society for Apheresis (ASFA) guidelines. The most common indication was myasthenia gravis, followed by autoimmune encephalitis and Antibody-Mediated Rejection (AMR) in kidney transplant recipients. Complications are documented in Fig 2. The most common complications were coagulopathy (43%), hypokalemia (41%), hyperglycemia (41% each), and hypotension (27%).

**Conclusions:** Overall, 14 diseases were noted as indications for TPE with myasthenia gravis being the most common. In terms of complications, depletion coagulopathy, hyperglycemia, and hypokalemia were the most common. This study exemplifies the utility of having a systematic audit to review the practice patterns and complications of TPE.

Lupus Nephritis: A Case Series on Hispanic Patients

Jordy Batista,<sup>1</sup> Denazir Atizol Rodriguez,<sup>1</sup> Irvianny Madera,<sup>1</sup> Eliana Bencosme,<sup>2</sup> Eliana Dina-Battle,<sup>1</sup> <sup>1</sup>Hospital Metropolitano de Santiago, Santiago De Los Caballeros, Dominican Republic; <sup>2</sup>Centros de Diagnostico y Medicina Avanzada y de Conferencias Medicas y Telemedicina, Santo Domingo, Dominican Republic.

**Introduction:** Lupus Nephritis (LN) is considered to be one of the main causes of death in patients with lupus systemic erythematosus (LSE). The evolution of this disease in the kidney may be insidious, showing no clinical signs of damage while creating irreversible changes to the kidney architecture. While clinical and laboratory assessment is used to gauge the progress of the disease, the kidney biopsy (KB) is paramount.

**Case Description:** KB results were taken from 26 patients of a large hospital in Santiago, Dominican Republic. 92.31% of the patients were female, all of them were hispanic, the mean age of biopsy was 29.5 ±10.4 years and the mean serum creatinine was 1.098 ±0.246 mg/dL. 96.29% of the biopsies reported with LN, while only 3.71% reported with focal segmental glomerulosclerosis (FSGS). Out of the biopsy reports of LN, the most frequent classes reported were IV and V, each having 23.08% of the total biopsies, followed by class III (19.23%). Among the coexisting findings, 2 arteriosclerosis, 3 FSGS, and 3 acute tubule injuries were reported. Incidentally, four out of the six patients who had a class V LN, also suffered from hypertension. There was no significant difference in the mean ages between the proliferative classes (I-IV) (27.53±4.77) and the non-proliferative class (31.17±8.5). The mean activity and chronicity indexes were 4.31±3.43 out of 24, and 1.92 ±1.51 respectively. In the immunostaining reports, 30.77% of the biopsies reported a full house staining (IgM, IgA, IgG, C3 and C1q positive).

**Discussion:** Serum creatinine values may not relate to the anatomopathological (AP) diagnosis of LN. Additionally, the same is to say when referring to the pathology report and the clinical manifestation of the patients at the time of the biopsy. Out of the patients with low C4 at the moment of biopsy, no specific class of LN was predominant. On the other hand, C4 values could be related to the presence of hypercellularity in the kidney interstice. Moreover, C3 levels were not related to the AP findings. Given the subtle nature of LN, patients and healthcare providers should be attentive of their condition to avoid further complications.

PUB273

Outpatient Safety on CT-Guided Percutaneous Kidney Biopsy: A Retrospective Cohort of 254 Patients in Two Private Hospitals of the Dominican Republic

Irvianny Madera,<sup>1</sup> Jordy Batista,<sup>1</sup> Denazir Atizol Rodriguez,<sup>1</sup> Eliana Bencosme,<sup>2</sup> Eliana Dina-Battle,<sup>1</sup> Hector A. Pantaleon,<sup>1</sup> Julia A. Gómez Jackson,<sup>3</sup> <sup>1</sup>Hospital Metropolitano de Santiago, Santiago De Los Caballeros, Dominican Republic; <sup>2</sup>Centros de Diagnostico y Medicina Avanzada y de Conferencias Medicas y Telemedicina, Santo Domingo, Dominican Republic; <sup>3</sup>Pontificia Universidad Catolica Madre y Maestra, Santiago de los Caballeros, Dominican Republic.

**Background:** The kidney biopsy (KB) is a vital tool for diagnosis and further management of kidney disease, with the drawback of possible complications particular to the procedure. In the past, to avoid these, KB were made as inpatient. Given the higher cost of the inpatient process and the safety of the procedure, KB started to be performed as outpatient, this sought to reduce the costs and, at the same time, did not alter the complication rate.

**Methods:** A retrospective analysis of Computerized Tomography (CT) guided percutaneous renal biopsies done at two private hospitals in Dominican Republic from January 2002 to May 2022 was performed. Clinical and laboratory data were collected for a total of 254 patients. Statistical analysis was performed using the Student's t-test for continuous variable and chi-square test for categorical variables.

**Results:** A total of 254 CT-guided percutaneous KB were performed between 2002 and 2022 of which 66.5% were made as an outpatient procedure. The prevalent gender was female (50.8%), the average age at the time of the biopsy was 35.7±17.5 years, and the most common comorbidities were hypertension (47.2%) and diabetes mellitus (14.6%). Only 15.4% of the population presented complications such as: hematoma (61.5%), pain (46.2%), hematuria (28.2%), and hypotension (15.4%). There was an association between increased number of platelets and hematoma development (p<0.001). Only nine patients (5.0%) that were biopsied as an outpatient had to be hospitalized due to arising complications, mostly hematoma (77.8%). All complications emerged between the 8 hour observation period. There were no associated biopsy major complications or mortality related to the procedures.

**Conclusions:** While the complication percentage of the ultrasound guided biopsy appears to be comparable to the CT guided, the latter boasts lower major complication rate, and while it is a higher cost than the go-to option, there could be a reduction in hospital costs. Additionally, this alternative should be considered in patients in more delicate states. Compared to the US, CT-guided biopsies generally are a better diagnostic tool, reducing the need to repeat procedures, therefore reducing further risks.

## PUB274

## Use of Narsoplimab in a Paediatric Patient With IgA Nephropathy

Louise Oni,<sup>1,2</sup> Vincent McCormack,<sup>1</sup> Caroline A. Jones,<sup>1</sup> Jonathan Barratt.<sup>3</sup><sup>1</sup>Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom;<sup>2</sup>University of Liverpool Faculty of Health and Life Sciences, Liverpool, United Kingdom;<sup>3</sup>Leicester General Hospital, Leicester, United Kingdom.

**Introduction:** Narsoplimab is an investigational fully human mAb targeting MASP-2, the effector enzyme of the lectin pathway of the complement system. We report the first example of narsoplimab in a paediatric patient with IgA nephropathy (IgAN).

**Case Description:** An 8-year-old girl presented in 2013 with history of macroscopic haematuria, proteinuria (urine albumin:creatinine ratio [UACR] 81 mg/mmol Cr) and a transient decline in estimated glomerular filtration rate (eGFR). IgAN was diagnosed with histological features of focal proliferative glomerulonephritis and IgA deposition. She received corticosteroids, mycophenolate mofetil, an ACE inhibitor and ran a relapsing, remitting course (Fig). In 2021 at age 16, there was an irreversible decline in renal function and rise in proteinuria. Renal biopsy demonstrated 70% global sclerosis (M1, E0, S1, T1, C1). Due to declining renal function, persisting active inflammation and promising adult studies, compassionate use narsoplimab was provided and administered by IV infusion over 30 min once a week. The patient was observed for 30 min after each infusion with weekly surveillance tests to detect adverse events. She received 9 of 12 planned doses between Dec 2021 and Feb 2022. Dose 7 was omitted due to intercurrent febrile illness and the final 2 doses were omitted to focus on preparation for renal replacement therapy. All 9 doses were well tolerated with no adverse events. Narsoplimab did not appear to influence renal function (eGFR dropped from 36 to 24 ml/min/1.73m<sup>2</sup>) but demonstrated a dramatic reduction in proteinuria (425 to 157 mm/mmol Cr) similar to adult trials (Lafayette et al. *KI Rep.* 2020;5:11).

**Discussion:** This is the first report of complement inhibition for paediatric IgAN. Narsoplimab was well tolerated and dramatically improved proteinuria. Irreversible histological features of resistant IgAN may have impacted narsoplimab use in this patient warranting earlier intervention. Studies into efficacy of narsoplimab in children with IgAN are required.

## PUB275

## Severe Pediatric Methanol Intoxication Treated With Novel Tablo System

Hanan K. Tawadrous, Alyssa E. Ruddy, Cynthia J. D'Alessandri-Silva. Connecticut Children's Medical Center, Hartford, CT.

**Introduction:** Morbidity and mortality from toxic alcohols like methanol is largely increasing across age and ethnic groups in America. Hemodialysis (HD) can efficiently remove methanol and improve patient outcomes. Current guidelines recommend HD when the methanol concentration is >50 mg/dL until concentrations are <20 mg/dL and acid-base disturbances have been corrected. We describe a case of methanol intoxication successfully treated with the novel Tablo® Hemodialysis System ("Tablo System"; Outset Medical, San Jose, CA, USA).

**Case Description:** A 15-year-old, 55 kg male with a history of depression and prior suicidal ideas was admitted for blurred vision after ingestion of antifreeze. Labs revealed Hemoglobin 14.5 g/L, Na 143 mmol/L, K 3.9 mmol/L, Chloride 108 mmol/L, Total CO<sub>2</sub> 22 mmol/L, BUN 9 mmol/L, Cr. 0.9 mg/dL, Alb 4.3 g/L, Amylase 67, Lipase 32 unit/L, pH of 7.32 and negative urine drug screen. Initial methanol level was 124 mg/dL with serum osmolality of 340 mOsm/kg. Mental status was normal. Vital signs stable with adequate urine output. The patient was started on fomepizole, folic acid, thiamine and received 2 HD treatments, first using the Tablo System with a Revaclear™ 400 dialyzer, at blood flow rate (Qb) of 350 mL/min and dialysate flow rate (Qd) of 300 mL/min for 240 minutes. Post treatment, methanol was 28 mg/dL, serum Osm 307 mOsm/kg, with serum pH 7.4. Second treatment was performed using a conventional HD device with a Revaclear 400, Qb 350, and Qd 700 for 240 minutes. Post treatment methanol level was 9 mg/dL. Calculated time to methanol clearance via logarithmic regression yielded 7.07 hours and was achieved in 8 hours.

**Discussion:** Methanol toxicity can be successfully treated within the standard of care using the Tablo System in the pediatric population. Lessons: Qd of 300 and 700 can equivalently remove toxic Methanol levels via HD in a pediatric patient. Pediatric patients are experiencing an increasing rate of intoxications and HD geared towards these needs must be expanded.

## PUB276

## Associations of Clinical Characteristics With Metabolic Acidosis in Pediatric Kidney Transplant Recipients

Stella R. Kilduff,<sup>1,2</sup> Matthew K. Abramowitz,<sup>2,3</sup> Nicole A. Hayde.<sup>1,2</sup> <sup>1</sup>The Children's Hospital at Montefiore General Pediatrics, Bronx, NY; <sup>2</sup>Albert Einstein College of Medicine, Bronx, NY; <sup>3</sup>Montefiore Medical Center, Bronx, NY.

**Background:** Adult transplant studies have associated metabolic acidosis with graft failure and mortality. No study has systematically examined metabolic acidosis in pediatric kidney transplant recipients.

**Methods:** Children <18 years of age who received a kidney transplant at Montefiore Medical Center from 1/1/10-12/31/18 and had 3-month post-transplant lab data were included unless they underwent multi-organ transplant or experienced graft loss or had eGFR <30 ml/min/1.73m<sup>2</sup> at 3 months. Cross-sectional associations with serum bicarbonate and with metabolic acidosis (serum bicarbonate <22 meq/L or requiring alkali therapy) were examined at 3 months post-transplant using multivariable linear and logistic regression, respectively.

**Results:** 63 patients were identified. Mean age at transplant was 9.9±5.4 years. Baseline serum bicarbonate was 21.7±2.4 meq/L, 45% had serum bicarbonate <22 meq/L and 48% were receiving alkali therapy; prevalence of metabolic acidosis was 68%. Each 1-year higher age and 10 ml/min/1.73m<sup>2</sup> higher eGFR were associated with 0.2 meq/L (95% CI 0.02-0.31) and 0.3 meq/L (95% CI: 0.03-.55) higher serum bicarbonate, respectively (Table 1). Older age at transplant was associated with 21% lower odds of metabolic acidosis (95% CI: 0.66-0.94) (Table 2). Patients with a living donor transplant had 84% lower odds of metabolic acidosis (95% CI: 0.03-0.89).

**Conclusions:** Lower age and eGFR were associated with lower serum bicarbonate in children 3 months after kidney transplantation. In addition to older age, living donor status was associated with lower odds of metabolic acidosis. Future studies should examine determinants of serum bicarbonate over time and the impact of metabolic acidosis on pediatric transplant outcomes.

Aberrant JAK/STAT Signaling in Nephrotic Syndrome

Carol L. Shen, Louise Malle, Ashley Richardson, Sofija Buta, Jeffrey Saland, Dusan Bogunovic. Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Nephrotic syndrome (NS) is one of the most common childhood kidney diseases worldwide. Despite evidence suggesting immunologic derangements as contributors to disease, detailed understanding of the pathogenesis remains elusive. Current non-specific immunosuppressive therapy carries significant morbidity and mortality. We recently identified *JAK1* gain-of-function mutation in a patient with NS and multisystem immune dysregulation who was successfully treated with a JAK inhibitor. We hypothesized that dysregulation of JAK/STAT pathway is also present in different NS disease entities.

**Methods:** We recruited 10 subjects age 8-18yr with various etiologies of NS and 7 age and sex-matched healthy controls. We stained heparinized whole blood with immune surface markers including JAK/STAT members and performed mass cytometry to characterize immune system breadth and steady state activity.

**Results:** Despite canonical immune cell distribution of patients (Fig 1), JAK/STAT pathway overactivity is present in various NS etiologies compared to controls (Fig 2A). While all patients had dysregulated pSTAT1, pSTAT3 and pSTAT5, in patients with FSGS and IgA nephropathy, pSTAT3 pathway overactivity dominated T and NK cell subsets, whereas in individuals with Henoch Schonlein Purpura, pSTAT1 and pSTAT6 in B cells. Treatment-refractory patients had augmented levels of JAK/STAT pathway overactivity (Fig 2B).

**Conclusions:** JAK/STAT pathway overactivity may be present in some individuals with NS. Better characterization of JAK/STAT activity could inform targeted therapy.

Figure 2. Phosphorylated (pSTAT) and unphosphorylated STAT member activity by (A) disease and (B) remission status. pSTAT and STAT activity analyzed by C/TOF was quantified and expressed as relative intensity (log2) of each patient to their age- and sex-matched control. FSGS = Focal segmental glomerulosclerosis; IgAN = IgA nephropathy; HSP = Henoch Schonlein Purpura

New-Onset Dyslipidemia After Pediatric Kidney Transplantation: Long-Term Outcomes

Emily E. Zangla,<sup>1</sup> Scott Jackson,<sup>2</sup> Dao Huynh,<sup>1</sup> Sarah J. Kizilbash,<sup>1</sup> <sup>1</sup>University of Minnesota Twin Cities, Minneapolis, MN; <sup>2</sup>Fairview Health Services, Minneapolis, MN.

**Background:** The incidence of dyslipidemia after pediatric kidney transplant in the United States is unknown, as are its long-term consequences. We sought to identify the incidence of dyslipidemia and its effects on cardiovascular events (CVEs), allograft rejection and graft failure in pediatric renal transplant recipients.

**Methods:** We performed a single-center retrospective study of patients ages 0-21 who underwent kidney transplantation from 2011-2021. Dyslipidemia was determined by the terms: hypercholesterolemia, hypertriglyceridemia, hyperlipidemia and dyslipidemia. The composite outcome was time to a CVE (myocardial infarction, stroke, angina, arrhythmia, or cardiomyopathy), allograft rejection or failure. Dyslipidemia-free survival was analyzed using Kaplan-Meier curves, and the effect of dyslipidemia on the composite outcome was evaluated using Cox proportional model, treating dyslipidemia as a time-dependent covariate.

**Results:** 139 patients were included. Dyslipidemia-free survival after ten years was 67% (95% CI 55-81%). We found no effect of age, gender, race, BMI or steroid-based immunosuppression on dyslipidemia-free survival. Post-transplant dyslipidemia did not affect the likelihood of the composite outcome (HR 1.46; 95% CI 0.41-5.16). 6 patients (4.3%) received statin therapy for dyslipidemia without any adverse effects.

**Conclusions:** Dyslipidemia is common after pediatric kidney transplantation. We found no effect of dyslipidemia on cardiovascular events, allograft rejection and graft failure.

**Nutcracker Syndrome: A Rare Cause of Gross Hematuria**  
Vimal Master sankar raj. Division of Pediatric Nephrology *University of Illinois Chicago College of Medicine at Peoria, Peoria, IL.*

**Introduction:** Nutcracker syndrome (NCS) is a unique vascular compression disorder, where the left renal vein (LRV) is trapped between the aorta and superior mesenteric artery (SMA). We present here a pediatric patient with solitary kidney and this rare presentation.

**Case Description:** 12-year-old boy with prior H/o R multicystic dysplastic kidney, surgically removed, presented with bright red hematuria and abdominal pain for a day. His evaluation showed normal vitals and renal function. U/A with 2+ protein and 3+ blood. Further workup for GN was normal. A renal visceral duplex exam was done which showed an adequately enlarged solitary L kidney at 14.5 cm with duplex studies showing, a narrowed LRV as it crosses between SMA and aorta. The renal vein ratio was elevated at 5.8 confirming the diagnosis. He was conservatively treated with fluids and resolution of hematuria in 24 hrs.

**Discussion:** The term Nutcracker syndrome (NCS) refers to LRV compression between SMA and aorta. Prevalence remains unknown due to the variability of symptomatology. Clinical features are non-specific presenting as varying degrees of abdominal pain, flank pain, hematuria, proteinuria, varicocele, chronic pelvic pain, dyspareunia and dysmenorrhea. Affected individuals tend to be tall and thin contributing to an acute angle between aorta and SMA. Though gold standard for diagnosis is venography, CT scan and renal duplex are also useful tools to establish diagnosis. Ultrasound being noninvasive and radiation-free should be the preferred initial modality of imaging in pediatrics. Diagnosis can be made successfully when the rate of systolic peak velocity between the site of compression and vein at renal hilum is > 4.7. Treatment varies based on the severity of presentation and age at presentation. Conservative management is the norm in children as they may outgrow the condition. In patients with recurrent severe presentations and those who have failed conservative management, IR techniques such as stent placement or conventional surgical procedures may be indicated.

LRV compressed between aorta and SMA

**PUB280**

**Stability of Novel Urinary Biomarkers Used for Lupus Nephritis**  
Ellen Cody,<sup>1</sup> James Rose,<sup>1</sup> Rebecca Hopkins,<sup>1</sup> Megan Quinlan-Waters,<sup>1</sup> Catherine E. Robben,<sup>1</sup> Tingting Qiu,<sup>1</sup> Bin Huang,<sup>1</sup> Prasad Devarajan,<sup>1,2</sup> Hermine Brunner.<sup>1,2</sup> <sup>1</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH; <sup>2</sup>University of Cincinnati, Cincinnati, OH.

**Background:** We have developed and validated the Renal Activity Index for Lupus (RAIL), a composite score of six urinary biomarkers including neutrophil gelatinase – associated lipocalin (NGAL), monocyte chemoattractant protein-1 (MCP-1/CCL2), kidney injury molecule-1 (KIM-1), ceruloplasmin, adiponectin, and hemopexin) to monitor disease activity. It is critical to establish optimal sample handling conditions and storage prior to widespread clinical deployment and meaningful use in clinical trials. We have previously demonstrated the excellent short-term storage stability of NGAL and KIM-1; here we expand testing to include the other 4 RAIL biomarkers.

**Methods:** Urine was collected from 10 patients enrolled in the SLE Clinical and Research Database (IRB 2008-0635). The urine was then aliquoted and tested under shipping conditions, including freeze/thaw, ambient and longer-term storage (Figure 1). MCP-1, Ceruloplasmin, Adiponectin and Hemopexin were assayed by single-plex ELISA assay via commercially available kits. We performed Pearson Correlation Coefficient, Deming regression and Bland-Altman analysis.

**Results:** There was no statistical difference in biomarker concentrations in any of the four biomarkers in any of the experimental conditions. Urinary MCP-1, Adiponectin, Hemopexin and Ceruloplasmin are stable following storage at -80°C for up to 3 months, and at 4° or 25°C up to 48 hours followed by -80° C. In addition, shipping on dry ice or with refrigeration leads to no significant loss of signal. The addition of 1 or 2 additional freeze thaw cycles also did not change mean biomarker levels.

**Conclusions:** RAIL biomarkers are stable following short-term storage at clinically relevant conditions, including shipping on ice.

**Pediatric Kidney Transplant Recipients' Emergency Room Visit Alert**Amal G. Ezzaiyani, Arwa Nada, Rima S. Zahr. *The University of Tennessee Health Science Center, Memphis, TN.*

**Background:** Pediatric kidney transplant recipients are a unique patient population who have a complicated medical history requiring multidisciplinary care. Improve care between different teams involved in kidney transplant (KTx) patients, including emergency room (ER) physicians, is imperative. Aim: Quality Improvement project to improve timely communication between ED staff and KTx team from 74.4% (1/2017-12-2018) to 100% by June 30th 2021.

**Methods:** Key Drivers: using electron medical record (EMR) to alert ER team of patients' transplant status. (Figure 1)

**Results:** As shown in Figure 2, over time the EMR alert improved communication between the ED team and the KTx team to 100%.

**Conclusions:** EMR alert significantly improved communication to 100% between ED staff and the KTx team. The alert allowed for improved communication between the ER team members and the nephrology service, further allowing for a timely managed visit for this vulnerable population.

## PUB282

**Content Analysis of Online Birth Club Forums in Relation to Antenatal Kidney Defects**Katie Sullivan, Davy Weissenbacher. *University of Pennsylvania, Philadelphia, PA.*

**Background:** Despite being one of the most common congenital abnormalities, we know little about woman's experiences and what kinds of information they may seek when receiving diagnoses of Antenatal kidney defects. Objective: With the large adoption of Social Media by pregnant women as sources of information during their pregnancy, we propose to apply machine learning methods to analyze online pregnancy forums to better understand how women seek information from a community of online peers regarding renal defects. This will help us to address gaps in knowledge and ultimately provide more personalized, effective prenatal care.

**Methods:** We collected posts from seven "birth club" forums (March-November 2021) from WhatToExpect.com and analyzed the initial posts from each thread (n = 15,000). We computed the topics discussed with the Latent Dirichlet Allocation statistical model, and, after manual review of the topics, we grouped them categorically.

**Results:** Largest topic categories included worry about the abnormality detected on anatomy scan (33 percent) followed by posts offering reassurance of a normal life with the kidney anomaly (31 percent).

**Conclusions:** Women do use online forums to discuss antenatal kidney defects, but these posts are relatively rare compared with the frequency of kidney defects (6.8 percent). This suggests potentially that women diagnosed with antenatal kidney anomalies talk about these less commonly online than women diagnosed with other antenatal defects. Amongst the relevant posts, the most common anomalies mentioned are also the most common antenatal renal anomalies, hydronephrosis and unilateral renal agenesis.

## PUB283

**Transition Readiness in Kidney Disease**Isabelle Lopez, Sarah K. Coufal, Taryn Shappell, Elaine Ku. *University of California San Francisco, San Francisco, CA.*

**Background:** To mitigate the challenges faced by patients transferring into adult care, we established a Transition Clinic to support adolescents with kidney disease during the transition to adult care. The clinic focused on improving self-efficacy including educating patients about their baseline kidney function, laboratory values, and concrete health care management skills necessary for post-kidney transplant care. The clinic also performed assessments of mental health.

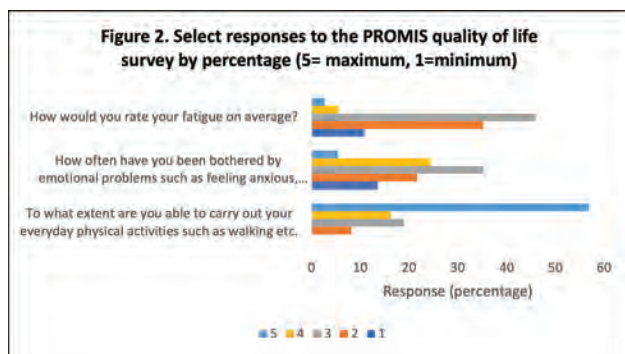

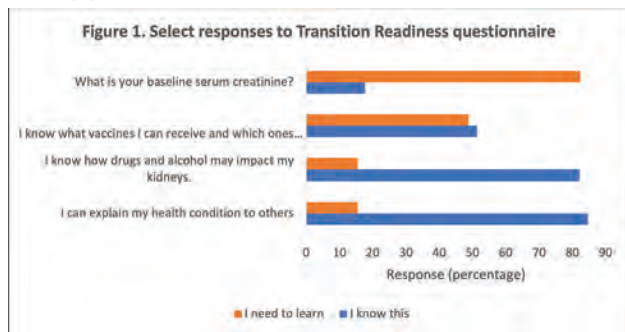

**Methods:** 40 participants >18 years of age were asked to complete a survey on their transition experience, quality of health (using the PROMIS survey), and transition readiness. Subjects were asked to self-report hospitalizations and emergency room visits over the prior 12 months. Chi square tests were used to relate knowledge about kidney disease and quality of mental health with use of emergency room or hospitalizations.

**Results:** The mean age of participants was 23 and 52% had a functional kidney transplant. Overall, knowledge regarding kidney disease (Figure 1) and participants' self-reported mental health varied (Figure 2). We found that 60% of patients who did not know their baseline serum creatinine had at least 1 emergency room visit in the past year.

Additionally, 66% of patients who rated their mental health "very good" had no hospital overnight stays in the past year, versus 65% of patients who rated their mental health poor had at least 1 overnight stay.

**Conclusions:** We found that individuals who did not know their baseline serum creatinine were more likely to have emergency room visits and subjects who reported poor mental health tended to be admitted to the hospital. Addressing specific knowledge gaps and recognizing individuals with poor mental health may improve outcomes in this vulnerable population.

## PUB284

### Diuretic Exposure in Critically Ill Pediatric Patients Who Progress to Continuous Renal Replacement Therapy

Rosanna Fulchiero,<sup>1</sup> Benjamin L. Laskin,<sup>1</sup> Sarah J. Schrauben,<sup>2, 1</sup> *The Children's Hospital of Philadelphia, Philadelphia, PA; <sup>2</sup>Hospital of the University of Pennsylvania, Philadelphia, PA.*

**Background:** Fluid overload (FO) is common in critically ill children and is associated with substantial morbidity, including prolonged mechanical ventilation (MV), need for continuous renal replacement therapy (CRRT), and mortality. The optimal management of FO remains unclear and diuretic use among critically ill children with FO is not well described. In this study, we aim to characterize diuretic exposure in children with FO who progressed to CRRT.

**Methods:** This is a single center retrospective cohort study of pediatric patients admitted to a general pediatric intensive care unit (ICU) in a large academic children's hospital from 2018-2020, who progressed to CRRT for a primary indication of FO as determined by: comparison to admission weight, MV dependence, oliguria and/or clinical exam. Charts were manually reviewed for all study variables. Diuretic exposure was calculated as mg/kg/day for each respective medication class in the 72 hours prior to initiation of CRRT. Outcomes included % FO at CRRT initiation, CRRT duration, hospital length of stay and mortality. Clinical outcomes were compared between groups using Kruskal-Wallis or Pearson's chi-squared tests as appropriate.

**Results:** Fifty patients (age 0-20 years) met the inclusion criteria within the study period. All patients (100%) were on MV prior to CRRT. Forty (80%) received a diuretic in the 72 hours prior to CRRT; of which, all received a loop diuretic, and 38% also received chlorothiazide or metolazone. Loop diuretic dosing differed among groups (Table 1). Total hospital stay was longest among those in the loop/chlorothiazide group (p=0.049). There was no difference between groups for % FO at CRRT initiation, CRRT duration, or mortality (Table 1).

**Conclusions:** To our knowledge, this is the first study to report diuretic exposure in critically ill pediatric patients with FO that progressed to CRRT. Future research is necessary to determine optimal timing and dosing of diuretic therapy to mitigate adverse outcomes associated with fluid overload.

**Funding:** Other NIH Support - T32 GM 075766-15

### Renin Mediated Hypertension in Pediatrics

Miranda J. Floen,<sup>1,2</sup> Arwa Nada,<sup>1,2</sup> *UTHSC, University of Tennessee Health Science Center, Memphis, TN; <sup>2</sup>LeBonheur Children's Hospital, Memphis, TN.*

**Introduction:** Hypertensive crisis is uncommon in children, however when children present with severely elevated blood pressure or acute change in blood pressure further evaluation is needed for secondary causes. Presented are 3 separate cases of renin mediated hypertension due to 3 different pathologies.

**Case Description:** Twenty one month old boy presented with severe hypertension, imaging and lab work up showed elevated renin (32 ng/ml/hr) & aldosterone (68ng/dL). CT angiography (CTA) showed findings consistent with mid-aortic syndrome (figure 1A). The second was 6 years old girl presented with salt craving, emesis and seizure; hypokalemia (1.8 mmol/L), high renin (42 ng/ml/hr) and aldosterone (60ng/dL). CTA was showed poorly enhancing 0.2mm x 0.3mm cortical lesion (figure 1B) that was surgically resected. Pathology confirmed a juxtaglomerular cell tumor. The third patient was a 13-year-old female with known hypertension admitted with a hypertensive crisis, hypokalemia (2.7 mg/dL), high renin (38 ng/ml/hr) and aldosterone (16ng/dL). Renal ultrasound and Doppler noted interval growth of a right renal complex renal cyst (Figure 1C), noted on previous imaging. Pathology completed following partial right nephrectomy identified renal cell carcinoma.

**Discussion:** The stepwise diagnosis of high renin HTN in pediatric population is shown in figure 2.

A: Patient 1 with mid-aortic syndrome; B: Patient 2 with juxtaglomerular cell tumor; C: Patient 3 with complex renal cyst/renal cell carcinoma

### Daily Medication Volume of Phosphate Binder Therapies

Nupur S. Mistry,<sup>1</sup> Nadia Khambati,<sup>3</sup> Pramod Gupta,<sup>2</sup> Suresh Vayalakkada,<sup>2</sup> Stuart M. Sprague,<sup>1,3</sup> *The University of Chicago Medicine, Chicago, IL; <sup>2</sup>Unicycive Therapeutics, Inc., Los Altos, CA; <sup>3</sup>NorthShore University Health System, Evanston, IL.*

**Background:** Elevated phosphate concentrations are associated with a significantly increased risk of cardiovascular events and mortality in patients with chronic kidney disease. The current KDIGO guideline recommends lowering elevated serum phosphorus concentrations toward normal range in patients with ESKD on dialysis through restriction of dietary phosphorus intake, increase in clearance by dialysis, and the use of phosphate binders. There is evidence that 78% of patients are not adherent to phosphate binders. This is thought to be the result of phosphate binders' large sizes and high pill burden. A high daily medication volume creates a barrier to adherence and can negatively impact the quality of life. Thus, a phosphate binder that maintains efficacy with a lower daily medication volume could improve adherence, quality of life, and potentially clinical outcomes. This study evaluated the daily medication volume of various phosphate binders to determine the option with the lowest required daily volume.

**Methods:** The daily dose volumes for lanthanum dioxycarbonate (RENAZORB™), sucroferic oxyhydroxide, calcium acetate, lanthanum carbonate, ferric citrate, and sevelamer carbonate were calculated. The volume for each binder was determined by fluid displacement method, which measures the increase of volume after placing the binder into a graduated measuring cylinder with a fixed volume of liquid. Each measurement was performed in duplicate. The mean daily dose volume was calculated by multiplying the volume per tablet by the mean number of tablets taken per day, based on literature.

**Results:** Lanthanum dioxycarbonate and sevelamer carbonate had the lowest and highest daily dose volume, respectively (Fig 1). The daily dose volume for lanthanum dioxycarbonate was 3-to-4-fold lower than other phosphate binders, with a total daily volume similar to ~3.5 M&M's.

**Conclusions:** Lanthanum dioxycarbonate, a novel investigational nanotechnology product, may be a welcome choice for patients to manage their hyperphosphatemia. Improved size (easily swallowed) and tolerability have the potential to increase medication adherence and phosphate control.

## PUB287

### Comparison of Hydroxychloroquine Concentration Among Whole Blood, Serum, and Plasma Samples in Indian Patients With Lupus Nephritis

Arun Kumar Subbiah, Ujjalkumar S. Das, Thirumurthy Velpandian, Sanjay K. Agarwal. *All India Institute of Medical Sciences, New Delhi, India.*

**Background:** Lupus nephritis (LN) is an important risk factor for morbidity and mortality in systemic lupus erythematosus (SLE). Hydroxychloroquine (HCQ) is an integral part of the therapeutic armamentarium for SLE, both in prophylaxis and treatment. Data regarding HCQ levels in whole blood, serum and plasma and recommended therapeutic cut-offs have not been reliably determined. The present study aims to estimate and correlate HCQ concentrations in whole blood and its components (serum and plasma) in LN patients in Indian subpopulation.

**Methods:** Lupus nephritis patients on HCQ therapy for a minimum of 3 months were included in this study. HCQ blood levels (ng/mL) in same patient from EDTA whole blood, plasma and serum were measured by liquid chromatography-tandem mass spectrometry and correlation among different bio sample was done.

**Results:** In this cohort study, 51 patients were included with mean age of 29.5±8.98 years, of which 88.2% were women. The mean HCQ dose was 4.9±1.7 mg/kg/day. The mean HCQ levels in whole blood, plasma and serum were 934.3±707.7 ng/mL, 357.2±259.4 ng/mL and 354.93±276.44 ng/mL, respectively. The mean levels in whole blood were approximately 2.5-fold the levels in serum and plasma. Whole blood concentrations of HCQ had positive linear correlations with both plasma and serum concentrations, with a correlation coefficient of 0.549 and 0.778 (p<0.001), respectively (Figure 1). Whole blood levels with dose of 200 mg/day were lower than 400 mg/day (736±666.40 ng/mL vs 1117.45±814.66 ng/mL).

**Conclusions:** This is the first Indian study to look at HCQ concentrations in patients with lupus nephritis in whole blood, serum and plasma. All three samples' sources have good correlation and any sample can be used from clinical point of view.

## PUB288

### Improving Opioid Utilization for Pain Management in Patients Suffering From CKD5 and ESRD

Marcus Castillo,<sup>1</sup> Charles Bonanno,<sup>2,3</sup> Michael M. Samiratedu,<sup>2,3</sup> Alier Nunez Sanchez,<sup>2</sup> Marie A. Sosa.<sup>2,1</sup> <sup>1</sup>University of Miami School of Medicine, Miami, FL; <sup>2</sup>University of Miami Health System, Miami, FL; <sup>3</sup>Jackson Memorial Hospital, Miami, FL.

**Background:** The use of morphine and codeine to treat pain in patients with CKD5 or ESRD has been associated with neurotoxic side effects due to the accumulation of drug metabolites secondary to impaired renal clearance and altered pharmacokinetics. Guidelines that offer physicians alternative treatment options with a safer side effect

profile are essential. The goal of this project is to reduce the unnecessary use of these drugs in these patients at the University of Miami Hospital (UMH).

**Methods:** A retrospective study was performed to determine the baseline metrics for how often morphine and codeine were prescribed to CKD5 and ESRD patients at UMH. From August 1st 2021 - January 31st 2022, data obtained from the Epic Electronic Medical Records showed that these opioids had been prescribed to this patient population a total of 532 times. Additionally, of 32 opioid related ADRs in 2021, 12 (38%) were seen in patients with renal dysfunction. Following a root cause analysis, the team detailed interventions to optimize treatment for these patients including: 1) offering brief educational materials 2) providing an evidence-based adapted WHO analgesic ladder with alternative treatment options, 3) creating physician and pharmacist electronic safety and best practice alerts (BPA) 4) initiating a daily report by the Opioid Stewardship for the prescription of these drugs in ESRD whereby pharmacists contact providers with recommendations.

**Results:** This quality improvement project is currently being implemented.

**Conclusions:** Following these interventions, we will analyze patient data to see if there has been a reduction in the overuse of these medications with the goal of reducing the number of opioid related ADRs from 38% to less than 10% in the 6 months following the PDCA cycle.

Figure 1. Codeine and Morphine Prescribed in CKD5 and ESRD at UMH 8/1/21 - 1/31/22.

### Role of Cell-Free DNA in the Follow-Up of CKD Patients After Kidney Transplantation

Chiara Leotta,<sup>1,2</sup> Leah N. Hernandez,<sup>1</sup> Lubomira Tothova,<sup>3</sup> Milan Chromek,<sup>1</sup> Paola Ciceri,<sup>2</sup> Mario Cozzolino,<sup>2</sup> Peter Stenvinkel,<sup>1</sup> Karolina Kublickiene.<sup>1</sup> Renal division of Karolinska Institute and University of Milan ASST Santi Paolo e Carlo <sup>1</sup>Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Università degli Studi di Milano, Milano, Italy; <sup>3</sup>Univerzita Komenského v Bratislave, Bratislava, Slovakia.

**Background:** Circulating cell-free DNA (cfDNA) has emerged as a novel biomarker in patients who have undergone an organ transplant but also in pregnant women and cancer patients. Studies have shown that cf-DNA strongly correlates with cell damage and rejection after transplantation. In particular mitochondrial-DNA is known to be related to the inflammatory state. Cf-DNA is a potential non-invasive marker that could be used for diagnosis and monitoring of possible graft rejection and organ damage.

**Methods:** Plasma samples were collected from 44 chronic kidney disease patients before and two years after kidney transplantation. The group of patients consisted in 33 males and 11 females with age ranging between 25-80 years old, undergoing conservative therapy and haemodialysis. Clinical inclusion criteria were at least one of the following: diabetes, hypertension or cardiovascular disease. Cf-DNA were isolated from plasma and then quantified with fluorometric method. A qPCR procedure was used to quantify and distinguish between the mitochondrial and the nuclear cf-DNA amount.

**Results:** Total cf-DNA from kidney transplant patients showed decreased trend from baseline to two years post-transplantation. The same decreased pattern of total cf-DNA were also observed among males and females, however it was not statistically significant. Further evaluation of the two cf-DNA fractions, mitochondrial cf-DNA was significantly higher than nuclear cf-DNA both for the baseline and two years after transplant (p<0.05). Sex disaggregated analysis showed also a trend in males having a higher mitochondrial and nuclear cf-DNA than females at the baseline and at two years follow-up, although not statistically significant.

**Conclusions:** Our preliminary results suggest that transplant may reduce the inflammatory state of patients and this is supported by the lower levels of mitochondrial-cfDNA 2 years after transplant compared to baseline. The lack of differences between males and females may suggest that kidney transplantation has the same effects in both sexes, although extended studies are required, including separation between mitochondrial and nuclear cf-DNA. Further studies are ongoing to assess if cf-DNA could serve as an accurate non-invasive method for monitoring the response to organ transplant in the future.

**Funding:** Government Support - Non-U.S.

## PUB290

**Anemia in the First Year Post Kidney Transplantation**

Ziad Arabi,<sup>1,2</sup> Talha M. Youssouf,<sup>1,2</sup> Dr Junaid Iqbal,<sup>1,2</sup> <sup>1</sup>*Division of Nephrology, Department of Medicine, King Abdulaziz Medical City, Riyadh, Saudi Arabia;* <sup>2</sup>*King Abdullah International Medical Research Center, College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.*

**Background:** Anemia, defined as hemoglobin (Hb) <120 g/L in women and <130 g/L in men, is a common finding before and after kidney transplantation (KT). Late post transplantation anemia is defined as anemia which develops after 6 months. There is no previous data about anemia post KT and the associated factors of late anemia at our center.

**Methods:** A single center retrospective study of kidney transplant recipients (KTR) from 2017 to 2020. We collected data about patients' demographics, cardiovascular risk factors, and the values of hemoglobin at baseline (before KT), and up to 24 months post KT. We defined anemia as above.

**Results:** We included 287 KTR. 74% were  $\geq 30$  years, 58% were men and 80% were living-donor KTR. Pre-emptive KT was performed in 10.1%. Pre- KT dialysis modality was PD in 11.5% and HD in 78.4% (AVF: 42%). Dialysis vintage was  $4.8 \pm 3.3$  years for deceased donor KT versus  $2.4 \pm 2.6$  years for living donor KT. Mean Hb (g/L) at baseline (before KT):  $114.3 \pm 17.3$ ; at 1- 6 months:  $101.5 \pm 15.3$ ; at 6-12 months:  $138.6 \pm 19.4$ ; and after 12 months:  $141.2 \pm 20.1$ . Average hemoglobin change from baseline to 12 months was 26.6 (23.8 to 29.5). P value: <0.001. Figure 1 illustrates average Hb at the time of KT, 1-6, 6-12 and after 12 months post KT. Anemia was identified in 197 (68.6%) at baseline (before KT) but it decreased to only 31 (10.8%) by 12 months and only 21 (7.3%) KTR had severe anemia at 12 months. There were no association between anemia at 12 months and patients' demographics including age, gender, blood group, type of dialysis, and type of access; nor baseline cardiovascular risk factors.

**Conclusions:** Anemia is common among renal transplant candidates. Hemoglobin levels drop further, early, after transplantation but progressively improve by 12 months. There was no association between the incidence of late anemia post KT and baseline patients' demographics or pre-transplant cardiovascular risk factors.

Changes of hemoglobin (HG) post kidney transplantation

## PUB291

**The Management of Dyslipidemia in Kidney Transplant Recipients According to Kidney Disease: Improving Global Outcomes vs. the Guidelines of the American Heart Association**

Ziad Arabi,<sup>1,2</sup> Ahmed S. Alnasrullah,<sup>1,2</sup> Abdullah A. A. AlGhamdi,<sup>1,2</sup> Mohammed H. Tawhari,<sup>1,2</sup> <sup>1</sup>*Division of Nephrology, Department of Medicine, King Abdulaziz Medical City, Riyadh, Saudi Arabia;* <sup>2</sup>*King Abdullah International Medical Research Center; College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.*

**Background:** The management of dyslipidemia, according to the guidelines of the KDIGO organization of kidney transplant recipients (KTR), has not been reviewed in terms of the more recent guidelines of the American Heart Association (AHA).

**Methods:** We conducted a single-center, retrospective study with KTR, from 2017 to 2020. The data included the demographic characteristics, cardiovascular risk factors, and the lipid profile (pre-transplant and at 12 months post-transplantation). The study aimed to compare the rate of achieving the target goals of dyslipidemia management, as defined by the two guidelines.

**Results:** In total, 287 KTR were included, 214 (74.6%) were  $\geq 30$  years old (yo), 58.2% male, and 80.5% a living-donor KTR. Of the 214 patients 30 years and older, 80% received a statin. Statins were prescribed in 93% and 96% of the patients with Diabetes (DM) or coronary artery disease (CAD) respectively. The LDL targets were achieved in 62% of the group  $\geq 30$  yo (LDL target of 2.6), or in 19% (LDL target of 1.8).

**Conclusions:** Despite a high compliance rate with statin prescriptions, based on the protocolized approach of the KDIGO guidelines, a significant proportion of the KTR with risk factors did not achieve the LDL targets proposed by AHA guidelines for dyslipidemia management.

## PUB292

**Differential Control of Systolic and Diastolic Blood Pressure in Kidney Transplant Recipients**

Ziad Arabi,<sup>1,2</sup> Nayef Alawadh,<sup>1,2</sup> Abdullah S. Bawazir,<sup>1,2</sup> Nasser M. Alnazari,<sup>1,2</sup> Mubarak I. Abdalla,<sup>1,2</sup> Faye F. Alhejaili,<sup>1,2</sup> Dr Junaid Iqbal,<sup>1,2</sup> <sup>1</sup>*Division of Nephrology, Department of Medicine, King Abdulaziz Medical City, Riyadh, Saudi Arabia;* <sup>2</sup>*King Abdullah International Medical Research Center; College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.*

**Background:** Differential control of systolic and diastolic blood pressure (BP) is well documented in the treatment of hypertension in the general population but there is limited data in kidney transplant recipients (KTR).

**Methods:** A single center retrospective study of KTR who received kidney transplantation (KT) between January 2017 and May 2020. We reviewed BP readings before transplant and at one month, 6 months, and 12 months after kidney transplantation. We also reviewed the number of BP medications at the same intervals post transplantation. Blood pressure goal was <140/90 mmHg during the time of this retrospective study as per published guidelines. BP measurement in clinic was standardised.

**Results:** The number of anti-hypertensive medications post KT decreased with time (Table 1). There was positive correlation between SBP and number of BP medications, however DBP fell as number of anti-hypertensive medications increased (Table 2 and Figure 1).

**Conclusions:** Diastolic BP appeared much amenable to control than systolic BP in the first year and it required significantly a fewer BP medications to control to target. Further research is warranted to confirm this interesting observation.

Table. 2 The correlation between BP meds and SBP and DBP in the first year after kidney transplant

	Coefficient	P value
Systolic BP & number of meds at 12 months	0.379	<0.001
Diastolic BP & number of meds at 12 months	-0.154	0.016

Number of medications	1 month	6 months	12 months	P (For 1 month vs. 12 months)
0	67 (23.3%)	82 (28.6%)	84 (29.3%)	0.001
1	91 (31.7%)	93 (32.4%)	89 (31.1%)	
2	85 (29.6%)	83 (28.9%)	81 (28.2%)	
3	27 (9.4%)	18 (6.3%)	18 (6.3%)	
4	6 (2.1%)	2 (0.7%)	6 (2.1%)	
5	2 (0.7%)			

Table 1: Number of BP medications in the first year post KT

## PUB293

**The Impact of Dialysis Vintage on Cardiovascular Risk Factors and the Findings of Cardiovascular Screening Workup of Renal Transplant Candidates**

Ziad Arabi,<sup>1,2</sup> Talha M. Youssouf,<sup>1,2</sup> Mohamad Y. Abdulgadir,<sup>1,2</sup> Hazim S. Alghamdi,<sup>1,2</sup> Abdullah S. Bawazir,<sup>1,2</sup> Nayef Alawadh,<sup>1,2</sup> Mohammed H. Tawhari,<sup>1,2</sup> Mubarak I. Abdalla,<sup>1,2</sup> Faye F. Alhejaili,<sup>1,2</sup> <sup>1</sup>*Division of Nephrology, Department of Medicine, King Abdulaziz Medical City, Riyadh, Saudi Arabia;* <sup>2</sup>*King Abdullah International Medical Research Center; College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.*

**Background:** Although dialysis vintage is associated with increased mortality risk in patients receiving dialysis, the association of dialysis vintage with cause-specific mortality is unclear.

**Methods:** In a single center retrospective study, we reviewed the renal transplant recipients who underwent renal transplant from 2017 to 2020. We divided the group based on their dialysis vintage, < 3 years versus > 3 years. We collected the data about the patients' demographics, cardiovascular risk factor, dialysis modality, and pre-transplant work-up images.

**Results:** We included 278 patients, 109 patients in the longer vintage group and 169 patients in the shorter vintage group. The mean age  $43.8 \pm 16.1$  and 164 patients (59%) were male. The mean dialysis vintage in the shorter group was  $1 \pm 0.1$  year, and  $5.7 \pm 2.7$  years in the longer vintage group,  $p < 0.001$ . The most common comorbidities were hypertension (76%), followed by diabetes mellitus (41.7%), and were present in similar proportions of both groups. Compared to the shorter dialysis vintage group, those who had longer dialysis vintage were more likely to have a deceased kidney donor (36.7% vs 8.9%,  $p < 0.001$ ), receive hemodialysis (88.1% vs 76%;  $p = 0.006$ ), predominantly through an arteriovenous fistula (55% vs 20.7%;  $p < 0.001$ ). The results of pretransplant work up including cardiac stress test, calcium scoring, coronary angiogram, cardiac ejection fraction, left ventricular hypertrophy, wall motion abnormalities and the degree of calcifications of pelvic arteries on pelvic Ct scan did not differ between the two groups.

**Conclusions:** Dialysis vintage up to 3 years was not associated with increased incidence of the traditional cardiovascular risk factors, nor changes of cardiovascular imaging. This suggests that the increase of mortality related to dialysis vintage might be related to other factors such as uremia, electrolytes shifts and / or infections. Further studies with longer follow up are needed.

## PUB294

### Hyperglycemia (Hemoglobin A1c) in the First Year Post Kidney Transplantation

Ziad Arabi,<sup>1,2</sup> Aya K. Alkhudhairy,<sup>1,2</sup> Nayef Alawadh,<sup>1,2</sup> Reem A. Baduwaylan,<sup>1,2</sup> <sup>1</sup>*Division of Nephrology, Department of Medicine, King Abdulaziz Medical City, Riyadh, Saudi Arabia;* <sup>2</sup>*King Abdullah International Medical Research Center; College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.*

**Background:** There is limited data about hyperglycemia and its risk factors in the first year post kidney transplantation (KT).

**Methods:** A single center retrospective study of kidney transplant recipients (KTR) who underwent KT between 2017 to 2020. We reviewed the patients' demographics, weight changes and A1C values (at baseline and every 3 months) for 12 months post KT.

**Results:** A total of 287 KTR were included. 74% were  $\geq 30$  years, 58% were men and 80% were living-donor KTR. Preemptive KT was 10.1%, PD: 11.5% and HD: 78.4%. At baseline, obesity stage 1 (BMI: 30-34.9) was present in 20.2% of patients and obesity stage 2 (BMI 35-39.9) in 4.2%. Diabetes (DM) was present in 99 (34.5%), [DM type I: 25 (25.3%) and DM type II: 74 (74.7%)]]. By 12 months, both females and males significantly gained weight [6.33 Kg versus 5.79 Kg respectively]. The percentage of (weight gain / baseline weight) was numerically higher in females than males (10.6% versus 7.8%;  $p = 0.588$ ). In females, A1C was  $5.3 \pm 1.1$  at baseline, and increased by 1.44 (0.82 to 2.06) at 12 months;  $p < 0.001$ . Whereas in males, A1C was  $6.5 \pm 5.8$  at baseline, and increased by 0.8 (0.14 to 1.47) at 12 months;  $p = 0.02$ . The increase of A1C was statically significant higher in females ( $p = 0.04$ ). See Fig. 1. By one year, (n:22, 7.7%) developed post KT diabetes mellitus. Predictors of A1C increase of  $> 0.5\%$  were: age (OR: 1.05, CI: 1.02 to 1.08,  $P < 0.01$ ), weight change (OR: 1.05, CI: 1.01 to 1.10,  $P = 0.01$ ) and hypertension (OR: 3.01, CI: 1.25 to 7.23,  $P = 0.01$ ). Baseline A1C was a negative predictor (OR: 0.45, CI: 0.32 to 0.62,  $P < 0.01$ ) but gender and dialysis vintage were not associated.

**Conclusions:** A1C increased significantly in the first-year post KT especially in females. Age, weight gain, lower A1C at baseline were positively correlated with increment in A1C.

HbA1C increase in the first year post KT

### Factors Associated With a Higher Need for Antihypertensive Medications at 12 Months Post Kidney Transplantation

Ziad Arabi,<sup>1,2</sup> Talha M. Youssef,<sup>1,2</sup> Elwaleed A. Elhassan,<sup>1,2</sup> <sup>1</sup>*Division of Nephrology, Department of Medicine, King Abdulaziz Medical City, Riyadh, Saudi Arabia;* <sup>2</sup>*King Abdullah International Medical Research Center; College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.*

**Background:** In this study we examined risk factors of “difficult to treat hypertension” at one year post kidney transplantation (KT).

**Methods:** A retrospective study of kidney transplant recipients (KTR) who underwent KT between 2017 and 2020. We reviewed results of pretransplant cardiovascular (CV) imaging, and the changes of CV risk factors during the first-year post KT. We divided patients according to the number of their BP medications at one year into two groups; those who required  $\leq 1$ , and those who required  $\geq 2$  medications “difficult to treat hypertension”. The target BP during the time of this retrospective study was  $< 140/90$  mm Hg as per the published guidelines.

**Results:** A total of 278 KTR were included. Of them 74% were  $\geq 30$  years, 58% were men and 80% were living-donor KTR. Preemptive KT was 10.1%. PD and HD were 11.5% and 78.4%, respectively. At one year, 70.1% of the patients attained the target BP goal. Thirty eight percents of the patients had “difficult to treat HTN”. Risk factors were: age (50 vs. 39 years,  $P < 0.01$ ), prior history of HTN ( $P < 0.01$ ), prior AV fistula ( $P = 0.04$ ) and diabetes mellitus ( $P < 0.01$ ). Whereas, dialysis vintage (including preemptive transplantation), type of dialysis, type of KT, and smoking were not different among the two groups. Patients with “difficult to treat HTN” at one year were more likely to have abnormal pre-transplant CV baseline imaging including abnormal ejection fraction  $< 55\%$  ( $P = 0.04$ ), abnormal wall motion on echocardiography ( $P < 0.01$ ), abnormal perfusion stress test ( $P < 0.01$ ), higher calcium scoring ( $P < 0.01$ ), abnormal cardiac catheterization ( $P < 0.01$ ), and a higher degree of calcifications on CT of pelvic arteries ( $P < 0.01$ ). Patients with “difficult to treat HTN” were likely to have a higher BMI at 12 months ( $P = 0.02$ ), whereas rejection, change of creatinine, persistent hyperparathyroidism and anemia at 12 months were not different among the two groups. Multivariate analysis indicated a relation with age (aOR: 1.025); male gender (aOR: 2.41); DM (aOR: 2.07); baseline HTN (aOR 2.58). However, the odds ratio for BMI at 12 months was insignificant ( $P = 0.98$ ).

**Conclusions:** At one year post transplantation, about a third of KTR required two or more BP medications. These patients were more likely to be older, males, diabetic, previously hypertensive and to have abnormal baseline pre-transplant CV imaging.

## PUB296

### Kidney Transplantation and Statins' Effects on Dyslipidemia in Kidney Transplant Recipients

Ziad Arabi,<sup>1,2</sup> Abdullah A. A. AlGhamdi,<sup>2,1</sup> Ahmed S. Alnasrullah,<sup>2,1</sup> <sup>1</sup>*King Abdullah International Medical Research Center; College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia;* <sup>2</sup>*Division of Nephrology, Department of Medicine, King Abdulaziz Medical City, Riyadh, Saudi Arabia.*

**Background:** To review the effect of kidney transplantation (KT) and adding of statins on dyslipidemia in kidney transplant recipients (KTR)

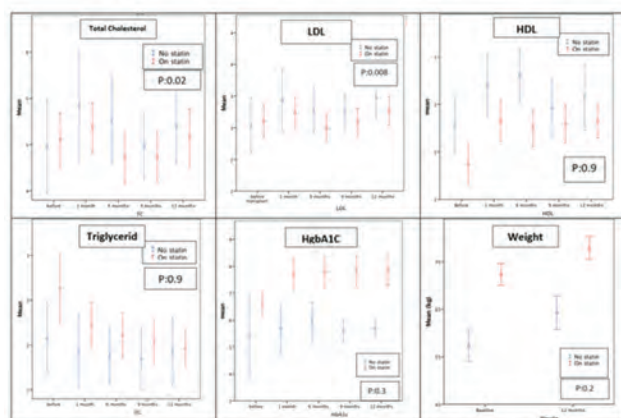

**Methods:** A single center retrospective study of KTR, from 2017 to 2020. Lipid's profile and Hgb A1C were reviewed at baseline (before KT) and at average 12 months of KTR who received statins or not

**Results:** We included 287 KTR, 74% were  $\geq 30$  years. Statins were prescribed to 80% of KTR who were  $\geq 30$  years old. The most common statin used was Atorvastatin at 10 mg in 60% or 20 mg in 23% of the cases. In KTR who did not receive statins: KT was associated with an increase of total cholesterol (TC) by 0.31 mmol /L ( $P = 0.02$ ) and an increase of LDL by 0.40 mmol /L ( $P < 0.01$ ). On the other hand, and despite weight gain of average 6.9 kg ( $P < 0.01$ ), and increase of A1C by 0.71 ( $P < 0.01$ ); KT was associated with an increase of HDL by 0.17 mmol /L ( $P < 0.01$ ) and down trending but not statically significant decrease of triglyceride (TG) by -0.09 mmol /L ( $P = 0.28$ ). In KTR who received statins: despite weight gain of 5.6 kg ( $P < 0.01$ ) and increased of A1C by 0.93 ( $P < 0.01$ ), HDL improved by 0.17 mmol /L ( $P < 0.01$ ) and TG decreased by -0.34 ( $P < 0.01$ ). Statins were associated with a numerical decrease of TC by -0.06 ( $P = 0.51$ ) and nonsignificant increase of LDL by only 0.04 ( $P = 0.60$ ). Statins were associated with improvement of TC and LDL compared to no statins. The mean changes of TC (from baseline to 12 months) while on statins versus none were (-0.06 versus 0.31,  $P < 0.02$ ) and the mean changes of LDL (from baseline to 12 months) while on statins versus none were (0.04 versus 0.40,  $P < 0.01$ ).

**Conclusions:** Despite weight gain and the increased level of A1C seen after KT, KT was associated with improved TG and HDL. Adding statins in patients at higher risk of dyslipidemia not only maintained the beneficial effects of KT on HDL and TG but also had significant “buffering” effect against the rising of TC and LDL

## Lipids profile changes in the first year after renal transplant

P values were calculated for the difference of changes from baseline to 12 months for those who were on statins versus no statins

## PUB297

### The Trend of Blood Pressure in the First Year Post Kidney Transplantation in Kidney Recipients With Uncontrolled Hypertension

Ziad Arabi,<sup>1,2</sup> Talha M. Youssouf,<sup>1,2</sup> Mohamad Y. Abdulgadir,<sup>1,2</sup> Hazim S. Alghamdi,<sup>1,2</sup> Abdullah S. Bawazir,<sup>1,2</sup> Faye F. Alhejaili,<sup>1,2</sup> Reem A. Baduwaylan,<sup>1,2</sup> Dr Junaid Iqbal,<sup>1,2</sup> <sup>1</sup>Division of Nephrology, Department of Medicine, King Abdulaziz Medical City, Riyadh, Saudi Arabia; <sup>2</sup>King Abdullah International Medical Research Center; College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.

**Background:** It has been shown that both systolic and diastolic BP significantly trend down in the first-year post kidney transplantation (KT). We investigated if BP follows the same pattern in kidney transplant recipients (KTR) with uncontrolled hypertension (HTN).

**Methods:** A single center retrospective study of KTR who underwent KT between 2017 and 2020. We recorded and compared trends of systolic and diastolic BP readings at baseline (before transplant), and at 1-, 6- and 12-months post-transplant in addition to the number of BP medications post- KT at the same intervals. The target BP was <140/90 mmHg as per published guidelines at the time of this study. We divided patients according to their BP control at one-year post-transplant into two groups, controlled ( $\leq 140/90$ ) and uncontrolled ( $> 140/90$ ). We compared BP trends and the number of medications in the first year in those with controlled versus uncontrolled HTN at 12 months.

**Results:** A total of 254 KTR were included. Of those, 74% were  $\geq 30$  years, 58% were men and 80% were living-donor kidney recipients. Preemptive transplantation was 10.1%, PD 11.5% and HD 78.4%, respectively. At one year, 76 (29.9%) did not attain target BP goal. Systolic BP decreased by  $7.2 \pm 18.6$  mmHg from baseline in the group with controlled BP and whereas it increased by  $3.5 \pm 16.9$  mmHg in the group of uncontrolled BP ( $P < 0.001$ ). Diastolic BP decreased by  $4.1 \pm 12$  mmHg in the group with controlled BP whereas it increased by  $2 \pm 13.7$  mmHg in the group of uncontrolled BP ( $P < 0.001$ ). The number of BP medications in KTR with uncontrolled HTN was higher than those with controlled HTN as shown in Table.1.

**Conclusions:** Systolic and diastolic BP trended down from baseline after transplantation in KTR with controlled hypertension whereas both systolic and diastolic BP increased despite a higher number of BP medications in those with uncontrolled hypertension. This interesting finding requires further evaluation by a controlled prospective study.

Number of antihypertensive medications	Total 254	BP $\leq 140/90$ 178	BP $> 140/90$ 76 (29.9%)	P value
0	71 (29%)	40 (42.1%)	31 (20.7%)	0.006
1	80 (32.7%)	29 (30.5%)	51 (34%)	
2	72 (29.4%)	20 (21.1%)	52 (34.7%)	
3	17 (6.9%)	5 (5.3%)	12 (8%)	
4	5 (2%)	1 (1.1%)	4 (2.7%)

### The Impact of Dialysis Vintage on the Metabolic and Cardiovascular Risk Factors in the First Year Post Renal Transplantation

Ziad Arabi,<sup>1,2</sup> Mohamad Y. Abdulgadir,<sup>1,2</sup> Talha M. Youssouf,<sup>1,2</sup> Reem A. Baduwaylan,<sup>1,2</sup> Dr Junaid Iqbal,<sup>1,2</sup> Abdullah S. Althani,<sup>1,2</sup> Hamzah A. Alhamzah,<sup>1,2</sup> Aya K. Alkhudhairy,<sup>1,2</sup> <sup>1</sup>Division of Nephrology, Department of Medicine, King Abdulaziz Medical City, Riyadh, Saudi Arabia; <sup>2</sup>King Abdullah International Medical Research Center; College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.

**Background:** Although dialysis vintage is associated with increased mortality risk in patients receiving dialysis, the association of dialysis vintage with cause-specific mortality is unclear.

**Methods:** In a single center retrospective study, we reviewed the renal transplant recipients who underwent renal transplant from 2017 to 2020. We divided the group based on their dialysis vintage,  $< 3$  years versus  $> 3$  years. We collected the data about the patients' demographics, cardiovascular risk factor, dialysis modality, and the changes in metabolic and cardiovascular risk factors in the first post-transplantation year.

**Results:** We included 278 patients, 109 patients in the longer vintage group and 169 patients in the shorter vintage group. The mean age  $43.8 \pm 16.1$  and 164 patients (59%) were male. The mean dialysis vintage in the shorter group was  $1 \pm 0.1$  year, and  $5.7 \pm 2.7$  years in the longer vintage group,  $p < 0.001$ . The most common comorbidities were hypertension (76%), followed by diabetes mellitus (41.7%), and were present in similar proportions of both groups. Compared to the shorter dialysis vintage group, those who had longer dialysis vintage were more likely to have a deceased kidney donor (36.7% vs 8.9%,  $p < 0.001$ ), receive hemodialysis (88.1% vs 76%,  $p = 0.006$ ), predominantly through an arteriovenous fistula (55% vs 20.7%;  $p < 0.001$ ). In the first post-transplantation year, patients in the longer vintage group were more likely to have reduction in their systolic blood pressure ( $-7.1 \pm 20.7$  mmHg vs  $-1.6 \pm 17.5$ ;  $p = 0.027$ ) and were at a higher risk of developing persistent hyperparathyroidism (27% vs 18%,  $p = 0.003$ ). However, patients in the shorter vintage group were more likely to have post-transplant weight gain ( $6.8 \pm 8.8$  kg vs  $4.7 \pm$ ;  $p = 0.039$ ). Post transplantation diabetes at one-year post-transplantation was similar between the two groups.

**Conclusions:** Patients with dialysis vintage up to 3 years were not different in their baseline traditional risk factors. However they were at a higher risk of having persistent hyperparathyroidism at 12 months post renal transplant (27% vs 18%,  $p = 0.003$ ). On the other hand, patients with shorter dialysis vintage were more likely to have post-transplant weight gain ( $6.8 \pm 8.8$  kg vs  $4.7 \pm$ ;  $p = 0.039$ ).

## PUB299

### A Phase 1b, Multicenter, Open-Label Study to Evaluate the Safety, Pharmacokinetics, and Efficacy of Tegoprobart (AT-1501) in Patients Undergoing Kidney Transplant

Jean Tchervenkov,<sup>1</sup> Patrick T. Coates,<sup>2</sup> Matthew J. Kadatz,<sup>3</sup> Jeffrey D. Bornstein,<sup>4</sup> John S. Gill,<sup>5</sup> <sup>1</sup>McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada; <sup>2</sup>Royal Adelaide Hospital, Adelaide, SA, Australia; <sup>3</sup>Vancouver General Hospital, Vancouver, BC, Canada; <sup>4</sup>Eledon Pharmaceuticals, Irvine, CA; <sup>5</sup>St Paul's Hospital, UBC, Vancouver, BC, Canada.

**Background:** Calcineurin inhibitors (CNIs) are the backbone of kidney transplant anti-rejection therapy, and they substantially reduce the risk of acute rejection, providing excellent one-year patient and graft survival. However, only ~50% of the grafts survive 10 years, with these graft failures often being due to either late onset antibody mediated rejection or the direct nephrotoxicity of the CNIs themselves. CNIs are also associated with an increased risk of new onset diabetes after transplant, tremor, cognitive impairment, and other adverse events. As such, an agent that could produce comparable one-year results while improving long term outcomes and reducing CNI toxicities would address a significant unmet medical need. Tegoprobart (AT-1501) is a monoclonal antibody directed against the CD40 ligand (CD40L), a key mediator of co-stimulation. Inhibition of CD40L should result in a decrease in both cell and antibody mediated immunity and create a more tolerogenic immune environment. Tegoprobart has been shown to be effective in animal models and is currently being studied in kidney transplant recipients.

**Methods:** This pilot study will investigate the use of tegoprobart to prevent rejection in human kidney transplant recipients. Up to 12 participants will be enrolled in this open label study, and enrollment will be staggered such that the second subject cannot be screened until the first subject completes 28-days post-transplant and the DMC completes a review of the data. Adult recipients of their first allograft are eligible if they meet inclusion / exclusion criteria and if the donor kidney does not meet extended criteria, have a prolonged cold ischemia time, or come from a donor with cardiac death. All study participants will receive rATG induction therapy and a maintenance regimen of tegoprobart dosed at 20mg/kg IV every 3 weeks after a loading dose, MMF and corticosteroids. The safety of the regimen, PK of tegoprobart, and the ability of this regimen to prevent rejection will be assessed.

**Results:** The results will be presented when available.

**Conclusions:** Tegoprobart is a potential alternative to CNI in maintenance therapy for the prevention of allograft rejection in kidney transplant recipients. A Phase 1b trial to assess its safety, PK and efficacy is ongoing.

**Funding:** Commercial Support - Eledon Pharmaceuticals

## PUB300

# High HLA Class II Epitope-Mismatch Load and Low Tacrolimus Level Are Associated With the Development of Donor-Specific Antibodies and Poor Graft Outcome

Dong Ryeol Lee, Byung chang Kim. *Maryknoll Medical Center, Busan, Republic of Korea.*

**Background:** HLA matching has been an essential role in the risk assessment for long-term graft outcomes in kidney transplantation recipients. Recent HLA epitope matching at HLA-DR and HLA-DQ loci between donor and recipient are better predictors for the development of de novo DSAs (donor-specific antibodies) and graft outcome. Limited data are available on the association between HLA class II epitope-mismatch load and the development of de novo DSA. The purpose of our study is to evaluate the clinical significance of HLA class II .epitope mismatch for the development of de novo DSA and graft outcome.

**Methods:** We examined 178 kidney transplant recipients for the development of DSAs from June 2015 to June 2018. We excluded patients whose data on HLA-DQ matching were missing and HLA class II epitope matching was not available. A nadir FK trough level was collected over 6 months prior to the development of de novo DSA. We compared HLA-DR/DQ matching / HLA class II epitope matching and a nadir FK level over 6month prior to DSA occurrence for the development of de novo DSA and graft outcome

**Results:** 25 of 178 stable KTRs (14.0%) had HLA class II DSAs (10DR-DSA/14DQ-DSA, 1 combined DR- and DQ-DSA) on SAB. The median follow-up was a 90.0±5.9 month (range 0-215). Mean HLA mismatch numbers were 3.5±0.2. Six (3.4%) of 25 de novo HLA class II DSA had biopsy-proven CABMR (chronic antibody-mediated rejection). Three of 5 DQ-DSA positive patients and one of 1 DR-DSA positive patient were lost graft function to CABMR. Not High DR epitope mismatch load (DR epitope mm≥10) but High DQ epitope mismatch loads (DQ epitope mm ≥17) and the lowest FK trough level (<6ng/ml) during the past 6month prior to de novo DSA occurrence were significantly associated with the development of de novo DQ-DSA. Independent predictors of graft failure on multivariate analysis were CABMR and the development of de novo DQ DSA.

**Conclusions:** Our study showed that combined high DR /DQ epitope mismatch loads and less than 6ng/ml of FK trough levels over 6month prior to the development of de novo DSAs are associated with the development of de novo DSAs which subsequently lead to CABMR and graft failure. Our study needs to verify whether intensifying immunosuppression can prevent the development of de novo DSA among patients who have high DQ-epitope mismatch loads

## PUB301

# Outcome of Renal Transplant Recipients Admitted to the Intensive Care Unit: Long Term Follow-Up

Amgad E. El Agroudy. *Arabian Gulf University, Manama, Bahrain.*

**Background:** The goal of this study was to evaluate the course and outcome of kidney transplant (KT) recipients admitted to intensive care unit

**Methods:** We reviewed the data of all adult renal transplant recipients who are admitted to the ICU at our center, between 1997 and 2021 that included the demographic features, causes of end-stage renal disease (ESRD), causes of admission, time between transplantation and admission and ICU courses and outcome. Among 400 KT followed up in our center, 70 patients were admitted to ICU and were categorized to early (during first 3 months; n=32); intermediate (3–12 months; n=10); and late (12 months and afterwards, n=28).

**Results:** The rate of ICU admission was 17.5% and the mean age was 49.3 ± 10.6 years. The main cause of admissions was surgical complication (71%) in early group and infection (57% and 80%) in later groups, respectively. In early group, the major reason admission was postoperative surgical complications and care, like lymphocele (5 patients), wound dehiscence (3 patients), urinoma (2 patients) urinary leakage (3 patients). Four of the patients in this group were admitted after surgery unrelated to kidney transplantation (two after an operation for peripheral vascular disease and two after a laparotomy for intestinal obstruction). In late group, the most common cause of admission was infections. Mortality on discharge was significantly higher in late admission (56%) (p=0.0001) and the leading cause of death in all groups was sepsis (91%). Twenty-four patients required ventilator that was an independent risk factor for mortality (P < 0.05). There was statistically significant decrease in the overall 5-year and 10-year patient survival (P = 0.031) in KT patients admitted to the ICU.

**Conclusions:** Our study shows that the main reason for ICU admissions was infections especially in late admission. Mortality rate were relatively high and was linked to need for ventilators. Admission to the ICU is usually associated with decrease in the graft and patient survival.

## PUB302

# Diagnostic Components of Sarcopenia in Kidney Transplant Recipients: Prevalence and Associated Factors Study in a Single Center

Shok H. Ooi, Kok Peng Ng, Soo Kun Lim. *University Malaya medical center, Kuala Lumpur, Malaysia.*

**Background:** Chronic kidney disease (CKD) contributes to secondary sarcopenia which may be associated with adverse outcomes. The impact of kidney transplantation on sarcopenia remains uncertain. As sarcopenia is a potentially reversible condition, understanding contributing factors for the development of sarcopenia is important to

allow proper intervention. This study aimed to assess the prevalence and the predictors/ associated factors of sarcopenia in kidney transplant recipients (KTRs)

**Methods:** This is a cross-sectional study of stable KTRS at transplant clinic of University of Malaya. Consented patients will be subjected to the laboratory, questionnaire, and bio-impedance analysis evaluation. Sarcopenia was assessed based on the European Working Group on Sarcopenia in Older people (EWGSOP2) which include evaluation for presence of low appendicular skeletal muscle mass, low muscle strength, and/or low muscle performance

**Results:** 113patients were recruited with male to female ratio of 62.8%(n=71) and 37.2%(n=42). 17 participants (15%) had probable sarcopenia but none had confirmed/ severe sarcopenia. 15 of KTRs were found to have low muscle strength and 13%(n=15) deemed to have low physical performance. KTRs with probable sarcopenia had longer kidney transplantation vintage, and significantly lower serum albumin, body mass index (BMI), skeletal muscle mass (SMM), phase angle compared to no sarcopenia. Univariate analysis adjusted for age revealed factors like kidney transplant vintage, serum albumin, skeletal muscle mass (SMM), arm circumferences and phase angle are predictors of probable sarcopenic state. In our study serum albumin level negatively correlate with sarcopenia and is found to be an independent predictor after adjusting to age. This indicates that nutrition markers eg, albumin may be useful in predicting outcome

**Conclusions:** Sarcopenia is an established pathological entity in KTRs and its etiology may be multifactorial. Serum albumin level can be useful as a predictor for this aforementioned condition and potentially amenable for intervention

## PUB303

# Discordance in Cytomegalovirus Viremia in Kidney Recipients From the Same Donor Is Associated With Worst Outcomes

Emily E. Zona, Sonam Dolma, Margaret R. Jorgenson, Angelie Santos, Neetika Garg, Fahad Aziz, Maha A. Mohamed, Didier A. Mandelbrot, Sandesh Parajuli. *University of Wisconsin School of Medicine and Public Health, Madison, WI.*

**Background:** Cytomegalovirus (CMV) is a common viral infection in kidney transplant recipients (KTR) associated with adverse outcomes. The effect of concordance versus discordance in CMV viremia between two different recipients of kidneys from the same donor remains unknown.

**Methods:** In a retrospective study on adult deceased donor KTRs (DDKTR) at our center from 2014 to 2019, recipient pairs from the same donor were divided into groups based on the development of CMV viremia between the pair. Concordance no CMV (cc-no-CMV) if neither KTR developed CMV, concordant CMV (cc-CMV) if both KTRs developed CMV, Dc-CMV and dc-no-CMV referred to the discordant groups pertaining to individual CMV development or lack of, respectively. Outcomes included death censored graft failure (DCGF) and patient mortality.

**Results:** Of 578 KTRs, 67% were cc-no-CMV, 5% were cc-CMV and 28% were discordant; 14% dc-no-CMV and 14% dc-CMV. In the cc-CMV group, significant donor features include higher serum Cr (~1.27 mg/dl), mean kidney donor profile index (KDPI) and donation after circulatory death (DCD) donor (50%), while recipients have lower BMI (mean 26.8 ± 5.2) and received Basiliximab induction (50%). The prevalence of high-risk serostatus (D+/R-) was higher in cc-CMV (32%) and dc-CMV (32%) (vs 14% cc-no-CMV and 20% dc-no-CMV, p<0.001). As compared to cc-no-CMV, dc-CMV was associated with increased risk for DCGF (HR 3.90, 95%CI 2.01-7.57), so was advanced donor age, higher KDPI, diabetes mellitus and delayed graft function (DGF). Interestingly, high-risk serostatus and cc-CMV were not associated with DCGF. Development of CMV in cc-CMV or dc-CMV were not associated with mortality. The only factors associated with increased risk of mortality were advanced recipient age and DGF.

**Conclusions:** In this study of DDKTRs, discordant development of CMV viremia after transplant was associated with graft failure, but not mortality. High-risk serostatus, while a risk factor for subsequent viremia, was not a risk factor for graft failure or death, nor was concordant development of CMV. These findings reflect clinical anticipation of this event and suggest prompt management to prevent negative outcomes.

## PUB304

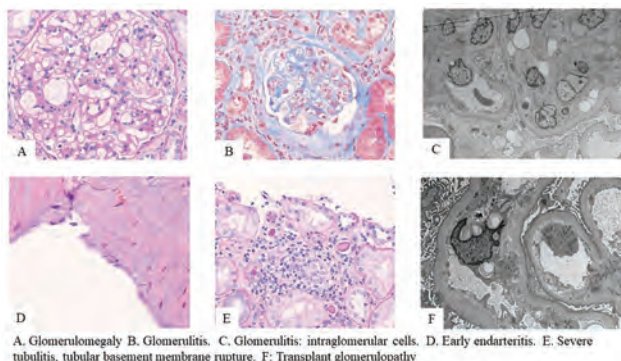

**Subclinical Kidney Allograft Rejection Without Maintenance Immunosuppressive Therapy (mIST)**

**Kulwant S. Bath,<sup>1</sup> Phuon-Thu T. Pham,<sup>2</sup> Sally Chau,<sup>1</sup> Jean Hou,<sup>3</sup> Svetlana O. Villano,<sup>1</sup> Vinod K. Valluri,<sup>1</sup> Golriz Jafari,<sup>1</sup> Anita Kamarzarian,<sup>1</sup> Susana M. Mendoza,<sup>1</sup> Phuon-Chi T. Pham.<sup>1</sup>** <sup>1</sup>*UCLA Medical Center Olive View, Sylmar, CA;* <sup>2</sup>*University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA;* <sup>3</sup>*Cedars-Sinai Medical Center, Los Angeles, CA.*

**Introduction:** Kidney transplant (KTx) generally requires mIST to prevent rejection and graft loss. A mother-to-son kidney recipient presents with preserved kidney function despite being off mIST for 26 years.

**Case Description:** A 44-year-old man with diabetes mellitus, unknown congenital kidney disease requiring peritoneal dialysis for 3y and KTx from his mother at age 13, and status post COVID19 infection 2m prior, presents with diabetic ketoacidosis due to insulin nonadherence. Patient received unknown mIST until age 18 when he self-discontinued therapy. Initial studies: Serum: glucose 1064 mg/dL, pH 7.28, +ketones, creatinine (Cr) 2.4 mg/dL (baseline Cr 1.1); Urinalysis 4-10 white blood cells/high power field, few bacteria; Urine protein/Cr 0.4 g/g, albumin/Cr 0.1 g/g Patient received insulin and fluid with Cr improved to 1.1 mg/dL. Fig 1 shows Cr timeline. Kidney biopsy was performed prior to discharge to determine the need for mIST reinitiation. While awaiting for pathology report as outpatient, Cr increased to 1.82 mg/dL. Pathology Fig 2: Chronic active T-cell-mediated tubulointerstitial rejection, active vascular rejection, and chronic active antibody-mediated rejection. Patient was readmitted for intravenous immunoglobulin & antithymocyte globulin with appropriate Cr improvement and discharged on prednisone, mycophenolate, & tacrolimus. Donor HLA-typing was not available for donor specific antibody testing.

**Discussion:** The case demonstrates 1) Subclinical rejection may occur in the setting of prolonged IST discontinuation and 2) Cr is insensitive in detecting rejection and raises the possibility of COVID19-induced exacerbation of ongoing low-level rejection.

## PUB305

**Seroprevalence and Management of *Strongyloides stercoralis* at a Large Tertiary Kidney Transplant Centre in London, United Kingdom**

**Mukunthan Srikantharajah, Mohd Radzi Rodzlan Akib, Eleanor C. Sandhu, Paul Arkell.** *Imperial College Healthcare NHS Trust, London, United Kingdom.*

**Background:** The soil transmitted helminth *Strongyloides stercoralis* is endemic across the tropics and causes pauci/asymptomatic infection which persists for decades when no longer living in an endemic area. In individuals who receive corticosteroids and/or organ transplantation, rapid replication and dissemination of larvae can result in *Strongyloides* hyperinfection syndrome (SHS), a severe multi-system illness with high mortality. This study aimed to determine the seroprevalence of *S. stercoralis* at our centre and assess whether screening and pre-emptive treatment may be beneficial.

**Methods:** Kidney transplant candidates registered at our institution in West London between July-November 2021 were tested for *S. stercoralis* IgG/IgM (NovaLisa® ELISA, Eurofins Biomnis Laboratory). Results were obtained from 5 different haemodialysis units. Those with positive results were reviewed by the Infectious Diseases and/or Nephrology team.

**Results:** 133 individuals were included. The mean age of the cohort was 52 years (range 19-79). 64% were male. 32% were Asian, 29% White, 24% Black, 13% Other, 2% Mixed. The most common underlying renal pathologies were Diabetes (30%), Unknown (21%), Glomerulonephritis (18%) and Hypertension (7%). 8/133 (6%) were found to be *S. stercoralis* seropositive. 7/8 of these individuals were born or had significant travel in the tropics but 1/8 had no identifiable epidemiological risk factors. Upon clinical review, 1/8 individuals had symptoms which were potentially attributable to strongyloidiasis, and 3/8 had eosinophilia. 7/8 were treated with ivermectin. 1/8 was concluded to be a false positive, most likely due to previous *Taenia solium* infection, and therefore was not treated. 5/8 individuals had previously undergone kidney transplantation and were at risk of SHS.

**Conclusions:** This study found a high *S. stercoralis* seroprevalence among renal transplant candidates. These individuals may be at risk of SHS upon receiving immunosuppression. Targeted screening and pre-emptive treatment is likely to be beneficial.

## PUB306

**Avascular Osteonecrosis in Kidney Transplant Recipients Is Associated With Increased Risk of Patient Death**

**Sonam Dolma, Emily E. Zona, Fauzia Osman, Angelie Santos, Fahad Aziz, Neetika Garg, Maha A. Mohamed, Didier A. Mandelbrot, Sandesh Parajuli.** *University of Wisconsin-Madison, Madison, WI.*

**Background:** Avascular Osteonecrosis (AVN) is a debilitating osseous complication associated with kidney transplantation. However, risk factors, and adverse outcomes of AVN in kidney transplant recipients (KTR) remains largely unknown.

**Methods:** This is a retrospective study involving all KTR and recipients of simultaneous pancreas and kidney (SPK) between 2001 and 2018 at our center. Recipients with AVN were compared to those who did not have AVN. Controls were selected based on the incidence density sampling at a 1:3 ratio based on the post-transplant interval if they do not have AVN. Outcomes of interest included acute rejection, death-censored graft failure (DCGF) and patient mortality.

**Results:** A total of 88 KTR or SPK (n=8) had AVN and were compared with 257 controls. Although we attempted to select controls at a 1:3 ratio, it was not possible in all cases. Most of the recipients and donors baseline characteristics were similar between the groups, except calcineurin inhibitor (CNI) based immunosuppression was more prevalent and non-white donors were less prevalent in the control group compared to the AVN group. Looking for risk factors for AVN, CNI based immunosuppression was associated with lower risk for AVN (HR: 0.46; 95% CI: 0.22-0.92) in the univariate analysis, but this was not true after adjustment of multiple variables in the multivariate analysis. In multivariate analysis, AVN was associated with increased risk for patient death (HR: 1.67; 95% CI: 1.14-2.45; p=0.008) but not for acute rejection (HR: 0.7; 95% CI: 0.02-1.27; p=0.08) or DCGF (HR: 1.53; 95% CI: 0.94-2.47; p=0.09).

**Conclusions:** Although limited by small sample size, we found AVN to be associated with increased risk for patient death among kidney transplant recipients. More studies are needed.

**Pseudoaneurysm in Pancreas Transplantation: A Rare and Life-Threatening Vascular Complication**

Naseer Khan,<sup>1,2</sup> Renat Kudyakov,<sup>1</sup> Phillip Wortley,<sup>1</sup> <sup>1</sup>Medical City Dallas Hospital, Dallas, TX; <sup>2</sup>Dallas Renal Group, Dallas, TX.

**Introduction:** Pseudoaneurysm is a very rare vascular complication in pancreas transplantation. Here we report a case of a kidney-pancreas transplant who presented 20 days post transplant with abdominal pain. She was diagnosed with Pseudoaneurysm of the donor splenic artery. Early suspicion & serial imaging led to proper diagnosis and non-invasive treatment without any complications.

**Case Description:** 28 year old female 20 days post deceased donor Pancreas-Kidney transplantation presented with abdominal pain. She underwent serial CT scans which detected expanding pseudoaneurysm at the anastomosis of the donor splenic artery. She was treated with endovascular stent placement by Interventional Radiology (IR). Patient remained stable without any complications of graft loss, morbidity or mortality.

**Discussion:** Surgical complications after Pancreas transplantations are mostly related to thrombosis often times needing heparin post-op. There are only a few case reports of life threatening Pseudoaneurysms in pancreas transplants recipients. In our case the pseudoaneurysm was diagnosed without being ruptured. Early diagnosis by serial exams and imaging was the key to prevention of rupture, graft loss and mortality.

Pancreatic pseudoaneurysm at donor splenic artery

## PUB308

**Application of Metagenomic Next-Generation Sequencing in the Treatment Guidance of Infection in Kidney Transplantation**

Ahebaota Baibutihan, Yue Qu, Jing Zhuang, Yan Li, Qingqing Zhang, Hongjuan Zhao, Hong Jiang. *People's Hospital of Xinjiang Uygur Autonomous Region, Urumqi, China.*

**Background:** Kidney transplantation (KT) exhibits many advantages compared to dialysis. Donation after citizen death (DCD) in China is playing a critical role in the KT. However, a relatively higher risk of infection in DCD organ recipients has been observed. Metagenomic next-generation sequencing (mNGS) can identify the microorganism pathogens. This study aims to detect the pathogenic microorganisms in the KT recipients using the mNGS, following guiding antiinfection therapy.

**Methods:** The 14 KT recipients and 7 DCD donors from October 2021 to April 2022 in our hospital were enrolled. The serum samples of recipients and renal vascular lavage fluid samples from donors were detected using mNGS and analyzed. In addition, clinical data, mNGS results and outcomes of the 14KT recipients were collected and analyzed.

**Results:** The mNGS results of 7 DCD donors showed, 1) bacteria detected: Enterococcus (4/7), Klebsiella (3/7), Acinetobacter (3/7), Monomonas (1/7); 2) fungi detected: Candida albicans (1/7); 3) DNA viruses detected: human polyomavirus type 2 (2/7), human polyomavirus type 4 (1/7), human alphaherpesvirus type 1 (1/7), human gammaherpesvirus type 4 (1/7), beta papillomavirus type 1, 2 (1/7). The mNGS results of 14 KT recipients revealed, 1) bacteria detected: Bacteroides (5/14), Enterococcus (2/14), Acinetobacter (2/14), Klebsiella (2/14); 2) fungi detected: Candida parapsilosis (1/14); 3) DNA viruses: human beta herpesvirus type 7 (2/14), human beta herpes simplex virus type 5 (1/14), human alphaherpesvirus type 1 (1/14), human gammaherpesvirus type 4 (1/14). The median time of obtaining the mNGS results was 1 day. The 14 KT recipients were routinely given piperacillin/sulbactam combined with caspofungin, imipenem/cilastatin and vancomycin were administered appropriately according to clinical data related to infection and mNGS results. All the infections were controlled very well and no serious complications occurred.

**Conclusions:** These findings suggest that Bacteria are possibly the main pathogenic microorganisms for KT recipients. The mNGS could timely and efficiently increase the positive detection rate of pathogenic microorganisms. Adjusting antimicrobial treatment approach according to the mNGS result could more precisely and efficiently decrease the serious complications and improve patient outcomes.

## PUB309

**Preemptive Living Kidney Transplantation in Asymptomatic CKD Stage 4 With Autosomal Dominant Polycystic Kidney Disease: To Transplant or Not to Transplant? That Is the Question**

Macauley A. Onuigbo,<sup>1,2</sup> Silviana Marineci,<sup>1,2</sup> Marios Prikis,<sup>1,2</sup> <sup>1</sup>University of Vermont College of Medicine, Burlington, VT; <sup>2</sup>University of Vermont Medical Center, Burlington, VT.

**Introduction:** Kidney transplantation (KT) is the sine qua non consummate form of renal replacement therapy for ESRD with higher patient survival, improved quality of life, and lower healthcare costs. In the US, pre-emptive kidney transplantation (PEKT), defined as KT prior to progression to ESRD and maintenance dialysis, occurred in 17% of recipients overall, and in 31% of living donor kidney transplantation recipients. Advantages of PEKT over KT after starting maintenance dialysis are fewer pretransplant blood transfusions, increased rate of patients continuing employment, improved long-term graft survival, lower rates of delayed graft function, fewer episodes of acute rejection and decreased healthcare expenditures. Annual dialysis payer expenses in the US range from \$60,000 - \$125,000 excluding dialysis access-related costs which range from \$7,000 - \$19,000. Although KT has relatively high initial costs associated with induction immunosuppression and the initial hospitalization, maintenance immunosuppression costs range between \$18,000 - \$23,000, annually. Conversely, PEKT may arguably be unnecessary for some patients with eGFR in the 15-25 range who are otherwise asymptomatic, and where eGFR decline is slow. We have such a dilemma.

**Case Description:** 71-yo male patient with CKD stage 4, controlled hypertension and ADPKD, current eGFR of 17 ml/min/1.73 m<sup>2</sup> BSA, as at January 2022. He is presently otherwise asymptomatic, is normally active, working from home since the COVID-19 pandemic, appetite is good, and exercise tolerance is good and unchanged over the past year. Electrolytes are normal or controlled, and hemoglobin was 14.0 g/dL. Serum creatinine was 1.1 mg/dL in September 2003. However, serum creatinine increase in the past 42 months has only been very slow (Figure).

**Discussion:** The QUESTION: To Transplant or Not to Transplant? (See Survey Link)

Serum creatinine trajectory from October 2018 - April 2022

## PUB310

## Anti HLA Antibodies and Their Association With Chronic Allograft Dysfunction and Kidney Allograft Loss in Western Mexico

Jesus A. Vega Lopez de Nava, Renato Parra Michel, Javier Soto-Vargas, Jorge fernando Topete reyes, Leonardo Pazarin-Villaseñor, Carlos A. Lepe, Luz Yareli Villegas Gutierrez, Juan O. Romero Tafoya, Rubén Lara Monterrubio, Alejandro Garcia Rivera. *Instituto Mexicano del Seguro Social, Guadalajara, Mexico.*

**Background:** Jalisco holds the first place worldwide in end stage kidney disease incidence and it is the state that performs more kidney transplants in Mexico per year. There is still a lack of information between the association of anti HLA antibodies and chronic allograft dysfunction (CAD) and allograft loss (AL) in Mexico. Few studies suggest a higher risk.

**Methods:** Retrospective cohort study that included patients 18 years or older, with studies that included serum creatinine and urine protein determination in a second level of attention hospital in Jalisco. These patients were followed until CAD or AL developed. We excluded patients with more than one kidney transplant.

**Results:** 292 patients with a median age of 30 years old were included, 65% were men. They were followed for a median time of 123.2 months. 49.3% had anti HLA antibodies. The median serum creatinine among those with anti HLA antibodies was 1.35 mg/dl with a median eGFR of 64.6 ml/min, 1.28 mg/dl with an eGFR of 66.5 ml/min for those without them. 60.4% developed CAD and 12.2% developed AL. The median proteinuria was 150 mg/g, with no significant statistic differences among groups. HLA class I antibodies were found in 39.5%, whilst for class II 41.4% patients and 22.3% had both class antibodies. Median time until the outcomes developed was 123 months.

**Conclusions:** We could not find a clear association between the presence of anti HLA antibodies and CAD and AL, which was attributed to survival bias, since the multivariate logistic regression analysis detected that time from detection of these antibodies since kidney transplant had a significant statistic correlation between both outcomes ( $p=.001$ , HR .893).

Log rank test for allograft loss

## POWERED Study Protocol: Prophylaxis With Metformin to Prevent Post-Transplantation Diabetes Mellitus

Michelle E. Allan,<sup>1,2</sup> Tahseen A. Chowdhury,<sup>1,2</sup> Stanley Fan,<sup>1,2</sup> Muhammad Magdi Yaqoob,<sup>1,2</sup> Kieran Mccafferty,<sup>1,2</sup> <sup>1</sup>Barts Health NHS Trust, London, United Kingdom; <sup>2</sup>Queen Mary University of London, London, United Kingdom.

**Background:** Up to 30% of renal transplant recipients develop post-transplant diabetes mellitus (PTDM). PTDM is associated with adverse graft and patient outcomes and increased financial burden to healthcare services. There is an urgent clinical need to discover therapies to decrease the risk of developing PTDM. Metformin offers a safe and cheap therapeutic option which can reduce the incidence of type 2 diabetes in a high-risk non-transplant patient group. We propose to study its safety and efficacy in preventing the development of PTDM. Ethical approval has been obtained from the relevant regulatory bodies.

**Methods:** POWERED is a single site, placebo-controlled, double-blind randomised clinical trial of metformin in patients without pre-existing diabetes mellitus who have received a new renal transplant. Eligible, consented patients at a tertiary renal centre are screened within 10 days post-transplant with an oral glucose tolerance test (OGTT). Patients with a negative OGTT and with eGFR > 30 ml/min are then randomised to a 3-month course of either metformin or placebo. All patients will receive the usual standard of care for transplant patients. Clinical and laboratory data will be collected and assessed at baseline and throughout their participation in the study. The primary endpoint is the development of PTDM at 1 year post-transplant as defined by a positive OGTT. Secondary endpoints include graft outcomes, pancreatic b-cell function and safety endpoints. Patients have fasting bloods including OGTT at 3, 6 and 12 months post-transplant.

**Results:** The study population is 60 patients. There are no interim analyses planned.

**Conclusions:** This is the first randomised controlled trial to use metformin in the immediate post-transplant period as prophylaxis against the development of PTDM. Our hypothesis is that early intervention will ameliorate the maximal pro-diabetogenic stimuli in the acute transplant phase, and will shield the pancreas from the directly injurious effects of tacrolimus. We postulate that waiting for overt hyperglycaemia to develop before intervening risks irreversible pancreatic toxicity and hence loss of benefit from any drug intervention. We look forward to publishing our results with ASN in the near future.

**Funding:** Clinical Revenue Support

## Baseline Characteristics and Representativeness of the BEST-Fluids Trial Participants: A Randomized Trial of Balanced Crystalloid Solution vs. Saline in Deceased Donor Kidney Transplantation

Michael G. Collins,<sup>1,2</sup> Magid Fahim,<sup>3,4</sup> Elaine Pascoe,<sup>3</sup> Philip A. Clayton,<sup>5,2</sup> Carmel Hawley,<sup>3,4</sup> David W. Johnson,<sup>3,4</sup> Kathryn Dansie,<sup>5</sup> Julie A. Varghese,<sup>3</sup> Rachael C. McConnochie,<sup>1</sup> Laura Robison,<sup>3</sup> Donna Reidlinger,<sup>3</sup> Charani Kiriwandeniya,<sup>3</sup> Steven J. Chadban,<sup>6,7</sup> The BEST Fluids Trial Investigators <sup>1</sup>Auckland City Hospital, Auckland, New Zealand; <sup>2</sup>Royal Adelaide Hospital, Adelaide, SA, Australia; <sup>3</sup>University of Queensland, Australasian Kidney Trials Network, Brisbane, QLD, Australia; <sup>4</sup>Princess Alexandra Hospital, Woolloongabba, QLD, Australia; <sup>5</sup>Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; <sup>6</sup>Royal Prince Alfred Hospital, Camperdown, NSW, Australia; <sup>7</sup>The University of Sydney, Sydney, NSW, Australia.

**Background:** Delayed graft function (DGF), the need for post-transplant dialysis due to poor graft function, is a major complication of deceased donor kidney transplantation. Isotonic 0.9% sodium chloride (saline) is a widely used intravenous fluid in transplantation but may increase the risk of DGF due to its high chloride content. BEST-Fluids is a pragmatic, registry-based, double-blind randomized controlled trial to determine if using a balanced low-chloride crystalloid solution (Plasma-Lyte 148) instead of saline will reduce the incidence of DGF and improve other transplant outcomes. The aim of this presentation is to describe the baseline characteristics and representativeness of trial participants.

**Methods:** Comparison of demographic and clinical characteristics between the BEST-Fluids participants and all other recipients of a deceased donor kidney transplant during the same period in Australia and New Zealand. Data were obtained from the Australia & New Zealand Dialysis & Transplant (ANZDATA) Registry.

**Results:** From January 2018 to August 2020, 2178 deceased donor kidney transplants were performed; 808 of these (37%) enrolled in BEST-Fluids. The groups were similar in age, gender, BMI, smoking, kidney failure cause, graft number, dialysis modality, co-morbidities (diabetes, cerebrovascular and peripheral vascular disease), HLA mismatches, peak panel reactive antibody, donor age, cause of death, terminal creatinine, expanded criteria donor status and total ischemic time ( $p > 0.05$  for all comparisons). However, trial participants had more coronary artery disease (24% vs 20%,  $p = 0.03$ ), longer mean dialysis duration (41 vs 35 months,  $p < 0.0001$ ), and their donors were less likely to be hypertensive (22% vs 27%,  $p = 0.01$ ), be a circulatory death donor (25% vs 31%,  $p = 0.002$ ), or be in the highest Kidney Donor Risk Index tertile (30% vs 35%,  $p = 0.02$ ).

**Conclusions:** BEST-Fluids trial participants had a slightly higher co-morbidity burden and received slightly fewer high risk deceased donor kidneys, but were otherwise representative of the wider transplant population. The trial results are likely to be applicable in a broad range of settings.

## PUB313

**Early Post-Transplant Vitamin D Improvement Is Associated With Better Long-Term Kidney Graft Survival**

Jung-hwa Ryu,<sup>1</sup> Tai yeon Koo,<sup>2</sup> Hyo Jeong Kim,<sup>3</sup> Ga Young Heo,<sup>3</sup> Jaeseok Yang,<sup>3</sup> KNOW-KT Study group <sup>1</sup>*Ewha Womans University Seoul Hospital, Seoul, Republic of Korea*; <sup>2</sup>*Korea University, Seoul, Republic of Korea*; <sup>3</sup>*Yonsei University College of Medicine, Seoul, Republic of Korea*.

**Background:** Vitamin D [25(OH)D] deficiency in chronic kidney disease (CKD) is usually ameliorated after kidney transplantation (KT). However, it is not conclusive if the post-transplant vitamin D deficiency is associated with poor graft outcome. This study aimed to investigate the effect of early post-transplant vitamin D status on clinical outcomes.

**Methods:** The KoreaN cohort study for Outcome in patients With Kidney Transplantation (KNOW-KT) is a multicenter, observational cohort study. Total 1,034 hundred subjects were included in this study. Annual serum 25(OH)D<sub>3</sub>, 1,25(OH)<sub>2</sub>D<sub>3</sub> and clinical outcomes; all-cause mortality, cardiovascular event, graft survival, and fracture were assessed according to vitamin D improvement.

**Results:** The Median follow-up duration was 7.4 years. Serum 25(OH)D<sub>3</sub> levels were increased after KT (before KT, 12.6±7.4; 1 year after KT, 22.6±6.4; 3 years after KT, 24.3±5.8 ng/mL). Vitamin D deficiency was present in 79.1% just before KT. The prevalence of vitamin D deficiency was decreased after transplantation; however, it was still 38.2% at 7 years after KT. The patients with 25(OH)D<sub>3</sub> improvement 1 year after transplantation showed higher 25(OH)D<sub>3</sub> level than the patients without improvement at any point during follow-up. At 7 year-follow-up, higher vitamin D level was associated with vitamin D improvement after KT and vitamin D analog supplementation during 1 year after KT. The 25(OH)D<sub>3</sub> non-improvement at 1 year after KT was a risk factor for poor graft survival (HR 2.408, 95% C.I.; 1.187-4.886, P=0.015).

**Conclusions:** The early vitamin D improvement after kidney transplantation was associated with better long-term graft outcome.

## PUB314

**Perioperative Anaphylaxis to Cefazolin During Renal Transplant: A Preventable Phenomenon?**

Salman Salehin, Anand Kumar, Hania Kassem, Nantian Harsell, Syed A. Hussain, Muhammad A. Muftaba. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

**Introduction:** Intraoperative anaphylaxis is a life threatening and multiorgan system hypersensitivity reaction that leads to cessation of operations. Anaphylaxis to Cephazolin is on the rise due to its growing popularity as a choice of intraoperative antibiotic. We describe a case of perioperative anaphylaxis to Cefazolin leading to the cessation of the deceased donor kidney transplant (TX) in a patient with no known beta-lactam allergy.

**Case Description:** A 56 y/o female with end stage kidney disease was admitted for planned cadaveric kidney TX. Anesthetic induction and intubation were uneventful. She was given 2 grams of Cefazolin at 21:26. Meanwhile, the patient had been draped appropriately in the operating table and the donor kidney prepared on the back table. At 21:29, patient's blood pressure plummeted from 116/60 to 40/18 and she had simultaneous desaturation to mid 80s with elevated peak airway pressures. Fortunately, the surgeon was able to abort the procedure just seconds before the skin incision was made. To combat anaphylaxis, patient was given 3 doses of intramuscular epinephrine and started on norepinephrine infusion prior to being transferred to the ICU. She was eventually stabilized and discharged 36 hours later. Luckily the 'uncontaminated' kidney was reallocated to another local recipient. Of note, patient had a positive outpatient skin prick test to Cefazolin in allergy clinic, thus confirming Cefazolin allergy. The patient did end up receiving a new kidney 6 months after this incident.

**Discussion:** Peri- or intraoperative anaphylaxis to Cefazolin is on the rise and its consequences in TX candidates are even more dire given the pre-existing end organ failure, financial burden for health care system, potential loss of donor organs, and emotional burden for recipients and their families. Pre-operative skin prick testing to Cefazolin, which is the most frequently used antibiotic in kidney TX surgery, could have prevented this case scenario. Furthermore, a sensitive assay should be established for pre-op allergy evaluation. Considering the fear of skin prick tests triggering systemic or anaphylactic reactions in some patients, there is a need for development of in vitro allergy testing to evaluate hypersensitivity to commonly used intraoperative agents, especially cefazolin to minimize risks of intraoperative anaphylaxis.

## PUB315

**ADOPTION Study Protocol: AZD1656 in Transplantation With Diabetes to Promote Immune Tolerance**

Michelle E. Allan,<sup>1,2</sup> Stanley Fan,<sup>1,2</sup> Federica M. Marelli-Berg,<sup>2</sup> Muhammad Magdi Yaqoob,<sup>1,2</sup> Kieran McCafferty,<sup>1,2</sup> *Barts Health NHS Trust, London, United Kingdom*; <sup>2</sup>*Queen Mary University of London, London, United Kingdom*.

**Background:** Transplant recipients with pre-existing T2DM commonly experience a deterioration in glycaemic control in the early post-transplant period, due to the effects of prednisolone on gluconeogenesis, CNI-related pancreatic beta cell toxicity and enhanced renal clearance of insulin. Elevated glucose profiles have been associated with poorer graft outcomes. The glucokinase activator AZD1656 has been shown to be a potent anti-diabetic medication and safe in patients with T2DM, including those with

chronic kidney disease. Recent data has shown that glucokinase activation increases regulatory T cell(Treg) migration and trafficking. We propose to study the safety and efficacy of AZD1656 in optimising glycaemic control and stimulating Treg migration to the transplant in a population of renal transplant patients with pre-existing T2DM. Ethical approval has been obtained from the relevant regulatory bodies.

**Methods:** ADOPTION is a single site, placebo-controlled, double-blind randomised clinical trial of AZD1656 in patients with T2DM and a new renal transplant. Eligible, consented patients at a tertiary centre are randomised to a 3-month course of either AZD1656 or placebo within 24 hours of transplantation. Clinical and laboratory data is collected and assessed at baseline and throughout their participation in the study. The primary endpoint is the mean change in peripheral Tregs between baseline and 3 months as analysed by flow cytometry. Secondary endpoints include graft outcomes, histological staining for Tregs, glycaemic control and safety endpoints. Patients are closely monitored for the first 14 weeks post-transplant. Their records are reviewed at 1 year.

**Results:** We plan to recruit 50 patients. There are no interim analyses planned.

**Conclusions:** AZD1656 offers the chance to achieve better glycaemic control in the early post transplant period, but of greater potential benefit is the immunomodulatory effect which could lead to improved renal outcomes. We hope to demonstrate that AZD1656 increases Treg localisation to the renal transplant and provides an effective and safe adjunct for the management of diabetes in the early post-transplant period. A positive signal generated by this pilot study would provide future opportunities for further study and we look forward to sharing our results with the ASN in the near future.

## PUB316

**Thrombotic Thrombocytopenia With Acute Graft Thrombosis (AGT) After Kidney Transplantation**

Julie Steinberg, *Cohen Children's Medical Center, Queens, NY.*

**Introduction:** Our case is a patient with AGT of multiple failed kidney transplants.

**Case Description:** A 15 year old F with Nephronphthisis and ESKD had a living unrelated kidney transplant (LUKT), when poor graft perfusion prompted arterial reanastomosis with improvement. After closure intrarenal doppler waveforms were poorly visualized. Given decreasing serum creatinine (SCr) and good urine output, she was observed. Hours later SCr rose with intrarenal blood flow (BF) on doppler. The graft was found mottled with AGT and thrombi in the right (Rt) external iliac artery, renal artery (RA) and vein (RV). Graft was removed, flushed with heparin/alteplase and reimplanted with doppler-confirmed BF. After closure BF was not detected with diminished Rt lower extremity pulses. The graft was necrotic and removed. Thrombi were removed from the Rt common/ iliac, femoral and popliteal arteries. HD was restarted with heparin. Within hours, thrombocytopenia worsened. Elevated D-dimer and positive platelet factor-4 antibodies (PF-4Ab) suggested heparin-induced thrombocytopenia (HIT) despite negative serotonin release assay (SRA). Heparin was changed to argatroban then apixiban. Following resolved thrombocytopenia and negative PF-4 Ab, she had a second LUKT on therapeutic argatroban. She again had AGT with intrarenal, RV and RA thrombi requiring graft removal. Workup showed positive Coombs and negative heparin Ab, suggestive of Ab-mediated consumptive coagulopathy consistent with vaccine induced thrombotic thrombocytopenia (VITT).

**Discussion:** Initially HIT was presumed, and heparin discontinued, yet AGT occurred despite heparin avoidance. Thus, symptoms were more consistent with VITT, a syndrome that can occur after COVID-19 vaccines with adenovirus vector. Yet, she was not vaccinated. Like HIT, VITT is thought to be from IgG binding to the PF-4-heparin complex, activating platelets and initiating a hypercoagulable cascade with platelet consumption. Although clinically similar, HIT and VITT are treated differently, thus it is vital to differentiate the two.

	HIT	VITT
Timeline	-PF-4 ab detectable 4 days after heparin exposure -Thrombocytopenia/thrombosis 5-14 days after heparin exposure	-5-24 days after COVID-19 vaccine
Laboratory Features	-Thrombocytopenia -+ PF-4 antibodies -+ SRA	-Thrombocytopenia -+ PF-4 antibodies - - SRA
Clinical Features	-Venous Thrombosis -Arterial Thrombosis	-Venous thrombosis -Cerebral venous -Splanchnic Vein -Pulmonary Emboli -Arterial thrombosis -Ischemic stroke - Acute limb ischemia - Myocardial Infarction
Treatment	-Removal/Avoidance of heparin/heparin products -Anticoagulation with alternative agent	-Anticoagulation (unclear if heparin should be avoided) -IVIG -PLEX

## PUB317

**A Rock and a Hard Place: Simultaneous Adenovirus Nephritis and Acute Rejection in a Kidney Transplant Patient**

Kathleen Borghoff, Audai Ma'ayah, Scott G. Westphal. *University of Nebraska Medical Center, Omaha, NE.*

**Introduction:** Adenovirus causes significant morbidity and mortality in transplant recipients, and may cause direct injury to the allograft. While antiviral therapy is frequently utilized, reduction of immunosuppression is often required, increasing the risk for simultaneous rejection.

**Case Description:** A 63 year-old man presented with fever and body aches 2 weeks after kidney transplantation. Immunosuppression included anti-thymocyte globulin induction followed by belatacept, mycophenolate, and prednisone, and he had immediate graft function. On presentation, he was febrile and tachypneic. Labs revealed leukopenia, mild transaminitis, but stable initial allograft function (serum creatinine 1.0 mg/dl). Infectious workup detected adenovirus in the urine, serum, and via nasal swab. Mycophenolate dose was reduced, cidofovir was initiated, and subsequently switched to brincidofovir to minimize potential nephrotoxicity. Despite therapy, fevers persisted, and serum viral load rose to 16 million copies/ml. His course was subsequently complicated by allograft dysfunction, with serum creatinine acutely increasing to 2.1 mg/dl. Biopsy revealed marked interstitial inflammation, tubulitis, and endotheliitis with areas of cortical necrosis, as well as positive adenovirus staining, suggesting the presence of both acute cellular rejection (Banff 2a) and adenovirus nephritis. Pulse corticosteroids were initiated, and antiviral therapy continued. In the subsequent days, fevers improved, clinical symptoms resolved and he had progressive decline in adenovirus viral load with eventual complete viral clearance. Allograft function improved as well, and current serum creatinine is 1.1 mg/dl.

**Discussion:** Antiviral therapies utilized for adenovirus infection demonstrate inconsistent efficacy and are limited by potential toxicity. As shown here, reduction of immunosuppression, which is often necessary, may increase risk of acute rejection. We discuss successful management of a rare and challenging case of simultaneous adenovirus nephritis and acute rejection using corticosteroids and antiviral therapy.

Endotheliitis and adenovirus stain.

## PUB318

**Bartonella Induced Hemophagocytic Lymphohistiocytosis (HLH) in a Kidney Transplant Recipient**

Sarah Mouawad, Costi D. Sifri, Kelly Davidson, Alden M. Doyle. *University of Virginia, Charlottesville, VA.*

**Introduction:** HLH is a rare, severe hyperinflammatory syndrome that can cause significant morbidity and mortality, especially if not recognized early. Transplant recipients are at elevated risk of HLH and infections that can drive this disease because of their immunosuppressive regimens.

**Case Description:** Herein we present a 63-year-old male with a history of end stage kidney disease secondary to diabetes mellitus who received a deceased donor kidney transplant in April 2019. Three years after transplant, he presented with fatigue and fever. He was found to have acute kidney injury and was urgently started on renal replacement therapy. He had anemia, thrombocytopenia, hyperferritinemia, abnormal liver function tests and splenomegaly. Hemolysis workup was negative. Presence of elevated ferritin led to investigation for HLH. The patient met 5 criteria for diagnosis of HLH: cytopenias, elevated ferritin, elevated CXCL9, splenomegaly and hemophagocytosis on bone marrow biopsy. HLH genetic panel was without abnormalities. Computed tomography scan of chest abdomen and pelvis were unremarkable for malignancy. Since the patient had a new 6-month-old cat, serologies for *Bartonella henselae* as a potential secondary cause of HLH were obtained and returned positive. The urine *Histoplasma* and *Blastomyces* antigens were also positive, both below the limit of quantification; serum *Histoplasma* and *Blastomyces* antigens and serologies were negative. Pathology stainings of bone marrow biopsy were negative for fungal or bacterial elements. *B. henselae* was suspected to be the causative pathogen, but given unable to definitively rule out fungal infection, the patient was treated with azithromycin, doxycycline, and posaconazole. Brain MRI and lumbar puncture failed to demonstrate CNS involvement, so intrathecal therapy was not indicated. Dexamethasone was initiated to treat HLH; with persistent cytopenias and elevated ferritin, etoposide was added. The patient improving with repeat bone marrow biopsy revealed absence of overt hemophagocytosis, down trending ferritin, and improving blood counts on a slow steroid taper and continued antimicrobials. The patient remains dialysis-dependent.

**Discussion:** HLH is a rare but severe disease that must be suspected early in kidney transplant recipients, without prompt recognition and treatment, prognosis remains poor.

## PUB319

**Impact of the COVID-19 Pandemic on Molecular Surveillance in the KOAR Registry**

Tarek Alhamad,<sup>1</sup> Andrew F. Malone,<sup>1</sup> Didier A. Mandelbrot,<sup>2</sup> Prince M. Anand,<sup>3</sup> Hani Wadei,<sup>4</sup> Nikhil Agrawal,<sup>5</sup> Kevin Pinney,<sup>5</sup> Amishi S. Desai,<sup>6</sup> <sup>1</sup>Washington University in St Louis, St Louis, MO; <sup>2</sup>University of Wisconsin-Madison, Madison, WI; <sup>3</sup>Medical University of South Carolina, Charleston, SC; <sup>4</sup>Mayo Clinic in Florida, Jacksonville, FL; <sup>5</sup>CareDx Inc, Brisbane, CA; <sup>6</sup>Loyola University Medical Center, Maywood, IL.

**Background:** The SARS-CoV2 pandemic increased the complexity of delivering clinical care and laboratory services for immunosuppressed kidney transplant (KTx) recipients. We evaluated how the pandemic impacted adherence with laboratory draws among patients in the Kidney allograft Outcomes AlloSure Registry (KOAR, NCT03326076).

**Methods:** 1663 KTx recipients undergoing post-transplant surveillance using donor-derived cell-free DNA (dd-cfDNA) were enrolled in KOAR between 2017 and 2021. Participating centers were free to individualize their surveillance strategies. We estimated adherence by using the pre-pandemic distribution of surveillance dd-cfDNA draws across participating sites to establish a baseline regimen, and then compared adherence before the pandemic (P1; through 1/2020) with two subsequent periods in 2020: P2 (2/2020 - 6/2020), coinciding with the first wave of infections, and P3 (7/2020 - 12/2020), which captures the bulk of the second and third waves in the US.

**Results:** The distribution of surveillance dd-cfDNA draws at participating sites before COVID (P1) identified 7 peaks corresponding to draw points at months 1, 2, 3, 4, 6, 9, and 12 [Figure 1a]. Estimated adherence during P1 based on this regimen was 60.5%. Over the subsequent 5 months (P2), reflecting the early months of the pandemic, adherence declined to 50.5% ( $p < 0.01$ ). After the expanded availability of mobile phlebotomy services in 7/2020 and despite rising SARS-CoV2 case counts and hospitalizations, adherence during P3 improved to 57.6% ( $p < 0.01$  compared to P2,  $p = 0.1$  compared to P1) [Figure 1b].

**Conclusions:** Our findings demonstrate that adherence to laboratory surveillance among transplant recipients enrolled in the KOAR registry declined in the early period of the SARS-CoV2 pandemic, however, a variety of adaptations in the latter half of 2020, including the widespread availability of remote phlebotomy for these patients, appears to have led to substantial improvements, with adherence approaching pre-pandemic levels.

**Funding:** Commercial Support - CareDx

## PUB320

**Anemia Is the Main Factor Related to Allograft Dysfunction in Kidney Transplantation**

Beatriz M. Silva, Thiago Terzian Ganadjian, Vinicius Pereira Leite Nakamura, Bárbara F. Domingues, Otavio H. Clemente, Jessica L. Andrade, Adelson Rodrigues, Miguel Angelo Goes. *Universidade Federal de Sao Paulo, Sao Paulo, Brazil.*

**Background:** Anemia is quite common in end-stage kidney disease patients. Anemia is associated with outcomes in kidney transplant patients. To evaluate the correlation between kidney pre-transplantation anemia and delayed allograft function (DGF), chronic kidney allograft dysfunction (CKAD), and the deceased donor kidney transplantation mortality.

**Methods:** An observational retrospective study with 206 kidney transplant patients from deceased donors in 2008 at Hospital do Rim, Brazil. We analyzed deceased donors and kidney transplant patients demographic data. Moreover, biochemical parameters, anemia status, and treatment were compared between DGF and non-DGF groups. Thus, a multivariate analysis was performed. Outcome comparisons were calculated at 1 year for CKAD and at 10 years for mortality.

**Results:** Within 1 week after the transplantation requirement, there was higher donor serum creatinine, and red blood transfusion frequency, but lower pre-transplant hemoglobin concentration (Hgb) in the DGF group. In addition, there was a pre-transplant Hgb with DGF independent association [OR 0.252, 95%CI: 0.159-0.401;  $p < 0.001$ ]. After 6 months of kidney transplantation, there was a Hgb concentration with both CKAD association [OR 0.798, 95% CI: 0.687-0.926;  $p = 0.003$ ] and mortality.

**Conclusions:** This study documented pre-transplantation anemia in relation to DGF. Besides, it was related 6 months post-transplantation anemia to both CKAD and mortality.

Delayed allograft function (DGF) vs. non-DGF	Odds Ratio (OR)	95% confidence interval for OR Lower/Upper	p value
Hemoglobin (g/dl)-pre-transplant	0.252	0.159/0.401	<0.001
Donor serum creatinine (mg/dl) #	2.038	0.919/4.518	0.08
Donor age (years)	1.002	0.950/1.057	0.37
Red blood cell transfusion within first-week post-transplantation (%)	1.609	0.541/4.771	0.39
Dose of rHuEPO (U)/week #	1.001	0.998/1.002	0.68
Kidney donor profile index (%)	0.999	0.974/1.024	0.91

## PUB321

### Kidney Transplant Patient Immunological Hyporesponsiveness to SARS-CoV-2 Vaccination

Olusola Sogbein, Asim Rizvi, Muhammad A. Mujtaba, Michael Kueht, Ann Kathleen N. Gamilla-Crudo, Syed A. Hussain. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

**Background:** Multiple studies have shown an association between immune status and SARS CoV-2 disease severity, however data on specific immunosuppressive medications is not fully described. Immunocompromised individuals are at increased risk of mortality and morbidity therefore, vaccination against COVID-19 is essential. Research also suggests that elevated IgG levels post-vaccination correlate with host viral neutralization. We present data indicating that induction and maintenance immunosuppression therapy affects responsiveness to SARS CoV-2 vaccination among kidney transplant recipients.

**Methods:** 48 kidney transplant patients at our institution were retrospectively analyzed after receiving two doses of the SARS CoV-2 mRNA type vaccine between January and March 2021. Kidney transplantation occurred between 1983 and 2020. SARS-CoV-2 spike antigen-specific IgG levels were measured after 30-days to evaluate immunological responsiveness to the vaccine.

**Results:** 35% of study subjects showed detectable peak COVID IgG serum levels 30 days after the second vaccine dose while 65% showed no response. Of the non-responders, (62%) were predominantly heavily immunocompromised; on either high dose Mycophenolate (at least 720 mg twice daily) in addition to standard Calcineurin inhibitor/Sirolimus +/- Prednisone, or had received high dose Thymoglobulin (6 mg/kg or more) within a year of vaccination. This contrasts to published reports of over 95% immunological responsiveness or viral neutralization after the second vaccination dose among immunocompetent patients.

**Conclusions:** Induction therapy with Anti-Thymocyte globulin and maintenance immunosuppression with Mycophenolate serve as the cornerstone of transplantation management. However, their utilization impacts B cell proliferation which is hypothesized to reduce antibody production and the effectiveness of the SARS-CoV-2 vaccine in transplant patients. This finding supports the need for a third or possibly fourth booster dose to achieve a sustained and effective response in combination with ongoing immunological surveillance post-vaccination among transplant patients.

## PUB322

### Operations Research to Solve Kidney Allocation Problems: A Scoping Review

Nigar Sekercioglu,<sup>1,2</sup> <sup>1</sup>Saglik Bilimleri Universitesi, Istanbul, Turkey; <sup>2</sup>University of Ottawa, Ottawa, ON, Canada.

**Background:** In the context of kidney transplantation, health, compatibility, and availability of organs need to be considered to allocate kidneys. Operations research enables health care administrators to optimize resource allocation problems (e.g., kidney allocation for kidney transplant) as well as scheduling problems (staff scheduling and patient scheduling). Operations research employs various techniques incorporating both soft and hard constraints in the equations. The goal is to reduce the gap between demand and supply using advance organ allocation systems and enable adequate access. This paper aims to synthesis the evidence on the use of operations research for allocating deceased donor organs. We also assessed the quality of published studies.

**Methods:** We searched MEDLINE and EMBASE databases from 1946 up to May 2022 without any restrictions. We included studies that explore the methods about the distribution of kidneys from a deceased donor using operations research methods for the conflict resolution if they explore the optimal threshold level to accept/reject a transplant and optimal kidney acceptance strategies for stochastically arriving organs. One investigator (NS) screened each title and abstract and reviewed full text articles and abstracted the data from eligible studies.

**Results:** This scoping review included three published studies that employed operations research techniques. Ahn and Hornberger et al. developed a semi Markov model with five states while examining minimal threshold level of accepting and rejecting the kidney based on QALY index based patient specific ratings. Later on, the sequential stochastic assignment model was developed by Su and Zenios in 2005 and included multiple patients and panelized those who rejected the offer. Stanford et al. suggested a blood type compatible queuing model for stochastically arriving kidneys from deceased donors.

**Conclusions:** The present study is the first to systematically review the operations research methods to manage time and limit wait times with establishing the optimal threshold level to accept/reject a transplant and optimal kidney acceptance strategies for stochastically arriving organs.

## PUB323

### Risk Factors Associated With Acute Respiratory Failure in Renal Transplant Patients

Phoenix Xu,<sup>1</sup> Aditi Saha,<sup>2</sup> Sasa Ivanovic,<sup>2</sup> Ehsen Z. Rao,<sup>2</sup> Anvitha R. Ankireddypalli,<sup>2</sup> Kushal Shukla,<sup>2</sup> Vagram Ovnianian,<sup>2</sup> Fariborz Rezai,<sup>2</sup> Patrick Hilden,<sup>2</sup> Nirav Mistry,<sup>2</sup> Paul C. Yodice.<sup>1</sup> *Rutgers New Jersey Medical School, Newark, NJ; <sup>2</sup>Cooperman Barnabas Medical Center, Livingston, NJ.*

**Background:** Renal transplant is the most common solid organ transplant. It improves quality of life and mortality for patients with end stage kidney disease and progressive chronic kidney disease. Despite the improvement in the 10-year graft survival rate over the past decades, acute respiratory failure (ARF) remains one of the most common causes of death and graft failure. Few studies have been done to study the risk factors associated with ARF in this specific population. The objective of this retrospective study is to assess the incidence and identify the risk factors associated with ARF within one-year post renal transplant.

**Methods:** All patients older than 18 years of age who received a renal transplant between January 1, 2015 and December 31, 2017 were included. Patients with ARF were evaluated against patients without ARF. ARF was defined as respiratory distress requiring non-invasive (bilevel positive airway pressure or high flow nasal cannula) or invasive mechanical ventilatory support in the ICU. Patients who were pregnant or had terminal diseases prioritizing comfort measures were excluded. Patients' demographics, substance use history, and past medical history were recorded.

**Results:** This study included 879 patients. Sixty-three (7.2%) met criteria to be included in the ARF group. Majority of ARF (6.9% accumulative incidence rate) occurred in the first 180 days post-transplant. Based on univariate analysis, increased age (P<0.001, hazard ratio [HR] 1.55), history of cardiomyopathy both ischemic (P<0.001, HR 2.78) and nonischemic (P=0.001, HR 2.83), smoking (P=0.011, HR 1.91), diabetes mellitus (P=0.024, HR 1.77), and hypotension intraoperatively and postoperatively (P=0.009, HR 3.09) were significant risk factors for ARF. Based on multivariate analysis, hypotension intraoperatively and postoperatively (P=0.035, HR 2.89), and history of cardiomyopathy both ischemic (P=0.039, HR 1.89) and nonischemic (P=0.008, HR 2.59) were significant risk factors.

**Conclusions:** Since ARF is a common cause of renal transplant failure and death, identifying risk factors can facilitate early recognition and treatment. Risk factors identified in this study were increased age, smoking, diabetes mellitus, history of cardiomyopathy, and hypotension in intraoperative and/or postoperative periods.

## PUB324

### Nocardiosis in Renal Transplantation: A Single Center Study From India

Anurag Gupta, Vaibhav Tiwari, Gaurav M. Bhandari, Vinant Bhargava, Manish Malik, Anil Bhalla, Ashwani Gupta, Devinder S. Rana. *Sir Ganga Ram Hospital, New Delhi, India.*

**Background:** Nocardiosis is a rare opportunistic infection seen in kidney transplant patients which is caused by an aerobic actinomycete. Disease manifestations can vary from a localized infection to multisystem organ failure. Despite the high mortality, there are limited data on nocardiosis in kidney transplant patients because of low incidence, non-specific clinical presentation, presence of coinfections that preclude further workup for nocardiosis.

**Methods:** Kidney transplant patients with age more than 18 years diagnosed with Nocardiosis on gram-stain, modified acid-fast stain, and culture between 2010 to 2019 were included. Clinical and microbiological data of these patients were retrospectively analyzed.

**Results:** A total of 1801 kidney transplants were done from 2010 to 2019. Sixteen cases of nocardiosis were identified. The median time from transplant to Nocardiosis was 21 months (IQR 9.75-45). Acute rejection episodes and CMV infection within 6 months of nocardiosis were found in 12.5% and 25% respectively. In the form of immunosuppressants, 15 out of 16 patients (93.75%) received Anti thymocyte globulin (ATG) while 1 patient received Grafalon (ATG-Fresenius). The most common organ involvement was the lungs (75%) followed by the brain (12.5%). Only 1 patient showed cutaneous involvement (6.25%). The severe form of the disease in the form of disseminated infection was seen in one patient. Sub-species identification was possible in the last 3 years of study after the introduction of MALDI TOF. Six patients were diagnosed with nocardiosis from 2017 to 2019, of which *Nocardia farcinica* was the most common type (4 out of 6 patients) and was resistant to cotrimoxazole. The mortality rate was 31.25%. Patients with brain involvement and disseminated infection had 100% mortality.

**Conclusions:** Though nocardiosis in kidney transplant patients has a very low incidence but is an important cause of mortality. *Nocardia farcinica* is the predominant species which is mostly resistant to cotrimoxazole. Cerebral and disseminated nocardiosis have a poor prognosis. Drug sensitivity, if available, is an important tool to guide treatment.

## PUB325

### Analysis of Graft Survival: 14 Years of Experience in a Dominican Transplant Program

Anthony J. Gutierrez,<sup>1</sup> Nicole M. Batlle,<sup>1</sup> Lorgis I. Jiménez,<sup>1</sup> Nicole M. Suárez,<sup>2</sup> Denazir Atizol Rodríguez,<sup>2</sup> Eliana Dina-Batlle.<sup>2</sup> <sup>1</sup>Pontificia Universidad Católica Madre y Maestra Facultad de Ciencias de la Salud, Santiago De Los Caballeros, Dominican Republic; <sup>2</sup>Hospital Metropolitano de Santiago, Santiago De Los Caballeros, Dominican Republic.

**Background:** Renal transplant is a life-changing intervention with many landmark changes in the past years. Latin America and the Caribbean have low-income health systems and limited access to proper interventions. Even where there is access to transplantation, the maintenance of the graft is an issue. Due to the lack of data to create personalized programs to enhance the renal transplantation experience in the Caribbean region, we aimed to describe the graft survival characteristics of a single-center experience.

**Methods:** This is a retrospective cohort observation in a renal transplant unit at Hospital Metropolitano De Santiago, Dominican Republic from 2008 to 2021. All patients consenting patients from the program were included. The statistics relied on descriptive statistics, survival analysis for the primary outcome and Cox regressions to adjust the shown effects.

**Results:** Analyzing 71 cases, we found that 75% of the population maintained their graft by the 8th year of observation and a propensity of 3.6x for graft loss by females. Only 5% of the grafts came from cadaveric donors, as for the graft survival analysis. The hazard ratio for patients with infection post-transplant is 3.58 (CI95%1.29-9.94), and for females, the HR is 3.66 (CI95%1.44-9.28). The Cox regression model shows that controlled by sex, the HR of post-transplant infection on graft survival is 2.55 (CI95%0.894-7.284), offering a confounding role of sex over post-transplant infection.

**Conclusions:** These results support that the standard treatment of the Dominican Republic is up to global standards concerning the survival of the graft. However, a clear predominance of graft loss by females was shown, contrary to the well-described pattern. Further observation to obtain a median value of survival and the addition of more patients would complement this analysis and increase its external validity.

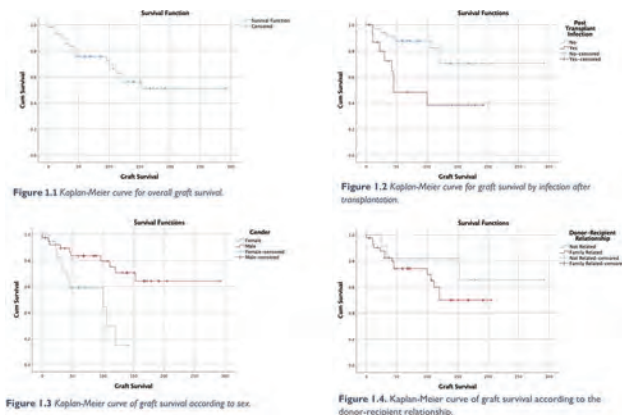

Figure 1. Kaplan-Meier curves of graft survival.

## PUB326

### Glycemic Control With Continuous Glucose Monitoring in Kidney Transplant Patients

Welly Agate,<sup>1</sup> Ngoc-Yen Pham,<sup>2</sup> Maria-Eleni Roumelioti,<sup>2</sup> Christos Argyropoulos.<sup>2</sup> <sup>1</sup>University of New Mexico School of Medicine, Albuquerque, NM; <sup>2</sup>University of New Mexico Health Sciences Center, Albuquerque, NM.

**Background:** Kidney transplant immunosuppressants result in challenging glycemic control. Continuous Glucose Monitoring (CGM) is associated with an improvement in hemoglobin A1c (HbA1c) in non-transplant patients with type 2 DM (T2DM). We investigated whether the implementation of CGMs in kidney transplants patients with T2DM would decrease the HbA1c and the average blood glucose (Glc) levels.

**Methods:** We reviewed retrospectively medical charts (3/2019-3/2022) in Cerner UNM. We included 23 adults with a kidney transplant and T2DM, on daily insulin therapy, and eligible for a CGM device. We collected demographics, antidiabetics, comorbidities, pre- and post-CGM markers of glycemic control (HbA1c, average serum Glc, Glc Management Indicator [GMI], Time In Range [TIR]). These markers were recorded from the Index visit (Day 1 of CGM) to subsequent and previous visits (1 year before & after the Index visit). Repeated observations were analyzed with linear mixed models to account for correlations in the same individual.

**Results:** Patients were on average 59.5 ( $\pm 15.1$ ) years old; 83% were white and 52% were males, while 65% were on Freestyle Libre. Most common comorbidities were: Hypertension (96%), Hyperlipidemia (57%), and Coronary Artery Disease (13%). Most patients (39%) were on 3 antidiabetic agents, and only 39% were on prednisone. We analyzed 128 repeated HbA1c measurements (65 obtained before CGM initiation). The use of CGM was associated with a reduction in the HbA1c (Figure 1) by  $-0.73 \pm 0.20$  ( $p = 0.0003$ ). Each 10% in TIR was associated with a reduction in the GMI by  $-0.23 \pm 0.03$  ( $p < 0.0001$ ).

**Conclusions:** Kidney transplant patients with T2DM may benefit from the use of CGM. Further studies should evaluate if the improved HbA1c and Glc control with CGM translates into a significant morbidity/mortality benefit.

## PUB327

**Efficacy and Safety of Cessation and/or Reduction of Mycophenolic Acid (MPA) in BK Viremia Post-Renal Transplant**

Ramyangshu Chakraborty, Michelle E. Allan, Tasnuva S. Kashem, Kieran McCafferty, Stanley Fan, Teresa M. Cutino Moguel, Muhammad Magdi Yaqoob. *The Royal London Hospital, London, United Kingdom.*

**Background:** Stopping antiproliferative agents is a common first-line response to patients with BK viremia with or without biopsy-proven nephropathy. However, the efficacy and safety of this strategy (resolution of viremia, breakthrough rejection/de novo DSA formation) remains unknown in a multi-ethnic cohort of renal transplant patients.

**Methods:** Retrospective study of incident kidney transplants at The Royal London Hospital, UK between 2017-2020 who developed detectable serum BK DNA. Patients received standard maintenance IS: tacrolimus, mycophenolate mofetil (MPA) and prednisolone (weaned to 5 mg/d) under induction with basiliximab or ATG. All patients had at least 1 biopsy. Data were analysed using R statistical software.

**Results:** 143 patients (62% male) were included. The mean (SD) age of the cohort was 51 (13.7) years. 32% were South Asian, 27% Caucasian, 21% Afro-Caribbean and 20% were mixed. 24.5% received a kidney from LD, 52.5% DBD, and 23.1% DCD respectively. The mean follow-up was 3.2 yrs. 113 (79%) patients had their antiproliferative reduced or stopped for BK viremia; the rest had no change in antiproliferative dose. Those who had no changes to antiproliferative dose were younger ( $p=0.04$ ), had longer follow up ( $p=0.04$ ), had lower peak BK titres ( $p<0.001$ ), had less biopsy-proven BKVaN ( $p=0.04$ ), recovered from viremia more frequently ( $p<0.001$ ) and had less eGFR loss ( $p=0.005$ ). There were no differences in donor or recipient types, induction agent, tacrolimus levels during viremia, and rates of rejection or development of de novo DSA between the groups. 70 patients from the cohort had resolution of viremia. The persistently viremic group had a higher cessation rate of MPA (78.1% to 48.6%,  $p<0.01$ ) and was associated with biopsy-proven BK nephropathy ( $p<0.01$ ).

**Conclusions:** Our study suggests that stopping/reducing antiproliferative medications as first line for BK viremia is safe but maybe an ineffective strategy for lessening the severity of the disease. A randomized controlled trial is warranted to compare stopping antiproliferative medications with targeting lower tacrolimus concentrations with and without mTOR inhibitors as the first option for BK viremia.

## PUB328

**Recurrence of Glomerular Disease in Kidney Transplant Recipients in a National Cohort**

Ana Dovc,<sup>1,2</sup> Andreja Ales Rigler,<sup>1</sup> Miha Arnot.<sup>1</sup> <sup>1</sup>University Medical Centre Ljubljana, Division of Internal Medicine, Department of Nephrology, Ljubljana, Slovenia; <sup>2</sup>Medical Faculty, University of Ljubljana, Ljubljana, Slovenia.

**Background:** Recurrence of glomerular disease after kidney transplantation is common and presents a management challenge. Knowledge of the incidence of glomerular disease recurrence in specific cohorts may facilitate shared decision-making.

**Methods:** We performed a retrospective analysis of all kidney transplant recipients at our national transplant center, who received a kidney transplant between January 1st, 2000, and May 1st, 2021, with a minimal follow-up of 1 year. We collected data on the cause of kidney failure of native kidneys from electronic medical records. We considered a recurrence of glomerular disease confirmed if glomerular changes were detected at any (indication or surveillance) kidney biopsy, and the findings matched the primary diagnosis.

**Results:** We included 1,033 kidney transplant recipients, of whom 856 (83%) had a known cause of kidney failure. The commonest diagnosis was glomerulonephritis (300 cases, 29%), followed by diabetic or hypertensive kidney disease (162 cases, 16%) and polycystic kidney disease (151 cases, 15%). IgA nephropathy was the predominant glomerular disease with 190 cases (27 recurrences, 14% incidence of recurrence), followed by focal and segmental glomerulosclerosis in 29 cases (10 recurrences, 34%) and membranoproliferative glomerulonephritis 22 cases (6 recurrences, 27%). Other glomerular diseases rarely recurred, including systemic vasculitides (21 patients, 1 recurrence), membranous nephropathy (12 patients, 1 recurrence), and systemic lupus erythematosus (11 patients, 2 recurrences). Patient survival was similar to the whole cohort (85.9% vs. 81.3%,  $p=0.358$ ), however, recurrent glomerular disease reduced graft survival, censored for death with function (60.9% vs. 81.1%,  $p<0.001$ ).

**Conclusions:** Recurrence of glomerular disease after transplantation was less frequent in our cohort than in the literature, possibly due to the preferred immunosuppressive regimen, biopsy practice, or some other factor. Recurrence of glomerular disease portends worse graft survival.

Recurrence of Glomerular Disease

## PUB329

**Concurrent Transplant Renal Artery Stenosis and Antibody- and Cell-Mediated Rejection**

Asim Rizvi, Syed A. Hussain, Ann Kathleen N. Gamilla-Crudo, Michael Kueht, Muhammad A. Muftaba. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

**Introduction:** Transplant renal artery stenosis (TRAS) is an increasingly recognized complication affecting 1-23% of kidney transplant recipients. Allograft rejection continues to be a concern in kidney transplantation as 10% of patients experience rejection in their first year. Even though an individual presence of each disease is common, seeing both together is rare. We present a case of concurrent TRAS and antibody- (ABMR) and cell-mediated (TCMR) rejection in a living-related kidney transplant (LRKTx) recipient.

**Case Description:** A 22-year-old female underwent preemptive LRKTx from her sister. Patient's primary cause of ESRD is unclear. Due to immediate post-operative low arterial blood flow and suspected partial renal artery thrombosis, patient had re-exploration and thrombectomy. Patient received induction with Alemtuzumab and maintained on Mycophenolate, Belatacept, and Steroids. Given AKI, proteinuria, HTN, and edema at 3 months post-transplant, doppler ultrasound and kidney biopsy with MMDx were performed, which revealed concurrent TRAS and TCMR and ABMR. Patient underwent PTA and received Thymoglobulin, steroids, and IVIG. Patient was readmitted at 4 months post-transplant with AKI and doppler imaging revealed restenosis that led to PTA and stenting. Patient is currently being followed up for 7 months.

**Discussion:** Concurrent TRAS and acute rejection can occur in kidney transplant recipients. Clinicians should suspect both among patients presenting with refractory HTN, new-onset edema, and allograft dysfunction. Doppler ultrasound followed by arteriography are reasonable next steps for TRAS diagnosis and subsequent intervention. The utilization of allograft rejection monitoring tools including dd-cfDNA and addition of MMDx to kidney biopsy to add precision can help with early recognition and timely intervention.

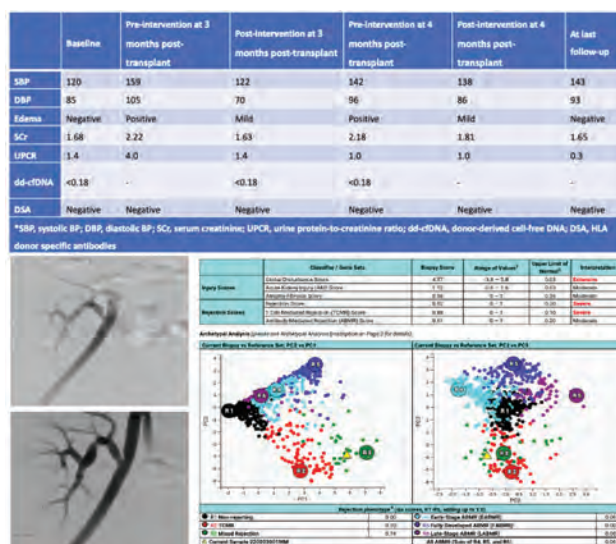

Figure. A) Patient's clinical parameters at baseline, pre- and post-intervention at 3- and 4 months, and at last follow-up; B) Percutaneous transluminal angioplasty (PTA) and stenting; and C) MMDx findings of acute antibody- and cell-mediated rejection.

## PUB330

**Cardiovascular Risk Assessment After Kidney Transplantation**

Elizabete Junk,<sup>1,2</sup> Inese Folkmane,<sup>1,3</sup> Evelina Merdane,<sup>1</sup> Kristofs Folkmanis,<sup>1,4</sup>

<sup>1</sup>Faculty of Medicine, University of Latvia, Riga, Latvia; <sup>2</sup>Sankt Bonifatius Hospital Lingen gGmbH, Lingen, Germany; <sup>3</sup>Pauls Stradins Clinical University Hospital, Centre of Nephrology, Riga, Latvia; <sup>4</sup>Kreisklinikum Siegen GmbH International Center for Robotic Urology Siegen, Siegen, Germany.

**Background:** Cardiovascular (CV) events are one of the leading causes of death in patients with functioning kidney transplants (KT) and long-term graft loss. Detection and modification of potential risk factors (RF) of CV events are essential for improving both graft and patient outcomes. The aim of this study was to evaluate the incidence of CV events, risk factors, and long-term patient survival in a Latvian cohort of KT recipients.

**Methods:** A retrospective cohort study was performed using KT data prospectively collected at a single institution. A total of 184 patients undergoing KT from 2008 to 2011 at the Latvian Transplantation Centre were included. For data analysis, patients were divided into two groups: patients with CV events (n=70) and patients without CV events (n=114). Traditional and non-traditional CV risk factors that predict CV events were analyzed. Recipients were classified as having graft dysfunction if their Glomerular filtration rate (GFR) was < 60 ml/min per 1.73 m<sup>2</sup> body surface area, calculated with the CKD-EPI Creatinine, 2021 equation. Logistic regression analysis was used to determine the risk factors. Kaplan-Meier analysis assessing survival of patients with and without CV events was also conducted.

**Results:** Overall, 70 (38%) of all recipients had CV events. Analysis of clinical-demographic data showed that patients with CV events had a higher mean age (60.37 years vs 48.61 years, p<0.001), a higher incidence of smoking (52.9 % vs 21.9%, p<0.001), and graft dysfunction were more common (85.7 % vs 72.8 %, p=0.03) than patients without CV events. In a multifactor analysis using logistic regression, significant CV risk factors were confirmed: age (OR:1.09; P<0.01); smoking (OR:5.80; P<0.001); proteinuria (OR:2.31; P=0.038), time on dialysis (OR:1.02; P=0.040), and graft dysfunction (OR=2.24; P=0.03). Kaplan-Meier 120-month survival curves for patients were significantly lower in patients with CV events (70% vs. 90%; P<0.0001).

**Conclusions:** It can be concluded that KT recipients have a high incidence of CV events, which occur in 38% of cases in our study. Important predictors of CV events were smoking, proteinuria, duration of hemodialysis, age, and KT dysfunction. CV events affect the survival of KTR compared to patients without CV events.

## PUB331

**Fatal Case of Epstein-Barr Virus-Negative Post-Transplant Lymphoproliferative Disorder With Hemophagocytic Lymphohistiocytosis in an Adult Kidney Transplant Recipient**

Sergio Mazzola Poli de Figueiredo, Syed A. Hussain, John C. Johnson, Muhammad A. Muhtaba, Rupak Kulkarni, Kirill A. Lyapichev, Alfred S. Lea, Michael Kueht. UTMB The University of Texas Medical Branch at Galveston, Galveston, TX.

**Introduction:** Renal transplantation requires lifelong immunosuppressive (IS) Medications to minimize rejection, which increase the risk of infection and malignancy. Post-transplant lymphoproliferative disorder (PTLD), a troublesome combination of both. Risk factors for PTLD include Epstein-Barr virus (EBV) infection and (IS). Although most cases are associated with EBV, EBV(-) PTLD is associated with worse outcomes. Hemophagocytic Lymphohistiocytosis (HLH) is a sepsis-like inflammatory syndrome, hyperferritinemic immune response that can rapidly progress to multi-system organ failure (MOF). Malignancies have been described as the main risk factors associated with HLH, but very few cases have been described associated with PTLD. Here, we describe a challenging case of an adult kidney transplant recipient who developed EBV(-)PTLD with HLH.

**Case Description:** A 68-year-old female with ESRD due to HTN and DMII underwent deceased donor kidney transplant. Donor and recipient were anti-EBV IgG (+) and anti-CMV (+). Thymoglobulin+solumedrol induction and maintain on belatacept, prednisone, and mycophenolate (MMF). Her Serum creatinine (Scr) was 1.38 mg/dL. She admitted 4 months later with altered mental status, fever, pancytopenia, lactic acidosis, refractory anemia, Scr 1.8 mg/dL coagulopathy, conjugated hyperbilirubinemia. She intubated received blood transfusion and antibiotics. Labs showed hypertriglyceridemia, hypofibrinogenemia and hyperferritinemia. Biopsy of inguinal lymph node consistent with EBV(-) monomorphic diffuse Large B-Cell Lymphoma. Given the clinical and laboratory findings without infectious source, HLH in the context of PTLD was diagnosed. The decision was made to withdraw care. Autopsy confirmed type A1 MN large B cell lymphoma with diffuse lymph node involvement.

**Discussion:** PTLD is a rare but serious complication of organ transplantation. Very few case reports on transplant recipients who developed PTLD with HLH. However, reported cases are EBV (+) PTLD with HLH in pediatric patients undergoing liver or stem cell transplantation. Our patient developed EBV (-) PTLD with HLH, in <4 months post-kidney transplant which has not been described previously in the literature.

## PUB332

**Living Kidney Donation From a Donor With a Remote History of Infection-Related Glomerulonephritis**

Sami Droubi, Heedeok Han, Michael B. Stokes, Lloyd E. Ratner, Andrew S. Bomback, Syed A. Husain. Columbia University Irving Medical Center, New York, NY.

**Introduction:** Although a history of active kidney disease is a contraindication to living kidney donation, the suitability of donors with a history of resolved glomerulonephritis has not been established.

**Case Description:** A 58-year-old woman was evaluated as a potential living kidney donor. Twenty-three years prior to evaluation, she had experienced an episode of gross hematuria associated with an upper respiratory tract infection and pharyngitis. Workup at that time showed serum creatinine 1.1mg/dL (baseline 0.4-0.5mg/dL), hematuria, proteinuria, and red blood cell casts, and a clinical diagnosis of post-streptococcal glomerulonephritis was made. Laboratory values normalized within 1 month of initial presentation. At the time of her donor evaluation, workup showed normal creatinine clearance and no hematuria or proteinuria. She underwent successful kidney donation, with immediate allograft function and reperfusion biopsy showing normal renal parenchyma and no evidence of active glomerular disease.

**Discussion:** Well-selected individuals with a history of mild, self-resolving glomerulonephritis and a low risk of recurrent disease should be considered suitable candidates for living kidney donation.

Light Microscopy of reperfusion biopsy. Hematoxylin & eosin stain showing a normal size glomerulus with normal cellularity.

## PUB333

**Clinical Outcomes of Simultaneous Heart-Liver-Kidney Transplant Recipients: Single Center Experience**

Juhi Bhargava, Sambhavi Krishnamoorthy, Michelle A. Josephson, Yousuf Kyeso. University of Chicago Division of the Biological Sciences, Chicago, IL.

**Background:** Multiorgan dysfunction is not uncommon in patients with end stage heart and liver disease. Simultaneous heart-liver-kidney transplants (HLK) are less commonly performed than simultaneous heart-kidney or liver-kidney transplants due to the complex nature of the surgery and challenges with patient selection. 25 HLK were performed in the US from 2011 to 2021, out of which 9 were performed at our center. Given the limited availability of organs for transplant and the lack of standardized qualifying criteria for these patients, it is imperative to understand the factors involved in better outcomes, to optimize utilization of scarce resources.

**Methods:** We performed a retrospective review of all HLK recipients at the University of Chicago medical center between 2011-2021 using Epic EMR. We evaluated their kidney outcomes, infection rates, number of hospitalizations, and mortality over a 12-month period post transplantation.

**Results:** Baseline characteristics are summarized in the figure. 5 (55.5%) were between the age of 50-64, 2 (22%) were between the age of 35-49, and 2 (22%) were between the age of 18-34. 6 (67%) had pre-transplant GFRs between 30-40 ml/min, 1 (11%) had a GFR between 15-30, and 2 (22%) had GFRs <15. 3 (33%) required renal replacement therapy pre transplant. All received grafts with a KDPI below 20% except 1 who had a KDPI of 59%. At 3 months, 8 (89%) had GFRs above 50 ml/min, out of which 5 (55.5%) had GFRs above 60, 1 (11%) had a GFR less than 15. At 6 months and 1 year, 3 (33%) had GFRs above 60, 3 (33%) were between 45-60, 2 (22%) had GFRs between 30-45. 2 (22%) developed delayed graft function. 1 died at 3 months post-transplant while 8 were alive at 12 months. 2 (22%) required a hospitalization within the 1st year post-transplant for infection related reason.

**Conclusions:** Our experience suggests that with careful selection of patients, simultaneous HLK can lead to successful patient outcomes at one year post transplantation. Longer follow up of these patients is needed to define long term allograft and patient survival which will help to standardize selection and allocation criteria of this subset of patients.

Acton Prolongatum™ Induces Remission of Proteinuria In Recurrent FSGS Following Renal Transplantation  
Karpagavalli Subramaniam, Srimathi Ponnusamy, Mangalakumar Veerasamy. *KMCH, Coimbatore, India.*

**Background:** Idiopathic focal segmental sclerosis (FSGS) carries 30-40% recurrence rate following renal transplantation. Repository corticotropin injection - Acthar gel® has been found to be effective in reducing proteinuria in recurrent FSGS. Acthar gel® is expensive and not available in India. We describe the effect of Acton Prolongatum™ (AP), synthetic porcine sequence corticotropin in carboxy-methyl cellulose in recurrent FSGS.

**Methods:** Injection Acton Prolongatum™ was given at a dose of 1IU/kg twice a week subcutaneously for 12 months in applicable cases. Routine post-renal transplantation monitoring was done as per standard of care.

**Results:** Patient characteristics are given in table 1. Change in uPCR is given in figure 1. Mean uPCR(SD) at 0,6,12,24,52 weeks were 3.6(1.9), 0.7(0.7), 0.3(0.7), 0.3(0.65) and 0.2(0.3) respectively. Two developed new onset diabetes mellitus and there was no graft loss.

**Conclusions:** Acton Prolongatum™ is a viable alternative to induce remission of proteinuria in recurrent FSGS. The major advantage would be the cost saving with this preparation (cost is USD 27.6 per vial). Head-to-head comparison using different repository ACTH preparations will help to establish whether they are equipotent in inducing disease remission or not.

Potential Utility of TruGraf in the First 3 Months Post Kidney Transplantation  
Tariq Shah,<sup>1,2</sup> Paige E. Beckman,<sup>2</sup> Payam Javaherizadeh.<sup>1</sup> *<sup>1</sup>Riverside Community Hospital, Comprehensive Transplant Center, Riverside, CA; <sup>2</sup>House of Transplant & Cancer, Riverside, CA.*

**Background:** Subclinical acute rejection (subAR) has been associated with inferior renal transplant outcomes. TruGraf, a PCR-based gene expression blood test, is a non-invasive screening tool for subAR in kidney transplant recipients. Its utility as a preliminary screening tool is not yet well defined. In this study, we evaluate the clinical utility of TruGraf in the first 3 months after kidney transplantation. We examined the predictive value of TruGraf for subclinical acute rejection, and its concordance with dd-cfDNA and DSA results.

**Methods:** In this retrospective cohort study, we compare TruGraf results to DSA, biopsy, and dd-cfDNA (TRAC) results available at the time of TruGraf testing. Patients within the first 3 months of transplantation with stable and delayed graft function were included in this study.

**Results:** There were 10 patients included in this study that underwent TruGraf testing within the first 3 months post-transplantation. Of these 10 patients, one underwent repeat testing within the first 3 months post-transplantation. As such, we evaluated 11 TruGraf results—7 were negative (TX), indicating immune quiescence, and 4 were positive (not-TX), indicating potential subAR or acute rejection. Of the 7 TX results, 3/7 had positive DSA results. Four TX patients underwent TRAC testing, and 3/4 were positive for levels greater than 0.70%. Only one TX patient underwent biopsy, which was negative for t-cell-mediated rejection (TCMR) and antibody-mediated rejection (AMR). Of the 4 not-TX results, 2/4 had positive DSA results. One of the not-TX patients underwent TRAC testing, and this patient tested positive with a level of 0.95%. This same not-TX patient was the only one to undergo biopsy, which demonstrated CN1 toxicity and FSGS.

**Conclusions:** Our small sample size made it difficult to assess the utility of TruGraf testing among kidney transplant recipients during the first 3 months post-transplantation. However, we will continue to prospectively expand our sample size to strengthen our investigation of TruGraf, as well as TRAC testing among this population of patients. SubAR, which is associated with inferior transplant outcomes, can occur early after transplantation. Omnigraf testing, among this population of patients, could lead to earlier identification and better management of SubAR and potentially improve renal transplant outcomes.

PUB336

BK Virus Associated With Collapsing Focal Segmental Glomerulosclerosis in a Renal Transplant Recipient  
Sujay D. Paudel, Surakshya Regmi, Rungwasee Rattanavich. *Loma Linda University, Loma Linda, CA.*

**Introduction:** BK Virus Nephropathy (BKVN) can occur up to 10% of renal transplant recipients. It is characterized by tubulointerstitial inflammation and less frequently with glomerular involvement. Here we present a rare case of BK virus associated with Collapsing Focal Segmental Glomerulosclerosis (FSGS) which could lead to persistent proteinuria and progressive graft dysfunction.

**Case Description:** 24 years old Caucasian male with ESRD secondary to lupus nephritis s/p living related donor kidney transplant in 12/2019, received thymoglobulin induction. He was on tacrolimus, mycophenolate mofetil and prednisone for maintenance immunosuppression, Cr baseline 1.2. In 11/2020, he developed BK viremia with viral load 260,000 copies/ml, Cr 1.4 mg/dL, spot urine protein to creatinine ratio (UPCR) 0.5 g/g. He was treated with reduction of immunosuppression and IVIG. Despite BK viremia improvement to 24,000 copies/ml, his renal function and proteinuria worsened, Cr 1.6 mg/dL, UPCR 2.3 g/g. Renal transplant biopsy showed interstitial nephritis, focal tubulitis with tubular epithelial nuclei positive for SV-40 staining, segmental sclerotic glomeruli with collapsed glomerular tufts, profound podocyte hypertrophy, moderate interstitial fibrosis and tubular atrophy 25%. No glomerulitis, peritubular capillaritis, vasculitis or endothelitis. EM revealed podocyte foot process effacement 30%, no immune complex deposits, no chronic thrombotic microangiopathy or tubuloreticular inclusions. These findings consist with BK virus nephropathy with collapsing FSGS. No evidence of active antibody mediated rejection or acute cellular rejection. Therefore, reduction of immunosuppression and IVIG were continued. His BK virus resolved but graft function slowly declined Cr 1.8 mg/dL with persistent proteinuria UPCR 2.7g/g.

**Discussion:** Collapsing variant of FSGS presents with moderate to severe proteinuria and have the worst outcomes among other variants. It could lead to graft dysfunction and subsequent graft loss. The pathogenesis of BK virus associated with collapsing FSGS remains unclear. We hypothesized that direct impact of BK Virus spread from adjacent tubules can cause direct podocyte injury. BK virus infection should be considered in the differential diagnosis of collapsing FSGS in kidney transplant recipient for therapeutic intervention to control the progression of disease.

PUB337

Posttransplant Lymphoproliferative Disorder Diagnosed After Gastrointestinal Bleeding a Decade After Kidney Transplantation  
Katerina Hysi, Saira Sajid, Dina R. Al-Tuhafy, Jean H. Ancion, James Drakakis. *NYU Langone Hospital - Long Island, Mineola, NY.*

**Introduction:** Post transplant lymphoproliferative disorders (PTLDs) are lymphoid proliferations or lymphomas that are the second most common tumors in adult transplant recipients. Most cases are associated with Epstein-Barr Virus (EBV), which in the setting of solid organ transplant, can induce B-cell proliferation. While clinical presentation is quite variable, it is only recently that iron deficiency anemia has gained traction as a presenting symptom. In fact, PTLD with GI involvement is felt to be less common. To our knowledge, it has seldom been associated with gastrointestinal (GI) hemorrhage, with histopathological diagnosis confirmed on endoscopic biopsy of a gastric mass.

**Case Description:** 67 year old male with history of end stage renal disease (from IgA nephropathy) who underwent living donor kidney transplant in 2011. Immunosuppression consisted of Tacrolimus and Myfortic. Post transplant course remained stable and uneventful, until routine blood work done to investigate new onset fatigue revealed hemoglobin of 4.5 g/dL (from established baseline of 14-15 g/dL). He was admitted to the hospital where he was stabilized with transfusion of packed red blood cells and upper endoscopy was performed. This showed a large, infiltrative, non-circumferential mass in the gastric fundus with a clean based ulcer in the center of the mass. Pathology

was consistent with monomorphic post-transplant lymphoproliferative disorder, diffuse large B-cell lymphoma (DLBCL). EBV was negative. He completed 6 cycles of R-EP(O) CH and PET/CT done 3 months after initial diagnosis revealed complete response with interval resolution of gastric wall thickening.

**Discussion:** The incidence of PTLD in kidney transplant recipients is noted to be 1-3%. While risk factors such as EBV serostatus and type/duration of immunosuppression have been associated, an accurate diagnosis hinges on histopathologic confirmation. While GI symptoms such as iron deficiency anemia may be present, PTLD presenting with an isolated gastric mass and GI hemorrhage appears to be less common. Our case illustrates an EBV negative PTLD/DLBCL diagnosed on biopsy of an isolated gastric mass after presenting with an acute bleeding episode/associated ulcer. One need consider PTLD in a transplant patient presenting with GI symptoms and render prompt endoscopic assessment.

## PUB338

### Hypomagnesemia in Solid Organ Transplant and Its Early Relevance

Miniolla Durosier Louis,<sup>1</sup> Jessie C. Fullmer,<sup>1,2</sup> Henry J. Fan,<sup>1</sup> Joshua Okoro-sokoh,<sup>1</sup> George N. Coritsidis.<sup>1</sup> Westchester Hospital, Department of Nephrology <sup>1</sup>Westchester Medical Center Health Network, Valhalla, NY; <sup>2</sup>The Brooklyn Hospital Center, New York, NY.

**Background:** Electrolyte abnormalities often follow solid organ transplants (TX), with hypomagnesemia (hypoMG) the most common. Information on post-TX electrolyte levels following solid organ TX abnormalities is scarce, and especially comparing Liver (LTx), Heart (HTx), and Kidney (KTx). In this study, considerable emphasis is placed on hypoMG, and what outcomes occur up to 1 year post solid organ TX.

**Methods:** A single Center retrospective EMR analysis from Jan 2015 – Dec 2020. Clinical data and Magnesium levels were collected on the TX day, at 3 months, and 1 year after LTx, HTx, and KTxs. Medications: PPI, diuretics, tacrolimus levels (TACRO) were recorded. EKG Abnormalities: new QRS and QTC prolongations, ectopy, arrhythmias, LBBB and fascicular blocks. Cardiovascular related hospitalizations: Non-infectious causes, CHF, dyspnea on exertion.

**Results:** 532 patient charts were reviewed: 46% KTx, 26% HTx and 28% LTxs. At 3 months 43% of patients had hypoMG and at 1 year 32% severely hypoMG. Elevated TACRO was seen more often in severe hypoMG than normals (54.7 vs 38.9%) while loop diuretics and PPIs were not significantly more prescribed in hypoMG patients. Surprisingly, less EKG abnormalities (p=.002) and hospitalizations (p=.01) were seen in hypoMG. However when correcting for hyperkalemia significance disappeared, except in LTx, where both EKG abnormalities (p<.04) and hospitalizations were increased (p<.004) now in severe hypoMG.

**Conclusions:** HypoMG was seen in solid organ TXs at 3 months and persisted to 1 year post transplant. Tacro levels appear to be of most influence compared to loop diuretics and proton pump inhibitors. Increased abnormal EKG findings, and hospitalizations were associated only in LTx once corrected for abnormal potassium levels.. Effects of hypoMg can vary according to solid organ transplanted and concomitant electrolyte abnormalities.

## PUB339

### Allograft Loss Secondary to Atypical Hemorrhagic Necrosis

Aditi A. Sen, Medha Airy. Baylor College of Medicine, Houston, TX.

**Introduction:** Atypical hemolytic uremic syndrome is characterized by hemolytic anemia, thrombocytopenia and renal failure caused by platelet thrombi in the microcirculation of kidneys and other organs. Genetic aHUS accounts for estimated 60% of all aHUS. It is associated reported mortality rate of 25% and about 50% progress to ESRD. In these patients, aHUS reoccurs in up to 50% kidney transplant patients while graft failure occurs in 9 out of 10 patients. It is important to investigate these cases to establish etiology and improve outcomes.

**Case Description:** 52-year-old lady with history of Lupus nephritis, ESKD received LRKT on 10/12/2021, initially admitted with gross hematuria and reduced urinary output and diarrhea for a day. Vitals were stable. Physical examination was benign. Labs: BUN 129mg/dl and creatinine 7.12 mg/dl Platelet count was 47, elevated LDH1600 and normal haptoglobin. Peripheral smear showed No schistocytes. INR was elevated to 5.9. Anti Xa: 325 (N= <190); Fibrinogen >700. She was on Tacrolimus that was held. ADAMTS -13 test and aHUS panel was sent. Renal biopsy resulted complete infarction of renal tissue due to coagulation necrosis and no viable cortical tissue. Genetic panel for aHUS showed homozygosity for complement factor mutations. She was positive for the large CFHRI-CFH3 homozygous deletion. Factor H autoAb. ADAMTS-13 were negative.

**Discussion:** Genetic aHUS accounts for estimated 60% of all aHUS. Individuals with genetic aHUS frequently experience relapse after completing therapy and 60% progress to ESRD. Mutations in CFH, CFHR3, MCP, CFI, CFB and C3 genes predispose to the occurrence of aHUS. Our patient had CFH mutation positive in the aHUS panel. A comprehensive evaluation of the complement pathway is recommended. In addition to the supportive care and plasma exchange, complement dysfunction needs to be addressed with specific monoclonal antibodies such as eculizumab. A study by Levi et al administered eculizumab to 12 renal transplant patients with history of aHUS confirming that eculizumab is highly effective in preventing post-transplantation aHUS recurrence.=Additional therapies are in pipeline for future and hence, these cases need to be diagnosed and treated to avoid graft failure.

## PUB340

### Mineral Metabolism Parameters and Bone Density During the First Year of Kidney Transplantation

Carlo Alfieri,<sup>1,2</sup> Paolo Molinari,<sup>1</sup> Edoardo Campioli,<sup>1</sup> Maria Teresa Gandolfo,<sup>1</sup> Anna Regalia,<sup>1</sup> Mariarosaria Campise,<sup>1</sup> Donata C. Cresseri,<sup>1</sup> Evaldo Favi,<sup>1,2</sup> Giuseppe. Castellano.<sup>1,2</sup> <sup>1</sup>Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; <sup>2</sup>Università degli Studi di Milano, Milano, Italy.

**Background:** The variations of mineral metabolism (MM) parameters, femoral and vertebral bone density in a cohort of kidney-transplanted patients (KTxp), during the 1<sup>st</sup> year of transplantation (KTx) were analyzed.

**Methods:** 383 KTxp (KTx 2004-2017 were studied). At 1st(T1) and 12th(T2) mth of KTx biochemical, femoral and vertebral DEXA data were recorded. T-score (Ts)-1>Ts>-2.5: Osteopenia (F-OPN/V-OPN); Ts<-2.5: osteoporosis (F-OPS/V-OPS).

**Results:** During the 1<sup>st</sup> year of KTx the steroids cumulative dose (SCD) was 2683±926 mg. An increase in BMI, Ca, P, 25OH-D, Hb, albumin was observed with a reduction in sCr, PTH and ALP. Femoral BMD (F-BMD) at T1 and F-Ts-T1 were 0.749±0.17 g/cm<sup>2</sup> and -1.55±1.06. F-OPS-T1 was present in 17.5% and F-OPN-T1 in 53%. F-BMD-T1 correlated with BMI-T1 and with 25OH-D-T1. F-Ts-T1 was correlated with DV, BMI-T1 and PTH-T1. KTxp with F-OPS-T1 had longer DV and lower BMI. At T12, F-BMD-T12 and F-Ts-T12 were 0.77±0.67 g/cm<sup>2</sup> and -1.4±0.9. F-OPS-T12 was present in 13.2% and F-OPN-T1 in 55.2%. F-BMD-T12 correlated with BMI-T12. F-Ts-T12 correlated with DV, Ca at T1, and T12 and with SCD at T12. F-DEXA category worsened in 3.5% of KTxp. At T1, V-BMD-T1 and V-Ts-T1 were 0.92±0.19 g/cm<sup>2</sup> and -1.5±1.58. V-OPS-T1 was present in 30% and V-OPN-T1 in 34.5%. V-BMD-T1 correlated with BMI-T1 and Ca-T1. V-Ts-T1 was correlated with DV, PTH-T1, Ca-T, ALP-T1. A direct correlation between V-Ts-T1 and BMI-T1 and 25OHD-T1 was present. V-OPS-T1 was more prevalent in males with lower BMI, albumin, higher Ca-T1 and ALP-T1. At T12, V-BMD-T12 and V-Ts-T12 were 0.90±0.22 g/cm<sup>2</sup> and -1.5±1.33 (NS vs T1). V-OPS-T12 was present in 27.7% of KTxp and V-OPN-T12 in 37.2%. V-BMD-T12 correlated with BMI-T1 and T12 and with Ca-T12 and SCD-T12. V-Ts-T12 was correlated with DV, SCD-T12 and with Ca at T1, and T12. A direct relation was found with BMI-T1 and T12. V-OPS-T12 was more prevalent in DD. They were older, had longer DV. V-DEXA category worsened in 32% of KTxp.

**Conclusions:** We found several modifications of MM in KTxp at 1<sup>st</sup> year of KTx. Femoral and vertebral DEXA were related to the pre-KTx status. Nutritional status and DV are related to bone status at T1. An important role on T12 bone and mineral status is taken by the SCD.

## PUB341

### Factors Associated With Acute Renal Graft Rejection in a Series of Transplanted Patients

Juan Gómez Fregoso, Manuel Arizaga Napoles, Emmanuel Palomera Tejeda, José David G. Barajas, Guillermo Navarro Blackaller, Jonathan Chavez, Lidia Guadalupe Navarro Espinola, Benjamin Gomez-Navarro. Hospital Civil de Guadalajara, Guadalajara, Mexico.

**Background:** The survival of renal graft is affected by the presence of acute rejection, so knowing the factors associated with acute renal rejection could eventually help develop a model of prediction of renal graft loss.

**Methods:** An observational, case-control study, retrospective, was carried out in patients over 18 years of age, both genres who were Kidney transplanted. During the period from June 2015 to December 2016. Acute rejection was diagnosed by renal biopsy. A statistical analysis was carried out in SPSS v. 25 consisting of descriptive and inferential statistics using the X2 and t of independent samples as inferential tests and a multivariate binary logistic regression type analysis to determine the factors independently associated with acute renal graft rejection. A p<0.05 will be considered significant.

**Results:** 134 kidney transplant patients of an average age of 30.7±10.4 years were included; 38.8% were female and 61.2% were male. The causes of kidney failure were indeterminate (82.1%), glomerulonephritis (3.7%), diabetes mellitus (3%), renal polycystosis (2.2%) and other (9%). 23.9% (n=32) had acute rejection in the first year after transplantation, the highest percentage of rejections occurred in the first 6 months. Patients with acute rejection had significantly higher levels of creatinine at baseline (1.8±1.5 mg/dL versus 1.2±1.1 mg/dL, p=0.016) and higher average of previous transplants (1.25 + 1.4 vs 1 + 0.2, p=0.002). The factors significantly associated with acute renal rejection in the bivariate analysis were: delayed graft function (OR=3.7, 95% CI 1.1-12.4) and a scheme other than Tacrolimus/Micophenolate/Prednisone (OR=7.4, 95% CI 1.3-42.6, p=0.026). In the multivariate analysis, the factors significantly associated with acute renal rejection were having had a previous transplant (ORa=6,354, 95% CI 1,867-21,627, p=0.003); and the use of an immunosuppression scheme other than Tacrolimus/Micophenolate/Prednisone (ORa=6,814, 95% CI 1,061—43,774).

**Conclusions:** The factors significantly associated with acute renal graft rejection were delayed graft function, having had a previous transplant and the use of an immunosuppression scheme other than Tacrolimus/Mycophenolate/Prednisone.

**Funding:** Government Support - Non-U.S.

## PUB342

**An Oldie but a Goodie: A Rare Case of Candida in a Kidney Transplant Recipient**

Asim Rizvi, Syed A. Hussain, Muhammad A. Muftaba, Alfred S. Lea, Michael Kueht, Ann Kathleen N. Gamilla-Crudo. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

**Introduction:** Infections in the transplant population are common especially if accompanied by other systemic diseases such as diabetes, malignancies and other immunocompromised states. Fungal infections, even more rare, can cause significant morbidity and mortality in transplant recipients.

**Case Description:** We present a 66 year old Hispanic male with well-controlled DM and HTN, who received a kidney transplant in June 2021. Induction was done with Thymoglobulin. Patient's postoperative course was complicated by delayed graft function. He was maintained on Prednisone, Mycophenolic acid, and IV Belatacept. Serum creatinine was <1.2 mg/dL two months post-transplant. He was doing well until seven months after transplant when he complained of left ear pain, facial swelling, and headache, and was diagnosed with malignant otitis externa. Ear drainage cultures were obtained and showed *Candida duobushaemulonii*. Right myringotomy and tube insertion was performed. He was treated with IV Micafungin then oral Itraconazole, IV Piperacillin-Tazobactam then oral Ciprofloxacin, and hyperbaric oxygen therapy. His maintenance immunosuppression was reduced by 75%. His serum creatinine has been <1 mg/dL. Follow-up MRI revealed improvement in infection along with improvement in patient's presenting symptoms.

**Discussion:** *Candida Duobushaemulonii* is an old but frequently unreported pathogen of the *Candida haemulonii* family. It has reduced susceptibility to amphotericin B, azoles, and echinocandins, thus making it difficult to eradicate. A high clinical index of suspicion accompanied by accurate tissue specimen analysis using unconventional methods such as PCR, with significant reduction in overall immunosuppression, is necessary to achieve treatment success and preservation of kidney allograft function.

## PUB343

**Pregnancy in Patients With C3 Glomerulopathy**

Mariam Charkviani, Fernando C. Fervenza, Vesna D. Garovic, Andrea G. Kattah. *Mayo Clinic Minnesota, Rochester, MN.*

**Background:** C3 Glomerulopathy (C3G) is a rare disease, characterized by proliferative glomerulonephritis with prominent complement factor 3 (C3) deposits and is caused by dysregulation of the alternative complement pathway. C3G in women of childbearing age is rare; thus, little is known about the natural history of C3G in pregnancy.

**Methods:** In this case series, we describe clinicopathologic features, clinical course, and maternal-fetal outcomes of 3 pregnancies in 2 women with C3G.

**Results:** We identified 4 patients with C3 glomerulonephritis (C3GN) by kidney biopsy with pregnancy episodes. 2 have ongoing pregnancies and not yet delivered. Of the 2 women with known pregnancy outcomes both developed the disease in adulthood, had stable kidney function that did not require immunosuppression, and treated with blood pressure control and RAAS blockade. Neither patient had known genetic mutations for atypical hemolytic uremic syndrome (aHUS) or C3G. The first patient had proteinuria prior to pregnancy that increased during pregnancy. Creatinine remained stable at 1mg/dL. She developed preeclampsia and required induction at 37 weeks. Her complement cascade showed low C3 and Factor H initially, but during pregnancy, the levels normalized. The second patient had two pregnancies; her creatinine was 1.5 mg/dl prior to pregnancy with proteinuria 167mg/24h. Similar to the first patient, she had low Factor H prior to pregnancy that increased to normal during pregnancy. During her first pregnancy, creatinine was stable, and urine protein remained below 1g/24h. Pregnancy was notable for rise in blood pressure at 33 weeks' gestation and she was induced for hypertension at 37 weeks. Postpartum her creatinine rose to 1.7 mg/dL, but then decreased to prior baseline. During her second pregnancy, her proteinuria and creatinine rose, and was again induced at 37 weeks due to hypertension. After delivery, creatinine returned to baseline. In all pregnancies, babies were born healthy, with normal birth weight and patients did not develop any significant postpartum complications.

**Conclusions:** We described characteristics, course, and maternal-fetal outcomes of pregnancies in 2 women with C3G. In contrast to aHUS, another disease related to dysfunction of complement system which can worsen during pregnancy, we found that in patients with preserved kidney function, pregnancy was well-tolerated, and no immunosuppression was needed.

## PUB344

**Pregnancy-Associated Hemolytic Uremic Syndrome: Two Case Series From the University of Vermont Medical Center**

Colton Jensen,<sup>1</sup> Carolyn Geraci,<sup>2,1</sup> Macaulay A. Onuigbo,<sup>1,2</sup> <sup>1</sup>University of Vermont College of Medicine, Burlington, VT; <sup>2</sup>University of Vermont Medical Center, Burlington, VT.

**Introduction:** Atypical hemolytic syndrome (aHUS) is rare, incidence 0.23/year/million; 10–20% occur around pregnancy - pregnancy-associated aHUS (PAAHUS). In a recent review, 47 of 50 (94%) occurred post-partum, with a median of post-partum day 2. We present 2 patients, seen in 2012 and in 2021, with some unusual features.

**Case Description:** Case I A 37-yo female was diagnosed in late 2021 with PAAHUS following a preterm delivery by Cesarean section (Figure). She started hemodialysis for oliguric AKI, hyperkalemia and metabolic acidosis. First plasmapheresis was aborted due to anaphylactic reaction to plasma. She had Eculizumab for 4.5 months; switched to Revalizumab in February 2022. She came off hemodialysis after 23 days. Peak creatinine was 11.53 mg/dL, and the latest creatinine was 1.41 mg/dL in April 2022. Case II A 33-yo woman with 3 previous Cesarean sections, and who delivered her fourth child by Cesarean section 8 weeks previously, was diagnosed with PAAHUS, following transfer from an outside unit in late 2012, with weakness, anemia, schistocytes and oliguric acute kidney injury (Figure). She had 14 plasmaphereses alternating with hemodialysis. She came off hemodialysis after about 84 days. She had Eculizumab for nearly 7 years; switched to Revalizumab in December 2019. Peak creatinine was 7.7 mg/dL, and the latest creatinine was 1.64 mg/dL in May 2022.

**Discussion:** Although the renal and splenic arteries enhanced with contrast on CT in Case I, the kidneys did not. Whether this is typical of aHUS or if exposure to IV Ketorolac contributed to this picture is unknown. The nearly 60 days' post-partum presentation for Case II is most unusual. Our patients have done well on continued Ravulizumab, with sustained AKI recovery, more so with Case II now spanning over 9 years.

Clinical Data	Case I	Case II
Age (years)	37	33
Gestational age (weeks)	24	8 weeks post Cesarean section
Previous pregnancies	1	3
Previous abortion	1	None
Gestational diabetes mellitus	Yes	None
Preterm labor	Yes - At 24 weeks 5 days	None
Delivery method	C section for arrested preterm labor	C section for previous C sections
Viable infant delivered	Yes	Yes
Oliguria	Yes	Yes
Nephrotoxic exposures	IV Contrast + IV Ketorolac	None
Onset of Acute Kidney Injury	Hospital Day 1	Uncertain
New onset Hypertension	Yes	Yes
Previous GbS history	Previous mysectomies	3 previous Cesarean sections
Post-partum Bleeding	Yes (At Day 2 post-partum)	Yes (At 8 weeks post-partum)
Neutrophils (K/mm <sup>3</sup> )	72	80
Neutrophil hemoglobin (g/dL)	6	5.3
LDH peak (U/L)	1166	5627
PT Ratio	1.1	0.8
PTT (secs)	49	27

**Trends in Pharmacotherapy Management In Pregnant Hemodialysis Patients**

Beatrice Drambarean,<sup>1</sup> Justyna I. Mastalerz,<sup>1</sup> Thomas M. Szwajnos,<sup>1</sup> Lisa M. Wendt,<sup>2</sup> Stephanie M. Toth-Manikowski.<sup>1</sup> <sup>1</sup>University of Illinois Chicago, Chicago, IL; <sup>2</sup>Rush University Medical Center, Chicago, IL.

**Introduction:** When patients on hemodialysis become pregnant, anti-hypertensive, anemia, and mineral-bone disease medications require adjustments to account for teratogenicity and intensified hemodialysis regimens. This can be a challenging experience for patients as they are at higher risk of pre-eclampsia, pre-term delivery, and fetal growth restriction. Over the years, studies have reported successful pregnancies with certain treatments, although data regarding medication dosing is lacking in this population. The purpose of this clinical case series is to trend medication dose adjustments based on changing laboratory values throughout pregnancy for patients on hemodialysis and provide examples of how pharmacotherapy management should be adjusted in this unique patient population.

**Case Description:** Data was retrospectively collected from 4 patients with a total of 5 pregnancies (A1, A2, B, C, D) from April 2019 through May 2021, e.g., hospitalizations, select laboratory values, vital signs, and medications for hypertension, anemia, and mineral-bone disease. Table 1 summarizes anemia medications used during pregnancy. All patients were on calcium and vitamin D supplementation and were switched to

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

nifedipine and/or labetalol for hypertension management. All patients delivered viable preterm infants ranging 30-36 weeks of gestation. Of 12 hospitalizations, 7 were related to hypertensive urgencies. Patient C required 2 blood transfusions due to a hemoglobin less than 7. Average hemoglobin values were 8 (A1), 8.9 (A2), 8.8 (B), 7.8 (C), and 7.9 (D). Average TSAT values were 17 (A1), 25 (A2), 24 (B), 47 (C), and 21 (D). Average phosphorus values were 3.5 (A1), 4.3 (A2), 3.1 (B), 3.0 (C), and 3.4 (D). Average calcium values were 8.6 (A1), 8.4 (A2), 8.4 (B), 8.4 (C), and 8.5 (D).

**Discussion:** All patients had successful pregnancy outcomes that have been described with the documented managements. Pregnant dialysis patients will require increased intravenous iron and erythropoietin doses to maintain adequate hemoglobin levels. Phosphorus supplementation is required at large doses up to 4 times daily; calcium and vitamin D is also required to maintain levels within normal limits.

PUB346

**Toward a Model-Based Patient Pre-Selection Tool to Identify Suspected Undiagnosed Albuminuria Using Electronic Health Records**  
Nils Svängård,<sup>1</sup> Anders G. Hildeman,<sup>1</sup> Peter J. Greasley,<sup>1</sup> Shameer Khader,<sup>2</sup> Philip D. Ambery.<sup>1</sup> <sup>1</sup>AstraZeneca FoU Goteborg, Goteborg, Sweden; <sup>2</sup>AstraZeneca R&D Gaithersburg, Gaithersburg, MD.

**Background:** Urine albumin (uACR), a key marker for chronic kidney disease (CKD), is not regularly screened for in the primary care, leading to many undiagnosed patients. Developing a tool to identify patients suspected of having undiagnosed Albuminuria could help prevent CKD progression and significantly reduce screen-failure rates in CKD trials. In this study we develop models using machine learning to classify the patients into two categories, uACR  $\geq 30$  and  $\geq 200$  mg/g.

**Methods:** We developed and calibrated the models on the US Limited IBM MarketScan Exploratory Claims-EMR Data Set (LCED) and validated the models on Optum® Clinformatics™ Data Mart (US) and two global clinical trial datasets (DECLARE & SAVOR). We perform retrospective test and validation, requiring subjects to have an uACR test ( $0 < \text{uACR} \leq 5000$  mg/g) and be of at least 18 years of age. Patient demographics (age, sex), vital signs (BMI, Blood Pressure) and the 30 most common blood tests were used as covariates, with the last value carried forward 6 months as imputation method. A tree based gradient boosting framework (LightGBM) was used to train the classifiers for uACR  $\geq 30$ , and  $\geq 200$  mg/g. The model was trained on 80% of the LCED patients, with the remaining used to calibrate the model for a 0.75 precision threshold. The model was then evaluated on all qualified patients in OPTUM, SAVOR and DECLARE using Area Under the Curve (AUC) and Precision (PPV).

**Results:** Preliminary results show that the models have discriminative power (Figure 1) and met the acceptance criteria of a PPV greater than 0.7 for both the US datasets and one of clinical trial datasets (Table 1).

**Conclusions:** The patient pre-selection models generalized from the US based cohort to a global population and shows promise as a tool to identify patients with suspected albuminuria after further development and validation.

**Funding:** Commercial Support - AstraZeneca

Dataset	uACR $\geq 30$		uACR $\geq 200$

PUB347

**Risk Analysis of Healthy Life Expectancy Based on Renal Function Using the Medical Information Database**  
Hisayuki Ogura, Tadashi Toyama, Megumi Oshima, Shiori Nakagawa, Taro Miyagawa, Shinji Kitajima, Akinori Hara, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada. Kanazawa Daigaku, Kanazawa, Japan.

**Background:** Extending healthy life expectancy is challenging in a super-aging society including Japan. Renal dysfunction is a risk for cardiovascular events, frailty, and sarcopenia. On the other hand, the relationship between renal dysfunction and healthy life expectancy, a more important outcome, has not been sufficiently investigated. We investigated the relationship between renal function and healthy life expectancy based on the available clinical records.

**Methods:** We analyzed the medical information database of residents of Hakui city, Ishikawa Prefecture, who were eligible for nursing care insurance, medical insurance and underwent health examinations between 2012 and 2020. The database contains care services, treatments, and medical examination results. The primary outcome was time to health-span composite defined as care levels  $\geq 2$  or death. Subjects were categorized into five groups by baseline eGFR. Associations between baseline eGFR categories and the outcome were analyzed using Cox proportional hazards model adjusted for baseline age, sex, care levels, body mass index, and smoking status.

**Results:** The number of subjects was 4,581, the median age was 65 years (1<sup>st</sup> and 3<sup>rd</sup> quartile: 62.0–70.0), the median eGFR was 72.6 mL/min/1.73m<sup>2</sup> (62.8–81.0), and the median observation period was 7.17 years (3.92–8.25). The outcome was achieved in 5.3% of patients during the observation period with eGFR 60–74 as the reference (hazard ratio [HR] 1.0). The analysis showed that the HRs for eGFR 45–59 and eGFR  $< 45$  were 1.07 (95% CI 0.77, 1.50) and 1.55 (95% CI 1.00, 2.40), respectively. HRs of the groups with eGFR 75–90 and eGFR  $\geq 90$  were 1.22 (95% CI 0.87, 1.71) and 1.72 (95% CI 1.16, 2.57), respectively.

**Conclusions:** For those who are eligible for nursing care insurance both lower and higher eGFR were risk factors for shorter healthy life expectancy.

PUB348

**CKD Risk Factors by Cluster in Mild- and Moderate-Risk Individuals**  
Tadashi Toyama, Megumi Oshima, Shinji Kitajima, Akinori Hara, Norihiko Sakai, Miho Shimizu, Yasunori Iwata, Takashi Wada. Kanazawa Daigaku, Kanazawa, Japan.

**Background:** Risk management of mild and moderate risk cases is a challenge in the risk management of CKD. We performed machine learning clustering based on clinical information to examine the association between renal events and risk factors in each stratum.

**Methods:** We randomly selected 10,000 adults with normal proteinuria/± and eGFR  $> 45$  mL/min/1.73 m<sup>2</sup> from adults with physical examination in Kanazawa. Individuals with diabetes were excluded. k-means clustering was used to classify subjects into 4 groups by risk factors including age, BMI, and blood pressure. A 30% decrease in eGFR was defined as renal event. The association between risk factors and renal event was analyzed by clusters.

**Results:** The subjects were on average 67 years old, and 7.2% developed renal events during a mean observation period of 5.8 years. Compared to group  $\alpha$ , groups  $\gamma$  and  $\delta$  had a significantly higher risk of renal events ( $P < 0.05$ ). Positive urinary occult blood (hazard ratio 1.66 [95% CI 1.13, 2.44]) was a significant risk factor associated with renal events in the  $\gamma$  group and low hemoglobin (hazard ratio 1.32 [95% CI 1.20, 1.45]) in the  $\delta$  group.

**Conclusions:** The general population at mild to moderate risk was classified into four clusters. The risk of renal events differed by cluster and the risk factors associated with renal events were different.

PUB349

**Reduction in Morbid Obesity With Bariatric Surgery and Improvement in Kidney Disease Burden**  
Syeda S. Bukhari,<sup>1,2</sup> Sonalika Agarwal,<sup>1,2</sup> Isha Puri,<sup>1,2</sup> Omar N. Elhawary,<sup>1,2</sup> Mary C. Mallappallil,<sup>1,2</sup> <sup>1</sup>Kings County Hospital Center, Brooklyn, NY; <sup>2</sup>SUNY Downstate Health Sciences University, New York City, NY.

**Introduction:** Obesity is a risk factor for chronic kidney disease and the suggested pathophysiology includes hyperfiltration and glomerulosclerosis in the kidneys itself and the worsening of comorbidities like diabetes and hypertension. In dialysis dependent kidney failure bariatric surgery is reported to be safe and patients may be referred for weight reduction therapy before kidney transplantation despite the obesity paradox. We present two cases of advanced chronic kidney disease where there was improvement in glomerular filtration rate, proteinuria and hemodialysis prescription.

**Case Description:** Case 1: A 48-year-old female with history of hypertension, diabetes, chronic kidney disease and morbid obesity undergone gastric bypass on 14<sup>th</sup> September 2021 with a total of 176 pounds weight loss. There was profound regression in her chronic kidney disease as her creatinine decreased from 3.44 to 1.76 with decrease in her urine protein creatinine ratio from 3.5 to 1.4. Her estimated glomerular filtration rate improved from 14 mL/min to 39 mL/min with postponement of dialysis access placement and transplantation listing. Case 2: A 38 year old morbidly obese man with congestive heart failure, hypertension, obstructive sleep apnea, asthma, end stage renal disease on hemodialysis 4 times a week for 4 hours with a body mass index of 67.5 and a weight

of 201Kgs undergone robotic sleeve gastrectomy on 3/30/22. Her weight reduced to 20 pounds and a new body mass index was 65.5 two weeks after surgery which lead to subsequent decrease in hemodialysis to three times a week for 4 hours maintaining his dialysis parameter of adequacy including Kt/V 1.1 URR 66% and fluid and electrolytes status.

**Discussion:** Morbid obesity is usually treated by with lifestyle modification and bariatric surgery. Patients with advanced renal disease are usually referred for bariatric surgery when they are considered for kidney transplantation. The above discussed two cases illuminate other ways like weight reduction that may decrease the burden of kidney disease in those with advanced Chronic kidney disease. The nephrologist needs to distinguish between the risk and benefits of obesity in patients with advanced kidney disease including those on dialysis.

## PUB350

### Discrepancies in Policies Applied to CKD Patients Before IV Contrast Studies: A Three Countries Survey-Based Study

Mahmoud H. Imam,<sup>1</sup> Rizk Sarhan,<sup>1</sup> Mona A. Metwally,<sup>2</sup> <sup>1</sup>*Benha University, Benha, Egypt;* <sup>2</sup>*Ain Shams University Faculty of Medicine, Cairo, Egypt.*

**Background:** Chronic kidney disease patients frequently need to perform intravenous contrast enhanced radiological studies. However, there is vast variation among hospitals in applying clinical guidelines. This study aims to detect the variation in the application of current policies among different hospitals.

**Methods:** This cohort study is conducted through an online survey distributed to radiological departments in many hospitals in 3 countries (USA, Egypt, and Saudi Arabia). The survey included the pre-contrast requested labs, is it fixed for all kidney stages or not?, when to request nephrology consultation before the scan, and whether the dialysis session schedule is altered for the sake of radiological study. The results were compared among the 3 countries.

**Results:** We received 182 completed surveys (103 from Egypt, 48 from Saudi Arabia, and 31 from the USA). In total, 58% of the radiology departments requested nephrology assessment for patients with eGFR > 50 ml/min/1.73m<sup>2</sup>. Also, 52% reported they had patient sessions rescheduled before the iv contrast scan. There was a significant increase in reschedule burden in Saudi Arabia in comparison with the other 2 countries (*p* 0.04). There were no different radiological policies for CKD stages 1-5 and stage 5d.

**Conclusions:** There is a significant variation in policies for CKD patients before IV contrast studies. The discrepancy in applying the policies among hospitals creates an unjustified burden on CKD patients. There is an urgent need for international combined guidelines involving both radiology and nephrology societies.

## PUB351

### Improving the Quality of CKD Care With Risk Prediction and Personalized Recommendations: The GEMINI Project

Navdeep Tangri,<sup>1</sup> Geoffrey A. Block,<sup>2</sup> Mary O. Dittrich,<sup>2</sup> Navid Saigal,<sup>3</sup> Amit Sharma,<sup>4</sup> Samuel T. Fatoba,<sup>4</sup> Pablo E. Pergola,<sup>3</sup> <sup>1</sup>*University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada;* <sup>2</sup>*US Renal Care Inc, Plano, TX;* <sup>3</sup>*Renal Associates PA, San Antonio, TX;* <sup>4</sup>*Bayer Pharma AG, Berlin, Germany.*

**Background:** CKD affects 1 in 7 Americans and can lead to progression to dialysis, cardiovascular disease, and early mortality. Effective interventions exist to slow the progression of CKD and prevent heart failure, but implementation remains a challenge, and use of guideline recommended testing and therapies remain low. Routine, complete collection of guideline recommended blood and urine tests allowing accurate risk prediction with personalized treatment recommendations can improve CKD care, when integrated into clinical workflow. Our objective is to implement risk prediction algorithms clinical decision support for identifying patients at risk of CKD progression in 5 large nephrology practices representing more than 100 nephrologists and 100,000 patients with CKD.

**Methods:** Data for estimated glomerular filtration rate, albuminuria, demographics, other laboratory tests and comorbid conditions will be extracted from the electronic health record (EHR). Patients already on dialysis will be excluded. The remaining individuals will be risk stratified using Klinrisk's proprietary risk prediction equations. A dashboard with disease specific educational information, personalized treatment recommendations and links to the EHR's of the identified patients will be created.

**Results:** We will aim to enroll 5 leading large US nephrology practices in the next 12 months. Eligible patients will be identified and quality of care as defined by appropriate testing (proportion of patients with albuminuria testing within 12 months), and appropriate therapy as recommended by the relevant guidelines (RAASI, SGLT2i, and non-steroidal MRA use) will be measured in the pre and post implementation period.

**Conclusions:** A highly accurate machine model for CKD progression when paired with EHR linked clinical decision support will improve testing and management of intermediate and GEMINI high-risk patients with CKD. Larger randomized trials of clinical decision support and practice audit applications will be needed to impact CKD management in primary care.

## PUB352

### Results From a Vermont CKD Navigator Program

Jeffrey M. Rimmer,<sup>1,2</sup> Kelly Julian,<sup>1</sup> Cydney J. Wolf,<sup>1</sup> Stacy Ladabouche,<sup>1</sup> <sup>1</sup>*University of Vermont Medical Center, Burlington, VT;* <sup>2</sup>*University of Vermont College of Medicine, Burlington, VT.*

**Background:** CKD is associated with suffering and expense. Programs involving education, healthy lifestyle, care management and patient motivation have been developed to improve outcomes. In advanced kidney disease, the focus is to select appropriate end-stage kidney disease (ESKD) therapy and ease transitions. In 2020, an 18 month project to improve care of patients with advanced CKD was started in Vermont.

**Methods:** In July a nephrologist recruited a nurse, half-time dietitian and social worker as navigators. Clinic patients with an eGFR ≤20 ml/min/1.73m<sup>2</sup> were identified by computer search. Navigators were trained in serious illness discussion skills. Education materials were reviewed and a curriculum was developed. Navigators developed education/assessments specific for their expertise. Patients were contacted by navigators. Participants had education/assessment sessions in CKD, health review, nutrition and social needs. Participant, family, navigator and MD met for a planning session after education. A plan for ESKD therapy was documented. Monitoring followed education/assessment and planning. Navigators followed patients monthly and laboratory every six weeks. Meetings were telephonic or videoconference.

**Results:** Clinic screening yielded 150 potential participants. During the year, 150 patients were contacted. 104 (69.3%) agreed to participate. 59 patients completed education, assessment, planning and entered monitoring. Planned ESKD choices were; peritoneal dialysis (PD) 30.5%, in-center hemodialysis (ICHD) 29%, transplantation 19%, supportive care (SC) 10%, home hemodialysis (HHD) 8.5% and no choice 3%. 3/59 died unexpectedly. Results for 13 who reached an endpoint with a plan include; 5 choosing ICHD started ICHD. All had a fistula. 4 required a bridging catheter, of 3 choosing HHD. 2 started HHD and one ICHD all with fistula. of 2 choosing PD both started PD. of 3 choosing SC. 2 died in hospice care while 1 dialyzed briefly then transferred to hospice. 54.5% of patients started dialysis with appropriate access. An additional 27.3% had a maturing access.

**Conclusions:** 71% of those participating in a Vermont CKD navigator program chose an ESKD therapy other than ICHD. 85% reaching ESKD maintained their initial choice. 40% of participants reaching ESKD started on home therapy. 81.8% started dialysis after access surgery. Increasing HHD and early kidney transplantation was difficult.

## PUB353

### Design and Pilot Implementation of an Electronic Patient-Reported Outcomes Measure (ePROM) for Nephrology Clinic

Dipal Patel,<sup>1</sup> Sumeska Thavarajah,<sup>1</sup> Morgan Grams,<sup>2,1</sup> Deidra C. Crews,<sup>1</sup> <sup>1</sup>*Johns Hopkins University, Baltimore, MD;* <sup>2</sup>*NYU Langone Health, New York, NY.*

**Background:** Patients with kidney disease face a variety of symptoms and psychosocial stressors which have a large impact on quality of life. Patient-reported outcome measures (PROMs) capture aspects of physical and mental health, reported directly by the patient, in a manner tailored to conditions being treated. With wide utilization of electronic health records (EHRs), the implementation of electronic PROMs (ePROMs) presents an opportunity to reach large numbers of patients and evaluate outcomes longitudinally.

**Methods:** In our academic nephrology practice, we designed a "Kidney Disease Symptom Survey" derived from portions of the Kidney Disease Quality of Life-36 survey, with additional questions assessing overall quality of life and urinary frequency. We proceeded with pilot implementation of this survey as an ePROM.

**Results:** The "Kidney Disease Symptom Survey" (Figure 1A) was translated into an electronic questionnaire on MyChart, the patient portal for Epic Health Systems. The questionnaire is automatically pushed to any patient with an ICD10 diagnosis of CKD seen for follow-up in nephrology clinic, and is estimated to take 3-8 minutes to complete. Patients receive an alert to complete the ePROM 7 days prior to their visit and can also complete the ePROM on a tablet in person upon clinic check-in. Patient responses are scored and uploaded into patients' EHRs (Figure 1B). With data linked to our academic institute's Kidney Precision Medicine Center of Excellence, we can study associations between ePROM scores and clinical outcomes including hospitalizations, progression of kidney disease, and mortality.

**Conclusions:** We demonstrate successful design of a kidney-specific ePROM for use in nephrology clinic. Scores can be discussed during clinic visits to better align patient and provider preferences. Studies are needed to assess whether ePROM use influences providers' therapeutic decisions, and improves patient satisfaction with care and clinical outcomes.

## Is the “Slippery Slope” of Declining Renal Function in CKD Inevitable?

Olivia M. Orteza,<sup>1</sup> James I. McMillan,<sup>1,2</sup> Enrica Fung,<sup>1,2</sup> <sup>1</sup>Loma Linda University, Loma Linda, CA; <sup>2</sup>Veterans Health Administration Operations, Loma Linda, CA.

**Background:** Patients with chronic kidney disease are expected to have a progressive decline in kidney function over time. Our study was inspired by a 65-year-old man with diabetes mellitus type 2 had kidney disease that had progressed from an eGFR of 55 down to 16 ml/min over 4 years. Fear of facing dialysis prompted him to significantly change his lifestyle including weight loss, exercise, smoking cessation, and dietary changes with a shift away from meat to vegetables and fruit, and eliminating sodas. Over the next 4 years his eGFR steadily rose to about 40 ml/min and now, 10 years after the change in lifestyle, he remains off dialysis. We assembled a retrospective cohort to examine the frequency of patients with declining renal function that experience a leveling or a sustained rise in renal function.

**Methods:** We selected patients in Loma Linda VA nephrology clinic with GFR < 60 between 2010 to 2020. Patients who had steady decline in GFR for at least 3 years were included in the study. We visually analyzed the GFR trend of each patient for a sustained rise, leveling, or continued decline in kidney function over at least 2 subsequent years.

**Results:** A total of 301 patients were screened. Of those, 208 patients had at least a 3-year decline in the GFR, and 21 were otherwise eliminated due to other exclusion criteria such as obstructive uropathy or receipt of transplant. This leaves 187 patients meeting final inclusion criteria. Of these patients, 58 (31.0%) had a rise in GFR, 14 (7.5%) had leveling of GFR and 115 (61.5%) had continued decline in kidney function.

**Conclusions:** GFR decline is generally accepted as inevitable in CKD. Our study challenges this dogma. Further larger studies will need to be performed to confirm and examine the reasons for the reversal or stabilization of GFR trends. We also found that observation of GFR trends can be quite subjective. This highlights the importance of using available tools such as kidney failure risk equation or development of more objective tools when examining GFR trends in patients.

	Total (N=187)	Rise in GFR (N=58)	Leveling in GFR (N=14)	Decline in GFR (N=115)	P-value
Age, mean $\pm$ SD	61.4 $\pm$ 9.6	62.5 $\pm$ 9.6	62.2 $\pm$ 6.7	60.7 $\pm$ 9.9	0.46
GFR at beginning of study, ml/min, mean $\pm$ SD	59.3 $\pm$ 19.3	53.4 $\pm$ 15.5	56.5 $\pm$ 14.4	60.6 $\pm$ 21.3	0.02
GFR at end of study, ml/min, mean $\pm$ SD	35.2 $\pm$ 11.2	38.1 $\pm$ 8.8	30.6 $\pm$ 8.5	34.3 $\pm$ 12.3	0.03
Diabetes, N (%)	118 (63.1%)	42 (72.4%)	7 (50.0%)	69 (60.0%)	0.16

## PUB355

## Hyperuricemia in Patients With Advanced CKD: Potential Impacts of This Often Overlooked Issue

**Leonard Stern,<sup>1</sup>** Richard J. Johnson,<sup>2</sup> Payam Shakouri,<sup>3</sup> Amod Athavale,<sup>4</sup> Lissa Padnick-Silver,<sup>5</sup> Brian LaMoreaux,<sup>5</sup> Brad A. Marder,<sup>5</sup> Sreedhar A. Mandayam,<sup>6</sup> <sup>1</sup>*Columbia University Irving Medical Center, New York, NY;* <sup>2</sup>*University of Colorado Health, Aurora, CO;* <sup>3</sup>*Advanced Kidney Care, Poughkeepsie, NY;* <sup>4</sup>*Trinity Life Sciences, Waltham, MA;* <sup>5</sup>*Horizon Therapeutics plc, Deerfield, IL;* <sup>6</sup>*The University of Texas MD Anderson Cancer Center, Houston, TX.*

**Background:** Advanced CKD patients (pts) are susceptible to developing hyperuricemia and gout. Hyperuricemia has also been associated with hypertension, obesity, heart failure, diabetes, heart attack, and stroke. However, hyperuricemia's influence on comorbidity occurrence and overall health has not been well described for advanced CKD pts. This study examines advanced CKD pts with and without hyperuricemia to better understand potential health sequelae in this high-risk population.

**Methods:** Medical record data of nephrologists' most-recently seen pts with Stage 3-5 CKD were reported. Pts who had serum uric acid values (sUA) from their most recent visit were stratified into hyperuricemic (HU, sUA $\geq$ 6 mg/dL) and normo-uricemic (NU, sUA<6 mg/dL) groups. Pt and CKD characteristics were examined and compared

between groups. Statistical significance was defined as  $p < 0.05$  and was examined using t-tests for continuous parameters and chi-square tests for categorical ones.

**Results:** 111 nephrologists reported on 746 advanced CKD pts. 247 (33.1%) had sUA recorded at their most recent visit, of which 143 (57.9%) had HU. Pts with sUA (age: 55.5±19.7 years, 54% male, BMI: 32.4±12.8 kg/m<sup>2</sup>, sUA: 7.3±4.1 mg/dL, eGFR: 32.6±13.6 ml/min/1.73m<sup>2</sup>) and NU (age: 58.4±19.8 years, 57% male, BMI: 33.2±12.9 kg/m<sup>2</sup>, sUA: 4.9±0.7 mg/dL, 33.8±14.2 ml/min/1.73m<sup>2</sup>) had similar characteristics, renal function, and comorbidity profiles (including diabetes). HU pts did however have higher HbA1c levels (7.4±1.4 vs 6.7±1.4; N=83, 57), parathyroid hormone levels (163.8±133.5 vs 118.0±101.7; N=119, 87), and loop diuretic use (48% vs. 31%; all p≤0.009). In addition, HU pts reported more gout symptoms, including gout flares (36% vs. 19%) and chronic back pain (21% vs. 11%; both p≤0.030), and more often required urgent (18% vs 5%) and emergency (17% vs 8%) care (both p≤0.026).

**Conclusions:** This analysis demonstrates that despite having similar comorbidity prevalences and eGFR, pts with HU had worse control of their diabetes and metabolic bone disorder which could lead to poorer health outcomes. Additionally, CKD pts with HU had higher occurrences of gout flares, chronic back pain, and acute-care utilization.

## PUB356

## Metformin-Associated Lactic Acidosis in a Patient With CKD

<sup>1</sup>Michigan State University, East Lansing, MI; <sup>2</sup>Sparrow Health System, Lansing, MI.

**Introduction:** Metformin use in the setting of chronic kidney disease (CKD) has become controversial. For many years it has been regarded as being contraindicated due to the known complication of lactic acidosis (LA). However, recent studies suggest that the benefits of metformin may outweigh the risks in this sub-population. Herein, we present a case of Metformin-associated lactic acidosis (MALA) requiring hemodialysis (HD).

**Case Description:** A 60 year old male with a history of CKD Stage III, Diabetes Mellitus Type II, Hypertension, and Prostate Cancer presented to the Emergency Department (ED) with altered mentation. Initial vital signs included a temperature of 92.5F, blood pressure of 107/30, heart rate 92, respiratory rate of 36, and oxygen saturation of 95%. Physical exam showed an ill appearing male, with coarse breath sounds, and generalized abdominal tenderness. He was intubated for airway protection due to decline in glasgow coma scale and admitted to the intensive care unit. Initial work up revealed: ABG pH 6.95, pCO2 41, pO2 104, potassium 6.3, bicarbonate of 2, lactate 20, BUN 95, creatinine 13.26, glucose 116, negative toxic alcohol studies, negative urine drug screen, and an unrevealing Computed Tomography of the brain, chest, abdomen and pelvis. The patient was started on a bicarbonate infusion and continuous renal replacement therapy. After one day, clinical status improved, he was extubated and reported that he had been prescribed Sitagliptin/Metformin eight weeks prior to presentation. The patient's creatinine remained elevated with oliguria and the patient was transitioned to intermittent HD which was continued in the outpatient setting.

**Discussion:** MALA is a rare complication of metformin use with an incidence of 4.3 per 100,000 patient-years and it is associated with up to 50% mortality rate. The majority of previous clinical trials revealed that metformin was not associated with increased risk for LA. Although current guidelines permit metformin use in CKD if eGFR is  $\geq 30$  mL/min, frequent monitoring of renal function is mandatory and patients should be educated to discontinue metformin in the setting of acute illness. Although metformin use has recently been considered safe for use in patients with CKD, the risk of causing lactic acidosis should not be disregarded. Further studies are needed to facilitate explicit guidelines on the use of Metformin in CKD.

## PUB357

## Age-Specific Estimated Glomerular Filtration Rate and Outcomes: Insights From the KNOW-CKD Cohort

Ji Hye Kim, Hajeong Lee. *Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

**Background:** Korea is one of the representative aging societies. We aimed to investigate the role of recently proposed age-adapted chronic kidney disease (CKD) definition and outcomes in Korea.

**Methods:** This study included 2238 patients from the KoreanN Cohort Study for Outcome in Patients With Chronic Kidney Disease. Patients were categorized into three age groups: <40, 40–64, and ≥65 years old. We defined CKD stages according to the estimated glomerular filtration rate (eGFR) calculated on centrally measured serum creatinine and cystatin C. Primary outcome was composite of renal events including end-stage renal disease (ESRD), fatal cardiovascular events (FCVE), and mortality.

**Results:** The aged ( $n = 471$ ,  $69.3 \pm 2.9$  years) patients had more metabolic and cardiovascular comorbidities, poorer socioeconomic status, and worse mental status compared to younger age groups. They had lower eGFR, but a similar proportion of albuminuria. During  $5.5 \pm 2.2$  years of follow-up, 588 (26.6%) ESRD, 182 (8.2%) FCVE, and 138 (6.3%) deaths developed. Unsurprisingly, the aged showed worse ESRD, FCVE, and mortality outcomes. Moreover, higher CKD stage was associated with worse kidney and patient outcomes in Kaplan-Meier estimate. Interestingly, however, the cutoff-off eGFR associated with worse outcomes was different according to the age groups. The aged showed an increased risk for primary outcome from CKD stage 4 (HR 4.03, 95% CI [2.13, 7.62]) and 5 (HR 14.19, 95% CI [6.96, 28.91]) whereas middle-aged patients from stage 2 after adjustment with age, sex, diabetes, previous coronary artery disease.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

smoking, body mass index, blood pressure, albuminuria, and total cholesterol. In all age subgroups, FCVE was not associated with CKD stages. ESRD risk increased from CKD stage 3b in aged group while middle-aged had increased risk even from stage 2.

**Conclusions:** This study suggested that the age-specific eGFR threshold associated with kidney and patient outcomes should be considered in Korean CKD patients.

## PUB358

### Telenephrology: Managing CKD During the COVID-19 Pandemic

Sanjib K. Sharma, B P Koirala Institute of Health Sciences, Dharan, Nepal.

**Background:** The management of kidney diseases is challenging in areas where discrepancy exist between number of nephrologist and patient with kidney disease. COVID-19 pandemic added to this challenges. We initiated a telenephrology service in 2020 with primary aim of education, targeted screening and treatment of kidney diseases focusing where there was no nephrologist.

**Methods:** In this study locally available paramedics were mobilized for information dissemination and follow up of index patient population. The consultation was performed by internists and nephrologist. After initial registration in telemedicine service, social media apps were used for communication. The mode of communication used was audio, text, photography, and video call when needed. Follow-up consultation was done as required and in 3 months which involved review of reports and medical advised as needed including medication. We analyzed the data from the records of telenephrology service provided from april 2020 to april 2021 and who has completed at least 6 months of follow up.

**Results:** A total of 266 participants who were known to have chronic kidney disease, hypertension, diabetes, and heart failure were enrolled. The mean age of the participant was  $54.21 \pm 17$  years. Female constitute 53% (n=141). The most common mode of communication was WhatsApp (86.5%), followed by Viber (5.6%). Patients were advised to undergo investigations in primary health care set up or elsewhere as needed. Most of the participants (88.0%, n=232) were managed without need for physical hospital visit. Physical visit to hospital was needed in 84 patients (17%) and 4.1% (n=11) needed hospital admission. During follow up, half of the participants (n=134) had performed tests as advised and 44.4% (n=118) followed the treatment advised, in initial consultation and needed further advice to do so. Five persons dies during follow-up (1.9%). Few participants 1.1% (n=3) said that they don't want to use the telemedicine service again.

**Conclusions:** Telenephrology services can bridge the gap in care in nephrology where access to nephrologists is limited.

## PUB359

### Methotrexate Use in CKD Patients With Sarcoidosis

Heidy Hendra, David Randall, Ravindra Rajakariar. *Barts Health NHS Trust, London, United Kingdom.*

**Background:** Sarcoidosis is a multisystem disease of unknown aetiology, characterised by presence of non-caseating granuloma in the organs involved; with lung, lymph nodes, skin, eyes, and liver being the most frequent affected sites. Treatments are initiated for those who does not have spontaneous resolution of the disease and those with extrapulmonary involvement including renal. Methotrexate has been used as an alternative agent for those with intolerance or insufficient response to steroids. It is contraindicated in advance CKD with eGFR < 10 ml/min and has not been recommended to be used in moderate CKD.

**Methods:** We identified patients with sarcoid who has been receiving methotrexate in our renal patient's database. Data including demographic, weekly dose of Methotrexate and renal function at initiation and current ones were collected.

**Results:** Out of 146 individuals who are on Methotrexates, 10 patients were diagnosed with sarcoidosis or granulomatous tubulointerstitial nephritis (TIN); half of them were men. Three patients have biopsy confirmed renal sarcoidosis. All patients have CKD at initiation of Methotrexate with 80 % being moderate with Class IIIA or IIIB (see Table 1 for details). None of the patients had significant adverse effect of Methotrexate or required treatment discontinuation. The medication dose was adjusted to the current eGFR (see Figure 1).

**Conclusions:** Methotrexate can be safely used in patients with sarcoidosis with moderate CKD at baseline. We also shown that it is an effective agent for treatment of granulomatous tubulointerstitial nephritis.

### A Case of Bradycardia, Renal Failure, AV-Nodal Blockers, Shock, and Hyperkalemia (BRASH) Syndrome in a 65-Year-Old Patient

Mohammad AL Wahadneh, Nidal Alhosainat, Mahmood Mubasher, Abdallah Hamayel. *Rochester Regional Health, Rochester, NY.*

**Introduction:** BRASH syndrome is a serious vicious cycle of complications in which renal failure causes hyperkalemia and accumulation of the patient's nodal blocking agent, both of which worsen bradycardia which leads to shock, further worsening renal perfusion, and so on. We are presenting a case of BRASH syndrome in a 65-year-old patient.

**Case Description:** A 65 year old Male with PMHx of hypertension, HIV, diabetes mellitus and end stage renal disease on hemodialysis, admitted with light headedness, fatigue and diarrhea for 3 days, was recently started on metoprolol. Physical exam revealed BP 113/54, HR 36-44 bpm, bilateral rales on lung auscultation. Labs were significant for hyperkalemia 6.9 mmol/L, bicarbonate 18 meq/L. ECG showing sinus bradycardia with 1st degree AV block and RBBB. The patient was medically managed, received hemodialysis and beta blockers discontinued with complete resolution of the Bradycardia.

**Discussion:** BRASH syndrome is a cycle of renal failure, shock and a synergistic effect of AV nodal blocker and hyperkalemia which causes profound bradycardia leading to shock and further worsening in renal function. Poor renal function leads to decrease clearance of AV nodal blocking agents with worsening bradycardia which is usually out of proportion to degree of hyperkalemia. The treatment should be aimed at correcting the inciting event of renal failure, correction of hyperkalemia either medically or by renal replacement therapy and stopping the AV nodal blocking agents, administration of beta agonist agents might be required in certain cases. Conclusion: Early detection of BRASH syndrome can be vital in the management of patients. Particular attention should be given to patients taking AV nodal blockers in the setting of worsening renal function.

## PUB361

**SGLT2 Inhibition Mitigates Intravascular Fluid Retention Driven by an Endothelin A Receptor Antagonist**

Robert I. Menzies,<sup>1</sup> Vandana Veenit,<sup>1</sup> Christine Ahlström,<sup>1</sup> Peter J. Greasley,<sup>1</sup> Stanko Skrtic,<sup>1</sup> Donald E. Kohan,<sup>2</sup> Pernille B. Laerkegaard Hansen.<sup>1</sup>  
<sup>1</sup>Astrazeneca, Gothenburg, Sweden; <sup>2</sup>University of Utah Health, Salt Lake City, UT.

**Background:** The development of endothelin receptor A antagonists (ETA<sub>R</sub>) in chronic kidney disease is hampered by mechanism-dependent fluid retention. Sodium-glucose cotransporter 2 inhibitors (SGLT2i) drive glucosuria and, in turn, osmotic diuresis with established benefits in T2D, CKD & HF.

**Methods:** We therefore hypothesized that co-administration of an SGLT2i with an ETA<sub>R</sub> would mitigate the fluid retaining effects of ETA<sub>R</sub> in a rat model using hematocrit (Hct) as an established surrogate of ETA<sub>R</sub> mediated hemodilution and fluid retention.

**Results:** In Wistar rats fed a high salt diet, 7-day treatment of the selective ETA receptor antagonist zibotentan (30, 100 and 300 mg/kg/day) resulted in a significant decrease in Hct compared to vehicle ( $p < 0.05$ ), an effect which persisted for 14 days with the 100 and 300 mg/kg doses. In a subsequent study over 7 days, co-administration of dapagliflozin (3.0 mg/kg/day) with zibotentan 30mg/kg/day attenuated the decrease in Hct. Zibotentan did not affect dapagliflozin-driven glucosuria at any dose tested.

**Conclusions:** These data support further evaluation of zibotentan and dapagliflozin in combination for a range of endothelin-driven pathophysiological processes.

## PUB362

**Protective Effects of Anti-Fibrotic Gene on Ischemia-Reperfusion Kidney Injury via Inflammasome Suppression in Mice**

Ha nee Jang,<sup>1,2</sup> Jin H. Kim,<sup>3,2</sup> Seunghye Lee,<sup>1</sup> Sehyun Jung,<sup>1</sup> Hyun-Jung Kim,<sup>1,2</sup> Se-Ho Chang.<sup>1,2</sup>  
<sup>1</sup>Gyeongsang National University Hospital, Jinju, Republic of Korea; <sup>2</sup>Gyeongsang National University Institute of Health Sciences, Jinju, Republic of Korea; <sup>3</sup>Biomedical Research Institute, Gyeongsang National University Hospital, Jinju, Republic of Korea.

**Background:** Acute kidney injury (AKI) is common comorbidity in hospitalized patients and the most important risk factor of chronic kidney disease (CKD). Renal fibrosis is a final common pathology of CKD. However, the molecular mechanisms of renal fibrosis remain unclear. As ischemia-reperfusion injury (IRI) is a major contributor to AKI, an effective therapeutic intervention for IRI is imperative. Anti-fibrotic gene is known as negative regulator of TGF- $\beta$ 1, but its role in renal fibrogenesis remains unknown. This study aims to elucidate the role of anti-fibrotic gene in IR-induced renal fibrosis.

**Methods:** Mice were assigned to sham, only IRI group, and anti-fibrotic gene-treated IRI group. The gene was administered at 5 min after reperfusion and once weekly. All mice sacrificed 21 days after IRI. The serum and urine were harvested for renal functional measurements. The kidneys were subjected to histological evaluation, and the biochemical changes associated with renal injury were assessed.

**Results:** This gene was abundantly expressed in the kidney and mostly in the nuclei of tubular epithelial cells in the steady state. Anti-fibrotic gene significantly attenuated the renal dysfunction associated with IRI, as well as tissue injury. Inflammatory cells infiltration like macrophage and Th17 cells were also significantly reduced in anti-fibrotic gene-treated mice as reflected by CX3CR1, CX3CL1, ROR- $\gamma$ t, and IL-17RA mRNA levels. Furthermore, the expression of inflammasome-related factors (NLRP3, cleaved caspase-1, IL-1 $\beta$  and IL-18) were significantly reduced following anti-fibrotic gene treatment. Finally, anti-fibrotic gene-treated IRI mice showed only moderate injury and minimal fibrosis and also larger reductions in the expression of extracellular matrix proteins and epithelial mesenchymal transition markers.

**Conclusions:** This is the first study to demonstrate that inflammasome-mediated inflammation might be a target of anti-fibrotic gene as a treatment for CKD from IRI.

## PUB363

**Kidney “Pathway Orphan” Genes as an Untapped Source of Novel Biology and Disease Understanding**

Dianne Acoba,<sup>1,2</sup> Sophie Gunnarsson,<sup>1</sup> Anna Reznichenko.<sup>1</sup>  
<sup>1</sup>Translational Science & Experimental Medicine, Research and Early Development, Cardiovascular, Renal and Metabolism, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; <sup>2</sup>Université Paris Cité, INSERM, INEM, Paris, France.

**Background:** A sizable proportion of the genome is still lacking functional annotation (‘pathway orphans’), and, as a result, is often overlooked in downstream analyses of omics data, that are thus inherently biased towards the genes with established pathway link. We hypothesized that uncovering the pathway orphan genes implicated in human chronic kidney disease might shed new light on disease pathogenesis.

**Methods:** A list of human protein-coding genes (N=19,222) was downloaded from HGNC and annotated with pathway membership using a comprehensive collection of the most commonly used pathway databases (GO, KEGG, Hallmark and Curated gene sets from MSigDB, Reactome). ‘Pathway orphans’ genes were interrogated for differential case-control expression in previously published CKD kidney tissue transcriptomics studies (GSE30122, GSE104954, GSE32591, GSE37455, Levin *et al.* 2020).

**Results:** 373 (2% of protein-coding genome) genes that did not belong to any of the currently known pathways or gene sets were identified as ‘pathway orphans’. Of the 5 studies that we investigated, a total of 26 (7%) ‘pathway orphans’ were statistically significant (at  $p < 0.05$ ) on differential expression analysis comparing the diseased vs control kidney tissue (glomerular and/or tubulointerstitial microdissected fractions).

**Conclusions:** Significant modulation of expression in the human CKD kidney potentially implicates some ‘pathway orphan’ genes into the disease pathogenesis. Further characterization of this previously overlooked fraction of the genome might expand our biological understanding and highlight novel disease drivers.

## PUB364

**The Uremic Toxin Indoxyl Sulfate Accelerates Senescence in Kidney Proximal Tubule Cells In Vitro**

Yi Yang,<sup>1</sup> Milos Mihajlovic,<sup>2</sup> Sabbir Ahmed,<sup>1</sup> Rosalinde Masereeuw.<sup>1</sup> Prof. Roos’ group <sup>1</sup>Universiteit Utrecht Utrecht Instituut voor Farmaceutische Wetenschappen, Utrecht, Netherlands; <sup>2</sup>Vrije Universiteit Brussel Faculteit Geneeskunde en Farmacie, Brussel, Belgium.

**Background:** Kidney fibrosis is the common final pathway of nearly all chronic and progressive nephropathies, it reduces the capacity for tissue repair and ultimately causes kidney failure. One cause may be the accumulation of senescent cells that arise from diverse tissue damage signals and secrete factors (senescence associated secretory phenotype, SASP), which promote fibrosis and inflammation. It has been suggested that uremic toxins, like indoxyl sulfate (IS), may play a role in the development of progressive kidney fibrosis. We demonstrated recently that conditionally immortalized proximal tubule epithelial cells overexpressing the organic anion transporter 1 (ciPTEC-OAT1) represent a valid model for studying kidney senescence by simply adjusting culture conditions [1]. Here, we investigated whether IS accelerates senescence in ciPTEC-OAT1, thereby initiating kidney fibrosis.

**Methods:** CiPTEC-OAT1 were seeded into 6-well format plates and grown at 33°C, then transferred to 37°C for maturation and culturing in absence and presence of IS for up to 9 days. The culture medium and cell lysates were collected on day 0, 3, 6, and 9, and used for senescence phenotype assessment, including DNA damage markers and common SASP factors.

**Results:** Maturation at 37°C affects the senescence phenotype, which was accelerated by IS. Cell viability results suggested that the tolerance of ciPTEC-OAT1 against IS increased time-dependently at the same dose of IS, which was accompanied by SA- $\beta$ -gal staining confirming the accumulation of senescent cells. Compared to the non-senescence group (Day 0), the senescence marker p21 showed an upregulation, while laminB1 showed a downregulation at different time points. SASP factors IL-6 ( $p < 0.01$ ) and IL-8 ( $p < 0.01$ ) showed significant upregulations on day 3 dose-dependently; IL-1 $\beta$  ( $p < 0.05$  or  $p < 0.01$ ) was remarkably upregulated at all time points in a dose-dependent manner.

**Conclusions:** Our results suggest that IS accelerates cellular senescence in ciPTEC-OAT1. Future studies will be directed to further evaluate the underlying mechanisms *in vitro* and *in vivo*.

## PUB365

**Establishment of an Adenine-Induced Nephropathy Mouse Model of CKD With Reduced GFR**

Jacob Nøhr-Meldgaard, Henrik H. Hansen, Lisbeth N. Fink, Mette V. Østergaard, Niels Vrang, Michael Christensen. Gubra, Hørsholm, Denmark.

**Background:** More than one out of seven of US adults are estimated to suffer from chronic kidney disease (CKD). While multiple factors (e.g. genetic, metabolic & acute kidney injuries) can lead to CKD, all CKDs clinically are characterized by a progressive decline in glomerular filtration rate (GFR). Various mouse models of CKD are available but often rely on surgical interventions, such as unilateral urethral obstruction or kidney ischemia reperfusion models, and do not consistently display measurable GFR decline. The rat adenine-induced nephropathy model is well-established (adenine is metabolized to 2,8-dihydroxyadenine forming crystals in the proximal tubular epithelium initiating inflammation as well as fibrosis) but has proven difficult to establish in the mouse model due to low palatability of the adenine-diet resulting in reduced diet intake and excessive weight loss. Here, we report an in-depth characterization of a mouse model of adenine-induced CKD.

**Methods:** Male C57BL/6J mice fed chow containing 0.2% adenine and flavours (banana and chocolate) were added to increase palatability. Following 6 weeks of dietary adenine administration, GFR was assessed (transdermal measurement of FITC-sinistrin clearance), urine/plasma markers of kidney function were measured, and kidney sections were stained for collagen 1a1 immunoreactivity.

**Results:** Compared to chow-fed controls, mice supplemented with dietary adenine displayed moderate and steady body weight loss, marked albuminuria, and elevated plasma levels of both creatinine and urea. Notably, GFR was robustly decreased indicating kidney failure, concurrent with development kidney fibrosis (increased collagen 1a1 expression).

**Conclusions:** Mice supplemented with adenine in the diet displayed functional and histological hallmarks of CKD, highlighting the suitability of the adenine-induced mouse model of CKD in preclinical drug development.

## PUB366

## RNA Sequencing of Renal Tubular Epithelial Cells Uncovers Novel Players in Renal Fibrosis

Vidhi Dalal,<sup>1,2</sup> Tomoko Hayashida,<sup>1,2</sup> <sup>1</sup>Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; <sup>2</sup>Northwestern University Feinberg School of Medicine, Chicago, IL.

**Background:** Tubular epithelial cells (TECs) play an important role in the development of renal fibrosis. When injured, they undergo dedifferentiation. Dedifferentiated TECs secrete cytokines that promote transdifferentiation of neighboring pericytes and fibroblasts into extracellular matrix (ECM)-producing myofibroblasts. TGF- $\beta$ 1 is a key fibrogenic cytokine that promotes TEC dedifferentiation after renal injury. Therapies targeting TGF- $\beta$ 1, however, have not been successful for treatment of renal fibrosis. This is likely because TGF- $\beta$ 1 also has protective functions, including anti-inflammatory effects and regulation of autophagy. Here, we used a transcriptomic approach to identify molecules downstream of TGF- $\beta$ 1 that specifically execute its profibrotic functions.

**Methods:** Cultured human proximal tubular epithelial cells (HKC) were treated with either 2.5 ng/mL of TGF- $\beta$ 1 or vehicle for 72 hours. Their RNA was extracted and subjected to RNA sequencing. Transcriptomic data from the renal tubulointerstitium of patients with various forms of chronic kidney disease (CKD) was also obtained via the GEO database. Genes significantly upregulated at the mRNA level in HKC after TGF- $\beta$ 1 treatment were compared to transcriptomic data from diseased tubulointerstitium. The genes that were upregulated in diseased tubulointerstitium across 3 or more GEO datasets and in TGF- $\beta$ 1 treated HKC were chosen for further evaluation.

**Results:** MARCKS and DOCK2 were the 2 genes from our *in vitro* RNA sequencing data that were most consistently and most highly upregulated across multiple GEO datasets. Their upregulation in HKC was confirmed by qPCR and western blot. Next, HKC were transfected separately with siRNA against each gene and then treated with TGF- $\beta$ 1. Knocking down MARCKS prevented upregulation of COL1A1 and  $\alpha$ SMA by TGF- $\beta$ 1 in HKC. However, knocking down DOCK2 further increased the upregulation of  $\alpha$ SMA by TGF- $\beta$ 1 in HKC.

**Conclusions:** MARCKS is likely a mediator of the fibrogenic activity of TGF- $\beta$ 1, given that knocking it down ameliorates the TGF- $\beta$ 1 induced fibrogenic changes in HKC. DOCK2 may be a negative regulator of TGF- $\beta$ 1 activity, upregulated as part of a negative feedback response. The functions of these molecules in tubular epithelial cells in the context of renal fibrosis need to be further characterized in an animal model of chronic kidney injury.

## PUB367

## Adenine Stimulates mTORC1 to Increase Matrix Protein Synthesis, Which Is Inhibited by Hydrogen Sulfide in Kidney Proximal Tubular Epithelial Cells

Hak Joo Lee,<sup>1,2</sup> Jingli Gao,<sup>1</sup> Li Liu,<sup>1</sup> Goutam Ghosh-Choudhury,<sup>1,2</sup> Balakuntalam S. Kasinath,<sup>1,2</sup> Kumar Sharma,<sup>1,2</sup> Center for Precision Medicine <sup>1</sup>The University of Texas Health Science Center at San Antonio, San Antonio, TX; <sup>2</sup>South Texas Veterans Health Care System, San Antonio, TX.

**Background:** Adenine promotes chronic kidney disease (CKD) and cardiovascular damage in rodent models. However, the underlying mechanism is poorly understood. Hydrogen sulfide ( $H_2S$ ) deficiency is associated with kidney injury seen in aging and CKD which is ameliorated by exogenous  $H_2S$  supplementation. We hypothesize that adenine induces kidney injury by activating mTORC1 to increase matrix protein synthesis which is ameliorated by  $H_2S$ .

**Methods:** We employed mouse kidney proximal tubule epithelial (MCT) cells. LY294002, MK2206 and rapamycin were used as inhibitors of PI3K, Akt and mTORC1, respectively. Sodium hydrosulfide (NaHS) was used as a source of  $H_2S$ .

**Results:** Adenine increased S6K phosphorylation, an index of mTORC1 activity, and fibronectin expression in a dose- and time dependent manner. Inhibitors of PI3K, Akt and mTORC1 abolished adenine-induced S6K phosphorylation. mTORC1 inhibitor also ameliorated adenine-induced fibronectin expression. Administration of NaHS inhibited adenine-induced S6K phosphorylation to ameliorate fibronectin accumulation.

**Conclusions:** Our results indicate that adenine-stimulated mTORC1 is regulated by PI-3K-Akt signaling. PI-3K-Akt-mTORC1 axis mediates adenine-induced matrix protein synthesis which is ameliorated by exogenous  $H_2S$  administration. Inhibition of mTORC1 by  $H_2S$  could be used as a therapeutic intervention for adenine-induced CKD.

## PUB368

## Effects of Sacubitril/Valsartan on Hypertension in Patients With CKD Stage 5D

Nan Chen, Xiao Li, Li Lin. Ruijin Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China.

**Background:** The purpose of this study was to evaluate the efficacy and safety of Sacubitril/Valsartan (SV) compared with angiotensin receptor blocker (ARB) in dialysis-dependent patients with CKD stage 5 (CKD stage 5D) complicated with hypertension, and to provide a reliable basis for the treating hypertension in patients with CKD stage 5D.

**Methods:** This is multicenter RCT study. CKD stage 5D patients with hypertension were prescribed SV vs ARB. Blood pressure, and adverse events were compared between the two groups at baseline, every 3 months of follow-up.

**Results:** 452 patients with CKD stage 5D (268 of HD and 254 of PD) were enrolled, with a median age of 58 (23-75) years old, and the male to female ratio is 1.9 to 1. 263 patients in SV group and 259 patients in ARB group. The 1 year treatment with SV 100-200 mg per day resulted in significantly reductions in mean BP from baseline (Figure 1). The mean sitting systolic BP (msSBP) was reduced from  $149 \pm 20$  mm Hg at baseline to  $144 \pm 18$  mm Hg,  $141 \pm 32$  mm Hg,  $137 \pm 17$  mm Hg,  $140 \pm 19$  mm Hg at 3, 6, 9 and 12 months ( $P=0.03$ ,  $0.02$ ,  $<0.001$ ,  $0.004$ ). The msSBP was lower in the SV group than in the ARB group at 3 and 9 months ( $P=0.041$ ,  $0.005$ ) (Table 1). During the follow-up period, SV was safe and well-tolerant in dialysis patients during.

**Conclusions:** The preliminary results of this study suggested that SV safely and effectively reduce blood pressure in patients with CKD stage 5D, and might be superior to ARB. The study also looked at the effects of SV on survival benefit, residual kidney function and blood pressure, and results will be released in due course.

Table1. SBP was lower in the SV group than in the ARB group

	ARB Group	SV Group	P value
	SBP(mmHg)	SBP(mmHg)	
Baseline	150 $\pm$ 21	149 $\pm$ 20	0.495
3-month	150 $\pm$ 36	144 $\pm$ 18	0.041
6-month	143 $\pm$ 33	141 $\pm$ 32	0.504
9-month	145 $\pm$ 18	137 $\pm$ 17	0.005
12-month	142 $\pm$ 10	140 $\pm$ 19	0.494

Figure1. Reductions of msSBP from baseline to 3, 6, 9, and 12 months of follow-up: -4mmHg( $P=0.007$ ), -6mmHg( $P=0.002$ ), -11mmHg( $P=0.003$ ), and -10mmHg( $P=0.001$ ). Reductions of msSBP from baseline to 3, 6, 9, and 12 months of treatment in the ARB group was -3mmHg( $P=0.040$ ), -6mmHg( $P=0.001$ ), -5mmHg( $P=0.001$ ), and -6mmHg( $P=0.001$ ).

## PUB369

## Development and Validation of Multivariable Prediction Models of Serological Response to SARS-CoV-2 Vaccination in Kidney Transplant Recipients

Bilgin Osmanodja,<sup>1</sup> Klemens Budde,<sup>1</sup> Eva V. Schrezenmeier,<sup>1,2</sup> Simon Ronicke,<sup>1</sup> <sup>1</sup>Charite Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>Berlin Institute of Health at Charite, Berlin, Germany.

**Background:** Repeated vaccination against SARS-CoV-2 increases serological response in kidney transplant recipients (KTR) with high interindividual variability. Still, no decision support tool exists to predict SARS-CoV-2 vaccination response in KTR.

**Methods:** We developed, internally and externally validated five different multivariable prediction models of serological response after the third and fourth vaccine dose against SARS-CoV-2 in KTR. Using 27 candidate predictor variables, we applied statistical and machine learning approaches including logistic regression (LR), LASSO LR, random forest, and gradient boosted regression trees. For development and internal validation, data from 585 vaccinations were used. External validation was performed in four independent, international validation datasets comprising 191, 184, 254, and 321 vaccinations, respectively.

**Results:** Internal validation using a rigorous resampling approach showed AUC-ROC of 0.825 for LASSO LR, which was then used for model fitting and external validation. LASSO LR performed on the whole development dataset yielded a 23- and 11-variable model, respectively. External validation showed ROC-AUC of 0.855, 0.749, 0.828, and 0.763 for the sparser 11-variable model, yielding an overall AUC-ROC of 0.809, and a negative predictive value of 0.752. The 23-variable model showed AUC-ROC of 0.853, 0.714, 0.844, and 0.778 in four independent validation sets, yielding an overall AUC-ROC of 0.818, and a negative predictive value of 0.795.

**Conclusions:** Both, an 11- and 23-variable LASSO LR model predict vaccination response in KTR with good AUC-ROC. Implemented as an online tool at <https://www.tx-vaccine.com>, it can guide decisions when choosing between different immunization strategies to improve protection against COVID-19 in KTR.

Predictive performance of the 11-variable model in four independent external validation cohorts.

#### Inhibition of Toll-Like Receptor 7 (TLR7) With a Selective Inhibitor of Human TLR7 ST-301 Reverse Lupus Progression in Murine Lupus Models

Michael Z. Yu,<sup>1,2</sup> Helen Lee.<sup>1</sup> <sup>1</sup>Hillhouse Medical Group, Houston, TX; <sup>2</sup>Singularity Therapeutics, Houston, TX.

**Background:** Toll-like receptor 7 (TLR7) is an endosomal innate viral RNA sensor, primarily expressed in plasmacytoid dendritic cells and B cells. A large body of evidence supports enhanced TLR7 signaling as a mechanism of human systemic autoimmune disease. Blocking the TLR7 pathway has been investigated in SLE disease models. ST-301 is a potent selective TLR7 inhibitor and has similar human and mouse potency. ST-301 was used to investigate the role of TLR7 signaling in murine lupus models.

**Methods:** MRL/lpr and NZB/W mice were treated with a vehicle or a selected dose of ST-301, prednisolone, and ST-301 plus prednisone. MRL/lpr mice were treated for 6 weeks on the early-stage disease with positive anti-dsDNA antibodies but negative proteinuria. NZB/W mice were treated for 20 weeks on the early-stage disease with positive anti-dsDNA antibodies but negative proteinuria, twelve weeks on established disease (proteinuria <100 mg/dL), and eight weeks on advanced disease (proteinuria >100 mg/dL).

**Results:** Six weeks of treatment with ST-301 on the MRL/lpr early-disease mice provided a significant delay of proteinuria onset, reduction of autoantibody production, and inhibition of IgG deposition in the kidney. Twenty weeks of treatment with ST-301 on the NZB/W early-disease mice resulted in a significant delay in the onset of lupus nephritis, onset of proteinuria, reduction of serum IgG level, and IgG deposition in the kidney. Treatment of NZB/W mice with ST-301 on established disease mice for twelve weeks and advanced disease mice for eight weeks resulted in a reduction of proteinuria, kidney IgG deposition, interstitial fibrosis, and a significant increase in survival in both established and advanced disease mice models. Serum autoantibody levels were significantly reduced in early-stage, established, and advanced disease mice models.

**Conclusions:** The novel highly selective TLR7 inhibitor ST-301 displayed robust efficacy in delaying the onset of Lupus nephritis, progression of Lupus nephritis, and survival benefit on MRL/lpr and NZB/W Murine Lupus Models. ST-301 significantly reduces proteinuria, autoantibodies production, and immune complex deposition. Resulting in a significant decrease of kidney interstitial fibrosis in established and advanced disease mice models. These results support that inhibiting the TLR7 pathway is a potential treatment for SLE.
